This preliminary finding is important for engineering educators. Engineering education in general is characterized by frequent and constant technical assessment and evaluation. Thus, technical competence or the perception of technical competence may be an underlying feature that influences many decision-making premises within the design process, such as ethical design decisions, above and beyond diversity effects. Taking this point into consideration engineering educators interested in facilitating diversity functions may need to acknowledge the pervasive role that technical competence plays within engineering team contexts, a role that may override other considerations. At the conference, we will expand on these results and additional findings related to diversity, ethics and implications for engineering educators.

kumar4@uwm.edu

Abstract—Undergraduate ethics instruction in engineering can be broadly divided into two models – disciplinary ethics (integrated within a course) and standalone semester-long ethics course. While both these models have educational value, they insufficiently prepare students in dealing with everyday routine ethical decision making that they might encounter in the workplace. This is because both these models barely consider the organizational or cultural context in their discussions. This study investigates the merits of using cognitive apprenticeship—a situated learning model, to enculturate millennial undergraduate students to everyday workplace ethical decision making. This quasi-experimental study was conducted at a large public Midwestern university. The study participants included a cohort of graduating seniors from the mechanical engineering class, 90% of whom had full/part time relevant work experience. In addition, 55% of them had prior standalone or disciplinary ethics instruction. Despite their work experience and prior ethics instruction, data analysis revealed that there were marked improvements in students' organizational ethical decision making. The quantitative comparative analysis indicated significant improvements in scenario-based scores between the pre and post tests. The nature and depth of the qualitative responses revealed that students appreciated situated ethics instruction because it informed them on how to deal with everyday ethical decision making in the workplace.

Keywords— *Situated learning; Workplace Ethics; Undergraduate Education*

I. INTRODUCTION

Over the decades, science and engineering advances have brought to question the role of ethics in the engineering profession, the most current prominent ones being genetic engineering, developments of drones, informatics and data management, as well as advances in nanotechnology. In his article, "Engineering ethics: some current issues," John Uff indicates that in the U.S.A, most engineering ethics developments have arisen as a result of court actions, while in Canada and Australia, ethics developments have occurred following disciplinary actions against individual engineers [1]. This raises a fundamental question: how can institutions of higher learning better prepare undergraduates who have minimal work experience for ethical professional practice? This study seeks to address this fundamental question by discussing engineering ethics instruction especially when carried out in a situated learning scenario, and draws from a

case study of a cohort of graduating mechanical engineering seniors.

II. ETHICS INSTRUCTION

In the U.S.A., engineering learning objectives are set individually by each engineering department in all institutions. However, all the objectives must address the nation-wide engineering students' learning outcomes set by the Accreditation Board of Engineering and Technology (ABET)—the not-for-profit agency that accredits programs on applied science, engineering, and technology [2]. One of the outcomes stipulates that students will have "an understanding of professional and ethical responsibility. Since ABET does not provide a specific method of assessment and the appropriate rubrics, departments decide on the methods, tools, rubrics and frequency of assessing this outcome. Whatever the forms of assessment and rubrics, most schools use the broad engineering codes of ethics set by the National Society of Professional Engineers (NSPE) as a basis for ethics instruction. These canons, however, serve a symbolic function and do little in preparing millennial graduates for ethically responsible professional practice in this dynamic global economy.

A. Overview of Engineering Undergraduate Ethics Education in the U.S.A.

Shepard et al. (2009) carried out a study to assess engineering ethics education in America. Their study sampled 100 engineering programs from 40 different institutions. They interviewed more than 200 instructors, 200 students and observed 60 classes [4]. Their study results indicated that: (i) nationally ethics education takes place in the form of (a) stand-alone courses in ethics provided within the engineering school, or broad-based ethics theory classes offered by the philosophy department, (b) disciplinary ethics modules which typically consist of a few classes dedicated to ethics discussion, (c) brief professional ethics discussions as they arise naturally in any class depending on the subject matter. (ii) Coverage of key issues in engineering ethics education was uneven across the country and in most cases minimal. (iii) In most cases, students were asked to analyze ethical real and hypothetical case studies by using the NSPE canons as a guide.

Drake et al. (2005) conducted a study to compare the effectiveness of stand-alone ethics model and disciplinary/module-based model. Their studies revealed

neither models showed significant increase in students' moral reasoning ability and ethical judgment [5].

McGinn (2003) conducted a study to test students' ability to apply knowledge acquired in ethics classes in their workplace. He sought feedback from several practicing engineers who unanimously agreed that they faced ethical dilemmas but did not feel that their engineering education adequately prepared them to handle these issues. His study revealed significant gaps between ethical realities of the workplace and current ethics instruction [6].

Overall, current engineering ethics instruction indicates no systematic and intentional uniformity when it comes to the scope and depth of coverage, as well as the stage at which students receive ethics instruction. Secondly, there is a dearth of efforts to ensure ethics knowledge is transferred from the classroom to the workplace. In this paper, we evaluate the effectiveness of cognitive apprenticeship, a situated learning approach, in enabling transfer of classroom learning to practice in the workplace.

B. Situated Ethics Education—A viable Alternative

Situated Learning Theory (SLT) was developed by Jean Lave and Etienne Wenger [7] in an effort to connect knowledge and practice. Before the advent of schools, colleges, and universities, students learned by observing the master craftsman or tradesman—a process referred to as apprenticeship. In such learning situations, knowledge and practice went hand in hand and the need to transfer knowledge from a learning context to a work context never arose [8]. Contemporary educational practices, however, separate the learning from the doing. Formal or classroom learning approaches assume that “knowledge is held in the minds of individuals and thus can be eminently transportable” to work contexts [9]. Echoing Quay's (2003) observations, Suchman (1987) says formal learning believes that, “mentalistic formulations of the individual are translated into plans that are the driving force behind purposeful behavior. Plans refer to a view of action that assumes that the actor has used past knowledge and a reading of the current situation to develop a plan from within the actor's individual cognitive process to intelligently meet the demands of the situation”. But when confronted with real-life situations, learners often are not able to readily draw from past learning and apply the learning in coherent ways to address the needs of a real-life work situation. For this reason, classroom learning is often described as abstract, decontextualized, and symbolic [10].

Situated learning principles then, help instructors show to their students how classroom learning can be applied in real-world contexts. This approach can take two forms – communities of practice and cognitive apprenticeship. Both these situated learning approaches are inspired from traditional apprenticeships.

Communities of Practice: refers to “a site of learning and action where participants coalesce around a joint enterprise as they develop a whole repertoire of activities, common stories, and ways of speaking and acting. Communities of practice

constitute reality in a particular manner and encourage specialized ways of acting and thinking” [7].

Cognitive Apprenticeship: refers to a learning method where “instructors describe out loud what they are thinking and doing and why they are doing what they are doing [11].” The process of the instructor verbalizing his/her thought process “provides the only available window into the mind of the expert [11].” Cognitive apprenticeship model of learning can be especially helpful in classroom situations where learning at the site of community of practice is not possible [12].

SLT, thus, says that learning ought to be a process of socialization of the beginner or those on the periphery of practice such as senior undergraduate students, into one's professional community. Students should learn not just about the practice but also how to be a practitioner. Context or situatedness involves a consideration of the cultural, historical, and institutional factors of the target context in the learning situation and for this reason, situated learning approaches are holistic. “Closer the match between the learning situation and the ultimate workplace situation, the easier the transfer will be [11].”

C. Millennials and Workplace Ethics

A study of generational cohorts in the workplace conducted by the Ethics Resource Center in 2009 and 2011 shows that the Millennials are the most likely to engage in misconduct [13]. The following attributes were noted in this study:

(i) Millennials lack basic literacy fundamentals, have very short attention spans, are not loyal to the employing organization, demand immediate feedback and recognition, are likely to change jobs quickly.

(ii) Millennials reported pressure to compromise standards, company policies, or the law; the youngest workers historically have observed misconduct compared to their older colleagues.

(iii) They have a tendency to integrate work and personal life, making them less likely than other generational cohorts, to draw boundaries between the two.

(iv) They grew up in the Internet age; therefore, they value confidentiality and privacy less than other age groups. In their thinking, information flow is virtually instantaneous and knowledge is meant to be shared rather than owned.

(v) Millennial workers are least likely to find it acceptable to give a cold shoulder to someone for reporting an edgy joke.

Because Millennials, of all the generational cohorts, have the least amount of life and work experience in the workplace, the cognitive apprenticeship situated learning model can be especially helpful in orienting the Millennials to the routine ethical decision making in the workplace. Cognitive apprenticeship, uses specific examples situated in authentic contexts to orient/socialize students to the various ethical scenarios they will encounter in the workplace, it provides opportunities to students to learn from experienced members of the community of practice they will be entering, and it

points the novice professional to cultural/organizational resources that they can consult when caught in an ethical dilemma.

III. CASE STUDY: SENIOR ENGINEERING STUDENTS

In this study, we develop and implement a situated learning ethics instruction in a mechanical engineering capstone design class at an institution in the Midwestern region of the U.S.A. The cultural elements that embody situated ethics instruction in our study include: (i) The use of organizational codes of ethics which are cultural tools and guides that explain terms and concepts with regards to professional conduct. In addition, they elaborate consequences of non-compliance, processes and procedures followed in case of misconduct, and point users towards appropriate resources when needed. (ii) The facilitation of the ethics instruction by an experienced practitioner who used his company’s code of ethics to explain to students the meaning of and rationale behind ethical terms and concepts used in the code – a method of instruction referred to as cognitive apprenticeship (iii) The incorporation of everyday real ethical scenarios with respect to specific ethical themes (e.g. confidentiality and data privacy, electronic communication), compiled in consultation with the practitioners that are situated in the organizational as well as the professional context.

Our study has a dual focus; situating the content as well as the method of instruction. We seek to address the following research question: What is the students’ level of understanding of the six areas of organizational codes of conduct? Towards this end, our study tests the following hypothesis: (i) prior to intervention, students will have a general understanding of the ethical themes of organizational codes, (ii) the study will provide the students with a situated understanding of professional organizational codes, (iii) the impact of the intervention will be higher in scenario-based questions that require students to elucidate on the rationale behind and the consequence of defying the six organizational codes.

A. Study Design and Study Population

We used a quasi-experimental approach in this study in which a cohort of 20 students—mechanical engineering capstone class was chosen. The mechanical engineering class is predominantly the largest at this institution; hence the subjects in the study were non-randomized. The capstone class was selected since the college assesses the ethics-related ABET learning outcomes through this course. First, the students were asked to respond to a questionnaire on whether they had prior work experience and ethics instruction. Figures 1 and 2 indicate the proportions of students that had prior ethics education either as stand-alone courses or modules incorporated into the curricula of other classes and prior work experience in engineering respectively.

Fig. 1. Proportion of students with prior engineering ethics instruction

Fig. 2. Proportion of students with prior work experience

A matched pre-posttest evaluation questionnaire was designed with questions of varying form, depth and intensity as summarized in Table I. For the sake of brevity, only the essence and form of the questions are indicated. The students responded to the pretest a week prior to the intervention. The situated ethics instruction (herein referred to as the intervention) was facilitated by a professional mechanical engineer, who is also a lawyer in the ombudsmen office of a multinational organization in located in the U.S.A. The professional speaker engaged the students in an hour discussion of the day to day definition, description, and application of the organizational codes of ethics and how they relate to the overall engineering codes of ethics. He used real scenarios from his organization to explain how the codes are used to help identify and resolve ethical situations and some consequences of noncompliance.

TABLE I. SUMMARY DESCRIPTION OF PRE AND POST QUESTIONS

Question	Summary Description
1	Company resource documents related to organization’s codes of ethics? (open ended question)
2	Company resource offices related to organization’s codes of ethics? (open ended)
3	Meaning of confidential company information. (true/false - framed statement)
4	List three documents/records that might be considered confidential. (open ended)
5	Understanding of the meaning of proprietary information. (open ended)
6	Privacy law governance for multi-national companies. (true/false - framed statement)
7	Code of conduct violated in given contextualized misconducts (scenario analysis).
8	Definition of official records. (open ended)
9	Description of patent, copyright, intellectual property, Trademarks. (open ended)
10	Codes of ethics with regards to electronic communication. (open ended, scenario-based)
11	Records management and information security. (open ended, scenario-based)
12	Conflict of interest– design of products. (open ended, scenario-based)
13	Conflict of interest– supplier/vendor relations. (open ended, scenario-based)
14	Reporting procedures with respect to whistle blowing. (open ended, scenario-based)
15	Reporting procedures with respect to respect for fellow colleague. (open ended, scenario-based)

Following the discussion, students responded to a matching post test. Each question on the pre and post test was graded on a Likert scale of 0 to 3 depending on the required detail of response in the designed rubric, (i.e. no knowledge = 0, partially correct but low score = 1, partially correct but high score = 2, and full score = 3). We will mention here that we had a 100% response rate given that the study was weaved in as part of the syllabus. However, following IRB's stipulations for voluntary participation, the participants of this study signed a consent form allowing them to withdraw from the study at any time.

IV. DATA ANALYSIS AND RESULTS

A. Quantitative Analysis

Table II contains a heat chart indicating the number of students who had little to no prior knowledge of a particular question. The color legend is such that for the pre and post test columns, red indicates worse scored questions (i.e. number of students scoring <2), orange to green indicates the number of student responses with increasing values of scores (i.e. decreasing number of students scoring <2). Likewise, for the improvement column, moving from red to green indicates progression in improvement of score from the pre to post test (i.e. red indicates no improvement while green indicates most improvement, hence areas of engineering ethics that posted the most improvement following the discussion session).

Generally, students had prior knowledge in most areas covered by the questions. The questions whose responses

indicated substantive prior knowledge (shades of yellow to green in the pretest column) involved listing regarding examples of organizational documents, offices that deal with matters of ethics and suggestive true/false questions. Considering that most students had relevant internship experiences, it was not surprising that students demonstrated higher level of knowledge in these areas.

Student's prior knowledge was particularly low for questions 5, 6, 8, 9b, 9c, 11, 12, and 13 (indicated by increasing shades of red). Most of these questions required the students to either define and describe the meaning of a code of ethics, or match the given ethical malpractice scenario to the code that was violated in a given scenario. The most improvements from the pre-to-post responses were evident in questions 4, 8, 11, 12, and 13 (shades of green in the improvement column). We, therefore, infer that the intervention was most impactful for these questions. In addition to the above descriptive analyses of responses, we carried out a paired T-test necessary for normally distributed, homogenous quantitative data, to test if:

$$H_0: \mu_{pre} = \mu_{post} \text{ versus } H_1: \mu_{pre} < \mu_{post}$$

The results showed that the mean performance in the post test was significantly higher than the performance in the pretest at 95% confidence level. Even though paired T-test are preferred with smaller sample sizes, we are not claiming that the results in this study are generalizable, but are using them as proof of concept.

V. CONCLUSION

Practicing engineers are required to make autonomous ethical decisions based on their interactions with clients, colleagues, organization policies and culture. Literature suggests that there is a gap between ethical knowledge and practice in the engineering profession especially for the millennial generation [1,4,5,6]. This study seeks to bridge this gap by investigating the merits of using cognitive apprenticeship, a situated ethics instructional model. We demonstrate how situated learning can be used to address the gap between learning and application; how principles of everyday cognition can be used to prepare students to deal with everyday ethical decisions. The study is deliberately aimed at graduating seniors. Positioning situated ethics instruction when students are about to graduate and join the workforce can help students see the relevance of the instruction and therefore, readily make the connection between learning and application. The quantitative results as well as the qualitative data demonstrate that there is a definite value in situated ethics instruction. The quantitative results showed a marked increase in the post-test responses of the students indicating an increased ability to explain the rationale behind the organizational codes and consequences of non-compliance. A natural extension to this study will be to follow-up with this cohort of graduates in their current places of employment and seek their feedback about the value of the situated nature of ethics instruction. In other words, to find out if they were able to apply the content in the ethical decisions they have to make in their places of work.

TABLE II. HEAT CHART INDICATING STUDENTS WHO SCORED <2 IN THE PRE-POST TEST

Question	Related Code	No. of Students with Scores < 2		
		Pre-test	Post-test	Improvement
Q1	Company resource documents related to organization's codes of ethics?	3	1	2
Q2	Company resource offices related to organization's codes of ethics?	0	0	0
Q3	Meaning of confidential company information	2	0	2
Q4	List three documents/records that might be considered confidential	4	0	4
Q5	Understanding of the meaning of proprietary information	7	4	3
Q6	Privacy law governance for multinational companies	8	6	2
Q7a	Misconduct in storage of company records	4	3	1
Q7b	Misconduct in data privacy	3	1	2
Q8	Definition of official records	11	6	5
Q9a	Description of patent	2	1	1
Q9b	Description of copyright	9	7	2
Q9c	Description of intellectual property	12	9	3
Q9d	Description of trademark	1	1	0
Q10	Codes of ethics with regards to electronic communication	0	0	0
Q11	Records management and information security scenario	10	2	8
Q12	Conflict of interest scenario – design of products	11	4	7
Q13	Conflict of interest scenario – supplier/vendor relations	9	1	8
Q14	Reporting procedures with respect to whistle blowing	0	0	0
Q15	Reporting procedures with respect to respect for fellow colleague	1	1	0

Abstract— This paper presents results from engineering student responses to the open ended question “Write a few sentences explaining how you define ‘Social Responsibility’.” Through emergent coding methods it was found that students were most likely to use a disassociated, third person voice in their definitions, as opposed to a first person voice where they included themselves in the group that help the responsibility. The responsibility that students talked about was most commonly held toward a general community or society, and occasionally toward the environment or the world as a whole. In describing how the responsibility manifested itself, students talked most often about giving back or helping others, but also about a responsibility to conduct acts of service or charity. Finally, students infrequently directly cited a source of the responsibility, though some described ethical or moral foundations while others talked about an obligation due to possessing certain skills or privileges. Few differences were found in these definitions based on gender, academic rank, or major. Understanding how engineering student’s view their social responsibility as both citizen and engineer is crucial towards shaping educational approaches to develop holistic engineers, able to work across disciplinary and cultural divides toward solutions of complex social issues.

Keywords—*Social Responsibility; Ethics; Morality; Engineering Identity; Qualitative*

I. INTRODUCTION

Engineering students hold a diversity of views when asked to define social responsibility:

“I think social responsibility has a lot to do with how you were raised...For me, I feel a great debt to society because I have been blessed with a lot and have not had to face many social challenges, and that makes me want to give back so others can be as privileged.”

“Everyone in a community has an obligation to support others in the community, for the good of the community as a whole. This includes making sure everyone’s basic needs are provided for, whether through work or through structured ‘safety nets’. To accomplish this it is necessary to pay particular attention to the needs of those whose voices are typically unheard or underrepresented.”

“It is my decision if I want to help society or not. No one has the right to force me into it. I may have the ability to greatly benefit society, but it is my life and I will live it my way.”

The work of engineers sits at the interface between scientific knowledge and society. The machines, structures, electronics and software that engineers develop are rooted in the base principles of physics, mathematics, biology and chemistry, but are fundamentally developed to benefit society, thereby bridging that gap. Central to the engineering code of ethics is the mandate to “hold paramount the safety, health, and welfare of the public” [1]. In their vision of the Engineer of 2020, the National Academic talks directly about this relationship, saying “one thing is clear: Engineering will not operate in a vacuum separate from society in 2020, any more than it does now.” [2]. The Engineering Accreditation Commission of ABET highlights the importance of educating engineers to interface with society in criteria 3 (f) “an understanding of professional and ethical responsibility” and 3 (h) “the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context.” [3]. The American Society of Civil Engineers’ (ASCE) Body of Knowledge reiterates a focus on professional and ethical responsibility, describing the inherent place of privilege and responsibility that civil engineers hold in society due to the profession’s “exclusivity in the design of the public’s infrastructure” [4, p. 151]. As a manifestation of this responsibility, ASCE states that the engineer should “put the public interest above all else” [4, p. 151] and thereby earn society’s trust. Other engineering disciplinary guidelines have similar language, acknowledging the centrality of the relationship between engineering and society.

Researchers have used the term social responsibility to represent a diversity of characteristics or views in education, engineering, and most other professional spheres. A national study of institutional support for “personal and social responsibility” used elements of empathy, ethical and moral reasoning, and a desire to contribute to the greater community to describe social responsibility [5]. Other studies used democratic ideals or civic participation as defining elements of social responsibility [6, 7]. A lack of social responsibility has

been explored through unethical behavior such as cheating [8]. The theoretical underpinnings of this study, rooted in the Professional Social Responsibility Development Model (PSRDM) [9] considers social responsibility as “feelings of obligation to help others as both a person and a professional, with a special focus on helping disadvantaged or marginalized populations” [p. 2].

In a provoking longitudinal study on engineering student views of public welfare beliefs, Cech found that student views decreased over their four years of education, supporting the development of a “culture of disengagement” among engineering students and then professionals [10]. This culture of disengagement, which can be considered the antithesis of good social responsibility, is characterized by a) beliefs that engineering work can be disconnected from social or political ramifications, which are seen as biasing the results (termed depoliticization); b) a cognitive separation between technical and social skills or considerations with preferential consideration given always to technical; and c) adherence to meritocratic ideologies whereby current social arrangements are seen as inherently just and fair with a lack of recognition of sources of power and privilege that may support social injustices.

Sakellariou examined the historical roots of the term ‘social responsibility’ in engineering, contrasting it with the term ‘social justice’ which is often times resisted by the engineering profession [11]. He found that the term ‘social responsibility’ was adopted by the engineering profession early in the twentieth century as a way to characterize the engineer as “creator of social good” [11, p. 254] as opposed to just employees loyal to a corporation. In this way, ‘social responsibility’ speaks to the engineer’s influence and obligation to social good, but, contrary to the term ‘social justice’, traditionally ignores issues of depoliticization and meritocracy.

These views, however, are representative of professional organizations and academics but may not be communicated to or adopted by engineering students during their academic formation. For this reason, it is crucial to learn how students see their social relationship, where those views come from, and how educational interventions could be used to positively affect them. Toward that end, this study begins the conversation by examining how engineering students view social responsibility through their definitions of the term. Student definitions were explored through the following four research questions:

RQ1. In engineering students’ definitions of social responsibility, who holds the responsibility (*voice*)?

RQ2. In engineering students’ definitions of social responsibility, who or what is the subject or recipient of the social responsibility (*subject*)?

RQ3. In engineering students’ definitions of social responsibility, what, if any, is the *source* of the responsibility?

RQ4. In engineering students’ definitions of social responsibility, how is the social responsibility enacted between the one who holds the responsibility and the subject of the responsibility (*action*)?

II. DATA COLLECTION

Between March and June in 2014, engineering students at 17 universities were solicited to complete the Engineering Professional Responsibility Assessment (EPRA) survey [12] via the online survey tool, Qualtrics®. EPRA was developed to operationalize the Professional Social Responsibility Development Model [9] and has been shown to have strong evidence of reliability and validity [12]. The tool is comprised mainly of fifty 7-point Likert-items to assess social responsibility attitudes, but also includes several open-response questions addressing the development of social responsibility. One such question, the focus of this paper, asked students to “Write a few sentences explaining how you define ‘Social Responsibility.’” This question came immediately after the Likert items, but before questions regarding influential classes on students’ views, their previous volunteer experiences, other influences to their views of community service, and demographic information.

At 15 institutions, students representing all undergraduate academic ranks and all engineering majors received the email asking for their participation, which was incentivized with drawings for gift cards at each institution; at two additional institutions only civil and environmental engineering majors were invited to participate. Graduate students were additionally included from 4 institutions if they had previously participated in a social responsibility study in 2013 [13]. The 17 universities used in the study represented a wide diversity of institutional characteristics including public and private, bachelors, masters, and doctoral granting institutions, religious, secular, and military affiliations, and a range in sizes from 150 up to over 7000 engineering students. In total, 2072 students completed the SR definition question. A summary of the respondents by demographic is given in Table 1. The response rates at individual institutions varied from 6% to 33%. Females were over-represented at 37% of the respondents, compared to about 20% of engineering undergraduate students nationally [14]. Response rates were lowest among first-year students.

III. DATA ANALYSIS

Emergent coding methods were used to analyze the write-in responses [15]. Codes focused both on the content of the response as well as the sentence formation, specifically the voice in which the definition was written. A subset of the data (220 responses) was used to determine inter-rater reliability (IRR) using Cohen’s kappa [16-18] between two reviewers. Per standard practice, codes with kappa values greater than 0.6 were considered to have ‘substantial’ agreement and codes with kappa greater than 0.8 had ‘outstanding’ agreement [19]. Codes with kappa values less than 0.6 were set aside for further refinement but some examples of other interesting elements in student responses will be discussed qualitatively in this paper to highlight the diversity of views. Potential differences in the responses between demographic groups were explored using chi-square tests, with $p < 0.05$ used to infer significant differences.

TABLE I. DEMOGRAPHIC BREAKDOWN OF SAMPLE POPULATION

Demographics	Number of respondents who defined social responsibility
Total	2072
Gender: Female	755
Male	1284
Academic Year: First-Year	243
Sophomore	490
Junior	498
Senior	518
Graduate	185
Majors: Mechanical, Aerospace, Materials	847
Civil, Environmental, Architectural, Construction	575
Computer, Software, Electrical	402
Chemical, Biological, ChemBio, Biomedical, BioME	219
Other – General, Industrial, Engr. Physics	113
Institutions: Religiously-affiliated	370
Secular	1702

Note: Students had an option to respond "Prefer not to say" to each demographic question and could also select multiple majors, therefore the sum of demographic breakdowns may not equal the total response number

IV. RESULTS & DISCUSSION

The responses varied substantially in length, ranging from 1 to 313 words with a median of 26 words and an average of 32 words. Among the responses of 3 or fewer words ($n=26$), some indicated an unwillingness to provide a definition (no, meh, no comment), others indicated that they didn't care, and some indicated that they didn't know. It is likely that the majority of the non-responses ($n=148$) also encompassed this range of attitudes. A few of these very short responses were very concise (helping others) or basically restated the term (being socially responsible). The longer responses provided opportunity for meaningful analysis; the correlation coefficient between the total number of codes assigned to a response and the response length was 0.68.

In the analysis of student open ended responses, it became clear that there were differences in both the construction and the content of the definitions. Regarding the construction of the definitions, one key theme found was which *voice* was used in the defining statement. Results from this group of codes addressed the first research question relating to who, in the definition, explicitly holds the responsibility that is being defined. Codes relating to the content of the definitions were used to answer the other research questions, namely, who were the recipients of the responsibility (*subject*), what, if any, was the stated *source* of the responsibility, and how was the relationship between the one holding the responsibility and the recipient characterized (*action*). Figure 1 presents a visual representation of the relationships between these four elements and sub-codes that were used for each. Each of these elements

will be discussed individually in the following sections and a final section will discuss interesting outliers in the student responses that shed insight into minority, but provocative perspectives of social responsibility. In the following sections, when discussing various codes, both the frequency of occurrence across the entire response population and Cohen kappa values for IRR are presented initially in parenthesis (frequency; kappa).

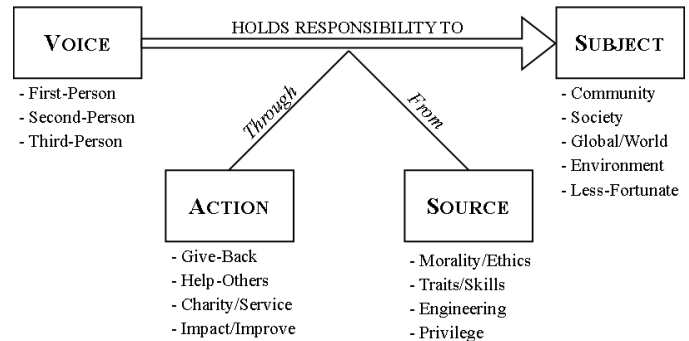

Fig. 1. Emergent topics and codes relational diagram

A. RQ1: Voice

This research question addressed the voice that students used in their definition of social responsibility (SR). It was interesting to see who the definition placed the responsibility on through the use of a first-person, second-person, or third-person voice. The focus on voice highlights whether the students directly included themselves into the group that holds the responsibility (first-person) or if they place the responsibility generally through second- or third- person. First-person was when the students talked about their personal responsibility and included themselves as being obligated to that responsibility. This responsibility was also seen in a collective voice where they talked about SR with respect to the people around them (our, us, we). An example is:

“Social responsibility is the obligation to not only treat others as I would like to be treated, but also to take the initiative to positively affect society. We as engineers have the responsibility to hold paramount the safety of the public and to provide help to society's problems.”

Second-person voice was evident when the definition addressed the reader (you, your) as having the responsibility. An example is: “Social responsibility is pulling your own weight in society. Making sure you are not a damaging part of society, and leave it the way you found it, or a little bit better.” Third-person voice was when the definition referred to a person, place, thing, or idea (he, she, it, their, each) as having the obligation to be responsible as well as definitions that had no clear subject in the construction. An example response that incorporated third-person voice was:

“Social responsibility is one's obligation to be both aware of the many different people and groups that coexist with this person and also willing to help address issues that face these other groups. One cannot just enjoy the benefits of living in

some sort of society. He or she should also feel obligated to ensure that others can enjoy the same benefits.”

The most common voice that the students used in their definition of social responsibility was third-person (61%; 0.778). Second- and first-person were less common (30%; 0.901 and 21%; 0.712, respectively). Some responses ($n=361$) contained more than one voice used in the definition. First-person voice was more common among students attending religiously-affiliated institutions (32%) than those attending secular institutions (20%). The concern with the dominance of a third person voice in definitions of social responsibility is that it could make it easier to avoid responsibilities that are held broadly, disassociating the individual from the responsibility by using ‘one’ or ‘people’ as opposed to ‘my’ or ‘our’. Alternatively, this could merely be the result of an engineering mindset that uses third person to imply objectivity, and as such is encouraged in technical writing training that many engineers receive [20]. There were not significant differences in the use of voice between genders, academic rank, or majors.

B. RQ2: Subject

In addition to the *voice* that was used in the construction of the responses, the content was also interesting, specifically the *subject* or recipient of the social responsibility. The subjects that were mentioned most frequently were a community or society, the world or some reference to the global community, the environment, and people who were less-fortunate. The following response illustrates a student’s definition involving several of these common subjects:

“Social responsibility is the duties that everyone has to make communities and societies function. Everyone has responsibilities to do what they can to improve other’s lives, and those with better social circumstances have proportionally more duties to help the less fortunate. All skill sets can be useful for social improvement.”

For this student, responsibility is held with respect to the community and society in the first sentence and then later “to help the less fortunate.” Some students mentioned that responsibility was more of an obligation globally or to the world. An example of global/world subject was: “Social responsibility in regards to engineers is the effort required by them to make the world better. Whether large sums of money are involved or not, we have a responsibility to use our knowledge to change the world.”

From the students who included a clear subject in their definition, the most common were community (38%; 0.990) and society (38%; 0.863). It was not surprising to see “community” and “society” as the most common subjects, given that ‘social’ was in the word students were asked to define. Female students more frequently described community (44%) than male students (35%). Obligations toward the global/world (10%; 0.864) or the environment (5%; 0.793) were mentioned much less frequently. Most closely related to the ideals of social justice and the definition of social responsibility used in framework of this study, “the less-fortunate” were present as the recipient of social responsibility in quite a few student definitions (16%; 0.97). An example of such a response is: “...I believe that those in any society who

are fortunate enough to be able to help others who are less fortunate should do so to their fullest capability.” Mechanical/aerospace/materials engineering majors included the less fortunate in their definitions at the highest percentage among the disciplinary clusters (19%). Students attending religiously-affiliated institutions included the less-fortunate in their definitions more frequently than those attending secular institutions (23% vs. 15%).

C. RQ3: Source

The third research question examined what students identified as the *source* of the social responsibility they defined. In their theories about the development of altruistic behavior, Schwartz and Howard [21] posited that sources of feelings of obligation to help others derived from two sources: a) internalized moral values and personal norms and b) perceived social norms of behavior. Similarly, Bar-Tel et al. theorized that individual’s initiate (or don’t) helping behavior due to perceived societal demands rooted in social understandings of acceptable behavioral norms around helping [22]. They suggested that people help because they are expected to do so and want to be viewed a good person in other’s eyes.

The majority of students didn’t speak to the source of expectations of social responsibility in their responses, though students that did oftentimes point to either internal or external sources of obligation. Students also talked about expectations of social responsibility being either individualized (up to each person) or collectively held (a result of being a member of a society). Though it proved difficult to obtain strong IRR related to external or internal sources of responsibility (and therefore discussions of frequencies of occurrence are not reliable), an example for each are:

Internal: “Social responsibility is the belief that ethically or morally you have an obligation to help society in some way. It’s a bit of a subjective concept, no one is “making” you responsible for anything. But some feel more of an obligation than others.”

External: “The responsibility of each individual to act in a manner consistent with social norms. The contribution of people to have a positive impact on their community. The inclination of people to give to their community in excess of what is expected.”

Other sources that students identified (though related to external and internal norms) were personal traits or skills (14%; 0.893), morality/ethics (6%; 0.961), personal privilege ($\kappa=0.333$), and engineering (6%; 0.857). The most common definition, traits, referred to the obligation for people who possessed unique skills, knowledge or abilities (such as engineering) to use those to help others. Here is an example: “Social responsibility involves using one’s skills to help others and behave in an ethical manner. Lack of social responsibility implies using one’s skills to harm or exploit others and have a negative impact on society.” Some students highlighted that a sense of responsibility was driven by issues of morality or ethics.

In the framing of this open-ended question, students were intentionally asked to define social responsibility in a broad manner, not specifically tying it to engineering. Six percent of the students, however, did tie their definitions to engineering. The following example portrays this: “As an engineer, our entire profession is based on improving the world around us. Therefore, it is also within our job to try to satisfy all members in an area in which we work.” As in this example, most times that students mentioned engineering it was either tied to a responsibility that engineers hold to society due to the impact that engineering work has, or because of the skills they possess as engineers. A higher percentage of seniors and juniors (9.1% and 8.5%) included engineering in their definitions than sophomores and first-year students (4.8% and 4.7%), likely reflecting the more central role of engineering in the identity of the upper-class students.

D. RQ4: Action

The final research question addressed the nature of the social responsibility held through the action or relationship that was highlighted between the holder and the recipient of the responsibility. The most common actions used in student definitions help-others (47%; 0.68) and impact/improve (47%; 0.623). A desire or obligation to help others was frequently used by students when discussing the way in which the social responsibility should manifest itself. Similarly, though not as often, students also talked about giving back (6%; 0.928) to the people or society. The use of impact or improve typically related to a desire or an ability to have a positive impact or to improve society. Students also talked about living positively, benefitting others, being a good example, or to improve individual's standard of living. An example definition that included these themes is:

“Social Responsibility is an understanding that any individual's life and choices have an impact on those of the people in their community; because of this understanding, every person should take the broader consequences (positive and negative) of their choices into consideration with the goal of improving rather than degrading the lives of those they affect.”

Students also mentioned being involved in charity or acts of service as important aspects of social responsibility (13%; 0.695). Oftentimes these definitions would point to myriad forms of charity and service including giving of time, money, talents, volunteerism, etc.

E. Outliers of Interest

One theme that was seen in the data but the two reviewers could not produce consistent inter-rater reliability was related to discussions of personal privilege as the source of one's obligation ($\kappa = 0.333$). An example of a student response related to recognition of personal privilege as the source of responsibility is:

“The opportunities I have been given in life have been numerous and vast, and I believe some of those opportunities now and in the future are chances to serve for the betterment of others. I feel 'social responsibility' is something we as members

of the human race have an obligation towards; that we should serve others for the betterment of all.”

In this example, the student points to the opportunities that they have been given and how those opportunities have given them an ability and responsibility to “serve others.” Similar to this example, oftentimes discussions of one's skills and abilities were tied with the opportunities they had been given along the way to develop those. Most of these definitions also emphasized the idea that if someone is more privileged and the opportunity comes up where they could help, then they have an obligation to use those advantages to help (“If you are in a position to help those around you then you should help them”).

The vast majority of students wrote definitions of social responsibility that were positive and attempted to pin down the bounds, nature, and source of that obligation. Some students (~2%, 0.535), however, responded to this prompt with definitions that were resistant to any forms of responsibility or hostile toward perceived social norms of responsibility. One such response was:

“Social responsibility: One that does not depend on the government to pay their way through life. One that takes life into their own hands and can self-sustain. It is not their responsibility to give handouts to those that are “too lazy” to find a job or think they are “entitled” to everything. If I see you using an EBT card and texting on your smartphone, something is wrong with this picture, because I myself can't afford a smartphone, so I have the cheaper flip phone and am not on food stamps, but am in debt because I wanted to go through higher education. Now, my taxes go to help you live, yet I'm in debt. Something is wrong with this picture...”

In this definition of social responsibility, we see that the student is criticizing social norms around government assistance. The definition is not so much a description of what social responsibility is, but seems to be a reaction to what social responsibility isn't (in his/her view). This example, and others with similar themes, seemed to support the culture of disengagement that Cech describes [10], particularly alignment with meritocratic ideologies. In this example, the reflection of conservative American social/political views around individuals who draw assistance from government programs as being “too lazy to find a job” or “think they are entitled to everything” supports this. Several other student definitions following similar messages as this one, that social responsibility was about individuals taking care of themselves and not relying on others (or the government) for help.

V. CONCLUSION

Student definitions of social responsibility presented in this paper have provided insight into how engineering students see their role society. Students were most likely to use a third person or disassociated voice in their definitions, removing themselves from directly holding said responsibility. Students often pointed to the community or society as being the recipient of that responsibility, but a minority also discussed the world as a whole, the environment, or peoples who are less fortunate. Students who directly discussed the source of the obligation pointed oftentimes to external or internal drivers, including morality or ethics, having given traits or skills, being

privileged in society, or through their roles as engineers. Finally, students most often cited helping others as the manifestation of that responsibility, but also engaging in acts of charity and service, having a positive impact, improving society, or giving back.

Knowing the ways in which students perceive their social responsibility is key in two ways: 1) it can be used as a reflection of professional messages that the current engineering education culture may be instilling in engineering students, and 2) it can provide a starting point for educators to build upon existing beliefs to strengthen engineering students' sense of personal and professional social responsibility. Seeing that students most often used disassociated or third person voices in their definitions may reflect the decontextualized problems that engineering students solve and the removal of social elements from engineering academic work. Perhaps developing a culture in engineering departments focused on how engineering interfaces with society and, more importantly, how each student as an engineer holds a responsibility in that relationship, would push students to see social responsibility as a personal, rather than abstract concept. Active- and service-learning pedagogies may be employed to help facilitate this shift. Institutional culture may also be a key component of student perceptions. Students at religiously affiliated institutions were more likely to use first-person and to refer to populations who are less fortunate in their definitions. Institutional messages around social justice or personalized religious obligations to help others may play a key factor in these differences.

Further work is needed in examining these results, specifically with respect to the relationship between student responses and other elements of the EPRA survey. Correlations between student definitions, their answers to the 50 Likert-items related to social responsibility, engagement in engineering service, or previous volunteer activities may provide useful information as to the personal experiences that helped form these views. Additionally, several themes emerged from the data (such as internal vs. external sources) that are interesting to explore but lacked good inter-rater reliability and so frequencies of occurrence couldn't be discussed. The iterative process of coding, focusing definitions and recoding takes time, but will be continued by the researchers for some of these other codes.

Educational practices in engineering need to guide students to recognize their roles as engineers in society, particularly the potential for both positive and negative impacts. This paper has presented how students see those views generally, through the task of defining the term "social responsibility." Understanding these views has set a foundation from which educators can examine the messages and practice that they employ, how they might support or oppose these perspectives, and explore ways in which they can help students further realize and internalize their social responsibility as engineers.

ACKNOWLEDGMENT

This research has been supported by a grant from the National Science Foundation (#1158863). Additionally, thank

for institutional support to distribute this survey, to the students who took time to honestly complete the survey.

Stages and Processes of Pedagogical Change - An application of TTM

James J. Pembridge, Kari L. Jordan, Heidi M. Steinhauer, Timothy Wilson, Douglas Holton
College of Engineering
Embry-Riddle Aeronautical University
Daytona Beach, FL

Abstract— Faculty adoption of evidence-based instructional practices and their overall approach to pedagogical change has primarily been examined through stage-based models of change. While not readily applied to education, the Transtheoretical Model of Health Behavior Change (TTM) provides a cyclic, stage-based model of change that provides processes to advance through the stages while recognizing faculty context and self-efficacy that will support their pursuit of pedagogical change. This paper compares the currently used models of change to TTM and explores the application of TTM to Engineering Education.

Keywords— *change models, evidence-based instructional practices*

I. INTRODUCTION

The amount of research dedicated to improving engineering education over the past decade has yielded a variety of innovation in new materials, strategies, and pedagogies. These, however, have not resulted in systematic change. Current reports on the adoption of evidence-based (research-based) instructional practices (EBIP) suggest limited success, indicating little connection between research and the development of effective curricular innovation. A large percentage of studies addressing educational change have applied strategies and change theories that yield moderate success.

Two commonly referenced models of adoption include Diffusion of Innovation (DoI) and the Concerns Based Adoption Model (CBAM), which have been noted as one of “the most robust and empirically grounded theoretical models for the implementation of educational innovations”. However, change theories from other fields have the potential to impact the way we study and guide pedagogical change.

The purpose of this paper is to introduce the application of the Transtheoretical Model of Health Behavior Change (TTM) to explore changes in engineering education pedagogy. This paper will address the following questions:

1. How does TTM compare to the DoI and CBAM models?
2. How does TTM inform processes that can mediate pedagogical change?

II. CHANGE THEORIES UTILIZED IN ENGINEERING EDUCATION

A large percentage of studies addressing educational change have applied strategies and change theories that yield moderate success [1-4]. In a review of change theories and models, Kezar [5] noted that change models could be evolutionary, teleological, life-cycle, political, social cognitive, and cultural. Two of the most common typologies in engineering education include the teleological and the life cycle. Teleological, focusing on intentional purpose, coincides with policy changes and imparts emphasis on change agents as well as techniques and strategies to manage change. Practices addressed in those studies have led to the development, testing, and distribution of curricular materials and “top down” policy to encourage the adoption of those practices. These approaches have had limited effectiveness in reforming STEM educational practices given the variety of contexts resulting from culture, institutional missions, and policies [1]. In contrast, life cycle typologies examine change related to phases of change that are situated on a timeline [5]. Two of the most common stage-based models include diffusion of innovation by Rogers’ and Fuller’s Concerns Based Adoption Model.

A. Diffusion of Innovation

In their work, Borrego and Henderson [4] described Diffusion of Innovation as an example of a model to guide change in an individualistic and prescribed approach. [6]. Diffusion of Innovation describes how an individual decides to adopt an innovation, noting the stages they follow (Table I), their adoption timeline, and factors associated with the adoption. However, Diffusion of Innovation is primarily focused on a specific innovation and how it is adopted by a culture until it is either a failed diffusion or reaches a critical mass of adoption.

B. Concerns Based Adoption Model

The Concerns Based Adoption Model (CBAM) has been noted as one of “the most robust and empirically grounded theoretical model[s] for the implementation of educational innovations” [7]. It explores the process of change that an individual undertakes when implementing new curricular materials and instructional practices, and how that change is affected by persons in change-facilitating roles. The model was developed out of the second component of Fuller’s stage model of teacher development [8, 9] that assessed teachers’ concerns in the context of innovation adoption [10]. The CBAM theory

and methods identify stages of concern, levels of use, and innovation configurations. Based on this model, the stages of concern regarding the adoption of an innovation proceed from awareness to informational, personal, management, consequence, collaboration, and refocusing.

TABLE I. COMPARISON OF STAGE-BASED MODELS OF CHANGE

	Diffusion of Innovation	Concerns-Based Adoption Model	Transtheoretical Model of Health Behavior Change
Stage comparison ↓	Awareness	Awareness	Precontemplation
	Interest	Informational	Contemplation
		Personal	Preparation
	Evaluation	Management	Action
	Trial	Consequence	
	Adoption	Collaboration	Maintenance
		Refocusing	Termination

III. TRANSTHEORETICAL MODEL OF HEALTH BEHAVIOR CHANGE

One of the primary limitations of these models is the strong focus on a specific innovation and the inability for a person to revert to a previous stage. With respect to teacher practice, it has been noted that when a pedagogical practice fails to work as planned, faculty will utilize strategic knowledge and are more likely to rely on their past experiences and intuition rather than empirical research [11]. In contrast to Diffusion of Innovation and Concerns Based Adoption Model, the Transtheoretical Model of Health Behavior Change, while classified as stage theory, is cyclical. It allows relapses to occur under certain situations and generically focuses on changing a specific behavior [12]. Using this perspective, teaching is classified as a behavior with changing of teaching practices that are directly related to a specific stage of change and to the associated process required for successful change. Within these change processes, strategies identified by Seymour [13] as being beneficial to engineering education [14] can be appropriately applied to advance the individual to the next stage of change. In order for change strategies to be successful, they must focus on the individual beliefs of the faculty and be capable of allowing designed interventions compatible with the context in which they are applied [1].

TTM was originally developed to integrate more than 300 theories of psychotherapy and behavior change with application to a broad range of health and mental behavior, including alcohol and substance abuse, anxiety and panic disorders, smoking cessation, and the adoption of drug regimens and exercise programs [15-17]. TTM uses a time dimension to describe both the stages of change and the process of change required to advance through the stages. In addition to stages and processes of change, Prochaska et al. [16, 17] noted that individuals pursuing behavioral change assess the pros and cons associated with the change. These pros and cons are assessments of the benefits and risks associated with improving behavior and the pros and cons of the process of change. While it is necessary to assess which stage the individual resides and the processes appropriate to advance to

the next stage of behavioral change, Prochaska et al. [16, 17] recognized that the individual requires the confidence (self-efficacy), based on the motivational constructs associated with Bandura's [18] self-efficacy theory, necessary to resist temptation and revert to a previous stage.

A. Stages of Pedagogical Change

The time component of TTM represents the core construct of several stages of change associated with a point in time that can be graphically represented as a spiral process that proceeds sequentially through stages with the possibility of relapse to a previous stage (Figure 1) [16, 17]. The stages include precontemplation, contemplation, preparation, action, maintenance, and termination.

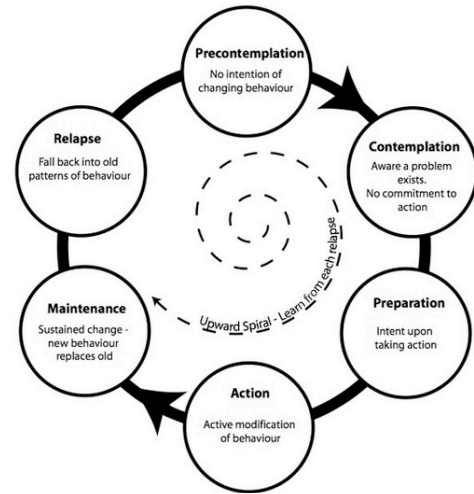

Fig. 1. TTM stages of behavioral change [16, 17]

The first stage, precontemplation, is associated with individuals who do not intend to take any action in the foreseeable future. Often these individuals are uninformed or unaware of the consequences of their behavior. They may have tried and failed to change in the past, becoming demoralized, resistant, and unmotivated with respect to change. In the educational context, these individuals can be recognized by their resistance to change and a lack of involvement in professional development activities that inform them about alternatives to their instructional techniques. These faculty may also be unaware of the need or opportunity to change their instructional approach.

The second stage, contemplation, is characteristic of individuals who are aware of the pros and acutely aware of the cons related to their behavior. Individuals can remain in this stage due to an overwhelming weight of cons and ambivalence to pros associated with changing a given behavior. Along with individuals in the precontemplation stage, these individuals are not ready for traditional action-oriented programs. In education, these programs consist of faculty development programs offered through local centers for teaching and learning, attendance at conferences, and reading education

publications. In their study of several engineering departments, Cutler et al. [19] noted that 35% of faculty had at one time implemented an evidence-based (research-based) instructional practice but no longer maintain that practice, 11% had never tried but had knowledge of the practices, and 3.2% had never heard of the practices. This indicates that almost 50% of the faculty surveyed would reside in the precontemplation or the contemplation stages rendering traditional forms of dissemination and faculty development ineffective.

The third stage, preparation, includes individuals who are intending to take action towards a behavior in the future. Typically, these individuals have a plan of action. Faculty in this stage would be members of professional education societies who receive publications and attend conferences with the interest of learning about new educational practices, as well as those independently investigating new instructional approaches. The fourth stage, action, is representative of individuals who are making specific modifications to their practices that equate to changing their behavior. Within education, these individuals may exhibit actions related to planning and developing curricula to integrate an EBIP into a course.

The fifth stage, maintenance, is characteristic of maintaining the action stage and preventing relapses to the pre-contemplation, contemplation, and preparation phases. The individual in this stage not only applies stimulus control processes to prevent triggers that encourage relapse but also develops helping relationships. Within health behavior, these helping relationships are commonly associated with support groups in health behavior, which can be interpreted as communities of practices (CoP) in education.

B. Processes of Pedagogical Change

In TTM, Prochaska et al. [17] identified the process of change as covert and overt activities that people use to progress through the stages. They have characterized 10 common processes as guides for intervention programs (Table II). In their work Prochaska, DiClemente, and Norcross [20] identified systematic relationships between the stage in which individuals reside and the processes they were applying to advance to the next stage (Table III). In order to advance through the earlier stages, individuals need to apply cognitive, affective, and evaluative processes [16]. Specifically, when

progressing from the precontemplation stage to the contemplation stage, processes associated with action are insufficient, and these individuals require processes such as consciousness raising and dramatic relief that require individuals to explore facts about incorporating EBIPs and to explore their negative emotions associated with not using EBIPs [17].

TABLE II. DESCRIPTIONS OF PROCESSES OF CHANGE IN TTM [16, 17]

Construct	Description
<i>Consciousness raising</i>	Finding and learning new facts, ideas, and tips that support the healthy behavior change
<i>Dramatic relief</i>	Experiencing the negative emotions (fear, anxiety, worry) that go along with unhealthy behavioral risks
<i>Self re-evaluation</i>	Realizing that the behavior change is an important part of one's identity as a person
<i>Environmental re-evaluation</i>	Realizing the negative impact of the unhealthy behavior or the positive impact of the healthy behavior on one's proximal social and/or physical environment
<i>Self-liberation</i>	Making a firm commitment to change
<i>Helping relationships</i>	Seeking and using social support for the healthy behavior change
<i>Counterconditioning</i>	Substitution of healthier alternative behaviors and cognitions for the unhealthy behavior
<i>Reinforcement management</i>	Increasing the rewards for the positive behavior change and decreasing the rewards of the unhealthy behavior
<i>Stimulus control</i>	Removing reminders or cues to engage in the unhealthy behavior and adding cues or reminders to engage in the healthy behavior
<i>Social liberation</i>	Realizing that the social norms are changing in the direction of supporting the healthy behavior change

TABLE III. PROCESSES ASSOCIATED WITH STAGE CHANGE IN TTM [16, 17]

	Stages of Change				
	Precontemplation	Contemplation	Preparation	Action	Maintenance
Process of Change	Consciousness raising				
	Dramatic relief				
	Environmental reevaluation				
		Self-reevaluation			
					Self-liberation
					Counter conditioning
					Helping relationships
					Reinforcement management
					Stimulus control

In order to progress through later stages individuals will require processes that rely on commitments, conditioning, and environmental controls [16]. These interactions between stages and processes imply that, in the educational context, appropriate interventions are needed for faculty to progress through the stages that lead to the maintenance or termination of past educational behaviors.

IV. CONCLUSIONS AND DISCUSSION

In order for change strategies to be successful, they must focus on the individual beliefs of faculty and be compatible with the context in which they are applied. An understanding of contextual influences (cultural norms, institutional missions, policies, leadership, values, economic, and political factors) that faculty face when they change their approach to teaching are critical to the support of their pedagogical change. By recognizing the stage of change, professional development programs and change agents can tailor interventions to meet the needs of the faculty at a particular stage.

Additional work will address the application of TTM to pedagogical change by utilizing empirical evidence to validate the stages and change processes. This validation will focus on characterizing faculty stages of change with respect to the adoption of evidence-based instructional practices and application of change processes that support their adoption.

Engineering Ph.D. Students' Career Preferences:

Levels, Changes, and the Role of Advisors

Neha Choudhary and Brent K. Jesiek

School of Engineering Education

Purdue University

West Lafayette, IN, USA

nchoudha@purdue.edu

Abstract—The Survey of Earned Doctorates indicates that almost three fourths of all doctoral degree recipients in engineering fields found employment in industry or business, and less than one eighth of them found employment in academia. Although these observations provide insight into the employment patterns, job opportunities, and realized career transitions of recent doctorate recipients, very few systematic studies have been conducted concerning potential mismatches between the career preferences and actual employment pathways among doctoral students in engineering. This issue is of particular importance given growing concern that these career patterns reflect fundamental imbalances between the supply of doctoral students seeking academic positions and the availability of such positions. Differences in job expectations and availability can also generate considerable dissatisfaction among students and may negatively impact relationships between students and advisors. In this preliminary study, the authors are investigating career preferences among doctoral students in engineering. The more specific focus of this paper centers on level and changes in preferred career choices during Ph.D. studies, as well as the role faculty advisors play in engineering doctoral students' career decision-making processes. For the purpose of this study, the research participants will be Ph.D. students in a specific level of their graduate study. The method for collecting and analyzing data will be quantitative survey method. The findings from this study have implications for higher education policymakers, faculty advisors, and other stakeholders (e.g., representatives of industry) related to better understanding engineering doctoral students' preferred career choices and changes in those choices during the course of their Ph.D. studies. More specifically, it is expected that the results will help policymakers, administrative staff, and faculty advisors encourage doctoral students to explore multiple career paths so these students can explore and be trained for the full range of likely job opportunities they will face upon graduation. In this work-in-progress paper, the authors will be discussing the relevant literature review and the research design of this preliminary study.

Keywords—academic advisor; doctoral students; career preferences; engineering; graduate students

I. INTRODUCTION

The 2012 Survey of Earned Doctorates (SED) indicates that only 13.4% of doctorate recipients in engineering fields found employment in academia, while 72.9% found employment in industry or business, and 2.9% found employment in non-profit organizations and 1.4 % reported other employment opportunities[1]. Although these statistics

provide insight into employment patterns, job opportunities, and realized career transitions of recent doctorate recipients, very few systematic studies have been conducted concerning potential mismatches between the career preferences and actual employment pathways among doctoral students in engineering. Through this preliminary study, the authors will be investigating career preferences among doctoral students in engineering, with a focus on four specific research questions:

- RQ1: What are the preferred career paths by engineering doctoral students or which career paths do engineering doctoral students find attractive?
- RQ2: Do career preferences of engineering doctoral students change over the course of Ph.D. program?
- RQ3: To what extent, external factors are responsible for change in preferred career choices of engineering doctoral students over the course of Ph.D. program?
- RQ4: To what extent faculty advisors encourage or discourage a specific career path of their engineering graduate students?

The remainder of this paper begins by situating our work in the literature. We then discuss our research design and methods. We expect that our efforts will be of particular interest of policymakers, administrative staff, and faculty advisors as they encourage doctoral students to explore multiple career paths so that those students can explore and be trained for the full range of likely job opportunities they will face upon graduation.

II. LITERATURE REVIEW

There is a growing concern in the science and engineering community that Ph.D.-trained scholars face a shortage of available faculty positions, which are considered to be the most desired careers in many fields [2]. For example, data from the National Science Board's 2012 Science and Engineering Indicators shows that the share of full-time faculty among all academic Science & Engineering (S&E) doctorate holders fell from 88% in the early 1970s to 73% in 2008. Especially in engineering fields, data show that the share of full time faculty holders fell significantly, from 91% in the early 1970s to 76% in 2008 (Science and Engineering Indicator, 2012). In a research study based on the data from the US Survey of Doctorate Recipients from 1973 to 1999, Stephan pointed out that by the mid-1990s industry surpassed

all types of academic employment for engineering doctoral recipients. As noted above, recent data from the SED report similar shows that nearly three quarters of graduates earning doctoral degrees in engineering assume employment in industry or business settings. [3]. These observations challenge the traditional expectation that Ph.D.'s are trained to join academia [4].

Yet while government data can provide insights into current employment patterns, job opportunities, and realized career transitions, very few systematic studies have been done on the engineering doctoral career preferences, including the potential for mismatch between the observed career paths and engineering doctoral students' preferences. Some of the studies that discussed other issues related to Ph.D. career paths include: incentives for doing a Ph.D. [5], expectations and realities regarding employment [5, 4], and employability of people with a doctoral degree [7]. A recent study by Sauermann and Roach did focus on career preferences, although the focus of this study was limited to doctoral students from life sciences, physics and chemistry [8]. Given that employment opportunities, funding resources, incentives from specific jobs, and job satisfaction depend upon the particular field, additional studies are needed to determine the career preferences of engineering doctoral students and the mismatch between job availability and preferred career.

Additionally, some of the literature suggests that career preferences may change during the Ph.D. program, but there is very limited empirical evidence available to support this claim [9]. More generally, Arnett found that during emerging adulthood, people adjust their career choices from ideal to more realistic according to the requirements of the careers in their set of acceptable alternatives [10]. And in an interesting study regarding incentives of enrolling in science Ph.D. programs, Mangematin found that Ph.D. students in applied sciences do not conform to academic criteria during their Ph.D., but at the end of the Ph.D. they conform to the recruitment criteria of their expected employer [5]. Additionally, Mendoza found that students entered graduate school with very positive views on pursuing a faculty career, but as they gained experience in the graduate program they tended to value other career options such as industry [11]. A study by Sauermann and Roach found that science doctoral students' interest in academic research declined over the course of their training while other careers became relatively more attractive, but they did not look into the underlying reasons or factors associated with these changes [8].

The role of the advisor is considered to be crucial in graduate students' life. Research has shown that effective support from a faculty member has been associated with "increased job satisfaction, higher salary, faster promotion, and firmer career plans" [12]. Corcoran and Clark investigated the impact of advisors or other faculty on students' later careers or involvement in the academic community [13]. Mentoring, which is one of the key roles of the faculty advisor, is reported to be very valuable and to facilitate securing initial employment and might, in turn, result in intentional and generative career development for doctoral students [14], [15] [16]. Few studies have also looked into the role of advisor in exacerbating labor market imbalances in the

field of science, but no systematic and empirical data are available in the field of engineering [17],[18]. In the next section of this paper, we will discuss the research design of this study that will help researchers to answer research questions for this study. This section will include context and research participants, operationalization of concepts and data collection and analysis plan of this study.

III. METHODS

A. Context and Research participants

In this preliminary phase of the study, we are planning to collect and analyze data from engineering doctoral students. We focus specifically on the engineering doctoral students who have either cleared their qualifying/preliminary exams (i.e., Ph.D. candidates) or in their final year of Ph.D. program (thesis writing phase) in the three largest engineering disciplines (mechanical engineering, chemical engineering, and electrical and computer engineering) at a large research-intensive university in the U.S. Midwest. It is important that research participants should be at this particular stage or level (qualifying/preliminary exams or thesis writing phase) of their Ph.D. program because at this stage they start making career decisions and choices. One of the main reasons for selecting these disciplines is because they are the largest engineering discipline in terms of number of Ph.D. students enrolled. To recruit research participants, we are using *random* or *probabilistic sampling* strategy. We are planning to distribute this questionnaire online among engineering doctoral students of mechanical engineering, chemical engineering and industrial engineering. We are estimating the population size to be 200-250. Depending upon this, using sample size calculator, the sample size for this study will be around 132-152 doctoral engineering students for achieving 95% confidence level. I will be collecting the contact email ids from the department's administrative staff. The questionnaire is created using an online survey software. Qualtrics Surveys and will be distributed using email and other through other social media. A consent form and a cover letter will also be sent along with the questionnaire via email.

B. Operationalization

Based on four research questions, the major concepts in this study are: career paths; preferred career choices of engineering doctoral students; changes in preference over duration of the PhD program, factors influencing for changes in preferred career choices, and faculty advisor's encouragement to a specific career options. For this study, we are defining career paths as faculty job with focus on research; faculty job with focus on teaching; industry job with focus on research; government job with focus on research; or job as an entrepreneur. In this study, preferred career choices are defined as the students' perception of the most interesting career options for them, given no constraints on available job opportunities. For this study, the external factors that may influence in changes in preferred career choices are defined as passion for research, passion for teaching or training, family

responsibility, advisor's engagement, employment benefit/salary, and awareness for other career options.

C. Data Collection and Analysis

In this study, quantitative survey research method questionnaire will be used to collect and analyze the data. This questionnaire instrument consists of 8 multiple choice questions and three single answer questions. Three out of 11 questions are used to collect demographic information. The rest of the 8 questions are intended to measure the key concepts of the study, i.e., preferred career choices of engineering doctoral students, changes in preferred career choices over the time of Ph.D., factors influencing these changes, and extent of faculty advisors' encouragement to a specific career. The questions related to the preferred career choices include list of career options, e.g.: faculty job with focus on research; faculty job with focus on teaching; industry job with focus on research; government job with focus on research; job as an entrepreneur; etc. The response options related to preferred career options are based on 5 point scale ranging from 1 (extremely unattractive) to 3 (neither attractive nor unattractive) to 5 (extremely attractive). The response options related to changes in preferred career choices are based on 5-point scale ranging from 1 (certain not to pursue) to 3 (uncertain whether to pursue) to 5 (certain to pursue). The response options related to extent to which faculty advisors encourage a specific career options are also measured on a 5-point scale ranging from 1 (strongly discouraged) to 3 (neither encouraged nor discouraged) to 5 (strongly encouraged). The question related to the factors influencing career choices includes passion for research; passion for teaching; family responsibility; and salary. We will be using statistical analytical methods to analyze collected survey responses. We will be using 5 point Likert scale which is coded from level 1-5 to measure most preferred career options ranging from faculty job with focus on research; faculty job with focus on teaching; industry job with focus on research; government job with focus on research; or job as an entrepreneur.

IV. CONCLUSION

In this work-in progress paper, we discussed relevant literature review and research design of a preliminary study. In this preliminary quantitative study, we are proposing to investigate preferred career choices of engineering Ph.D. students, changes in those choices, factor influencing those changes and role of faculty advisors' encouragement in making those career decision. The findings and implications from this study will be useful to higher education policy makers, faculty advisors, and other stakeholders (e.g., representatives of industry) to understand engineering doctoral students' preferred career choices and changes in those choices during the course of their Ph.D. studies. More specifically, it is expected that the results will help policy makers, administrative staff, and faculty advisors encourage doctoral students to explore multiple career paths so that those students

can explore and be trained for the full range of likely job opportunities they will face upon graduation.

Abstract—The adoption of research-based instruction strategies (RBIS) by faculty is generally perceived as being slow. Faculty resist change, reject data that demonstrates the effectiveness of RBIS, and prioritize research over teaching. Even when faculty attempt to use RBIS, they often do so with poor fidelity to the original design of the RBIS. By organizing faculty into communities of practice, we are observing a sudden surge in the adoption of RBIS across STEM departments. Through this work in progress we present preliminary data that we have collected to understand exactly why many faculty are now adopting RBIS. While this effort has led to the adoption of many RBIS, we focus on the adoption of personal response systems (clickers) and Peer Instruction. Preliminary data suggests that faculty adoption is being driven by community and collaborative instruction.

Keywords—change; research-based instructional strategies; communities of practice; clickers

I. INTRODUCTION

Our understanding about how to create change in engineering education primarily focuses on all the ways that change is difficult or slow. We now know that many change efforts rely on develop-disseminate models in which faculty develop new Research-Based Instructional Strategies (RBIS) and then disseminate them through publications and workshops [1-3]. These models have proven ineffective [4]. Faculty resist using RBIS due to clashes with their professional identities and challenges arising from a lack of time or access to training and development [5]. Even when faculty do attempt to implement RBIS, their fidelity of implementation is low [6].

In 2012, the College of Engineering created the Strategic Instructional Initiatives Program (SIIP) to transform and revitalize core engineering courses at the University of Illinois at Urbana-Champaign. During its three years of existence, the program has sparked the rapid spread of RBIS across the college and has created a thriving community of faculty invested in improving undergraduate instruction. For example, context-rich collaborative problem solving [7] (students

working in teams to solve difficult, real-world engineering problems) has been integrated into 14 courses in five departments and has now been practiced by 27 faculty instructors, most of whom had not been using this RBIS before SIIP [8]. Further, SIIP has expanded beyond the confines of the College of Engineering and its model is being replicated across Science Technology Engineering and Mathematics (STEM) departments in other colleges through NSF WIDER funding (DUE-1347722).

These efforts have rallied faculty around the simple message of “Teach like we do research.” Central to both SIIP and WIDER is a central model of change (See Figure 1). Somewhat counterintuitively, the primary goal of these efforts is not to stimulate the adoption of RBIS. Rather, the primary goal of these efforts is to create faculty communities of practice (CoPs) that provide an environment of shared vision and practice through which faculty seek to create collaborative, joint ownership of a target course or set of courses [2, 9]. Within these CoPs, faculty commit to an implement-evaluate development cycle for which the CoP must commit to collecting data about their innovations and using the data to inform iterative development. Finally, we expect that the adoption of RBIS will organically emerge without any particular mandates from the leadership team or administration [2]. Indeed, we have been seeing this organic emergence of RBIS adoption within our CoPs.

This work-in-progress paper provides our first steps toward understanding how and why these CoPs have supported such rapid adoption of RBIS in such a short time. In this paper, we present our preliminary efforts to track and explore the spread of personal response systems (clickers) and Peer Instruction [10, 11]. We begin by providing a brief background on the theory behind CoPs and Peer Instruction. We then describe our efforts to understand the spread of Peer Instruction and provide some lessons learned from preliminary data collection.

II. ORGANIZATIONAL CHANGE THEORY

Learning theories such as transformational learning theory [12, 13] and other situative frameworks such as Communities of Practice (CoPs) [9, 14] provide insights into why emergent, environmentally-focused change strategies can be effective. Decision-making during instruction and curriculum development is driven by faculty’s implicit epistemologies,

This work was support by the University of Illinois’s College of Engineering. This work was also supported by the National Science Foundation under grant DUE-1347722. The opinions, findings, and conclusions do not necessarily reflect the views of the National Science Foundation or the author’s institution.

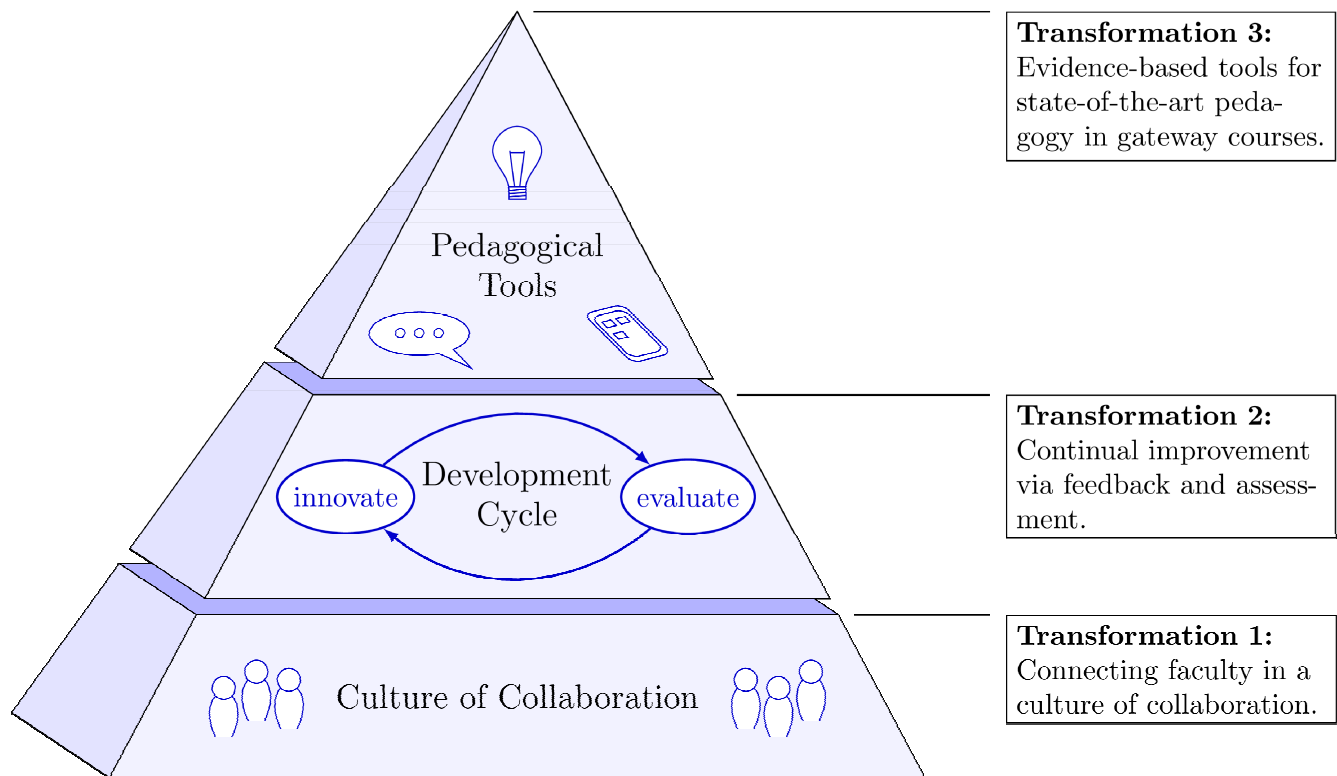

Fig. 1. Three key levels of sustainable education transformation used to guide SIIP and WIDER; Each layer supports the transformations above.

beliefs, and commitments [5, 15-17]. When these implicit value systems do not align with the implicit value systems of RBIS, faculty resist the initial adoption of those RBIS or will fail to persist in their use [17]. Transformational learning theory posits that implicit value systems can be changed only through mutual reflective engagement about communal practices such as teaching practices or curriculum design practices [12, 13]. CoPs provide a place for this mutual reflective engagement, inviting faculty to engage in continuously deeper levels with RBIS, from the periphery to the core [9].

Critically, faculty frequently have a central identity of self as expert in this classroom [5], an identity that can be at odds with student-centric RBIS. The mismatch in values can create a psychological “immune response” that seeks to guard existing identities and value systems and ward off invading identities [18, 19]. CoPs provide a safe environment for challenging this immune system, surrounding resistant faculty with respected colleagues, thus mitigating the perception of identity threat [9, 14]. Within CoPs, faculty engage in long-term situated learning, participating in community-valued practices [9, 14], creating a place for the assimilation of new values that align with RBIS.

III. DESCRIPTION OF PEER INSTRUCTION

A class that uses peer instruction is characterized by short presentations that are followed by conceptual questions. Students ponder and answer these questions, then discuss them with peers, with the goal of achieving consensus [10, 11].

After the peer discussion, the students again answer the question, and the instructor debriefs students’ responses [10, 11]. The conceptual questions play a key role in peer instruction, and should be written such that students get “a chance to explore important concepts, rather than testing cleverness or memory, and to expose common difficulties with the material” [11]. Students can provide answers to these conceptual questions through a show of hands, flashcards, or more recently, through the use of clickers [20].

While instructors have identified some challenges to using peer instruction, including the time needed to create appropriate conceptual questions, less time for lecturing, and some students’ discomfort with this method [21], students benefit greatly from this method. Peer instruction has been found to increase students’ conceptual learning and problem solving, and to decrease student attrition [20].

Interestingly, peer instruction benefits students regardless of whether students respond through clickers [20]. However, using clickers benefits instructors in a variety of ways: they “allow instructors to get precise real-time feedback,” they allow the instructor to archive student responses for future reference, and they move instructors to “shift their focus toward conceptual instruction” [20].

In their study on the fidelity of implementation of clickers, Borrego et al. identified four critical elements required for high fidelity of implementation of Peer Instruction: 1) Answer multiple-choice conceptual questions (MCQ) with distractors (incorrect responses) that reflect common student misconceptions, 2) Discuss a problem in pairs or groups, 3)

Use clickers or similar means to ‘vote’ on the correct answer of a MCQ, and 4) Provide answer(s) to a posed problem or question before the class can proceed [6]. It was observed that Peer Instruction has the lowest fidelity (11%) of implementation of all RBIS studied [6].

IV. CONSTRUCTION OF THE SURVEY

Project monitoring and evaluation revealed that many innovation CoPs created through SIIP and WIDER had begun using clickers in their classrooms. We also observed that some faculty used clickers in ways that aligned with principles of Peer Instruction, while others used alternate techniques. We decided to explore whether we could use a survey to study the spread of RBIS and their fidelity of implementation. While this particular survey focuses on clickers, we expect to use similar studies to examine other RBIS.

We constructed a survey to begin exploring two research questions.

1) How do faculty describe their own use of clickers?

2) Why did faculty decide to adopt clickers? Are the reasons for adoption of clickers different among SIIP and WIDER participants than other faculty?

The survey begins with five questions exploring when faculty first heard about clickers, how faculty first heard about clickers, when faculty started using clickers, what interactions or sources led faculty to adopt clickers, and what reasons (if any) delayed their initial adoption of clickers.

The second part of the survey explored the teaching practices that faculty used with clickers. A list of teaching practices was constructed both from the literature on Peer Instruction and from our observations of how faculty were using clickers in their classrooms. Faculty rated a list of practices (shown in Table I) on a Likert scale based on the frequency with which they used each of the teaching practices in conjunction with clickers. Three of the teaching practices (highlighted in Table I) were specifically focused on the critical components identified by Borrego et al. [6] and listed in the previous section. Faculty were also allowed to add any additional teaching practices they used that we did not list.

In addition to the Likert scale questions, faculty were asked to describe their ideal use of clickers and their perceptions of the benefits and tradeoffs of using clickers in their classrooms.

The final part of the survey was focused on tracking the spread of clickers. Faculty were asked to identify who or what persuaded them to use clickers, identify who they had persuaded to clickers, and identify others who they happened to know used clickers.

Sampling for this survey uses a snowball sampling method in which initial survey participants identify additional survey participants in their responses. This sampling method enables the sampling of targeted populations without a priori knowledge of where those populations reside. The Principle Investigators of the NSF WIDER project served as the initial seed samples for the survey.

TABLE I. FREQUENCY THAT FACULTY USE CLICKERS TO SUPPORT VARIOUS TEACHING PRACTICES. THE THREE HIGHLIGHTED ROWS CORRESPOND TO THE REQUIRED ELEMENTS OF PEER INSTRUCTION AS IDENTIFIED BY BORREGO ET AL. [6].

	Almost Never	Occasionally	Usually	Almost Always
Track Attendance	2	3	0	8
Warm-up quiz w/ feedback	3	3	4	3
Warm-up quiz w/out feedback	10	1	1	1
MCQ w/out peer discussion	6	2	4	1
MCQ w/ peer discussion	1	0	6	6
Immediately reveal MCQ performance	0	0	4	9
Instructor leads discussion after MCQ	3	3	5	2
Adjust pace of instruction	2	4	5	2
End-of-class quiz w/ feedback	9	2	1	1
End-of-class quiz w/out feedback	12	1	0	0
Collect early informal feedback	9	3	1	0

V. PRELIMINARY RESULTS

The survey has had 13 respondents at the time of publication. Due to the small sample size, we do not provide any statistical analysis of the data, but provide some initial tentative observations that we hope to explore further as we increase our sample size.

A. Why Did Faculty Adopt Clickers?

Figure 2 plots the year that faculty adopted clickers in their teaching practice against the year that faculty first heard about clickers. The earliest year reported for the use of clickers is 2005 – the year that i>clickers were invented on our campus. Not surprisingly, the first adopters were the inventors of i>clickers and their close colleagues. The only other early adopter is currently a principle investigator for the WIDER project. The majority of our sample (10 of 13) adopted clickers after the start of SIIP in 2012. A few of the senior faculty in the study heard about clickers shortly after the invention of i>clickers, but their adoption took place after being embedded into SIIP and WIDER CoPs (In Figure 2, see three data points of faculty who heard about clickers in 2006 and 2007 and adopted them after 2012).

Fig. 2. Plot of the year that faculty adopted clickers in their teaching practice plotted against the year that faculty first heard about clickers. An equal-year line indicates

Awareness and adoption of clickers was driven primarily by interactions with colleagues. Figure 3 shows that most respondents heard about clickers through conversations with colleagues or observation of another instructor. Noticeably, none of the adopters first learned about clickers from publications.

Fig. 3. Sources of faculty knowledge about clickers

Faculty's free responses to questions about why they adopted clickers similarly reflect the critical role of colleagues in their adoption as 10 of 12 responses indicate the role of colleagues in persuading them (the creator of i>clickers is omitted from these responses). Four of the respondents specifically mentioned their involvement with SIIP and WIDER CoPs.

Because of the preliminary nature of this data, exemplar quotations are provided to give readers a sense of faculty responses, but qualitative analysis of this data will occur after sampling has ceased.

"I had thought they were a great idea as soon as I heard about them; however, it was not until I took over a class in which the previous instructor had already used them that I decided to use them myself."

"Existing course format required their use. Co-teaching with an experienced instructor (Prof. X) who was using

them. He learnt about them from physics, I believe. I used them once with X in 2009, but it wasn't a great experience (bad format), so I didn't use them again until 2013 when I started using them as part of the SIIP project."

B. How Are These Faculty Using Clickers?

Confirming the observations of the principle investigators, all of the listed teaching practices in Table 1 were chosen by the faculty. While each of the teaching practices are in use, the most common self-reported teaching practices align with the critical elements of Peer Instruction and tracking attendance. These results suggest that faculty connected with SIIP and WIDER may be using Peer Instruction with a higher fidelity than reported in previous studies, but these results are preliminary and firm conclusions should not be drawn from this data.

These results also reveal that faculty use clickers using a mixture of practices that align with the critical elements of the RBIS with practices that are not supported by the literature.

Faculty's free responses seem to corroborate these observations. Again, because of the preliminary nature of this data, exemplar quotations are provided to give readers a sense of faculty responses, but qualitative analysis of this data will occur later.

"I like iClicker questions best when they reveal common conceptual problems. By using them to reveal in real-time the misunderstandings that students have, the students become highly engaged to fix their faulty understanding of course concepts. I like to use mass-misunderstanding moments to open up discussions with their neighbors as an opportunity for students to truly consider the validity of their often-flawed reasoning. Then, by following up with a re-poll, I can open the floor for a student to explain what is hopefully the proper reasoning. This opportunity can be used to provide encouragement to students to confidently express their reasoning."

"My best uses of iClickers is when I can sprinkle 3-4 questions throughout my lectures so that students stay focused and get immediate feedback on whether they understand the material. The other 'best' use is when I have a particularly tricky topic and can 'wake up' the students by showing them that a significant portion of the class is struggling with the concept."

"To test on the same question first without allowing for discussion, and then again but after discussion"

VI. FUTURE WORK

This preliminary data suggests that faculty communities and social networks play an important role in faculty awareness and adoption of RBIS. Deeper analysis of the data will commence after the snowball sampling reaches saturation. These results suggest that we should conduct social network analysis to better understand the interconnections between faculty.

We expect to expand this survey to explore the spread of other RBIS and explore the generalizability of these findings.

Abstract— In order to develop the engineers of the future, engineering departments need to embrace innovative, student-centered practices. The development and sustained growth of organizational improvement practices like those needed to improve engineering education depend upon an institutions' or departments' collective and individualized attention to human resources, leadership, knowledge development, revenue development and opportunities for continuous engagement. The literature in engineering education related to sustainability and curricular change indicates initial training and dissemination is necessary though not sufficient for change to take root, that all change agents need mentoring, collaboration opportunities, and venues for sharing their work, that innovative practices may vary across settings, and that a systemic effort needs continuous attention to remain robust. The paper provides CAHSI as an example of sustained innovation, and details the ways in which CAHSI was designed for sustained impact in engineering education across partnering Hispanic Serving Institutions. The paper highlights programmatic considerations and evaluation design, and describes how the results can inform leadership regarding progress and needs for sustaining change.

I. INTRODUCTION

In order to develop the engineers of the future, engineering departments need to embrace innovative, student-centered practices. Creating and maintaining pedagogical change in computer science and engineering departments is challenging, given short programmatic funding cycles and multiple demands on faculty time. This paper describes strategies employed by an alliance of eleven departments and external partners to improve educational outcomes for underrepresented students in computer science and engineering. The development of organizational capacity within this multi-institution initiative is important for engaging all members in the mission of the alliance and, over time, is crucial for contributing to sustainability of the alliance beyond the life of National Science Foundation funding. This paper situates the CAHSI model within the organizational change literature regarding how to motivate and sustain innovation in a department or institution. The paper provides CAHSI as an example of sustained innovation, and details the ways in which CAHSI was designed for sustained impact in engineering education across partnering Hispanic Serving Institutions. The paper highlights programmatic considerations and evaluation design, and describes how the results can inform leadership regarding progress and needs for sustaining change.

II. CAHSI

The Computing Alliance for Hispanic-Serving Institutions (CAHSI) is a Broadening Participation Alliance funded by the National Science Foundation. CAHSI is a cooperative effort among 11 core institutions that implements changes in computing pedagogy, research, and professional development opportunities in higher education collaborating to spread the promising practices developed at each institution. The goals of the alliance are to recruit, retain and advance Hispanics in computing. This paper documents elements of design and implementation within the organization that have supported sustainability and organizational change among member computing and engineering departments, and highlights ways in which the sustainability has been measured and monitored throughout the course of CAHSI's 10 years.

Throughout its history, CAHSI has provided deep and broad support to students and faculty at all educational stages. The CAHSI model has consistently fostered deep student engagement throughout their undergraduate and graduate experiences. For instance, in the 2013-14 academic year alone, CAHSI departments provided:

24,840 hours of introductory computing content to 552 students, nearly 2/3 were Hispanic or other underrepresented minority students.

49,335 hours of undergraduate-led supplemental instruction through peer-led team learning (PLTL) to 1,905 students, nearly 60% were Hispanic or other underrepresented minority students.

10,305 hours of coursework using the Affinity Research Group (ARG) model to 255 students; 75% were Hispanic or other underrepresented minority students.

7,800 hours of out-of-class research experiences provided to 27 students; 71% were Hispanic or other underrepresented minority students.

These opportunities for substantive technical learning and deep engagement with the discipline build students' self-efficacy, sense of mastery, and increase their aspirations to pursue graduate education and computing careers. During the last five years, 77% of all ARG undergraduate students reported that they were more likely to pursue graduate school because of their research experience; many of the remainder stated that they were already strongly committed to graduate study. CAHSI students also have higher aspirations than a national sample of computing students surveyed by the Computing Research Association. For example, 19% of

CAHSI students aspired to a doctoral degree, while only 12% of the national sample of students expressed that goal.

CAHSI has worked to sustain efforts and expand in manageable ways given shrinking governmental funding opportunities. This paper illustrates the ways in which CAHSI has made a concerted effort to leverage resources to support transformational educational practices. This paper is a case study of a long-standing collaborative organization. The data collected over 10 years of evaluation of the program describes some of the ways in which the design and implementation of the alliance across institutions has led to its longevity and impact. Building on organizational change literature, the evaluation of organizational capacity building efforts is described. Illustrative examples show how CAHSI has supported sustained curricular and co-curricular innovation in member institutions and beyond.

The research questions addressed in this paper are:

What factors of initiative design and emerging practice have supported sustainability for CAHSI?

What challenges remain in sustaining the CAHSI initiative?

III. ORGANIZATIONAL CHANGE LITERATURE

The development and sustained growth of organizational improvement practices like those needed to improve engineering education depend upon an institutions' or departments' collective and individualized attention to human resources, leadership, knowledge development, revenue development and opportunities for continuous engagement [1,2,3]. Johnson, Hays, Center and Daly [4] designate the need for *infrastructure capacity building* in change efforts. According to the authors, infrastructure capacity building objectives include the ability of the organization to:

"a) strengthen and maintain structures and formal linkages, b) strengthen, maintain, and cultivate leadership, c) increase or maintain resources to sustain innovation, d) build and maintain expertise to sustain the innovation."

A. Innovation in Engineering

Studies of innovation in engineering education have looked at the most promising practices for sustaining innovation over time and for influencing other practitioners to incorporate inclusive, student centered approaches in their classrooms to promote change. Borrego and Henderson [5] described four types of change strategies employed in educational settings, and note the strategies that honor complexity, assume changes must occur within environments rather than only at the individual level, and that emergent rather than prescribed change might have the best chance at succeeding. Similarly, Sidiqi and Adams [6] called for approaches to educational change that moved beyond diffusion or propagation approaches in which curriculum as a bounded object is passed to multiple intended users. Instead, educational change efforts that address explicit assumptions about students, learning experiences, and goals prompting innovation might be more effective in creating lasting improvements in engineering education.

A National Science Foundation funded coalition of engineering education institutions reflected on their curricular change models as they evolved over time in the partnership, and concluded in its fourth generation change model that curricular change involved persuasion, developing tools and resources that would work for multiple audiences, and a need to provide structures that support curricular use and further development [7]. The literature in engineering education related to sustainability and curricular change reflects lessons learned in the CAHSI community—that initial training and dissemination is necessary though not sufficient for change to take root, that all change agents need mentoring, collaboration opportunities, and venues for sharing their work, that innovative practices may vary across settings, and that a systemic effort needs continuous attention to remain robust.

B. Transforming practice in HSIs

Hispanic serving institutions, defined by Title V of the United States federal government as institutions with 25% or greater full time enrolled students who identify as Hispanic/Latino, have particular demographic realities that shape the way postsecondary institutions address their needs. Hispanic serving institutions may have a higher than average number of community college transfer students, and may enroll a greater proportion of students with significant financial need, as well as students with school experiences at the K12 level that did not sufficiently prepare them for the rigors of engineering education [8,9]. It is said that new educational initiatives can be expected to transfer to new sites based on the extent to which the educational sites are similar [10]. By partnering with other HSIs in transforming education in engineering, institutional agents can start from a place of common ground and develop shared and complementary expertise to transform education.

In a large scale study of transformative change among HSIs, Nunez, Hurtado, and Galdeano [11] document effective practices for engaging collaboration in Higher Education. In their research work with partnering HSIs primarily in the southern and western United States, they found four themes that related to institutional change and improved student outcomes in these strategic HSI partnerships: cross-institutional mentoring, changing mindsets, mutual encouragement and action, and the 'ripple effect'. CAHSI was designed and implemented in ways that complement these 4 themes, and the themes serve to structure the results presented in this paper for research question 1.

IV. METHODS FOR EVALUATING ORGANIZATION CHANGE IN CAHSI

Evaluating organizational change across organizations involves a multilayered, mixed methods evaluation plan that documents student outcomes, programmatic reach, and based on needs of the funder, the impact of the partnership beyond the original funded organizations. To sustain the educational initiatives that serve students in alliance departments, the alliance must have the capacity to do the following:

a) replenish and fortify the pipeline at critical educational junctures (K-16 to graduate education) through continuous improvement of initiatives and pedagogy, including outreach and retention strategies that keep students engaged in engineering and computer science;

b) hold training sessions for the broader community on research-based practices that improve recruitment, retention, and advancement of students to ensure expertise is sustained and developed at each institution,

c) develop staff and faculty in new pedagogical, co-curricular, and research practices and understanding of innovative educational reforms so that departmental and course-level improvements continue to meet the needs of students and other stakeholders

d) extend the cadre of staff and faculty who commit to the alliance's core purpose and practices.

The evaluation measures direct impact of interventions on student enrollment, retention, and advancement in computing, as compared with comparable institutions. The Integrated Postsecondary Education Data System (IPEDS) maintained by the United States Department of Education serves as a source for comparison data used in establishing key student outcomes in computing at CAHSI schools in comparison with other public and private non-profit colleges and universities. Trends indicate CAHSI schools have weathered the downturn experienced in computing in the past decade better than their peers.

To best support the changes CAHSI implemented at member institutions to support Hispanics in computing it is vital to simultaneously focused on the support structures, training and reengagement activities, recruitment strategies, and policy work necessary to sustain innovation in engineering education. This work is carried out through surveys, interviews and observations within CAHSI departments and activities that focus on organizational capacity building across and within institutions, as well as actions that link CAHSI to partners across policy, education, philanthropy, and technical communities.

V. TRANSFORMING ENGINEERING EDUCATION PRACTICES IN HISPANIC SERVING INSTITUTIONS

Results of the CAHSI evaluation to date are framed using the model provided by Nunez, Hurtado, and Galdeano [11] to describe transformative practices in higher education, specifically with regard to HSIs. In their research work documenting the change processes, they found four themes that led to institutional change and improved student outcomes in these strategic HSI partnerships: cross-institutional mentoring, changing mindsets, mutual encouragement and action, and the 'ripple effect'. The following sections detail how CAHSI was designed and implemented throughout its decade in practice in ways that support collaborative transformation. The results section highlights activities and structures put in place organizationally to maintain commitments to change in education. This paper provides illustrative data from CAHSI's 10 year history that highlight the mixed-method nature of the

evaluation and how the measurement and feedback involved in formative evaluation can influence sustainability.

A. Cross institutional mentoring

CAHSI was designed with the implicit goal of mentoring professors across institutions. This goal is evident in the recruitment of faculty, particularly Hispanic faculty, to the annual meeting. The CAHSI annual meeting (now the Summit) provides a forum for Hispanic computing professionals and students that is not available elsewhere. No other national conference specifically fosters professional development and community among Hispanic computer scientists and engineers.

The relatively small size of the CAHSI annual meeting, its focus on student development as a central focus, and the largely Hispanic audience make it unique and valuable for attendees. Each year the annual meeting was held as a stand-alone event an overwhelming majority of both students and computing professionals reported that they had contacted someone they met at the CAHSI annual meeting in the month following the meeting. Thus, the CAHSI annual meeting is a method that fosters and enriches connections among the Hispanic computing community.

In the most recent evaluation of annual meeting faculty attendees, evaluation findings showed that professionals network with other conference attendees at a high rate. For example, faculty and industry professionals were asked to describe their networking and other professional follow-up activities in the month following the 2010 CAHSI annual meeting. Faculty contacted other faculty at their own institution at increasingly higher rates (50% in 2009, 81% in 2010, 94% in 2011). Professionals' rates of networking with faculty at other CAHSI institutions was strong (63% in 2011).

Fig. 1. Cross Institutional Mentoring: Faculty activity following annual

meeting

1) Case study: Mentoring faculty to support change

Evaluation data collection and analysis involved annual case studies to deepen understanding of specific elements of the CAHSI support network, particularly as it related to mentoring. An excerpt from a faculty member interview is used to illustrate how cross institutional mentoring can make a difference in educating Hispanics in computing.

At the time of the study, Guadalupe was a Latina tenure track assistant professor in a small public university. She viewed her career as one shaped by mentors in a network of professionals who took an interest in her professional career contributing to her capacity to expand her technical, research, and teaching skills. As an assistant professor, she needed to develop a research agenda to support her case for tenure. She noted two reasons for her desire to acquire student help in her research efforts; first, the need to produce more research; and second, to support her desire to help students.

"I needed to have a research agenda. I was worried that I wasn't going to do that. If I don't have students that work with me in my particular research area, I don't think I'll be successful because my current job is in a teaching institution transitioning to research; even if I could do my research on my own then I'm not helping really anybody."

Guadalupe's role as a professor in a transitioning institution involves the triad of interlocking roles, including service, teaching, and research. However, research in higher education consistently supports the master narrative that successful tenured professors produce research above all other job duties, including teaching and service [12,13].

At her campus, Guadalupe recruited a group of students to work with her on her research. She received small grants to support their participation and, through the CAHSI network, built relationships with more experienced Latinas in the field who mentored her in workshops that contributed to effective management of student researchers. She described the alignment between her teaching and research goals for students: *"My goals for teaching were to help students participate outside of the classroom and to get them involved in research...I want it to be really student centered."*

Her curriculum vita echoes this focus on research as a method for teaching. Her teaching statement espouses the value of both teaching and research.

My goal as a teacher is to find creative ways to facilitate active learning and outreach to potential students. I believe more than ever that teaching is all about participation; inside and outside the classroom. Currently, I am applying the (undergraduate research model) towards the creation of an interdisciplinary research group.

Throughout the interview, Guadalupe spoke of her successes in terms of student experiences and aspirations to persevere in research. For example, she described how one student changed his major to the more technical computer science major (rather than the information systems major, which tends to have more managerial and business-related coursework) and how another student was accepted at a prestigious PhD program following her experience in the research lab. She also explained how two students traveled with her to a research opportunity at a national lab for the

summer. While these experiences further her research work, her focus in the telling is on student progress, not her own development of a research agenda. And yet, inherent in the telling is the establishment of a research agenda and dissemination efforts that support her success as a professor.

The case of Guadalupe shows how mentoring a professor can be supportive of the professor's career trajectory while also ensuring transformative change in the institution. Providing students what have been called High Impact practices in higher education [14] can shift learning out of the classroom and into co-curricular practices that support retention. Faculty members need mentoring and training to make that transition sustainable and mutually beneficial for students and faculty alike.

B. Changing Mindsets

To truly make transformative changes in HSI engineering departments, it is not enough to simply inform faculty of research based pedagogical approaches that may improve student performance [15]. Instead, faculty and staff must be supported in challenging norms that serve as barriers to student achievement.

1) Informing minds with social science

Another effort CAHSI made as an organization to influence mindsets regarding Hispanic students in computing emerged at the CAHSI annual meeting in San Juan, Puerto Rico. This themed meeting brought together social scientists and educational researchers from a multitude of institutions and organizations to discuss challenges and opportunities engaging Hispanic youth in computing (<http://cahsi.cs.utep.edu/about>).

2) Evidence of changing mindsets from faculty perspectives

Evidence from faculty surveys supports the notion that CAHSI is influencing departmental culture and faculty mindsets regarding their role in education. Surveys with faculty asked respondents to compare their departments before and after the initiation of the alliance. Over a third of faculty report spending more time with students since CAHSI began (34%) and 39% responded that their colleagues spend more time with students since CAHSI began¹. Given the importance of faculty-student interaction to learning outcomes, this finding is significant in illustrating how collaboration can change mindsets that can potentially lead to higher student outcomes.²

C. Mutual encouragement and action

A norm in computing departments is an expectation of strong background knowledge in computing for incoming students [16] which researchers note privilege male students from moderate to high socioeconomic backgrounds and high performing schools [17] Initiatives that engage stakeholders from multiple institutions and are viewed as manageable to implement both challenge these norms and lead to action that

¹ 7% of participants felt their colleagues spent less time with students at the time of the study than they did before CAHSI, and the remaining respondents indicated no change.

² This paper focuses on organizational capacity for change rather than student outcomes. For more information on CAHSI's results for students please see [18,19]

provides opportunities to serve student learning needs may be particularly impactful for creating change.

1) CS-0: Policy and Pedagogy Designed for Change

The computer science zero courses (CS-0) implemented across CAHSI schools fit that description, as the purpose for including them in curricula was to serve students with limited computer science background who entered the college program at CAHSI schools. The course was relatively easy to add to a curriculum as an elective, and provided a venue for serving multiple student groups for a variety of purposes—from engaging with computer science as they took developmental courses to recruiting students from other majors into computer science, the course was flexible enough to engage instructors with multiple perspectives and yet cohesive enough in intent and scope to foster collaboration across partner institutions. The course took many forms across the differing institutions, allowing for sharing of teaching practices, computer languages, lessons, and approaches to recruitment of students. While implementation differed, the CAHSI community collaborated to try out new approaches in specialized workshops for CAHSI members, shared resources and tools via email and website dissemination, and contributed to the larger dialog about initial experiences in computing through conference papers and journal articles.

Evidence suggests that the course was successful in preparing first year students with little background who intended to study computer science. In focus groups and interviews students involved in CS-0 at CAHSI schools described an approach to learning programming that was well suited to novices as well as those having trouble with the jargon of programming in a more advanced course. They noted the importance of having an interactive, engaging instructor who was willing to answer questions students posed. As the students were interviewed towards the end of CS1, they were able to describe how the supported, structured, and visual nature of CS-0 allowed them to understand concepts they later used in more advanced programming.

2) Mutual engagement of faculty-social network analysis

Mutual engagement assumes regular contact with stakeholders in the alliance. In 2014, the evaluators implemented a social network analysis [20] to track connections made across institutions, with the leader at each institution completing a survey that documented interaction. Figure 2 depicts the interactions reported by lead faculty at each of the 11 member institutions in a given three month period. Lines indicate direct communication was reported between key stakeholders for that quarter. Thicknesses of the lines indicate the richness of that communication as it related to collaboration. While a solid, thin line connecting the shapes means the two leaders were in direct communication to share information, a thick line represents collaborative or “integrative” activity, such as coordinating a conference, or developing a grant proposal.

Fig. 2. CAHSI social network analysis: quarterly communication between originating institutions (triangles) and adopting institutions (squares)

The network appears robust, with all institutions showing at least three connections that are made quarterly. Nearly all originating institutions have more frequent communication with at least one other institution in the alliance. All originating institutions and two newer members engaged in integrated activities with Alliance partners during the year in question. Integrated activities involve co-development and co-organization among all member organizations, the most developed form of collaboration monitored in this survey. Intensity of collaboration is moderately but not completely correlated with frequency, meaning that some interactions occur more often between two institutions but to lesser degrees of intensity.

3) Encouragement and engagement in developing new revenue, new opportunities to support Hispanics in computing

In order to sustain, CAHSI members need to continue to find funding to support their work transforming education in engineering. This can be an area of mutual engagement that feeds the need for continuous contact across collaborators that supports collective work as it shapes transformations to come in future educational practices. In measuring CAHSI’s moves towards sustainable change, the evaluators have documented collaborative efforts to bring in funding. Five CAHSI institutions engaged in cross-institutional educational initiative proposal writing/grant implementation during the 2013-2014 school year, and two institutions submitted research collaborations that would serve CAHSI students. By proposing joint efforts, CAHSI faculty keep in contact, coordinate pedagogical change and are better positioned to collaborate regarding other efforts beyond the grant opportunity. Maintaining connection in joint enterprise is viewed as important for sustainability to be realized.

D. Ripple effects

Ripple effects occur when unintended transformations in practice, policy, or action develop out of collaborations designed to transform engineering education. Data from multiple sources and varied levels of the CAHSI organization (faculty, department, and organization as a whole) illustrate

how CAHSI's efforts have established ripple effects that transform practice.

1) CAHSI faculty impressions of departmental visibility and reputation changes since becoming engaged in CAHSI.

Though not one of CAHSI's intended goals, a positive consequence of the CAHSI alliance mentioned by a few PIs and determined anecdotally by evaluators has been the impression that the CAHSI alliance may elevate departmental visibility and reputation. According to faculty survey results, nearly a third of respondents described a change in visibility on campus or beyond campus. Six note on-campus visibility differences for the increasing number of activities, and eight describe off-campus visibility improvements related to publicity from regional press and through participation in CAHSI conferences.

This visibility may contribute to increased scholarship and increased faculty network development- 16 faculty note they participated in one or more proposals that mentioned CAHSI as relevant prior work. The majority of proposals mentioned CAHSI involvement as evidence of strong student development (via ARG, PLTL strategies) and recruitment and advancement of underrepresented students in computing. In addition, open-ended responses show that faculty are collaborating more often with peers off campus, and their students are also discovering new networking opportunities.

Opportunities to engage in educational transformation can lead to career-enhancing dissemination opportunities for faculty. When faculty see an added benefit to their careers from engaging in pedagogical improvements, they may be more personally invested in the transformation efforts. Fifteen faculty members note their dissemination of CAHSI-related efforts beyond their institution, in research venues such as Super Computing, ACM conferences, FIE, SACNAS, ITCSE, and disciplinary workshops. In fact, 21 of 35 reported they either disseminated or wrote a proposal that leveraged CAHSI results, indicating departmental investment in the initiative.

2) Departmental "ripple effects"

CAHSI departments felt ripple effects from CAHSI efforts to transform education. Some specific examples are described below. These narrative descriptions of additional ways in which CAHSI is influencing outside individuals and organizations are not intended to show systematic implementation, rather they point to creative ways in which CAHSI stakeholders are expanding their work locally, and in some instances, point to the ways in which CAHSI's reputation at the campus level is beginning to lead to greater transformation of engineering education.

A member institution in a highly urban commuter campus redefined one of the CAHSI practices to better meet the needs of students engaging in peer led team learning. The synchronous online offerings peer leaders developed for CS1 and CS2 have led to instructional innovation, primarily designed collaboratively by the peer leaders themselves. The students were able to showcase their work in online PLTL through conference participation at the Peer Led Team Learning International Society conference in May of 2014.

At another institution, a faculty member who leads student research training workshops for CAHSI was tapped by the academic dean to train other faculty members in student research skill development. The computer engineering department is thus disseminating best practices to other departments on campus to support pedagogical change.

A CAHSI initiative to support students in preparation of fellowship applications was leveraged to serve students across the campus. Institutionalization of the effort supports sustainability and may have already influenced students beyond the CAHSI computing department. The institution in question has produced a substantial number of NSF fellows in the years since FellowNet took shape.

Multiple institutions report engagement in cross disciplinary funding opportunities that leverage CAHSI pedagogical practices to bring them to more STEM departments at their own institutions. As of this writing one external, government grant was successful in securing funding.

3) Alliance "ripple effects"

CAHSI has extended its national influence through leadership, policy actions, and collaborative efforts across academic, non-profit, and industry partners. CAHSI has been listed in the national Examples of Excelencia database as an effective national initiative that accelerates Hispanic student success at the baccalaureate level. As a member of the Excelencia in Action Network, CAHSI contributes to national efforts to advance the Hispanic national agenda. CAHSI has distributed alliance advocacy across campus leaders to in turn spread CAHSI knowledge of best practices beyond the alliance—nine faculty members represent CAHSI in national and regional organizations interested in improving and diversifying the computing workforce. CAHSI has disseminated its initiatives beyond member departments, reaching 62 faculty/staff members in more than 9 disciplines at over 40 institutions, serving over 800 students.

VI. CHALLENGES TO GROWTH AND SUSTAINABILITY

While CAHSI has worked towards sustainability and growth, the organization has faced challenges. Like most distributed organizations, CAHSI depends on local leadership to implement initiatives in the classroom and in the focal departments. CAHSI has found that while departmental chair leadership has been important for supporting CAHSI, trained faculty and staff members are also necessary for implementing CAHSI. Turnover in any of these areas requires a shift of workload and additional training that takes time to address. Growth is an area of concern for CAHSI members—specifically the mechanisms for joining the organization in official ways. The organization has maintained that membership must be tied to institutions' and individuals' support of CAHSI's core purpose- to recruit, retain, and advance Hispanics in computing. The organization has evolved to include multiple "levels" of membership to acknowledge individual commitments faculty and staff might make to the CAHSI core purpose, including individual and departmental membership for CAHSI adopters, yet more

established processes may be needed to better define membership and related responsibilities and benefits.

VII. RELEVANCE AND SIGNIFICANCE

This work describes how a long term multi-institutional engineering education innovation project influenced faculty, staff and students at 11 institutions over the course of its 10 year history. Alliance design, implementation, and evaluation metrics have coalesced to maintain and grow the CAHSI alliance and its research based educational practices. The partnership has developed mentoring networks across institutions, as well as continued opportunities to work at changing mindsets about students' current abilities, capacities to learn, and future pathways. Mutual engagement in integrated activities has allowed for continuous collaboration, and helped to initiate ripple effects, or unintended but welcome expansion of the CAHSI community and its practices. Including sustainability and organizational change as a focus of evaluation has provided information about growth that may not otherwise be available. These data can be informative in shaping future alliance initiatives and outreach.

STEM CORE
Lubbock, TX, U.S.A

Abstract— Science, technology, engineering and mathematics (STEM) and the important role that it plays in society and education is receiving increased attention throughout the United States. Even universities, which have been at the frontline of educating STEM professionals, are reviewing and updating their policies and responsibilities. Faculty members often find themselves torn between their commitment to scientific research and their responsibility to prepare the next generation of STEM professionals. The proposed paper will examine the following research questions: • How can universities be structured such that the efforts of faculty members who prioritize the quality of undergraduate STEM education are recognized and supported? • How can universities be structured such that the efforts of faculty members who prioritize K-12 STEM education outreach are recognized and supported? The study, which will be discussed in the proposed manuscript, was conducted at a large public research university with student enrollment in excess of thirty thousand. New faculty members at this institution were asked to complete a survey concerning STEM education and outreach in 2012 and 2014. The survey addressed the faculty member's perceptions of the following: i) personal views concerning STEM education and outreach, ii) peers' attitudes towards STEM education and outreach, and iii) the value the university system places on STEM education and outreach. This survey was coupled with a university-wide effort, which was implemented between the years of 2010 and 2014, to support and encourage faculty who were interested in STEM education and outreach. The results of this investigation support the assertion that new faculty attitudes were better with respect to STEM education and outreach in 2014 when compared to 2012. On average, new faculty felt better prepared to mentor undergraduates in STEM in 2014 than did the new faculty in 2012, with 52% and 79% reporting to be "well prepared," respectively. Additionally, new faculty reported a better overall morale in 2014 when compared to 2012 within the institution. The proposed paper will provide further details concerning the changes that were made within the institutions between 2010 and 2014 and the faculty responses to the survey.

Keywords— Faculty development; STEM education; STEM Outreach

I. INTRODUCTION

The advancement of modern society is inextricably linked to developments in science, technology, engineering and mathematics (STEM). Employment in the United States is increasingly requiring individuals who have knowledge,

expertise and training in the STEM fields.¹⁻³ Universities, especially those that have traditionally served STEM fields, are increasingly exploring methodologies for improving STEM education on and off campus. Particular attention has been paid to the preparation of students from feeder or K-12 schools through outreach. Some universities are encouraging their faculty to play an active role in STEM outreach and mentoring programs. These programs may become overly taxing on faculty who have a primary commitment to their own students and research.^{4,5} This paper explores a university program that is designed to create a balance among outreach, teaching and research amongst its faculty. Through this program, faculty are rewarded for both on- and off-campus efforts to improve STEM education.

This article examines a program at Texas Tech University (TTU) in which education and outreach are recognized and rewarded as part of the annual faculty evaluation process. New faculty members learn in the first year of employment that educational efforts, on and off-campus, are considered to be part of their job. This program moves beyond familiarizing faculty with empirically-supported teaching strategies^{4,6,7} to encouraging faculty activities in education and outreach. In order to evaluate the impact of this program, two-university-wide surveys were conducted. Changes in faculty attitudes with respect to education and outreach were tracked over a two-year period. Responses to these surveys were used to begin to answer the following research questions:

- How can universities be structured such that the efforts of faculty members who prioritize the quality of undergraduate STEM education and outreach are recognized and supported?
- Does administrative restructuring of the tenure and promotion requirements with respect to STEM education and outreach negatively affect faculty morale?

II. METHODS

The following two sections describe the participating university and the survey instruments that were used.

A. University

As of the fall 2013, TTU had an undergraduate student enrollment of approximately 27,000 with 93% of the student body consisting of state residents. On average, undergraduates

are predominantly traditional college students (e.g. recent high school graduates) with the average student age of 21 with only 10% of students 25 or older. The university has roughly 1,200 full-time instructional faculty.⁸

B. Subjects

Table 1 provides the total number of survey responses for both “New Faculty” and “General Faculty” members in the STEM disciplines. These faculty include tenured and tenure track faculty as well as instructors with teaching duties only. The group does not include graduate teaching assistants. “New Faculty” members are defined as faculty who began working at the university the same academic year as when the survey was administered, the “New Faculty” populations for 2012 and 2014 consist of two mutually exclusive samples. The “General Faculty” included faculty who were beyond their first year; this sample was not mutually exclusive from 2012 to 2014. Table 1 provides the number of individual survey responses for both new faculty and general faculty for the 2012 and 2014 surveys.

TABLE I

	2012 n	2014 n
General faculty	175	204
New faculty	21	28

C. Instruments

General and New Faculty surveys were administered in spring 2012 and spring 2014 and are displayed in Fig. 1. The General Faculty survey contained all of the questions displayed in this figure; the New Faculty survey contained only the starred questions. These surveys were designed to track faculty participation and planned participation in STEM outreach, attitudes with regard to mentoring students in STEM, and faculty morale with regard to changes to faculty evaluation. The General and New Faculty surveys differed slightly, in that the General survey was designed for an experienced faculty population and the New Faculty survey was designed for a non-experienced responding population.

General and New Faculty STEM Survey Questions: (“*” indicates question appeared on the New Faculty survey as well as general faculty survey)**

STEM Definition- In 2001 Judith A. Ramaley, the former director of the National Science Foundation’s education and human-resources division, designed a new approach to teaching education in Science, Technology, Engineering, and Mathematics (STEM). TTU has a number of related STEM and STEM Outreach programs that overlap in the area of recruiting new students, as well as in the mentoring of STEM students from underrepresented groups.

STEM:

- Are you aware of the STEM Outreach programs?***
 - ☐ Yes
 - ☐ Somewhat
 - ☐ No
- Have you participated in any STEM Outreach programs?***

- ☐ Yes
 - ☐ No
- Do you plan to participate in the STEM Outreach programs within the next year?***
 - ☐ Yes
 - ☐ No
 - Have administrators included STEM in their assessment of faculty at TTU?
 - ☐ Yes
 - ☐ No
 - Do you believe that the attitude towards STEM outreach work (funding, rewards) has changed at TTU?
 - ☐ Yes
 - ☐ Somewhat
 - ☐ No
 - ☐ Does not apply
 - Do you believe that the reward structure for STEM has changed at TTU ?
 - ☐ Yes
 - ☐ Somewhat
 - ☐ No
 - ☐ Does not apply
 - Do you believe faculty have a strong understanding of the educational benefits from STEM Outreach programs?***
 - ☐ Yes
 - ☐ Somewhat
 - ☐ No

STEM MENTORING:

- How well prepared do you feel to mentor your undergraduate students, with respect to STEM?***
 - ☐ Well prepared
 - ☐ Somewhat prepared
 - ☐ Ill-prepared
- How well prepared do you feel to be able to mentor your female undergraduate students, with respect to STEM?***
 - ☐ Well prepared
 - ☐ Somewhat prepared
 - ☐ Ill-prepared
- How well prepared do you feel to be able to mentor minority undergraduate students, with respect to STEM?***
 - ☐ Well prepared
 - ☐ Somewhat prepared
 - ☐ Ill-prepared
- How well prepared are you to mentor you older, non-traditional students (over the age of 30), with respect to STEM?***
 - ☐ Well prepared
 - ☐ Somewhat prepared

TABLE II

STEM – Change from 2012 to 2014							
Question	General Faculty				New Faculty		
	Yes %	Somewhat %	No %	Does not apply %	Yes %	Somewhat %	No %
1	-1	5	-2	-	-11	6	5
2	0	-	1	-	12	-	-12

☐ Ill-prepared

12. How well prepared are you to mentor students with a learning disability, with respect to STEM?*

☐ Well prepared
☐ Somewhat prepared
☐ Ill-prepared

13. How open is the line of communication between you and your STEM students?

☐ Very open
☐ Somewhat open
☐ Not open
☐ Does not apply

14. How open is the line of communication between you and your STEM advisor?

☐ Very open
☐ Somewhat open
☐ Not open
☐ Does not apply

STEM CAMPUS CULTURE:

15. Do you believe that the “campus culture” has changed since you have been a faculty member at TTU?

☐ Yes
☐ Somewhat
☐ No

16. Do you believe there is a generational gap in terms of language while teaching undergraduate students?*

☐ Yes
☐ Somewhat
☐ No

17. Do you believe there is a generational gap in terms of communication while teaching undergraduate students?*

☐ Yes

☐ Somewhat

☐ No

18. Do you believe there is a generational gap in terms of technology while teaching undergraduate students?*

☐ Yes
☐ Somewhat
☐ No

19. Do you perceive that there is a lack of trust in procedures and policies at TTU?

☐ Yes
☐ Somewhat
☐ No

20. Do you think faculty members have a role in the governance structure at TTU?

☐ Yes
☐ Somewhat
☐ No

21. Do you feel disconnected from any decision making processes within your department?

☐ Yes
☐ Somewhat
☐ No

22. Is there a structure for conflict resolution that faculty members can follow, if a problem arises?

☐ Yes
☐ Somewhat
☐ No

23. On a scale of 1 to 5 (1 low and 5 high), what do you think is the morale level of the faculty is at TTU?*

☐ 1, 2, 3, 4, 5

24. On a scale of 1 to 5 (1 low and 5 high), what do you think your overall morale level is at TTU?*

- ☐ 1, 2, 3, 4, 5
25. Do you feel that your career at TTU has progressed to your satisfaction over the past few years? **
- ☐ Yes
- ☐ Somewhat
- ☐ No
26. Please provide 3 core missions or values that you believe your department is trying to achieve. **
27. Please provide 3 core missions or values that you believe TTU is trying to achieve. **
28. Gender: Male/Female **
29. Ethnicity: Black or African American, American Indian or Alaska Native, Asian, Native Hawaiian or Other Pacific Islander, White, Hispanic or Latino, More than one race reported. **
30. Department: faculty members will fill in their department **

D. Administrative Changes

In fall 2009 TTU was awarded a pivotal NSF grant to foster a culture of STEM education and outreach on the campus.⁹ This NSF program provides funding for the integration of outreach programs and stimulates changes in the campus culture related to STEM education and outreach. This grant was the catalyst for a campus wide dialogue on tenure and promotion policies and culminated in a change to the university policies in July 2012. The critical innovation was the inclusion of outreach and engagement among the criteria to be recognized for tenure and promotion. The College of Arts & Sciences formally adopted similar criteria in September 2012.

III. RESULTS

A. General STEM Opinions

The first set of questions in both the general and new faculty surveys probed overall opinions of STEM outreach as held by the faculty. Questions 1 through 3 and question 7 appeared in both the general and new faculty surveys. Questions 4, 5, and 6 were exclusive to the general faculty survey. The first four questions addressed the faculty member's awareness of STEM outreach programs (Q1), prior participation with STEM outreach (Q2), plans to participate with STEM outreach (Q3), and whether the faculty member felt that fellow faculty members have a strong understanding of the educational benefits of STEM outreach (Q7). A summary of faculty responses to the first seven questions is provided in Table 2.

Overall the general faculty population reported little change

from 2012 to 2014. The largest changes were witnessed in questions 4, 6, and 7. Question 4 asks if the faculty believes that administrators include STEM in their assessments of the faculty members' work. The "yes" response increased from 25% to 34% from 2012 to 2014. The general faculty also displayed an increased belief that fellow faculty understand the benefits of STEM outreach (Q7) with 10% fewer responding "no" and 9% and 3% more responding "somewhat" and "yes," respectively. These may be partially explained by the new faculty of 2012 moving to the general faculty in 2014. The general faculty further displayed a negative trend with regard to question 6, which asks if the faculty member believes that the reward structure for STEM has changed. The interpretation of this response is challenging. We know that the administration sought to change the reward structure in 2012, at least in their written documents. Given there was no boundary placed on the time period that the question addressed, the faculty may have been considering a shorter time period which did not include the changes made in 2012. Faculty may be accepting the changes made in 2012 as common practice by 2014.

The data for new faculty indicated several encouraging shifts. A higher portion of new faculty members report participating (Q2) and planning to participate (Q3) in STEM outreach in 2014 when compared to 2012. This is oddly coupled with a decrease in reported awareness of STEM outreach programs (Q1). Lastly, for the final new faculty question in this section (Q7), which asks if the new faculty member believes that fellow faculty have a strong understanding of the benefits of STEM outreach, there was a polarization of the population with fewer neutral responses and an increase in both "Yes" and "No" responses. It is important to note that the positive change for the affirmative response is a factor of three larger than the negative response.

B. Mentoring

Faculty STEM interest is best served when the faculty member feels well equipped to mentor students in STEM, which is the topic covered in questions Q8 through Q12 (Table 3). The most striking change from 2012 to 2014 came from the new faculty data, with the most shifts in opinion witnessed in questions 8 and 11. These questions pertain to

TABLE III

STEM Mentoring						
General Faculty				New Faculty		
Question	Well Prepared	Somewhat Prepared	Ill-Prepared	Well Prepared	Somewhat Prepared	Ill-Prepared
	%	%	%	%	%	%
8	3	1	0	27	-20	-6
9	6	-1	-1	9	-8	-1
10	3	2	0	6	0	-6
11	2	3	-3	28	-23	-6
12	-5	14	-5	7	-19	12

TABLE IV

STEM Campus Culture – TTU Faculty and Individual Morale Level					
General Faculty					
Question	1	2	3	4	5
	%	%	%	%	%
23	-2	-12	7	7	2
24	-4	-1	-1	0	9
New Faculty					
Question	1	2	3	4	5
	%	%	%	%	%
23	4	7	-39	21	11
24	0	-10	6	-11	20

how prepared the new faculty members feel with regard to mentoring both students in general (Q8) and older, non-traditional students (Q12) with respect to STEM. The proportion of new faculty responding that they are “well prepared” increased by 27% for Q8 and by 28% for Q11.

This survey section also displays mixed results for general and new faculty concerning STEM mentoring for students with a learning disability (Q12). The general faculty reported a large increase in those feeling “somewhat prepared” with decreases to both “ill-prepared” and “well prepared.” The new faculty reported a drastic decrease in those feeling “somewhat prepared” with a slight increase in those feeling “well prepared” and a larger increase in those reporting that they feel “ill-prepared.” Both of these trends reveal that both new faculty and faculty in general could benefit with more support with regards to how to mentor STEM students with learning disabilities.

C. Faculty Morale

There is a concern that altering standards for faculty evaluation will impact faculty morale. Interestingly, there are discernible positive trends in both new and general faculty’s perception of morale (see Table 4 and Fig. 2. and Fig. 3.). The question 23 asks faculty to gauge the morale level of fellow faculty. The general faculty population reported an overall positive trend with low-end responses (1 and 2) receiving fewer responses while neutral (3) and positive attitudes (4 and 5) grew. New faculty, on the other hand, had a more divided reaction with there being a large drop in neutral responses (3) coupled with growth in both negative and

positive responses with a net larger growth in positive attitudes (4 and 5) – similar to the general faculty population.

IV. CONCLUSIONS

Returning to the research question posed at the start of this manuscript, it appears that inclusion of outreach and engagement among the criteria to be recognized for tenure and promotion may have a positive impact on faculty members’ attitudes with respect to STEM education. The most significant impact appeared to be on the new faculty. New faculty are likely to be more aware of current tenure and promotion

procedures than are their more senior counterparts. New faculty reported being more likely to have participated in STEM outreach and to be planning to participate in such activities in the future. They also reported feeling better prepared to mentor undergraduate students, including older, non-traditional students.

Encouraging trends for the general faculty came in the form of an increased awareness of administrators’ inclusion of STEM outreach during faculty evaluation. The general faculty also reported the belief that fellow faculty understand the benefits of STEM outreach. Based on the outcomes of this survey, faculty morale was not negatively impacted by the administrative changes. In general, new and general faculty reported a relatively high morale for both surveys.

These results indicate that universities seeking to improve STEM engagement and outreach should consider explicitly adding such activities to the criteria for tenure and promotion. Doing so demonstrates to the faculty member that STEM outreach is valued by the institution and thereby alleviates concern that outreach is being done at the expense of the faculty member's professional advancement. Under this model, outreach would not be treated as an add-on but rather as a regular component of the academic promotion process.

Using Flipped Classroom, Peer Discussion, and Just-in-time Teaching to Increase Learning in a Programming Course

Håkan Jonsson

Department of Computer Science, Electrical and Space Engineering
Luleå University of Technology
Luleå, Sweden

Abstract—In this paper we report on an experiment conducted in an attempt to improve further the learning environment in a basic campus course on Object-Oriented Programming and Design given to first-year engineering students studying Computer Science and Engineering. This course has for years had the same traditional set-up that is common also in other engineering schools around the world including lectures, mandatory programming assignments, and a final written exam. What we did was to substitute the lectures for in-class sessions based on a variant of the teaching method known as "flipping the classroom" combined with certain elements of Peer Discussion and Just-in-time teaching. To make all this work, we introduced a web-based MOOC tool into the course.

To be able to investigate the quantitative effects of our experiment, we had an experiment class consisting of 70 students taking the course in this new way and a control class of 57 students taking the course in the traditional way. On the final written exam, which was identical for the two classes and marked the same way, 81% of the students in the experiment class passed compared to 60% in the control class. Moreover, the share of students passing with good grades was 58% in the experiment class compared to 32% in the control class. So, not only did the share of students passing the course increase by a third, but also the share of students passing with good grades almost doubled.

Index Terms—Computer science education; engineering education; programming; blended learning; active learning; flipped classroom; peer discussion; just-in-time teaching.

I. INTRODUCTION

For more than 10 years, we have offered a basic campus course on Object-Oriented Programming and Design to first-year engineering students studying Computer Science and Engineering. This course has the same traditional set-up as is common also in other engineering schools around the world. It consists of lectures, mandatory programming assignments, and a final written exam. A course web page provides links to course material and information. The course has always been greatly appreciated by not only students but also involved professors and assistants. The only issue with the course is that, despite all praise, many students fail the examination.

In an attempt to improve matters, we conducted an experiment in which we introduced a web-based MOOC (*Massive Open Online Course*; see Ref. [1] for an overview) tool [2] and a variant of the teaching method known as "flipping the classroom" [3], [4] into the course. In short, the main idea with this method is that, rather than attending traditional

lectures, students learn course content on their own by watching recorded videos while activities traditionally considered homework, such as solving problems, is instead done in class. We changed the course in this manner, also interleaving numerous multiple-choice questions into the videos and adding elements of Peer Discussion and Just-in-time teaching [5] to the in-class sessions.

We recorded 140 videos (comprising more than 20 hours of screencasts) and grouped them into blocks roughly corresponding to the old lectures. To each in-class session, suitable problems were authored, printed, and bundled into handouts for students to work on in groups. Based on statistics provided by the MOOC tool, we could adapt the in-class sessions and prepare feedback/clarifications on content many students had misunderstood. Apart from working on solving problems, students also actively discussed pros and cons of randomly selected (and anonymized) student solutions.

To be able to investigate the quantitative effects of our experiment, we had an experiment class consisting of 70 students taking the course in this new way and a control class of 57 students taking the course in the traditional way. Both classes covered the same course content. Students were subject to the same requirements to pass. They were eventually given the same final exam, which was marked and graded in the same way. The only difference was the way the classes were taught.

On the final exam, 81% of the students in the experiment class passed compared to 60% in the control class. Moreover, the share of students passing with good grades was 58% in the experiment class compared to 32% in the control class. So, not only did the share of students passing the course increase by a third, but also the share of students passing with good grades almost doubled.

In the next section, we go through related work and underlying theory. In Section III we then describe the course and in the subsequent section we present the experiment and the two different ways the course was taught. Well-versed readers, mostly interested in the results of the experiments and their implications, can skip directly to Section V and the discussion in Section VI.

II. THEORY AND RELATED WORK

The teaching we studied is based on *Constructivism* (see, for instance, Biggs [6]) where the idea is that students construct their own understanding and knowledge of the world, through experiencing things and reflecting on those experiences, and *Active Learning* which has been described as "anything that involves students in doing things and thinking about the things they are doing" [7]. One such teaching approach, that in its modern form dates at least from the early 1990s, is the *flipped classroom* [3], [4]. Here, students are activated at home, where they learn the course material on their own, as well as at in-class sessions, where they carry out what is traditionally regarded as homework such as solving problems.

Flipped classroom as we used it in our experiment is an example of *Blended Learning* [8] where face-to-face teaching is combined with computer mediated teaching. Out-of-class, students watched recorded videos introducing course content and answered short quizzes using a web-based MOOC tool [2]. The use of videos in flipping a classroom is seen as positive by students [9]. Previous research also suggests that video lectures is at least as good as in-person lectures with respect to the effect on learning, and that interactive on-line videos in fact outperform in-person lectures [10]. The in-class sessions (see Section IV-C2) were inspired by *Inductive Learning* [11] where students learn from examples and "notice" general concepts. The design of these sessions were partly influenced by how the students as a group did on the quizzes while watching videos. Such last moment adaptation of the teaching to better fit the need of the students is an example of *Just-in-time teaching* [12]. The actual instruction was inspired by *Visible Learning* [13] in that the professor, for instance, a) defined clear goals and criteria for achieving these goals, b) was clear about organization, explanations, examples, procedures, and assessments, and c) built honest and trustful relations to the students by respecting their different backgrounds, listening to them, and showing empathy and attention. The idea is that the student's confidence in the professor creates a feeling of security, and that this leads to better results. The literature contains quite a few studies of flipped classroom and also some on using this technique in Computer Science related courses [14]–[20]. Our work complements these studies by combining flipped classroom, peer discussions, and just-in-time teaching.

III. COURSE DESCRIPTION

The course, known as *D0010E Object-Oriented Programming and Design* [21], earns the student 7.5 ECTS¹ credits once completed. The course is given in Quarter 3, a roughly 10 week long period that starts in January, and designed so that the typical student spends a total of 200 hours (1200 minutes)

¹The *European Credit Transfer and Accumulation System* [22] aims to harmonize higher educations in Europe.

studying in class and at home².

The course is an introductory course on the bachelor's level and part of our MSc and BSc degree programs in Computer Science and Engineering [23], [24]. These educational programs, which last for 5 and 3 years respectively, are officially accredited under public Swedish law [25] and highly inspired by the ACM/IEEE Curricula Recommendations [26]. The course is part of an "early CSE start" during the first two years of study created to ease the transition of first-year students in our degree programs into engineering studies [27]. The Fall semester, that precedes D0010E, starts with a course on programming and a course introducing the vast area of Computer Science and Engineering. This is followed by courses on Discrete Mathematics and Physics (Fig. 1).

A. Entry requirements

D0010E requires that the student has previously completed an introductory course on programming. This course need not, but should preferably, introduce structured/procedural programming so the student is familiar with fundamental computer programming concepts and can put together small solutions to simple computational problems using an imperative programming language.

B. Course aim

After the course, the successful student

- has knowledge about the scientific foundation of object-oriented programming and design as well as the proven experience gathered by programmers in this field of computer science;
- is able to carry out teamwork, where programs are designed and implemented through collaboration, both in groups where the students choose themselves whom to work with and in groups put together by others;
- can create, analyze, and critically evaluate various technical solutions in terms of the design and implementation of large computer programs by using a modern object-oriented programming language;

²In Sweden, one week of full-time study amounts to 40 hours of work and grants the successful student 1.5 ECTS credit. At our university, students normally take two courses in parallel, studying 20 hours per week in each course.

- can plan and use appropriate methods to undertake programming tasks faithful to given specifications.

C. Course content

As its name suggests, the course stands on two legs: a programming part and a design part. As these parts obviously depend on each other, when larger programs are to be created, they are in practice interwoven through-out the course.

1) *Part A: Object-oriented programing*: The first part is broad and concerned with the construction of computer programs using the basic constructions offered by modern object-oriented programming languages. Students learn how to encapsulate methods and data structures into what will be objects at run-time and implement these objects as classes based on inheritance, a mechanism for reusing code and defining types, effectively creating reusable polymorphic program parts. Topics include

- core concepts like objects (integrating code and data), classes (defining types), and inheritance (relating types and promoting code reuse);
- programming techniques based on modularization, encapsulation and information hiding;
- basic algorithms (for sorting and searching) and linked (recursive) data structures (lists, trees, and graphs);
- error-handling through both the use of rigid type systems to catch errors at compile-time and exceptions to catch errors during run-time;
- Java [28], an object-oriented programming language;
- well-known parts of Java's standard library, their use and implementation;
- graphical user interfaces (GUI:s) in Java;
- Eclipse [29], an industry-grade integrated development environment.

2) *Part B: Object-oriented design*: The second part is smaller than the programming part and introduces tools to the student to more easily create large programs working individually as well as in groups. By "large" is meant a computer program whose implementation is so intricate and full of detail that individual programmers can not be expected to keep it all in their minds. Moreover, the program is developed by several programmers working in parallel now as well as in the future to maintain and further develop the program that is assumed to never be completely finished. While no program in the course really meets this definition, students are still prepared and taught how to cope with the implementation of such programs. Topics include

- modeling of classes using *Unified Modelling Language* (UML) [30] as a tool for visualizing overall program design and aid development among programmers;
- informal reasoning based on *abstract data types* (ADT:s) and the use of contract programming (*Design by Contract*) with preconditions, postconditions, and invariants;
- basic (software) design patterns;
- external and internal documentation, typically producing webpages based on *Javadoc* for external documentation

and decorating code with internal comments for implementation specific documentation.

D. Assessment

The examination consists of five (practical) laboratory assignments with deadlines roughly every two weeks and a final written (theory) exam at the end of the course. Students are expected to spend 120 clock hours (60% of the total time devoted to the course) on practical work while the remaining 80 clock hours (40%) should be spent on learning theory.

The laboratory assignments are concerned with the implementation of object-oriented programs. Two assignments – the first and the third – are carried out individually while students carry out the other three in groups. The assignments are graded (just pass or fail) in the laboratory where students demonstrate their solutions and are questioned by the either the professor or a laboratory assistant (a last year student).

- 1) The first assignment is a crash course on Java and Eclipse in which students program static programs with no explicit creation of objects. In steps, students program and evaluate recursive programs to test *Collatz conjecture* [31] and perform exponentiation by squaring.
- 2) In Assignment 2, students are fully exposed to objects and create a simple GUI in which lines and colored rectangles drawn on a canvas represent rectangular "rooms" on a level in a building. The rooms being interconnected by one-way corridors, students effectively implement a directed graph with operations to insert and visualize new arcs (corridors) and nodes (rooms).
- 3) Assignment 3 has a cover story in which the student works in a team at a software company and gets to implement two classes as part of a larger program whose remaining parts have already been written by (imaginary) team members. The student is not handed code but only an abstract specification of the program given as a UML diagram and abstract data types.
- 4) In the 4th assignment, students implement a networked board game (*Gomoku* or *Five-in-a-Row*) for two players with an interactive GUI. Students get the networking code but must figure out how to program the clients.
- 5) Finally, the 5th assignment is to implement a general discrete event-driven simulator from scratch. The actual implementation is preceded by a design step the students must complete in order to get permission to go on with the implementation.

In contrast, the exam is given once and at the end of the course. Although it is primarily on the theoretical content of the course, it also asks the student to write down solutions in the form of (short) programs that solves computational problems and/or implement basic data structures in suitable ways. The exam is "closed book" and usually contains 5-6 problems, where some problems might consists of subproblems. Students have 5 hours to complete the exam using pen and paper only.

IV. THE TEACHING EXPERIMENT

In this section, we present the two fundamentally different ways to teach the course we are comparing in this paper. We do this in terms of the two actual classes, one being the *control class* (Class C) and the other the *experiment class* (Class E), that were given in the experiment and taught in the two different ways. To be precise, by *course* we mean a discrete study unit defining entry requirements, content, aim etc. By *class*, on the other hand, we mean a particular instance of a course given a certain time period for a specific group of students and with assigned professors, class rooms, laboratory space etc. Our two classes hence covered the same content and had the same examination, as outlined above. They were given in isolation from each other. Our aim in the experiment was to study how Class E did in relation to Class C.

A. Common to both classes

There were great similarities in how the classes were taught.

- The classes lasted 10 weeks and were taught by the same professor.
- They had the same laboratory assignments scattered over 35 practical laboratory sessions (each lasting 2×45 minutes) scheduled in computer laboratories and under the guidance of the professor and a varying set of laboratory assistants³.
- While the examination was mandatory and had deadlines students had to meet, participation in teaching activities (including laboratory sessions) were optional.
- Students in both classes had access to a simple course webpage that was written and maintained by the professor as the course proceeded. This page served as a connection point and information central for the students, and contained lecture slides, laboratory instructions, dead-lines, extra material etc.

B. Specific to the control class

This class had 57 students and was taught in a traditional manner with a total of 17 lectures (also lasting 2×45 minutes each) given by the professor using AV-equipment (no writing on blackboards) a couple of times each week through the quarter. Apart from the laboratory assignments there was no formal homework. Students were expected to read ahead in the course book, including the exercises, but no effort was made to ensure this.

Since the course had been given like this by the professor for more than 10 years, during which the course and presentation material had successively been refined, there was no real need to adopt the material further or to create new material.

C. Specific to the experiment class

The new way of teaching was carried out in the Class E and called for substantial preparatory work that essentially meant two changes compared to how Class C were taught. The first

was to substitute lectures with recorded interactive videos. The second was to introduce so called problem sessions.

1) *Videos*: For each of the lectures of Class C, except the first and the last, a set of videos was recorded based on the powerpoint slides and thus covering the same topics as the lecture. These videos were made as screencasts with the professor explaining theory and concepts while going through the slides and running demos of program snippets in Eclipse as illustrations. The average length per video was 9 minutes and a total of 140 such videos were recorded, edited, and assembled into what we call *interactive video lectures* (IVLs). In total, 15 such lectures were created.

Videos were organized into IVLs using the web-based MOOC tool [2]. Such a lecture consisted of 8-9 videos (on average). Watching a video was much like watching a video on the video service *youtube* [32]. In fact, the videos inserted into the MOOC tool were stored in *youtube* and just embedded in the tool to provide some extra options like the ability to, by a single click on a button, mark a section that was experienced as confusing or not very clearly explained.

We also created a total of 143 multiple-choice questions on the content. The MOOC tool made it possible to not only group videos into IVLs but also to interleave such questions into the videos and at specific times. This had the effect that when a student watched a video and reached a question, the viewing automatically stopped, the question was displayed, and the student was asked to pick an answer. If the student picked the right answer, the viewing was continued. If not, the student got a new chance. This, of course, made it possible to pass a question by guessing but that did not matter since the questions were not marked and did not influence the final grade the student got. The purpose of the questions was to re-enforce learning and make students reflect on what was presented. Being fully interactive, students could navigate freely and watch previously seen videos at any time, also when picking an answer.

2) *Problems sessions*: To each of the 15 IVLs, a so called *problem session* was setup and subsequently scheduled so that students had ample time to go through the IVL before the problem session. To each session, an average of 7 problems were authored. These were selected to illustrate the topics in the corresponding IVL. All problems were printed and distributed to the students as handouts at the corresponding problem session.

The reason students got paper copies of the problems was to make it simple to collect solutions and put them on display. Each problem was presented on a paper sheet printed in landscape mode and single-sided. The left half of the sheet contained the problem statement and the right half was deliberately left empty so students could write their solutions (and make notes) there. The backside of the paper was intentionally kept blank so students could write their names there should their solutions be reviewed. This made it possible to display a solution without revealing the name of the author and still be able to return solutions to their authors. By collecting $k \geq 3$ solutions, mixing them randomly, and then

³Assistants attended different laboratory sessions in a rather random pattern depending on when they did not have classes to go to themselves.

showing the students only $k-1$ of them, it was possible to keep the identity of the author of each displayed solution a secret. Anonymity increased the willingness of students to hand in their solutions so we could discuss them in class. Again, the purpose was not to mark and grade but to enable a fruitful peer discussion where students and (to some degree) the professor together commented on and criticized the solutions in public.

The room used for the problem sessions had the following crucial equipment: Two screens out of which one was connected to a document camera and the other was connected to a laptop. A problem session was carried out as follows.

Upon entering the room, students got a copy of the problem bundle and seated themselves next to fellow students they liked to work with. Seating was free but, as shown in Fig. 2, where a student decided to sit was still important because students were grouped into groups of three based on where they sat in the room. Although not required to actively cooperate, this seating arrangement was in place to motivate and make cooperation natural among the students. The professor repeatedly reminded the students to discuss in their groups (which students then typically did, to a higher degree, once reminded to do so).

The actual problem session started with a short introduction where the professor, based on statistics over student performance with the quizzes in the IVL, brought up issues and things a large proportion of the students had misunderstood. Via the MOOC tool it was possible to get a full screen that displayed a quiz question together with a histogram that plotted the answering alternatives against the share of students that had answered the various alternatives and with the correct answer pointed out. In addition, the professor could choose to answer questions asked by students while they viewed videos.

Then the following was repeated as long as there were unsolved problems in the bundle:

- The professor asked the students what problem, of those remaining, they liked to work on. It could also be, especially in the beginning, that based on student performance in the MOOC tool, the professor made the initial picks as to make sure problems essential to the whole class got worked on.
- The professor put the problem on display using a laptop connected to a video projector so all students could see.
- The professor then announced an amount of time, typically 8-10 minutes, during which students were to work on the problem in their groups, solving and writing down a solution while discussing. To make the time clear to everyone, a countdown timer was put on display on the laptop screen. To set a specific time like this was just done to have a deadline to work against. If more or less time was needed, the deadline was adjusted accordingly.
- While the students worked, the professor circulated in the room answering questions and helping students out.
- When time was up, or the professor felt many students were done, the professor called for solutions to show and discuss. To volunteer a solution was optional.
- Once at least three solutions had been collected and mixed randomly, so that no one knew who wrote which

Fig. 2. Schematic view of how in-class problem sessions were carried out. Working in front of, on the sides, and along the aisle of the 108 seats making up the class room, the professor displayed problems and solutions as well as provided help to students. Shown is also how students were grouped three and three based on seating.

solution, they were put on display – one at a time. The students got to discuss the presented solutions first in their groups and then in the entire class. The latter amounted to students commenting on the solution, and each others comments. The main role of the professor was to be an enabler and get this discussion going but also to take active part and add to the discussion, if needed.

- When all solutions except one had been scrutinized this way, all solutions were once again mixed and then handed back to the students. Keeping authors of solutions unknown to the whole student group was essential to have students also volunteering solutions they were not particularly proud of and/or solutions they knew contained errors. Such partly incomplete, slightly erroneous, and even directly unsuitable solutions were, of course, still valuable to discuss.

Attendance at problem sessions was optional. Students that attended did not have to actively work on the problems. If they liked, they were welcome to just sit in passively and take notes. However, it turned out that if students attended, they also took some active part.

V. RESULTS

The experiment was conducted by giving the course in the traditional way for the control class (Class C) and in the new way for the experiment class (Class E). Class C had 57 students while 70 students took Class E. All the students had very similar educational backgrounds and abilities. The average grade point average of Class C when applying to university (a number between 10 and 20) was 16.71 with a

TABLE I
RESULTS ON THE FINAL EXAM.

Class	Size	Result			
		Fail		Pass	
		Number	Share	Number	Share
C	57	23	40%	34	60%
E	70	13	19%	57	81%

standard deviation of 1.78 while the average in Class E was 16.78 with a standard deviation of 2.46. Moreover, on the Swedish SAT⁴ the students in Class C, that had taken the test, on average achieved 1.039 (out of 2.000) with a standard deviation of 0.268 while the average in Class E was 1.053 with a standard deviation of 0.306.

Afterwards, data was assembled from different sources and summarized to be able to follow-up on the effect the new way of teaching might have had. These sources were the results on the final exam, levels of participation in problem sessions and IVLs, and statistics based on standardized questionnaire-based course evaluations students filled out directly after the course.

A. The final exam

Both classes were given the same exam which consisted of 5 problems that were to be solved individually using pen and paper only. The problems were on the following topics.

- 1) Theory and concepts.
- 2) Iterative and recursive methods (computing substrings).
- 3) Container classes (a class for a hand of playing cards).
- 4) UML class diagrams making up an inheritance hierarchy and short written specifications (create classes representing different kinds of vessels).
- 5) Linked data structures with inner nodes (a circular list).

To pass the exam, a student had to get at least 50% of the maximum score. The number of, and the share of, students failing and passing in each class is tabulated in Table I. While 60% of students in Class C passed, no less than 81% passed in Class E. Students that passed got a grade that increased with the number of correct solutions. Grades 3 (*satisfactory*), 4 (*good*), and 5 (*very good* – the best possible) were given for achieving 50, 66²/₃, and 83¹/₃ percent of the maximum score respectively. In Figure 3, the share of students in the two classes that got these grades can be seen. Note that the share of students that passed with good grades (4 and 5) was almost twice as large in Class E as in Class C. Furthermore, each problem gave between 0 and 6 points so the maximum result on the exam was therefore 30 points. Table II presents statistics on how these points were on average awarded per problem. For each problem, μ stands for the arithmetic mean of the points awarded and σ denotes the standard deviation. What this reveals is that the average number of points awarded to the students in Class E was at least half a point higher than the points awarded in Class C and this regardless of which problem we consider. A last detail we investigated was the

⁴This test is optional and, while a good result can make it easier to gain admission to higher education in Sweden [33, pp. 9], not all students take it.

Fig. 3. Grade distribution. Grade F (*fail*) is given for achieving no more than 49 percent on the exam. 3, 4, and 5 are the passing grades.

TABLE II
AVERAGE NUMBER OF POINTS AWARDED PER PROBLEM (μ) WITH STANDARD DEVIATION (σ).

Class	Problem number									
	μ	σ	μ	σ	μ	σ	μ	σ	μ	σ
C	3,7	1,6	3,3	2,3	3,7	1,8	3,7	1,8	3,4	2,4
E	4,7	0,8	4,0	2,0	4,1	1,8	4,2	1,5	3,9	2,4

TABLE III
NUMBER OF OMITTED ANSWERS.

Class	Problem number					In total
	1	2	3	4	5	
C	0	4	10	11	18	43
E	1	2	2	2	9	16

tendency of students to hand in problems. Table III details these numbers and shows that students in Class C omitted to hand in far more solutions than students in Class E.

B. Participation

The second source of data was participation, by which we mean attendance at problem sessions and number of IVLs completed. Table IV shows average participation (μ) and standard deviation (σ) for each of the two activities as well as both of them combined into one (new) teaching activity. The MOOC-tool had a built-in subsystem that tracked for each student his or her progress in the system. The participation statistics regarding the completion of IVLs was extracted from this subsystem. As for the numbers concerning the attendance at problem sessions they were based on the 11 last sessions. The attendance at the first four problem sessions are unfortunately missing and as a result these numbers are probably a bit too low to reflect the total attendance at all problem sessions. These numbers were acquired manually by the professor by having the students sign a list at the problem sessions.

C. Course evaluations

A third source of data came from the standardized questionnaires the university have the students fill out after each quar-

TABLE IV

Result	Participation					
	Problem sessions		Interactive video lectures		In total	
	μ	σ	μ	σ	μ	σ
Fail	3,7	3,2	4,4	4,5	8,1	6,7
Pass	6,2	4,2	9,9	5,5	16,1	8,0

Fig. 4. Students' estimation of time spent. Spending 100% means 20 clock hours per week (the nominal amount a student should spend).

Fig. 5. Numbers (arithmetic means) showing how well students agreed with the statements from the questionnaire-based course evaluations listed in Table V. Answers could range from 0 (*Strongly disagree*) to 6 (*Strongly agree*). Error bars show standard deviations.

ter, if they like (it is not mandatory). In Class C, 47 students filled out the questionnaire and in Class E the questionnaire was filled out by 40 students. From the automatically compiled summaries of these questionnaires we chose to include in this paper only the top relevant statistics needed to be able to substantiate, at least to some degree, how students experienced their class and what they thought of it. These were the time estimates (Figure 4) and student opinions (Figure 5) on the statements listed in Figure V. On each of the questions, the students in Class E agreed more than the students in Class C⁵ even though none of the classes spent significantly more time studying than the other class.

⁵In fact, they agreed to a higher extent not only with these statements but all statements.

TABLE V
SOME RELEVANT STATEMENTS FROM THE COURSE EVALUATIONS.

Item	Statement
2.2	The contents of the course help to achieve/meet the course's aims.
3.2	It has been worthwhile attending the lectures.
3.3	The (practical) labs have been worthwhile.
3.4	The learning platforms/e-learning resources have been satisfactory.
6.1	The course workload is appropriate for the number of credits given.
6.3	My overall impression is that this was a good course.

VI. DISCUSSION

So, what does all of this tell us? What did the new way of teaching the course lead to?

A. The final exam

To start with it is clear from the results on the final exam (Table I) that Class E did better than Class C. In the class taught in the new way, the share of students that passed was up over 30% (from 60% to 81%) compared with the class taught in the traditional way. The grades also increased. As can be seen in Figure 3, this is in particular the case for the high grades awarded where 32% of students in Class C did well, and achieved grade 4 and 5, while the corresponding share of students was 58% in Class E. At the same time, the percentage of students achieving just a pass (grade 3) was roughly the same in both classes. This indicates that the new way to teach was not only superior in respect to the share of students that passed but also increased the performance of those students so that an almost twice as large a share of them managed to get good grades.

Another aspect is how the results on individual problems were affected. The numbers in Table II show that, on each problem and on average, Class E did at least half a point better than Class C. In fact, the improvement was larger on the first, simpler, problems compared to the improvement on the later, harder, problems. This indicates that learning was increased over all topics and subjects covered by the exam, and not just limited to some. Moreover, the standard deviation stayed the same or decreased. This also suggests that Class E performed more uniformly than Class C.

Yet an interesting detail is that students in Class C omitted to hand in substantially more solutions than the students in Class E (Table III). In relation to class size, in Class C students did not hand in $43/(57 \cdot 5) = 15.1\%$ of the solutions. In Class E, on the other hand, students omitted to hand in only $16/(70 \cdot 5) = 4.6\%$ of the solutions, or less than a third of what was not handed in i Class C. This could, perhaps, be seen as an increase in self-confidence in Class E when it comes to attempting to solve and hand in solutions. However, another explanation is that this is yet a symptom of the increased learning that took place in Class E. A student that knows more, and is more able, needs to spend less time coming up with solutions and are therefore likely to produce more and better solutions. We see also that fewer solutions were handed in on the harder problems than on the simpler ones. This can be explained by the fact that while wild guessing is possible on

simple theory questions, it is extremely hard (impossible) to guess at random when intricate code is asked for. All in all, we see this also as a sign of increased learning in Class E compared to Class C.

B. Participation

So far we have compared Classes C and E to argue that learning was better supported in Class E. Now, we will argue that within Class E, the difference between a successful student and a student that failed had to do with the level of participation in the new teaching activities. If we count the number of attended problem sessions and the number of completed IVLs (Table IV), we see that the students that passed did on average almost twice as much as the students that failed. This is to be expected since everything else is, as far as we know and in general, equal. For instance, laboratory work had to be completed on time and this students did (in both classes). However, one should note the relatively high standard deviations that means there was a large variation in what individual students actually did. We still interpret the numbers as indications of a positive, although weak, correlation between participation in these new teaching activities and good result on the exam.

C. Course evaluations

Turning to the course evaluation, we see that despite the difference in the results there was little difference in the time spent by students in the two classes (Figure 4). Only a small fraction of the students (8-10%) spent more than the 20 clock hours per week a student should spend when taking this course. It is only in Class C that some students did as little course work as 25% of what they were expected to do. Apart from this it is hard to differentiate between the two classes given the coarse-grained statistics (intervals of size 25%) available from the course evaluation system. Just looking at the histogram, one might think Class E on average worked more hours than Class C but that is a premature conclusion. Going to extremes, assuming all students in Class C worked as much as possible (so their time estimates all ended up on or near the upper interval boundaries) while students in Class E worked as little as possible (and their estimates ended up at the lower interval boundaries), students in Class C spent on average 12.7 hours per week and students in Class E spent 9.3 hours. If it instead was the other way around, so that hours in Class C were minimal while those in Class E were maximal, Class C spent on average 8.4 hours and students in Class E spent 13.8 hours. The truth lies somewhere in between these extremes but with no more data it is hard, if not impossible, to say exactly where. The observation we make, though, is that there is no overly dramatic difference between the classes. Students in both classes spend roughly the same time on the course and, more importantly, roughly the same share of students (90-92%) spend no more time than they should.

Finally, considering the class sizes (which are moderately large for our university) and comparing with other courses of the same sizes, both classes agreed to a remarkably high

extent with the statements in the course evaluation (Table V). However, Class E consistently agreed more than Class C (Figure 5), which indicates that students in Class E found the course more meaningful and rewarding than the students in Class C. Interesting is also the fact that the standard deviations were smaller for Class E than Class C in all cases. This shows a higher tendency in general of students to appreciate being taught in this new way rather than in the traditional way.

VII. CONCLUSION

By substituting traditional lectures for interactive video lectures and in-class sessions based on a variant of the teaching method known as "flipping the classroom" combined with certain elements of Peer Discussion and Just-in-time teaching, we have shown how learning can be increased in a course on object-oriented programming and design. Key to this result was the use of a web-based MOOC tool, for the efficient handling of the interactive video lectures, and the introduction of hands-on problem sessions into the course rather than passive lectures.

On the final exam, 81% of the students in a class taught this new way passed compared to 60% in a class taught in a traditional way where theory was taught with lectures only. The share of students passing with good grades increased to 58% compared to 32% in the class with lectures. So, not only did the share of students passing the course increase by a third, but also the share of students passing with good grades almost doubled. The increase in learning occurred on all topics and subjects covered while students spent roughly the same time on the course as before. Moreover, students appreciated to a higher extent the new way of teaching than the traditional way. All this naturally came with a price. Producing new teaching material, like videos and meaningful problems, took on average 20 clock hours per IVL and follow-up problem session. Over 300 clock hours was spent on developing this new way of teaching the course. So, from a purely economical point of view, this rather high initial development cost can probably only be justified in courses with large class sizes or courses with moderately sized classes that are given very often.

One reflection is that the students' participation in the new teaching activities was on average quite low. It would be interesting to find ways, meaningful from a learning point of view, to improve participation and see if this also further improves learning. It would also be interesting to follow up on how the students did afterwards, in other courses, to determine whether this new way of teaching has any particular long term effects.

ACKNOWLEDGMENT

The authors would like to thank Sara Markstedt for kindly assisting in the process of digging out statistics over student performance and Anna Holmbom for general assistance during the preparation of this paper. This work was partly supported by a grant from the faculty board at Luleå University of Technology (*Flexible Learning*, dnr 188-12).

Abstract—Helping college freshmen to learn basic computer programming is a longstanding research topic. Various environments, tools and languages have been developed to ease the initial steps of novice programmers. However, to be used to their full extent, such artifacts should be better combined with an appropriate learning approach. This work describes pre-term workshops offered to Computer Engineering undergraduate freshmen that combines the use of the Scratch learning environment with a learning approach based on peer support, game development and a strategy of challenge-response. Results are derived from quantitative data analysis: surveys and artifact analysis. Students evaluated the workshop well: they found it stimulant, lightweight, with good teaching, useful, well-organized, and conducive to learning. Results suggest the effectiveness of the approach to reduce initial difficulties for freshmen learning programming concepts.

Keywords—peer learning, programming, environments for novices, Scratch, game-based learning, challenges.

I. INTRODUCTION

For years, undergraduate computing programs have faced the challenge to teach programming to freshmen with no previous background in the field [1]. A large variety of concepts and skills is usually required, ranging from algorithmic thinking to expression in a formal language, from data structures to mastering an IDE [2]. To make matters worse, faculty typically adopt a formal approach that is usually detached from students' worries and preferences.

Previous work is prolific with alternative approaches to teach college introductory programming, especially with environments geared to the novice [2], [3]. Among such environments, Scratch is one of the most popular, originally conceived to be used by both children and teenagers, and based on design decisions that make the environment more tinkerable, meaningful and social [4].

Nonetheless, even the most well designed environment may be misused if not accompanied by appropriate teaching and learning approaches. To us, students benefit more from learning environments when an active learning approach is used. For two years, we have been perfecting an approach that combines the use of Scratch, peer support, a strategy of challenge-response, and game development. We have also applied this approach by means of freshmen workshops, usually a week before the academic term starts.

In this paper, we describe one of our latest workshops, a one-week, 20-hour pre-class workshop with freshmen of a Computer Engineering program in a state university in Brazil, offered in August 2014. The workshop intended to overcome the initial difficulties with programming that students face. Three sophomore peer students guided the workshop presented to 18 freshmen. The challenges proposed led to the gradual development of an animation in Scratch, and three classic games: Pong, Bow and Arrow, and Space Invaders. One last challenge was the development of a simple calculator to allow a smooth transition from Scratch to the C language. To evaluate our approach, we used a quantitative approach based on artifact analysis, i.e., the projects students produced, and two surveys: one right after the workshop was over, and another one month after the term started, when students finished their first project in the CS1 course¹.

Students evaluated the workshop well in various criteria: they found it stimulant, lightweight, with good teaching, useful, well-organized, and conducive to learning. Students considered stimulant the active and playful learning approach. They also evaluated Scratch as having a friendly user interface and simple working logic, especially the Lego-style block fitting. The most used blocks were interface commands (Appearance), selection and repetition structures (Control), and movement commands (Motion), which were also the ones students asserted as less difficult.

Even though most students were not using Scratch after the workshop, 70% of them asserted that the tool helped a lot to learn programming. Especially regarding selection and loop structures, 80% agreed that, to some degree, the workshop helped them to develop their first project in the CS1 course. This seems remarkably relevant since these are concepts usually hard to grasp in regular courses. On the other hand, the same did not happen with the use of variables. Though used in the games, they were not the main student concern when answering the challenges.

Results point to the effectiveness of an approach based on game development, a challenge-response strategy, peer support and programming environments for novices. The gathering of empirical evidence in this work also contributes to the field, helping to better evaluate learning initiatives and tools.

This paper is organized as such: Section II discusses

¹CS1 is the name usually given to the computer science introductory programming course.

the background for this paper and related work. Section III describes the research methods used. Then, Section IV presents results, followed by a discussion in Section V. Conclusions are derived in Section VI together with suggestions for future work.

II. BACKGROUND

In this section, we describe related work on causes for dropout and failure in CS1 courses, on programming environments for novices, and on guidelines and alternative initiatives in introductory programming courses.

A. Causes for dropout and failure in programming courses

Why is programming hard to learn? This question has been thoroughly pursued by the community of computing education for around five decades. Robins et al. surveyed the topic and describe differences between novice and expert programmers and between effective and ineffective novices. They also describe the complexity of the problem by devising a programming framework based on knowledge, strategies and mental models needed to design, generate and evaluate programs [5]. Program design involves knowledge of planning methods and algorithm design, strategies for planning and problem solving, and models of problem domain. Program generation requires knowledge of languages, libraries and tools, strategies for implementing algorithms and for coding, and models of a desired program. Finally, program evaluation requires knowledge of debugging and testing tools and methods, strategies for testing, tracing and repairing, and models of an actual program.

A survey among 67 higher education institutions all over the world reported a high variation in fail rates, reaching values as high as 60% [6]. Robins discusses the likely causes described by the academic literature to distinguish students between programmers and non-programmers [7]. Factors range between cognitive capacity, cognitive development, cognitive style, attitude and motivation. However, this author suggests that those factors do not actually predict student success, and proposes an alternative explanation, named learning edge momentum effect, where acquiring one concept eases the learning of other closely related concepts.

Another work investigates students' decisions to quit the CS1 course in high school, with reasons ranging from lack of time to lack of motivation [8]. Those reasons are affected by factors such as perceived difficulty of the course, general difficulties with time management and planning studies, or the decision to prefer something else. Low comfort level and plagiarism also play a role in dropout levels. Finally, authors explain that dropout reasons accumulate, making efficient intervention require a combination of various different actions.

Lewis et al. use structural equation modelling to investigate the effect of technical and soft skills (i.e., emotional intelligence) on the affinity (i.e., satisfaction with the CS major) and the intention to quit the CS major [9]. Unexpectedly, they found that technical skills were less important than soft skills to predict affinity. They suggest incorporating soft skills in the curriculum of computing undergraduate programs.

Part of the difficulties with learning introductory programming is related to both programming languages and development environments used in the learning process. Researchers have investigated those issues [2], [3], which we shortly describe in the following.

B. Programming learning environments

Kelleher and Pausch have developed a taxonomy of programming environments and languages for novices [3]. Two large groups of environments and languages are proposed: teaching systems, which aim to help people learn to program, and empowering systems, whose goals are to empower users to build things tailored to their own needs. Inside each group, they classify environments and languages by their approach to either ease learning or to empower users.

Guzdial describes the evolution of learning environments for novice programmers [2]. He discusses three families of programming learning environments: the Logo family, the rule-based family, and the traditional programming family. He identifies three research trends: a clear trend towards tool development with traditional language syntax; students prefer to work on computational artifacts that have meaning to them; and environments and tasks should give students immediate feedback on their work.

The trends identified by Guzdial led to the development of some popular programming learning environments, where learning happens by developing and playing games and animations in microworlds, such as in Scratch [10], Greenfoot [11], Alice [12], Robocode [13] and AppInventor [14]. Utting et al. discuss the goals, mechanisms and effects of Scratch, Alice and Greenfoot, providing an interesting account of the affordances of each tool [15].

Scratch, the tool we use in this work, is based on three design concepts: being more tinkerable, more meaningful and more social [4]. It is more tinkerable because programming happens by fitting programming blocks together, just like blocks in Lego toys. It is more meaningful for its investment in diversity and personalization, allowing their users to create different project types such as games, simulations and animations. Finally, it is more social, because of its social network that allows sharing projects, creating new projects from previous ones through mixing, and cooperating with pairs to develop collaborative projects. Scratch uses a kindergarten learning cycle that fosters creative thinking [16]. The cycle uses the steps of imagining, creating, playing, sharing and reflecting to aid in the learning process. Immediate feedback from the tool and the use of the Scratch social network allows for the cycle to be performed easily.

C. Learning introductory programming in CS1 courses

Robins and colleagues argue that most CS1 courses in a conventional curriculum are based on a lecture and lab approach, and are largely focused on knowledge, especially knowledge of language features [5]. They recommend instruction focused not only on language features, but also on program design and the combination of those features. They also suggest addressing programming mental models, such as models of control, data representation, program design and

problem domain. Finally, they reinforce the pedagogical role of lab activities as case-based problem solving sessions.

A systematic review of approaches to teaching introductory programming, based on 60 intervention reports, shows that alternative teaching interventions improve passing rates in CS1 courses by around one-third on average, when compared to a traditional lecture and lab approach [17].

Pears et al. collect and classify the literature of three decades of research on teaching introductory programming, identifying influential, synthesis and emerging work [1]. They classify 45 selected papers into four categories: curricula, pedagogy, language choice and tools for teaching. On the pedagogy category, they divide the studies of programming courses into three emphases: problem solving, learning a particular language, and code production.

Regarding assessment of alternative approaches in CS1 education, it is useful first to resort to Gross and Powers' work, which evaluates various assessments of novice programming environments [18]. They classify assessment techniques as anecdotal, analytical or empirical, and then present an evaluation rubric for the quality of such assessments, evaluating the earlier assessments with the rubric.

There is a huge amount of literature of experience reports and assessments of alternative approaches for CS1. We focus here on some papers that uses the Scratch environment for higher education. One experience with Scratch uses it during the first three weeks of a CS1 course [19]. In this course, Scratch replaces the typical course sequence devoted to algorithms and pseudo-code. Students expressed higher motivation in contrast with the regular courses. However, no changes were found in either dropout rates or obtained scores when compared to the baseline course. Another experience uses Scratch during a two-week period to provide scaffolding for novices to learn basic programming concepts, and a tool for advanced learners to remain engaged through challenging work [20]. Both experiences are similar to ours in using Scratch to introduce programming concepts during a short period. Our approach, nonetheless, is different since our workshops happen before classes start, are led by peers, and are based on challenges and free interaction with the environment, instead of regular classes.

III. METHODOLOGY

The research approach used in this work is the case study. A case study is a contemporary phenomenon delimited in space and time [21], [22]. In this approach, the researcher is interested in investigating the phenomenon in a real environment, and in all its complexity.

A. Research Design

Our case was a five-day, 20-hour workshop of introductory computer programming for Computer Engineering freshmen undergraduates, which happened in August, 2014. The workshop used a particular learning approach, based on peer support, game development, a challenge-response strategy, and a playful programming environment for novices (i.e., Scratch). The phenomenon studied was the learning process developed during this workshop.

Our data analysis approach is both exploratory and quantitative. In an exploratory case study, one tries to answer research questions related to the phenomenon with no predefined hypotheses. The quantitative analysis intends to measure variables inside the case that are related to the phenomenon. To do such, we surveyed participants and we also analyzed the artifacts (i.e., software) they produced. We also performed qualitative data analysis, but the data are still under analysis and will be reported in a later work.

Our main goal was to understand the limitations and affordabilities of the aforementioned learning approach, and the learning issues that develop during the workshop.

Our research questions were four:

- 1) How do participants assess the workshop structure?
- 2) How do participants assess the workshop learning approach?
- 3) How do participants assess the Scratch learning environment?
- 4) Which skills and knowledge do participants acquire in the workshop?

Finally, approval for this research was obtained from the Institutional Review Board at the State University of Feira de Santana (UEFS).

B. Participants

Eighteen students participated in the research: 15 male and 3 female. All of them were freshmen in the Computer Engineering Undergraduate Program at the State University of Feira de Santana (UEFS). All participants signed an informed consent form, allowing their participation in this research.

C. Workshop Planning

Our workshop was based on previous workshops we have been offering since February, 2013. The present workshop happened one week in advance of the academic term, when students are free from activities of regular courses. The workshop was conducted during five consecutive days, four hours each day, in a computer lab with one desktop computer per student. Students were invited during enrollment and through notices at the UEFS Computer Engineering web site.

The main learning goal was that, after the workshop, students could understand and apply basic concepts of algorithms and programming to develop small applications in a graphic programming language, thus, reducing potential difficulties in the first regular course on programming (CS1).

The learning approach used in the workshop was based on a combination of:

- *peer support*: three sophomore students led the workshop, helping participants to clear their doubts;
- *game development*: participants developed games in order to learn programming skills;
- *challenge-response strategy*: tutors challenged participants with small challenges during game development, instead of providing detailed explanations;

- *learning environments for novices*: the Scratch environment was used as the main tool to learn programming, avoiding issues with language syntax and compilation.

The challenges proposed led to the gradual development of an animation and three classic games: Pong, Bow and Arrow, and Space Invaders (see Table I). One last challenge was the development of a simple calculator to allow for a smooth transition from Scratch to the C language.

TABLE I. WORKSHOP SCHEDULE

Day	Challenge	Main Content
1	Animation	Motion, Looks
2	Pong	Motion, Control, Sensing
3	Pong / Space Invaders	Motion, Looks, Control, Sensing, Operators, Variables
4	Space Invaders / Bow & Arrow	Motion, Looks, Control, Sensing, Operators, Variables
5	Bow & Arrow / Calculator	I/O, Variables, Operators, Conditionals, Loops

One undergraduate tutor conducted the workshop, and was aided by two other undergraduate assistants. Initially, the tutor presented a short overview of the Scratch environment. Then, she proposed building an animation by interactively exploring the environment. Later, the tutor challenged the participants by showing the Pong game, and then asked them to produce that game. Then, she started to propose small challenges to develop parts of the game. Students actively explored the environment to answer to the challenges. Whenever they needed, tutor and assistants cleared their doubts. The same process happened with the other games.

D. Data Collection and Analysis

We used both quantitative and qualitative data collection procedures in order to deepen and enrich the research. This strategy is known as methodological triangulation. If the results of different procedures lead to the same conclusion, the research provides a higher degree of confidence [23], [24].

We used surveys and analysis of source code as quantitative data, and interviews and observations as qualitative data. However, we only describe quantitative results in this paper, since qualitative data are still under analysis. Two surveys were conducted with participants: one immediately after concluding the workshop (response rate of 72.2%, with 23% female and 77% male), and a second survey one month after term begin, right after the students had turned in their first lab assignment (response rate of 55.5%, with 20% female and 80% male). Even though the second survey was conducted *in loco*, the response rate was low because research participation was optional. Average age in both surveys was 18.6, with a standard deviation of 1.25 and 1.34, respectively, for the first and second surveys. Regarding the source code analysis, we examined only those kept in the computer desktops after the workshop, totalling nine student projects. From these, only four students fully participated in the five days of workshop.

IV. RESULTS

All the respondents of the first survey asserted that used the Internet every day. Regarding previous experience with programming, only one had thorough knowledge of the subject,

Fig. 1. Workshop Assessment

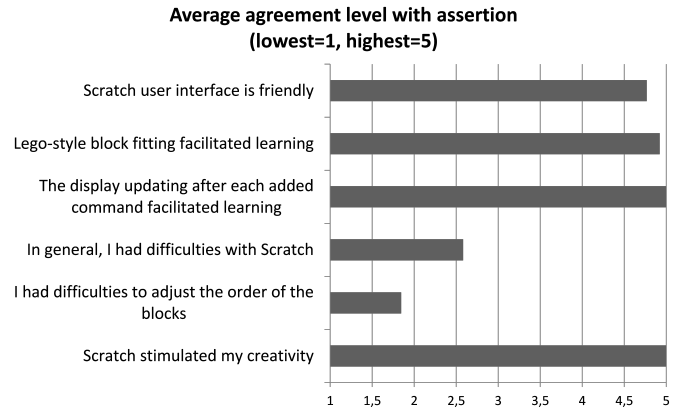

Fig. 2. Tool Assessment

while the rest had either no or few knowledge of it. None of them knew or had heard of Scratch before the workshop.

A. Workshop Assessment

We used a five-point scale between two extremes to let participants assess the workshop. For instance, one assessed criterion was the boring/stimulant dimension. The more to the left (right) the answer, the more boring (stimulant) the workshop was. The other criteria are described in Figure 1. All criteria but one had average value above 4.5. The workload was considered a little tiresome by some students.

B. Tool Assessment

Participants also assessed the tool, i.e., the Scratch programming environment, as shown in Figure 2. The friendly user interface was one of aspects best assessed, both the interface itself and the ability to immediately see code change results. Another relevant aspect was that the tool motivated participants' creativity. The playful way how coding blocks are fitted was also well valued. Few students had difficulties to use the tool (23% of partial agreement), while very few had issues with block fitting (8% of partial agreement).

C. Learning Approach Assessment

Participants assessed the learning approach used in the workshop as well. Figure 3 shows participants' opinions on

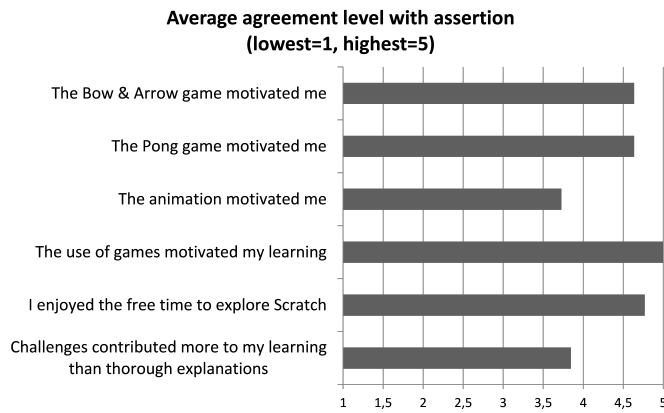

Fig. 3. Learning Approach Assessment

the learning approach we used. It is worth reminding that we provided only brief explanations of either the tool or of programming concepts, and we fostered participants to solve challenges we posed. The use of challenges had 76% of agreement to some degree, while 23% disagreed. The importance of free time to explore the tool was unanimous among participants. The adequate quantity of tutors available during the workshop also had unanimous agreement (38% partially agreeing, and 62% agreeing). Everyone fully agreed with the use of games, although there was some variation according to the particular game. The animation with the Scratch cat character was the less well assessed item. When asked to grade, between 1 and 5, how much the workshop motivated their learning, 85% of the participants graded it with 5 points.

We analyzed students' multitasking behavior, rather common in this generation [25]. Parallel access to the Internet for goals unrelated to the workshop issues was almost zero: 92% asserted that had not accessed the Net (only one student recognized using it a little). Listening to music, although not significant, was more common than Internet use. One student said he had listened a lot of music, while 62% asserted not listening to any music at all.

D. Assessment of the Knowledge Construction Process

The Scratch tool groups programming blocks by theme, one tab for each theme. The analysis of student answers about the degree of difficulty to learn each theme showed that: Variables, Operators and Sensing had the highest degree of difficulty, while Control, Motion and Looks had the lowest, as shown in Figure 4. Nonetheless, in a scale between 1 and 5 (1=none; 5=substantial), no theme had average degree of difficulty higher than 3. The themes of Pen and Sound were not assessed, since they were not used during the workshop.

Table II shows the number of coding blocks used by each student, organized by theme, for the Space Invaders game, the most complex game in the workshop. This game was developed in two days, but students 4, 5 and 7 were present in only one day. On average, each student used 450 blocks. Looks, Control and Motion were the most used blocks.

Table III shows the features implemented by each student in the Space Invaders game. Each row refers to one par-

Fig. 4. Scratch Theme Assessment

TABLE II. BLOCKS PER STUDENT IN THE SPACE INVADERS GAME

	Motion	Looks	Control	Sensing	Operators	Variables	Total
Student 1	73	238	441	72	39	80	943
Student 2	183	106	218	58	52	0	617
Student 3	94	192	248	29	2	0	565
Student 4	46	47	82	31	17	28	251
Student 5	61	139	131	34	6	16	387
Student 6	110	98	201	37	0	0	446
Student 7	29	6	28	3	0	0	66
Student 8	68	42	89	21	23	30	273
Student 9	111	59	180	48	28	72	498
Average	86.1	103.0	179.8	37.0	18.6	25.1	449.6
Standard Deviation	45.6	75.6	121.5	20.3	18.6	31.3	252.2
Total	775	927	1618	333	167	226	4,046

ticular feature, while each column refers to one participant. For fully implemented features, we assign value 1. Partially implemented features receive value 0.5. And unimplemented features get zero. Averaging over the features, we noticed that seven students had a game completion average of at least 0.7. Student 7, who missed one workshop day, was below average. Students 4 and 5 had average greater or equal to 0.7, even though they also missed one day.

TABLE III. FEATURES PER STUDENT IN THE SPACE INVADERS GAME

	Student 1	Student 2	Student 3	Student 4	Student 5	Student 6	Student 7	Student 8	Student 9	Average
Life and Score	1	0	0	1	0.5	0	0	0	0.5	0.3
Game Over	1	0	1	0	0	0	0	0	1	0.3
Cannon Moving	1	1	1	1	1	1	1	1	1	1.0
Alien Moving	1	1	1	1	1	1	0.5	1	1	0.9
Alien's Costume Changing	1	1	1	1	1	0	0	1	0	0.7
Cannon's Costume Changing	1	0	1	0.5	0.5	0	0	0	1	0.4
Cannon Shooting	1	0.5	1	0.5	0.5	0.5	0	0.5	1	0.6
Alien Shooting	1	1	1	1	0.5	0.5	0	1	1	0.8
Average	1	0.7	1	0.8	0.7	0.4	0.1	0.7	0.8	-

Computing the Pearson correlation for the average blocks per student and the average features per student, we get a value of 0.69, showing strong correlation between both variables. In the Bow & Arrow game, correlation grows to 0.83. Obviously, quantity does not imply quality. But quantity of blocks is important, in this case, to successfully implement a feature.

Table IV shows the sum of blocks used for all games but the animation. Results show 5,550 blocks for all the nine students whom we retrieved the source code. Sensing, Variables and Operators were the least used blocks, while Control, Looks and Motion were the most used. We also show the number of days students have attended the workshop. The ones who came every day used more than 700 blocks, while the others used less than 600.

TABLE IV. BLOCKS PER STUDENT FOR ALL THE GAMES

	Days	Motion	Looks	Control	Sensing	Operators	Variables	Total
Student 1	5	108	288	520	80	51	100	1147
Student 2	5	232	184	337	98	64	21	936
Student 3	5	150	240	341	52	3	13	799
Student 4	4	68	47	107	36	25	34	317
Student 5	2	80	147	155	37	6	16	441
Student 6	4	146	125	253	53	1	0	578
Student 7	4	58	30	84	13	2	2	189
Student 8	4	99	70	142	35	27	34	407
Student 9	5	153	107	282	70	40	84	736
Average	-	121.6	137.6	246.8	52.7	24.3	33.8	616.7
Standard Deviation	-	55.3	86.3	144.0	26.4	32.2	55.1	321.8
Total	-	1094	1238	2221	474	219	304	5,550

Finally, to get an idea of the effects of the workshops in our CS1 course, which uses the C language, we surveyed participants right after they finished their first coding lab assignment, one month after term begin. From 10 respondents, 90% asserted that either have not used or have briefly used Scratch after the workshop. Regarding the C language, 70% fully agreed that enjoyed programming in that language, while 40% agreed in some degree that had difficulties to code in that language (with 75% of these with partial agreement).

When asked whether the use of Scratch before the term helped them to learn how to solve the first assignment, 70% asserted it did so, either reasonably or a lot. The more specific we were, the more agreement there was: 80% agreed to some degree about the learning of control structures, while 90% said so for logic operators.

V. DISCUSSION

Here we discuss our findings, in the light of our goals and the literature. Discussion is ordered by our research questions (RQ), established in III-A.

A. RQ1: How do participants assess the workshop structure?

In general, the workshop was well evaluated by the students, who considered it: (1) stimulating: in general, they kept quite entertained throughout the days, working on the challenges proposed. Being stimulating is critical in that it is their first contact with the knowledge area that they chose to pursue a career in. Moreover, the current generation has a low threshold for boredom. In this sense, another evidence

was the lack of multitasking behavior, reported by students, and observed by researchers. This type of behavior, which manifests as holding two or more usually unrelated complex tasks either simultaneously or alternately [26]. Recurring work in the literature point out to disruptions in learning when such behavior arises [27]–[29]; (2) useful: students learned skills that would be useful in the short term, in the CS1 course they began to attend a few days after the workshop; (3) organized: workshop schedule followed as planned, as described in Section III, along with well-defined goals, helped the fluency of activities with no setbacks, as perceived by participants.

Furthermore, the average workshop reviews of being conducive to learning and with good teaching by the peers were significant. Only the tiresome-light binomial scored a little low when compared to the others, maybe because the workshop took all morning shifts for five consecutive days. However, one should also consider that producing almost two games per day may have triggered some exhaustion, i.e., the workshop workload may have been excessive. Various students failed to implement all the proposed features of all the games. Therefore, either removing one of the games or rethinking the schedule in a next workshop offering should be considered.

B. RQ2: How do participants assess the workshop learning approach?

As previously stated, the workshop learning approach was based on a combination of peer support, a challenge-response strategy, game development, and a learning environment for novices. All participants agreed, to some degree, that the approach was adequate. With 18 participants for three tutors, we had a ratio of six students per tutor. Peer support is a widely used strategy in introductory programming learning, as reported in the literature: both formal and informal, in classroom or in the lab, or even outside the classroom [30]. Our approach is distinct from other experiences because the workshop is made by students and for students. Two positive consequences follow: (1) integration: since the workshop happens a week before regular classes begin, it ends up being an event where freshmen get to know each other, and integrate with senior students; (2) sense of belonging: being next to fellow senior students allows freshmen to feel they belong in that community.

The use of challenges was well received by students. The goal was that they explored both solutions and the environment in a self-directed way. Tutors gave just short explanations, and intervened only when needed or requested. In any case, that strategy led more to the use of leading questions instead of giving straight answers.

Challenges are one of the foundations of active learning, a widely discussed topic in pedagogy [31]. An example of active learning is problem-based learning (PBL), which has been widely used in computing courses [32], [33]. In PBL, challenges take the form of a problem that resembles professional practice, arousing students' interest on content knowledge, and stimulating self-directed learning, among other benefits [34]. A difference from our approach to PBL is that although we encourage discussion among students, it happens only in a few moments, while in PBL, discussion takes most of the group

meetings devoted to solving problems. By the way, similarities between challenges and PBL are welcome in our context, since our Computer Engineering undergraduate program is strongly based in PBL.

One benefit of using challenges is letting students free to advance in their own pace. Sometimes they did more than requested, making them more proactive. We had, for instance, some students who took their project home and improved them with more features. Such attitude was encouraged by the tutors.

Using games as challenges has proved a right decision. It may seem obvious, but the fact that participants rated games like Pong or Bow and Arrow more motivating than the initial animation suggests that they prefer more complex tasks, provided that they are motivating. Challenges that assume a playful facet, such as games, are relevant because such activities are part of human beings' history, and involve various elements such as rules, goals, tension and competition [35] — also present in the workplace. Indeed, we may say that game development is a challenging task, since it implies a substantial complexity in tasks of communication between objects, logical and mathematical operators, scenery, among others. In addition, the use of games adds at least two important features to the teaching-learning process: (1) everyday life: games are part of youth daily life. Thus, working with something that fascinates them, that is part of their reality, is likely to increase motivation; (2) amusement: learning by playing minimizes the view of studying as obligation, reinforcing entertainment and, hence, enhancing learning [36].

C. RQ3: How do participants assess the Scratch learning environment?

The choice of Scratch as the learning environment for beginners also facilitated the decision of merging games with challenges. First, participants strongly agreed that Scratch was favorable for game development and learning: a playful environment for creating other playful environments. Second, immediate feedback on the screen was also much appreciated. Third, avoiding issues of compilation and syntax was also welcome. Those features led to a good assessment by participants. They also had no bigger issues with using the tool, besides considering it user-friendly and leading to creativity development.

We must also highlight that, for the aforementioned factors, it is possible to build complex programs in Scratch in a relatively short time. An undergraduate student, new to programming, would likely take a long time to develop games such as Space Invaders using traditional programming languages, even at the end of the first term. But they did it after only a few days. It is worth noting that the workshop led to an average of 450 blocks used per student, for developing three games. Participants who came to every workshop day used more than 700 blocks. If we equate blocks to lines of code, we realize how much code our beginning programmers had developed in such a short period, especially when compared to the code students develop in their first CS1 classes.

Nevertheless, after the workshop, students made it clear that they did not keep using Scratch. Natural reasons for this were: they were then focused on learning a programming language, had a high workload for the courses they were

registered in, and needed to adapt to a new student routine. Another reason was that their perception of Scratch changed: Scratch was now perceived as an amateur language, while C felt as something more professional and, therefore, more relevant.

D. RQ4: Which skills and knowledge do participants acquire in the workshop?

The most used blocks were from the themes of Looks (user interface), Control (selection and repetition structures) and Motion (for moving objects in the game). These are precisely the themes that showed the least degree of difficulty for participants. Control blocks, which are usually hard for beginning programmers, were the most used blocks, while blocks of Operators and Variables were the least used. It is worth mentioning that the less implemented features in the Space Invaders game were counters (e.g., for life and score), even though the final results depended on these counters. This may likely have happened because counters require variables, one of the difficult themes according to the students.

The theme Operators, which handles logical and mathematical operators, had a greater degree of difficulty than the theme Control, responsible for selection and repetition structures. Interestingly, those structures are not usually easy to learn — hence the effort to offer this workshop — and require, a priori, a more elaborate logic than such operators. Working in a playful manner with such structures may have facilitated learning.

In summary, we finished the workshop with 5,550 blocks used (given that only nine participants provided their projects for analysis), which allows us to infer that students have really evolved in terms of introductory programming. Sensors, Variables and Operators were the topics less practiced, while Control, Looks and Motion, the most commonly used.

Finally, despite students have not kept on using Scratch, we may say that the experience contributed substantially to their learning of programming during the first month of the term. 70% asserted that the workshop helped a lot in the process of knowledge construction of the first CS1 lab project. 80% agreed, to some degree, that it helped on selection and repetition structures, and 90%, on logical operators. This result is significant, and it was precisely one of the workshop goals, suggesting that the learning approach together with the adopted tool provided a more fluid and meaningful learning of programming.

VI. CONCLUSIONS AND FUTURE WORK

This paper described a case study of a teaching and learning approach aimed at facilitating learning of programming concepts by Computer Engineering undergraduate freshmen. Our approach combined the use of the Scratch learning environment, peer support, a strategy of challenge-response, and game development. The case developed as a workshop for freshmen that lasted one week, with a workload of 20 hours. Three sophomore peer students guided the workshop, presented to 18 freshmen. The challenges led to the development of animations, games and a calculator. To evaluate our approach, we used a quantitative approach based on artifact analysis and

two surveys, one post-workshop, and another after students finished their first CS1 lab project.

Students assessed the approach well in some dimensions: stimulant, lightweight, good teaching, useful, well-organized, and conducive to learning. They also evaluated the Scratch environment as user-friendly, and with good working mechanics, especially the Lego-style blocks. Commands of interface (Looks), control structures (Control), and movement (Motion) were the most used, considered less difficult by the students. Although most students have not used Scratch after the workshop, 70% of them agreed that the environment helped them to learn programming. Regarding control structures, 80% agreed that the workshop aided them in developing their first CS1 project to some degree. This is relevant, for these are concepts usually hard to learn in regular courses. On the other hand, variables were not grasped so well, even though they had been used in the games. Results suggest the effectiveness of the approach. Moreover, the work also contributes to the field of computing education with empirical evidence, helping to better evaluate learning approaches and tools.

Further work should deal with qualitative analysis of these workshops, based on interviews and observation. We also intend to add a longitudinal dimension to the work, analyzing workshops from different terms and their evolution.

ACKNOWLEDGMENT

We would like to thank the freshmen students who voluntarily took part in this research. We also thank FAPESB – Bahia State Foundation for Research Aid, and UEFS – State University of Feira de Santana, for their funding of undergraduate research fellowships.

Abstract — Teaching of programming foundations has been subject of several investigations, because it is believed that the required activities can contribute to the development of students more able to solve problems and to adapt to any environment or situation. Some works have argued about the integration of Flipped Classroom and Problem-Based Learning in Computer Science courses to potentiate this kind of teaching, but fewer evidences that investigate the real application between these approaches were found. Thus, in order to enhance the Flipped Classroom in-class activities, this paper reports an experience to implement and apply Flipped Classroom and Problem-Based Learning approaches for a CS1 course. Additional concepts of programming contests, group formation and learning styles were also used. In general, the main findings suggest that the Flipped Classroom model, if well-planned and carefully designed, can benefit students. However, these initial benefits are more related to student's motivation and social behavior than those associated with grades and the effective learning. Results also indicate that PBL may be an adequate approach to enhance the face-to-face time in the inverted classroom.

Keywords—*Flipped Classroom; Problem-Based Learning; Programming Contests; CS1; Teaching Programming; Experimentation.*

I. INTRODUCTION

In spite of the existence of several investigations about the teaching of programming foundations [2, 7, 10, and 20], basic courses in Computer Science still have specific challenges to address in order to provide the students with the necessary knowledge and skills to follow the course and achieve a successful career in the workforce.

According to Partnership [9], students of the 21st century must have the following skills: 1) creativity and innovation; 2) critical thinking and problem solving; and 3) communication and collaboration. It is also necessary a model that defines the pedagogical and technological infrastructure that best support the

acquisition and development of these skills within the school context. Such infrastructure should: a) promote and evaluate students' performance; b) increase their engagement; c) facilitate communication and collaboration; and d) facilitate and maximize efficiency in the management of the results.

Considering the Horizon Report 2014 (Higher Education Edition)¹, which indicates the capable trends with practical application around the next 12 months, the Flipped Classroom (FC) model is part of a movement that is meant to be flexible, active, and more engaging for students, but particularly helping students to acquire the skills previously described.

A. Flipped Classroom

In general, Flipped Classroom refers to the model that inverts the logical organization of the classroom [3, 4, 5, 14, and 15]. However, we also consider another viewpoint to understand the FC which is consider this model as an opportunity for future changes in the classroom context for at least three main reasons. Firstly, this model can be a way to rethink learning and teaching process. As a second point, the teachers can act as learning designers. Finally, FC activities are also related or supported by other many educational theories or ideas such as Bloom's Taxonomy, User-Centered Learning, Self-Regulated Learning, Self-Determination Theory, among others.

Thus, from this model students have access to short explanations and specific materials that should be studied before each class, through any device, in any place where he/she is, such as at home, at work, on the bus. Out-class activities can be guided by e-learning and m-learning technologies, also including the adoption of Massive Open Online Courses (MOOCs) and Personal Learning Environments (PLEs) [10].

¹<http://cdn.nmc.org/media/2014-nmc-horizon-report-he-EN-SC.pdf>

In-class activities, in turn, can use available resources in classrooms and laboratories. Such activities can also be benefited from the use of already known Active Learning Strategies, such as Problem-based Learning [8, 21], and collaborative activities with teacher supervision.

B. Problem-Based Learning

According to Duch et al. [11], Problem-based Learning (PBL) is an instructional method that challenges students to “learn to learn”, working cooperatively in groups to seek solutions to real world problems. These problems are used to engage students’ curiosity and introduce or motivate the subject matter. PBL prepares students to critically thinking from the use of appropriate learning resources. The main idea behind PBL is that the starting point for the learning process should be a problem, a query or a puzzle that the student wishes to solve.

C. Programming Contests

One way to encourage students to improve their knowledge in a particular area is to encourage them to participate in knowledge contests [6] in order to solve real and interesting problems, queries or puzzles. There are several initiatives around the world, such as the Mathematical Olympiad², Portuguese Olympiad³, Astronomy Olympiad⁴, among others. When taking part in a competition, participants are shown engaged to prove their worth and knowledge.

In the Computer Science field, for instance, the number of knowledge contests is increasing, stimulated by large educational institutions, representing societies and companies that seek, in this kind of environment, students with the best performance and results. The idea is to contribute to the improvement of teaching programming concepts since students are motivated to participate.

In Brazil, for example, considering national competitions in higher education context, we can highlight the Programming Contest⁵ organized by Brazilian Computer Society (SBC), which is also the Brazilian selective for the International Collegiate Programming Contest, organized by the Association for Computing Machinery (ACM). This contest has fostered the creation of regional and local (or institutional) contests, which serve most often as internal tryouts contests for the national dispute [6]. In addition, those who become winners, more than receiving material rewards, they have the opportunity to place into their curriculum the record of participation in activities involving discipline, knowledge, dedication, teamwork, logical thinking and ability to solve the proposed problems.

In general, in Brazilian programming contests the teams are composed by three students and a set of problems, which need to be solved by them in five hours. Teams must submit their

solutions using an online judge such as BOCA⁶. The winner is the team that solves the most problems in a shorter time.

Additionally to the existence of online programming contests, such as TopCoder⁷, there are other several available tools to support programming contests training such as SPOJ⁸ (Sphere Online Judge) and UVA⁹ Online Judge. A well-known system developed in Brazil is the URI Online Judge Problems and Contests¹⁰. In short, the URI project aims to provide programming practice and knowledge sharing. Teachers can also create courses and lists of exercises for the students. They can also track the students’ progress, providing immediate feedback or interventions in their teaching method.

Teaching of programming together with the training to participate in programming contests has been a way to encourage and motivate learners to study programming techniques, in addition to increase the integration among them [18].

Whereas CS1 courses are typically based on solving problems in a particular programming language, an important issue considered in this work refers to the possibility that Programming Contests can promote problem-solving skills, as part of the PBL related activities. Thus, Programming Contests can be an attractive form of learning and improvement of programming skills [7], since PBL and Programming Contests can facilitate generic skills such as group work, planning, problem solving, independent learning, research skills, time management, writing and oral presentation, among others [8]. According to Herzber et al. [12], achieve a goal and overcome challenges can be motivating as it relates to getting the outcomes of their own labor and self-realization. In addition, motivated people tend to have more persistence and good performance.

So, in this paper we used programming contests to enhance the PBL capability. The students were encouraged to develop problem solving through programming and competitions. The next section presents the main motivation related with this work.

D. Motivation for applying FC and PBL

According to the survey conducted by Bishop and Verleger [5], there are few works employing controlled studies to determining the students’ performance in the Flipped Classroom. Moreover, Fassbinder et al. [17] identified some works that instigate the integration of Flipped Classroom and Problem-based Learning, but no studies that actually apply and investigate the integration between these two approaches were found to enhance the Flipped Classroom in-class activities.

Considering all issues discussed, in this paper we present an initiative to apply Flipped Classroom and Problem-Based

Learning approaches in a CS1 course at Brazilian Institute of Education, Science and Technology – IFSULDEMINAS – Campus Muzambinho, which is located in the countryside. Additional concepts of group formation, programming contests and learning styles were also considered.

The main findings suggest that Flipped Classroom model, if well-planned and carefully designed, can benefit students. Results also indicate that PBL may be an adequate approach for Flipped Classroom in-class activities.

The remainder of this paper is organized as follows. In Section II, we describe our first experiment for teaching CS1 in an integrated way, using Flipped Classroom and Problem-Based Learning. The main findings obtained are summarized and discussed in Section III. In Section IV, we present our conclusions and perspectives for future works.

II. THE EXPERIMENT

Our introductory programming course follows the ACM and IEEE guidelines for the first year programming courses of Computer Science, as well as the recommendations of the Brazilian Computer Society¹¹. The main subjects studied are Fundamentals of Programming, including Introduction to Computer Science, Control structures (conditional structures and repetition/loop structures), Data type (character string, array), Functions, Procedures and Recursive Calls.

For this experiment, we opted to not invert all these related subjects and neither flip the initial content (i.e., Introduction to Computer Science and Conditional Structures). So, only the repetition/loop structures were considered (“For”, “While/Do-While”). In our point of view and context, flip the teaching of repetition/loop structures was an appropriate choice for three main reasons. Firstly, the students were already familiar with their classmates and teacher. Secondly, it was possible to compare students behavior before, during and after the inversion of the content. Finally, this content enabled the inversion because it is a subject that follows that worked previously, so the students were already familiar with the definition of algorithms, problem solving and the use of structures.

A. Planning

The experiment lasted six weeks, starting in March 2014, with three face-to-face meetings per week. Each face-to-face meeting lasted two hours. About 40 students enrolled in a CS1 course participated in the experiment.

We consider an experiment “a study in which an intervention is introduced to observe its effects” [19]. Initially, in order to compare the results of Flipped Classroom application versus the traditional learning approach, students were divided into two groups (A and B), with 20 students each. While one group was participating in a traditional class, the other group was doing the Flipped Classroom in-class activities. Both groups worked at the

same time, but in different classrooms (spaces). Besides, the same content or subject was being worked in both the groups.

In the following week, the groups were switched. It is, therefore, an experimental approach based on within-subject ideas [19], in which each subject experiences all levels: control (traditional approach) and new variable (inverted approach). Results will be analyzed considering the differences between student’s motivation and grade, for both the environments (inverted and non-inverted situation).

Figure 1 shows an overview of the experimental design.

Fig. 1. Experimental Design for Applying FC and PBL.

The planning activities for each week and for each group are described next.

• Week 1: Group Formation

In order to reduce bias in the results and to create mixed ability groups, the theoretical framework used to group the students in A-group and B-group was based on the Socio-cognitive conflict and learning [16] and on the Learning Style Theory [13].

To stimulate the Socio-cognitive conflict during the activities related to the experiment, we consider data from two sources: grade point average and analyses of logical reasoning with games. Students were grouped in those who have distinct logical reasoning in solving algorithms. According to Adán-Coello et al. [1], this approach allows that, in a discussion about the different versions of programs implemented, students can perceive other solutions to the same problem and learn from controversy and knowledge exchange. As previously stated, student’s learning

¹¹ <http://www.sbc.org.br>

style was also considered in order to obtain homogeneous groups for the experiment.

Therefore, in this work the following strategies were adopted to mixed ability grouping:

Grade point average (average academic results)

Were considered the grades obtained by the students in previous assessments performed according to the traditional teaching model. These assessments measured students' knowledge on variable statements and conditional structures, such as if-then-else and switch-case. These were the subjects studied before the repetition structures. The grades were used to obtain more homogeneous groups. Both groups, A and B, had students with three different categories of grades (0-5: below to average, 6-8: average, 9-10: above average).

Analysis of logical reasoning with games

We also conducted a puzzle game activity in order to analyze the student's ability to identify the problem context as well as useful strategies for logical reasoning in his/her solution and considering the available resources. All the students had 30 minutes to play Light Bot¹². Meanwhile, teachers observed and wrote down the difficulties and the performance of each student. At the end, we obtained the completed rounds for each, as well as the number of steps needed to complete the tasks. These data were ranked.

Light Bot was used taking into account the study presented in [2]. It is an educational Flash game developed by Armor Games. The main goal of the game is to program a small robot to light up all the blue blocks on a board. This goal is achieved by giving the robot a series of instructions from a limited set of commands, such as sequential commands, functions, repetition structures (for, while, repeat) with a finite instruction space. As the levels progress, the board becomes increasingly more complicated and more sophisticated combinations of commands are needed to achieve the goal for the level.

Student's Learning Style

Learning styles were also considered in the group formation. The Felder-Soloman Index of Learning Style (ILS) questionnaire [13] is a tool that helps teachers to identify students' learning styles, according to four scales: active/reflective, sensory/intuitive, visual/verbal, and sequential/global. So, the teacher is able to identify the most appropriate learning materials for each student. The teacher can also use the learning styles to group students in order to obtain more homogeneous groups of discussion. In our experiment, we used ILS to find the existing learning styles and thus group the students with the same or complementary learning styles. Adán-Coello et al. [1] argue that these two situations appear opposite, i.e., we want to provoke the socio-cognitive conflict while we create groups of students with similar learning styles. However,

the idea is to group students who presented different solutions to the algorithms, but that can discuss these differences and reach a consensus solution in a friendly and profitable manner.

Weeks 2 and 3: Studying Repetition Structures: FOR

1st face-to-face meeting

Group A: Students received the first explanations through lectures from the teacher. After the lectures, they received a list of exercises that could be performed individually during this face-to-face meeting. At the end of face-to-face meeting, the remainder of the list should be completed outside the classroom as a homework.

Group B: Three or four days before the first face-to-face meeting, students of group B were asked to access the Sophia Learning Platform¹³ and to watch the proposed videos, do in-video quizzes, interact with learning objects and other programs that use the repetition structure FOR. Sophia Learning tool was used to help the inverted classrooms since it is a Personal Learning Environment that supports the Flipped Classroom approach. The first face-to-face meeting was based on the following activities: the teacher clarified the main students' doubts, took notes on students' performance and participation during in-class and out-class activities (in-class activities were monitored using the Sophia Learning Platform reports). After this contextualization, students had time to practice programming individually, using pencil and paper. They also had time for practicing programming in small groups.

2nd face-to-face meeting

Group A: Students took any question with the teacher. Teacher gave new lectures to complement the subject. Students continued to make a list of exercises.

Group B: Students had more practice time for programming individually and in small groups using pencil and paper. Teacher still acted as the coach and facilitator of the knowledge acquisition process.

3rd face-to-face meeting

Group A: In the Programming Laboratory, students took any questions with the teacher. Teacher gave new lectures about C programming language grammar using CodeBlocks Integrated Development Environment (IDE). Students transcribed the list of exercises previously performed to C programming language.

Group B: In the other Programming Laboratory, in the first half of the class, students had to solve programming problems individually. In the second half, students were asked for solving programming problems in small groups based on the contest style. They were grouped in teams of three members each, also using C language grammar and CodeBlocks IDE. In this last part, students used URI Judge Online to submit proposals for algorithms for the problems indicated by the teacher on URI

¹² <http://armorgames.com/play/2205/light-bot>

¹³ <http://www.sophia.org/>

System. In some sense, we made a mini-competition in order to encourage and engage students in the programming activities. The teacher still acted as the coach and facilitator of knowledge acquisition.

- **Weeks 4 and 5: Studying Repetition Structures: WHILE/DO-WHILE**

In this week, we followed the same strategies described before, in the three face-to-face meetings, but now the groups were reversed. That is, students belonging to group A (traditional classroom) attended classes of “repetition structures While/Do-While” in group B (Flipped Classroom) and vice versa. The problems to be solved were related to the use of these repetition structures.

- **Week 6: Students’ Evaluation**

In the last week, tests were applied in order to measure the knowledge acquired by the students in Repetition/Loop Structures.

B. Execution

Our proposal of applying Flipped Classroom and PBL approaches in a CS1 course is summarized in Table 1. According to Kay et al. [8], in the PBL approach, the class time is devoted to the development of problem solving skills such as:

- 1) defining a learning plan;
- 2) brainstorming to get started on a problem;
- 3) reflection;
- 4) articulation of problems and solutions;
- 5) self-assessment;
- 6) practice in active listening and other communications skills.

Table I shows our approach for the relationship between Flipped Classroom activities and PBL fundamentals. Thus, the last column associates the encouraged PBL skills for each Flipped Classroom activity proposed for CS1 courses.

TABLE I. AN EDUCATIONAL PRACTICE DESIGN TO ADOPT FLIPPED CLASSROOM AND PROBLEM-BASED LEARNING IN A CS1 COURSE.

Flipped Classroom	Activity Short Description	PBL
Out-class Activities	Lecture videos, in-video quizzes, learning objects, related example programs.	-
In-class Activities	Practice time for programming individually, using pencil and paper.	1; 2; 3; 4
	Practice time for programming in small groups, using pencil and paper.	
	Solving programming problems individually, using C language grammar, in lab.	5; 6
	Solving programming problems in small groups with a contest style, using C language grammar, in lab.	

C. Evaluation

Data was collected by teacher observations in the experiment and also using a post-test, like a survey at the end of the experiment. The survey used a Likert scale in order to get the students’ responses regarding the Flipped Classroom model, the instructional videos used for out-of-class preparation and in-class activities, and the general impact that the experiment with Flipped Classroom had on students. Items in the survey were measured using 5-point rating scales, with the answers ranging from “strongly disagree” to “strongly agree”.

Additionally, there were some items which gave students the opportunity to provide further information in an open-ended manner, such as “*What were the Flipped Classroom positives and negatives points?*”, “*Can Flipped Classroom be applied in other classes?*”, “*What improvements would you recommend for other experiences with Flipped Classroom?*”, “*What were the strengths and weaknesses of the videos and learning objects?*”, “*Do you have any other comments, criticisms or suggestions?*”.

Furthermore, control and test groups were compared for differences in learning. The comparison with historical data was evaluated for statistical significance. The main results are discussed in the next section.

III. PRELIMINARY FINDINGS

Considering the investigations carried by Fulton [3] and Herreid et al. [4], the main advantages of the Flipped Classroom model are: (1) students move at their own pace; (2) doing “homework” in class gives teachers better insight into student difficulties and learning styles; (3) teachers can more easily customize and update the curriculum and provide it to students 24/7; (4) classroom time can be used more effectively and creatively; (5) teachers using the method has reported seeing increased levels of student achievement, interest, and engagement; (6) related learning theory supports new approaches; (7) the use of technology is flexible and appropriate for 21st century learning; (8) there is more time to spend with students on authentic research; (9) students get more time working with scientific equipment that is only available in the classroom; (10) students who miss class can watch the lectures; (11) the model promotes thinking inside and outside of the classroom; (12) students are more actively involved in the learning process; and (13) they also really like it. However, for Herreid et al. [4], difficulties also exist: new students may be initially resistant since the model requires that they work at home rather than be first exposed to the subject matter in the classroom. Also, homework (readings, videos) must be carefully tailored by teachers for the students in order to prepare them for the in-class activities.

Tables II and III present the students’ perceptions about our FC/PBL approach. Notice that the results obtained in our study are consistent with those discussed by the aforementioned studies.

TABLE II. STUDENTS' PERCEPTIONS ABOUT FC STRENGTHS

"Greater interaction and more time for discussion between classmates and teachers."
"The process of understanding the problem seems to happen more easily because you will have to face the class knowing what is going on."
"More relaxed environment and easy access to the teacher to ask questions."
"It gives the student a chance to develop self-learning."
"New ideas from interactions with classmates."
"The teacher assesses the student at all times, understanding more easily his/her particular difficulties and learning objectives."
"The possibility to see the explanation (videos) as many times as necessary."

TABLE III. STUDENTS' PERCEPTIONS ABOUT FC WEAKNESSES

"Having to watch and study at home! Sometimes I do not have all the needed time because I work all day! "
"I cannot find myself in any group!"
"You need internal motivation to be the active subject of your own learning! This is a challenge because I've always been the traditional model of teaching."
"I dislike studying with people around me, I do not feel well. I prefer to carry out the activities alone!"

From the analysis of qualitative data we observed that one of the main positive results was related to communicative skills. FC in-class activities interaction among students and student-teacher was greater than those in traditional class. To confirm it, Figure 2 shows the students' attitudes towards interaction and communication in FC.

Fig. 2. Flipped Classroom allows more interaction and communication with my classmates and teachers?

Another positive result related with the FC activities is the frequency number. The number of absent students in inverted classes was practically null, whereas the percentage of absent students in the traditional classes was always between 15 and 30 per cent. In short, considering the experimental design (Figure 1), we can notice a change in the students' attitude, although this can be difficult to measure.

In contrast to the small number of absent students and the improvement of communicative skills, both positive results in

FC environment, the student's grades difference were not significant, considering traditional and inverted classes. Figure 3 shows the general average, in 100 points, for traditional and inverted classroom in two subjects: 'for' and 'while/do-while'. Although the difference was not significant, the student's grade attending traditional classes to learn about repetition structures was a little bit higher than the student's grade in inverted classes, for this experiment.

Fig. 3 – Differences between grades.

However, in general, considering the number of approved and disapproved students in the CS1 class it is possible to perceive an improvement in the results, taking into account previous year (2013) as shown in Figure 4. Of course, this experiment was applied only in repetition structures. So, more investigations about the real impact of FC approach in this kind of context still need to be performed.

Fig. 4. Comparison of the number of approvals and disapprovals in CS1 class in the years 2013 and 2014, considering a class of 30 enrolled students.

Finally, considering post-test results, we observed that 66% of the students accessed the internet to interact with Sophia Learning in their home, while 25% have accessed outside the home (company, cafe, friend's house) and 9% have accessed at school.

IV. CONCLUSIONS AND FUTURE WORKS

In order to enhance the Flipped Classroom in-class activities, this paper reports an experience to implement and test Flipped Classroom and Problem-Based Learning approaches into a CS1 course. We used problems from the programming contests

context to increase the PBL capability and to create an active and real learning experience.

To conclude, we observed that PBL may be a good approach for the face-to-face moment of the Flipped Classroom model, but with adaptations to the context, such as PBL for teaching programming. In our context, ideas based on programming contests were used to enhance the face-to-face moment. We also presented the main steps and tools needed for this application in a context of higher education in computer science, considering teaching CS1.

As a future works we intend to replicate this experiment in order to collect more data or evidences about FC model and its effectiveness. Besides, considering the use of programming contests to improve PBL activities in Flipped Classroom in-class environment, it is possible to wait that some students can react negatively to the pressure of competitive programming, even in a team.

In addition, may also be differences between males and females behavior. However, in our context, these situations where not identified. Are questions that can be further investigated in the future.

ACKNOWLEDGMENT

The authors are grateful to the Federal Institute of Education, Science and Technology – IFSULDEMINAS and the Brazilian funding agencies (FAPESP, FAPEMIG, CAPES and CNPq) for their financial support.

Abstract— This paper presents a qualitative study about programming logic teaching in high school, based on the Discourse of Collective Subject. The project where this study is embedded aims to encourage a greater number of students in the areas of engineering and natural sciences, primarily girls. The main goal is to present how the high school students participating in this project understand issues related to computing learning and women inclusion in this area.

Keywords— high school, girl, programming logic, discourse of collective subject

I. INTRODUCTION

Nowadays, the use of computers in education is diverse, interesting and challenging than simply transmitting information to the learner. The computer can also be used to improve learning environments and help students in their knowledge construction process. ProInfo (National Programme for Information Technology in Education) is a program developed by the MEC (Ministry of Education and Culture - Brazil) to introduce the computer and telecommunications technologies – telematics – in Public School [1]. The aim of this programme is that students acquire computational concepts such as computer operating principles, programming concepts and implications of computer in society. This approach was highly reported in the United States as "computer literacy" and it was the solution that many schools in Brazil to insert the computer in the teaching-learning process. Therefore, the curriculum was increased in the "Introduction to Computer Science" course, which aims to teach computing to the student to have access to the computer. However, from an educational point of view, it has not changed the way the content of other subjects are taught [2].

However, computing goes across the use of computers for performing routine activities such as access to internet (social networking, games, etc.) and produce texts. The computer can be used to develop new programs or games with different features, an activity that involves logic programming skills that can be applied in several areas, not limited to computers. The integration of programming logic in the basic and technical education can help to solve problems in a structured and rational way. The insertion of this new knowledge can make it visible to the students the role of sciences in development [1].

Researches reveal gender differences between male and female insertion in the field of engineering/natural sciences. Boyd and Bee (2011) said that a possible reason for this participation difference is indicated by studies showing that cultural attitudes also influence the performance of girls in science and "even girls who have great performance in science during high school have less confidence in their ability to be successful in science subjects at university and, therefore, they are less likely to specialize in hard sciences in college" [3].

From a problem, the researcher must be attending if it should/must be addressed through an empirical survey of qualitative validation. The Discourse of Collective Subject (DCS) is a technique for qualitative-quantitative analysis and it aims to get the whole spectrum of possible opinions on the issues studied in the research population. Therefore, the selection of subjects must necessarily allow different opinions in the interviews universe. For this purpose, it should be chosen from all people ideas about the researched problem. Therefore, the composition of the population strata is very important to the research [4].

The work in this paper is part of a project (Project. CNPq 18/2013 MCTI/CNPq/SPM-PR/Petrobras Project – Girls and Young make Natural Science, Engineering and Computing) which aims to teach programming logic in High School, ordering to encourage more students to the areas of engineering and natural sciences, primarily girls. Particularly, the students' responses are analyzed, based in the technique of the Discourse of Collective Subject, with a questionnaire with discursive questions. These students were young people between 15 to 17 years old that study in a Public High School. In this way, the aim of this paper is to present how High School students, participants this project, understand issues related to computer education and the inclusion of women in this area.

This paper is divided into 5 sections. Section 2 presents the theoretical framework linked to the Discourse of Collective Subject. Section 3 presents the methodology used and in section 4 presents the results. Section 5 presents the conclusions and future work.

II. DISCOURSE OF COLLECTIVE SUBJECT (DCS)

The proposal of the Discourse of Collective Subject (DCS) [5] is based mainly on the assumptions of the Social Representations Theory [6]. The DCS catalogs and associates a

series of operations on the statements collected in empirical surveys through open questions, which at the end of the process result in collective statements that are made from extracts of different individual statements. Each of these collective statements has a specific and distinct opinion or position, and such statements written in the first person with the idea of producing the effect of a collective opinion [5].

The initial applications of DCS technique was health field. After, other areas became to use the collective opinions expression and processing. The aims of DCS is to demonstrate the self-expression of the collective thought or opinion, respecting the qualitative and quantitative condition of it. But how to express this collective subject as a "subject-to-talk", and not as a mathematical expression [4]?

The collective subject cannot speak because, in Portuguese, the possibilities offered are precarious, just to access directly, the collective subject, which is the pronoun "we" of the plural first person, in the absence the alternative of "collective self". However, when the collectivity is expressed in the singular first person, and it illustrates the operation of the social representations system. In addition, the DCS is a feature that enables the social representations as collective facts inherent qualitative collectivity (speeches) and quantitative (of individuals), that is, individuals can share the same views but when such individuals opine individually may transmit only a portion of the view shared content [5].

A collective subject, the in DCS, tries to reconstitute a collective subject that, while collective person, is at the same time, speaking as if he/she was an individual, that is, as a "natural" speech subject, but linking to a representation with larger content.

III. METHODOLOGY

The purpose of this paper is the implementation of a sequence of steps described below. First, the students participated in programming logic courses using Scratch' [6] tool where they developed the programming logic of knowledge in a fun and creative way. Students implemented challenges from primitive conditional, such as "if" or "while" repeat. They developed their skills without to learn primitive syntax as Java [7] and C [8] languages. In this way, they were concerned with the development of the game logic itself, without worrying about implementation details (problems of programming, such as lack of brackets or braces) [9-11].

At the end of the course, the students answered a questionnaire with 12 discursive questions. The questions were as follows:

1. Before doing this course, which is your contact with computing?
2. What computer games or video game you know/play?
3. Do you like math? If you do not like, why?
4. Do you like mathematical/logical challenges? If you do not like, why? If you like, what kind of challenges do you like?

5. Did you like this course? Why? If you did not like, why?
6. Have you had difficulties during the course? Please, explain using examples of problems.
7. What did you learn (new things)?
8. Did you think the course improved your understanding about logic and mathematics in any way?
9. Would you think in following a career in computing?
10. Were the course teachers clear in their explanations? If not, what could be improved?
11. What do you mean by computing?
12. Why do you think that there are not so many girls in computing?

All questions were tabulated and analyzed to identify main idea, and setting an anchor category (DCS methodology). Thereby, the analysis of the DCS can be carried out in order to better understand how students understand the issues related to the project.

IV. RESULTS AND ANALYSIS

For the scope of this paper, here are presented the results of the questions 11 and 12 of the questionnaire, i.e., "What do you mean by computer?" and "Why do you think that there are not so many girls in computing?". Tables 1 and 2 show the obtained results, where in the "Key Expressions" column, the exact responses of students on the questionnaire are presented, respecting the tense verbs and original writings of them; in the "Central Ideas" column, there are the interpretation of the responses; and in the "Anchor" columns are the associated theories related with each central idea. For example, when a student says "When somebody talks about computing, I think about computer, internet, social networks, games," and we put as a central idea "Study and social networks", and the "Algorithms" anchor.

Note that the DCS was composed in the singular first person, with the key expressions of similar speeches meaning from 7 (seven) people between 15 and 16 years old of a Public High School, where 6 (six) were female and 1 (one) was male.

This collective person is talking as if it were an individual, i.e., as a discourse of the subject "natural", but it represents various individuals, allowing the emergence, both qualitative and quantitative, of a collective opinion: qualitative because it is a speech with expanded content, diversified for the construction of DCS. As the questionnaire was applied with young people, some answers had orthographic mistakes, that we kept exactly as they wrote, as the discourses presented.

TABLE I. TABULATED RESPONSES OF QUESTION 11

Key Expression	Central Idea	Anchor
Before the course I thought only learned to learn to work on computers	Knowledge of computer programs	Algorithms
When somebody talks about computing, I think about computer, internet, social networking, gaming, but I did not understand very well how these things formed, to come the course, I still have doubts, but most were understood	Knowledge of computer programs Overcoming difficulties / Motivation	Algorithms Motivational Theory
Which is not only a device is us, why are we put the codes the computer computing answers	Knowledge of computer programs	Algorithms
Programs (software) designed to make life easier for someone and for others not so much	Knowledge of computer programs	Algorithms
I understood that is a well-designed system	Knowledge of computer programs	Algorithms
It is a way to learn, for communication, information that sometimes we use on a day-to-day	Knowledge of computer programs	Algorithms
Computing, for me, is something created for communication and make researches faster	Knowledge of computer programs	Algorithms

Below, the DCS1 (Learn about computer programs), which the speech represents all participants:

“When somebody talks about computing, I think about computer, internet, social networks, games, finally, programs (software) designed to make life easier for someone and for others not so much. Understood that is a well-designed system. Thus, it is a way to learn, for communication, information that sometimes we use on a day-to-day, is something created for communication and make researches faster. Before the course I thought only learned to learn to work on computers, but it is not only a device is us, why are we put the codes the computer computing answers.

DCS1: Knowledge about computer programs

In the DCS1, we can observe that the dimension about the computer understanding has been expanded from the programming logic courses, being anchored by algorithms, which is the basis for development of computer systems. Before the course, students understood the computer only as a form of communication and research. However, the idea about the computer could be programmed according to user needs makes the students realize that this is no longer a passive user and he/she becomes an active user in the system development

process. The fact that one of the student said "it is not just a device, it is ourselves" shows the active user dimension (now developer/programmer) replace in his/her mind.

The algorithms are a part of day-to-day lives. For example: when the doctor gives instructions for the use of medicines, or when we follow a cooking recipe. An algorithm can be seen as a sequence of executable actions to obtain a solution for a particular type of problem, i.e., the programs represent a special class of algorithms that can be followed by computers. However, a computer can only understand programs built into machine language, which correspond to a sequence of specific and uncomfortable instructions. To work around this problem is necessary to build more appropriate languages to become easier the programming task that it could be translated by a computer into machine language [12].

TABLE II. TABULATED RESPONSES OF QUESTION 12

Key Expression	Central Idea	Anchor
Maybe the girls think that computing is just boys area	Define the professional future Gender differences	Professional Future Sexuality
I am not discriminating but I know, as women that men have a sense of faster logic and have a interesting about technology because usually girls are more social, communicate better and prefer to be with the others, for example doing medicine, veterinary medicine, and computing is different from that	Gender differences	Sexuality
Maybe girls were not interested, even by find it more men thing than women thing.	Define the professional future Gender differences	Professional Future
I think there is so many girls because maybe they think programs very complicated .	Gender differences	Sexuality
I do not know, maybe the girls are not interested about what exists behind a "machine", they usually are interested in sites or in games, but they do not care what were developed .	Define the professional future Gender differences	Professional Future Sexuality
Because boys usually have more interest in these area since children	Gender differences	Sexuality

Below, the DCS2 (Gender differences), which the speech represents all participants:

"I think we do not have so many girls because maybe they think programs very complicated. I am not discriminating but I know, as women that men have a sense of faster logic and

have a interesting about technology because usually girls are more social, communicate better and prefer to be with the others, for example doing medicine, veterinary medicine, and computing is different from that the girls are not interested about what exists behind a "machine". They usually are interested in sites or in games, but they do not care what were developed. Boys usually have more interest in these area since children

DCS2: Computer and gender differences

In DCS2, we can observe the differences of opinion between genders that can be supported through gender and sexuality theory anchored in the idea of biological and sexual differentiation of men and women as justifying social inequalities. This idea was refuted by feminist studies that tried to demonstrate that the male and female identities are constructed every day in the social sphere, not by sexual characteristics, but rather by how these characteristics are valued and represented in different historical contexts. Starting from the perspective that gender relations and sexuality itself are historical and social constructions, we can see the existence of academic literature on the inclusion of women in the field of Science and Technology (S&T). In this sense, are basically found three approaches types, according to Garcia and Sedeño (2006): a) who turn to the presence or absence of women in career and the barriers that are imposed upon them and, in this perspective, define exclusion situations of women in that area; b) who discuss the gendered content in S & T area; c) who consider it as an epistemological field of knowledge construction, under male domination. Although the vast literature treat about this diversity, emphasizing feminist heritage of most of these interests, some researches point out the emergence of the notion of "invisibility" of women in science, on the exclusion and dispossession of women scientists [14].

More recently, a study by Beede et al. (2011), by US Department of Commerce, showed that women occupy only 24% of jobs in science, technology, engineering and mathematics (STEM) in US and it confirms data from earlier research, pointed out that they earn, on average, 12% less than men in those careers. The document "Women in STEM: A Gender Gap to Innovation" [15] was written based on 2009 data, shows the gender inequality that has remained constant over the past decade, despite increased presence of women in higher education in STEM. This research also shows that, in careers in general, women account for 48% of jobs, a rate that is halved when it comes to careers in STEM [15]. The study also highlights that women with degrees in science, technology, engineering and mathematics are less likely to acting jobs in this area than their male counterparts, and these professionals tend to occupy positions in education or health [16-19].

V. CONCLUSIONS

The rates of inclusion of women at the college level in the areas of natural sciences, such as engineering is low, but the girls begin their studies with good results in mathematics, with a strong decline as they come to transition to the academic

community, so there is a greater significant number of men. Studies show that these differences are justified by the fact that men presented a better performance with math skills than women, these differences may be strongly influenced by cultural issues [17].

The Discourse of Collective Subject aims to show a thought or collective opinion from a group, based on a qualitative condition (individual opinions) and quantitative (group ideas).

Based in these two premises, this paper presented an analysis of two questions from an applied questionnaire to a group of students who participated in a course in logic programming, focusing mainly on the understanding what means the computer and the gender difference in this area. It is noticed that the DCS1 shows that the students broadening their knowledge about computing and logic. Moreover, students understood that the computer is more than a communication media. It is a tool that they can use in a lot of other purposes and they can develop new applications in their activities.

In the DCS2, we can see that the students still have some "prejudice" as the work of women in the area of natural sciences (include computing), stepped up by the social issues (and not cognitive issues) that influence the choice of careers in these areas. According to Schwartz et al. (2006), women always been excluded to research activities in universities, promoting the idea that natural science areas are not for women (they just could access the university via parents or husbands). In this way, we can conclude that, even after many years, this sensation of women could not work in natural science/math/computing still continues in our society.

As future works, new classes of the course will be done in the public high school, trying to better understand the logic programming in education and choice of career in the sciences and computing. Thereby, we expect to attract more female audience to our graduate students. Moreover, we will include in the questionnaire questions about professional future (in this analysis it is just mentioned), to contribute to a better understanding of it.

Abstract—We introduce an interactive tool called WebTA that facilitates learning through automatic critique of student source code. Our tool provides immediate feedback to students and gives them experience with test-driven development. Students receive the benefits of cognitive apprenticeship through the feedback they receive in the tool. This facilitates tight, productive cycles of inquiry, critique and learning.

WebTA compiles each student submission and executes it over a series of shakedown tests. Immediate feedback is given concerning errors and warnings, coupled with suggestions for debugging. The tool performs a textual analysis of the students source code and critiques programming style based on standard programming guidelines. To encourage inquiry through test-driven development, edge-case coverage, and API compliance, students develop and submit their own tests to be evaluated by the software.

We report on use of WebTA in one first-year programming course and one second-year data structures course. Lab and assignment scores have improved with WebTA, and student comments attest to the effectiveness of the tool. Preliminary results indicate students receive higher grades with WebTA. One area with mixed results is WebTAs analysis of student developed JUnit tests; this feature improved API compliance but reduced edge-case testing. With these successful initial results, we offer suggestions for future development.

I. INTRODUCTION: FOSTERING INQUIRY AND CRITIQUE IN A COMMUNICATION-RICH CURRICULUM

The principles of agile development, articulated memorably in the *Agile Manifesto* [12] as “individuals and interactions over processes and tools”, “working software over comprehensive documentation”, “customer collaboration over contract negotiation” and “responding to change over following a plan”, have had resonance throughout the software industry over the past two decades. While not all software problems and environments lend themselves to full agile development, it is safe to say that the building blocks of agile (e.g. adaptive rather than predictive planning [5], minimalist documentation [10], test driven iterations [3]), are finding their way into software processes of all kinds. Software developers of the future must be literate in agile methods.

With this shift comes a change in how we approach communication. At the heart of the agile approach is a recognition that requirements, priorities and obstacles in software projects are in constant flux. Consequently, agile methods encourage patterns of constant questioning, informing and debating. We have

identified three fundamentally communication-intensive agile activities: *inquiry* (strategies for resolving unknowns, coming to a shared vision, solving problems); *critique* (systematic analysis and evaluation); *reflection* (identifying and describing one’s own implicit or explicit work process). While each involves internal cognitive or metacognitive problem solving, they are all crucially mediated through communication in a team development setting, and agile methods honor and facilitate this communication. We have reported earlier on efforts to build reflection into our students’ software process [15]; the focus of this paper is inquiry and critique, particularly in programming-intensive courses that are not typically thought of as communication-intensive.

- *Inquiry*. Agile development demands a spirit of constant questioning. The famous Extreme Programming admonition to “embrace change” [4] implies continuous interaction with stakeholders to understand ever-changing requirements, priorities and obstacles. The spirit of inquiry extends to intra-team communication; in a process of continual self-optimization, teams self-organize and problem-solve together.
- *Critique*. Agile development demands continuous attention to good design, including refactoring when changing user needs and design demands dictate. Likewise, team organization and practices also under constant review. This requires developers to be willing and able to reassess current design and practices and to articulate areas of improvement.

We wish to engage students in agile communication practices early in the curriculum, so that they become a natural part of their internalized software process. Also, by recognizing the importance of communication and engaging in it at early stages, we expect to attract and retain students who are motivated by working in teams. These students are the ideal software developers of the future, since the reality is that software development is highly social and communicative.

A. Cognitive Apprenticeship

The Cognitive Apprenticeship model [11] is a constructivist approach to learning that focuses on teaching concepts and practices utilized by experts to solve problems in realistic

environments. It has special relevance in the context of software development, particularly in the communicative skills that we are interested in, because it emphasizes making implicit processes explicit to the learner. In typical computer science or software engineering educational settings, topics like communication are often deemphasized in favor of more technical topics; in the workplace, the communication-related knowledge that experienced developers possess is internalized, complicating their ability to pass it along to new employees.

Vihavainen and Luukkainen [24], [25] utilize Extreme Apprenticeship (XA), which builds on cognitive apprenticeship. The focus of XA is transforming the student into an expert by emphasizing learning-by-doing and starting early. This is accomplished primarily through modeling activities and scaffolding. Scaffolds are correctly-timed hints and feedback. Instructors emphasize "deliberate practice" and students complete hundreds of programming exercises during the course. The deliberate effort of programming on a day-to-day basis emphasizes that students are becoming professionals.

B. CS-POGIL

Our inquiry-based curriculum is situated in the CS-POGIL (Process Oriented Guided Inquiry Learning) approach, which originated in undergraduate chemistry education twenty years ago and has only recently been to computer science [13], [16]. At the heart of POGIL is a guided inquiry learning cycle of exploration, concept invention and application. Students work in small groups with well-defined roles – similarly to teams in agile software development – to encourage accountability and engagement. Each POGIL assignment has a common structure: supply students with initial data, guide them through leading questions that allow them to construct a unifying concept explaining the data, then provide means for them to apply and validate their newly constructed concept. It is in essence an application of the scientific method in a carefully crafted classroom setting. In addition to learning the core concepts at the heart of the assignment, students get practice in team problem solving and communication.

C. Automated Assessment of Programming Assignments

Programs are comprised of well-formed structures that may be easily parsed for evaluation. As such, many automatic approaches have been developed for evaluating student programs. Often these automated assessment tools take the form of testing scripts designed to support the instructor in testing and grading programs submitted by large numbers of students. However, automated assessment can also be used to support agile development processes and provide students with feedback.

Ala-Mutka [1] describes the advantages of automated assessment as "speed, availability, consistency and objectivity" but warns that "automated tools emphasize the need for careful pedagogical design of the assessment solutions". Ala-Mutka discusses many features of automated assessment approaches. Program characteristics assessed dynamically include functionality, efficiency, and testing coverage. In addition, static

analysis tools can be used to assess program characteristics such as coding style, programming errors, software metrics, and design.

One of the primary influences on the work provided here is the JUnit Generation (JUG) Autograder [6], [7]. JUG was developed to support instructors in grading and providing feedback on homework assignments in a data structures course. It provides supplemental feedback to improve student learning, and ease of use for the assignment developer and grader. The JUG system combines unit testing, evaluation and reporting to fulfill those goals. JUG performs dynamic assessment of functionality through generated JUnit testing and efficiency through measurements of execution time. JUG influenced the dynamic assessment portion of our application that evaluates student code by applying a battery of instructor developed JUnit tests to the student's code.

Another major influence on our work is Qiu and Reisbeck's Java Critiquer [19], [20], [21]. Developed to teach students how to write clean, maintainable and efficient Java code. Java Critiquer provides individualized feedback and just-in-time learning opportunities to students. The Java Critiquer performs static assessment of programming style, programming errors, and design by using regular expressions to match snippets of code with trigger patterns in instructor created rules. When a match is found in the student's code, the rule is fired and the advice encoded therein is dispensed to the student. Students use the tool iteratively to improve their code before submission. Ali, Hosking, and Grundy [2] categorize the Java Critiquer as an analytic critic, using text-based pattern matching through instructor authored rules to provide explanations and suggestions. The Java Critiquer influenced the static assessment portion of our application that evaluates the students' programming style.

Test My Code (TMC) is an automated assessment tool developed by Vihavainen *et al.* [26] as a tool for their Extreme Apprenticeship methodology. TMC is an assessment system that enables instructors to build scaffolding into programming exercises. TMC is integrated into the student's programming environment and provides tasks for the student to work on. TMC allows for scaffolding and automated instructor-initiated feedback. Test My Code is very close to the overall goals and functionality of our project. One important difference in focus is that TMC works within an environment of high instructor-student interaction, providing the ability for instructors to iteratively and precisely identify points of critique within student code. In contrast, the personnel constraints of our teaching environment offer less intensive interplay between student and instructor. We appreciate TMC's ability to facilitate direct communication between student and instructor, but our focus is on providing automated feedback to students that are detectable through dynamic or static methods, as anticipated by the instructor. Consequently, we use automated methods for style and design feedback in addition to test-related feedback.

II. WEBTA: A TOOL FOR AUTOMATED CODE CRITIQUE

WebTA is a tool developed by the authors to critique student programs in introductory computer science courses. The tool is designed to provide immediate feedback to students as they develop programmatic solutions to complex problems.

Traditional methods for teaching computer science — lecturing on abstract concepts, assigning a programming project related to the lectures, then grading the students' submitted finished products — resemble the outdated waterfall model of software development [22] in many ways:

- An instructor writes a specification and hands it off to students as an assignment.
- Students toil in isolation, without the benefit of instructor feedback or team communication.
- When they run out of time, students submit the assignment and hope for the best — not entirely sure that they interpreted the assignment in the same way as the instructor.
- Lastly, the instructor applies secret tests to the student work and assigns a grade, then moves on to the next topic, regardless of whether students have successfully constructed mental models sufficient to understand the current topic.

With WebTA, we employ an authentic approach for today's software world, teaching students test-driven agile development methods through small cycles of teaching, coding integrated with testing, and immediate feedback. We focus on this Learning Cycle [14] by providing students just-in-time code critiques for them to reflect on and feedback into a continuous development process (Fig. 1). This exposure prepares them better for today's software industry and reduces the frustration that students often experience in early programming projects, mitigating the risk of student burnout and helping with retention in computing-related majors.

Students in our introductory course work on 10–12 programming assignments per semester; of these, 5–7 are large, multi-week projects. Within these strict time bounds, students must parse the project specification, extract from this a suitable design, and implement it in code. The pace can sometimes outdo students, and they often feel they submit their assignment without a deep understanding of the project, its requirements, or a sense of the grade they will receive. In this context, the WebTA tool provides students with immediate

testing and feedback while they complete the assignment so there are no surprises at the end.

Students using WebTA are engaged in communication-by-proxy with the instructor. The instructor configures WebTA with common critiques that are triggered by errors, warnings, or textual analysis of the student's code. These critiques are issued to the students immediately; as needed by the student to support concept formation. This communication is not meant to replace instructor feedback; rather, it codifies common feedback scenarios to assist the instructor in reaching students in tight feedback loops just when the student is engaged in problem solving and learning. A particularly effective configuration is one in which students work in pairs — with appropriate mentoring in pair programming skills [17], [18] — and utilize both live feedback from the instructor and automated critique from WebTA. In this way, students get exposure to consulting and processing feedback from a range of sources.

When students connect with WebTA, a startup screen that explains the current problem and tells them which files they should upload to receive a code critique (Fig. 2). After clicking on the "Critique My Code" button, students receive an online report which includes a Critique Summary (Fig. 3). A stoplight metaphor, commonly used within the agile development community, is used to indicate student progress through the assignment. The stoplight indicators and code critiques prompt students to reflect and refactor. The critique summary includes a stoplight that tells the student at a glance if they succeeded in their programming task. A green light indicates a satisfactory state and a red light indicates serious errors.

In addition to the "pass-fail" criteria of the green-red stoplight metaphor (which are useful, especially if done in a scaffolded way like Test My Code), WebTA allows instructors to include more heuristic conditions that can be triggered when students may be diverging from "good practice", e.g. style or design issues that may not cause tests to fail. An amber light indicates the presence this type of problem. WebTA also allows for automated positive feedback. The assessment summary section also lists the parts of the critique and how the student performed in them.

Under the hood, the system has compiled their code and run it through a series of rigorous shake-down tests. Students can scroll down from the critique summary to view details of

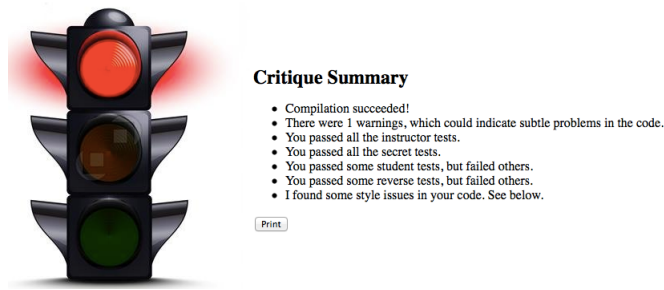

Fig. 3. WebTA critique summary.

Student Unit Tests

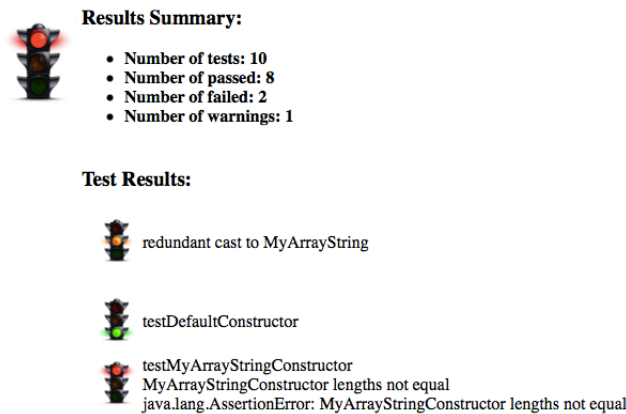

Fig. 4. WebTA student tests.

the critique, including errors and warnings generated both at compile-time and run-time. The instructor can configure the system to run both public and secret tests, run the student's own test code against their program, or assess the student's JUnit test cases to determine their ability to generate edge cases (Fig. 4).

Scrolling further down the code critique, students find a listing of each code file submitted that includes style advice generated via textual analysis of the code (Fig. 5).

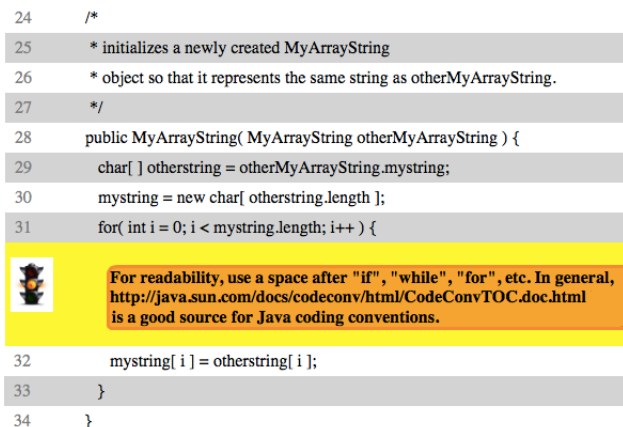

Fig. 5. WebTA style critique.

Students using WebTA are engaged in Learning by Doing [23]. Instructors provide students with authentic problems. While developing solutions to problems, students engage in an iterative conversation: developing code, receiving critiques, reflecting on feedback, and revising their solutions. WebTA applies Cognitive Apprenticeship practices that role-model authentic skills for students. Students are repeatedly exposed to patterns of coding and critiques from which they learn how to identify and communicate about issues that crop up during software development.

Features of WebTA include

- code compilation with student-friendly explanations of errors and warnings;
- rigorous, assignment-based unit test shakedown of student code, featuring both student-visible test to guide their code development and hidden tests to exercise their inquiry skills;
- evaluation of student test code, to support them as creative testers;
- textual analysis of source code, fully customizable by the instructor, to provide feedback on coding style;
- built-in plagiarism detection;
- preliminary grade assessment, for use by instructors or teaching assistants as a basis for final scores.

III. A WEBTA WALKTHROUGH

We provide a brief walkthrough of the WebTA critique process. For space reasons, we focus on the student perspective and provide a synopsis of the instructor actions.

A. Instructor setup

The instructor formulates the following assignment:

- Develop a class named *Fibonacci* that contains two methods: *fibIteration* and *fibRecursion* that given an integer n returns the long n^{th} element of the Fibonacci Sequence using iterative and recursive methods, respectively. if n is out of range, return -1.

For this problem, the instructor sets up three tests, one of them being secret. The tests, using JUnit test conventions, are as follows:

```
@Test
@CanvasTaTest( points = 5, name = "fibIterative Test.",
description = "Checks for all values of n from 0 to 9.",
hint = "Remember to track the previous two values." )
public void fibIterativeTest() {
    Fibonacci prog = new Fibonacci();
    long[] solutions = {
        0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377
    };
    for( int n = 0; n < solutions.length; n++ ) {
        long result = prog.fibIterative( n );
        if (solutions[ n ] != result) {
            fail( "fibIterative( " + n + " ) = " + solutions[ n ]
                + ". Your method returned " + result );
        }
    }
}

@Test
@CanvasTaTest( points = 5, name = "fibRecursive Test.",
description = "Checks for all values of n from 0 to 9.",
hint = "Remember to test for the base case." )
public void fibRecursiveTest() {
    Fibonacci prog = new Fibonacci();
```

```

long[ ] solutions = {
    0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377
};
for( int n = 0; n < solutions.length; n++ ) {
    long result = prog.fibRecursive( n );
    if (solutions[ n ] != result) {
        fail( "fibRecursive( " + n + " ) = " + solutions[ n ]
            + ". Your method returned " + result );
    }
}
}
// Secret Test
@Test
@CanvasTaTest( points = 5, name = "fibRecursive Edge Case",
description = "Checks for n = -1" )
public void fibRecursiveEdgeCaseTest( ) {
    Fibonacci prog = new Fibonacci( );
    long result = prog.fibRecursive( -1 );
    if ( result != -1 ) {
        fail( "fibRecursive( " + -1 + " ) = " + -1
            + ". Your method returned " + result );
    }
}
}

```

The instructor also creates (or reuses existing) rules for the style critic. Rules consist of a regular expression, that matches with a problematic code snippet, coupled with advice the instructor would give a student who wrote such code. For example, anticipating that the student might not space code within parentheses, such as:

```

for(int i = 0;i < n; i++){
    x = y;
    y = x + y;
}

```

The instructor might develop a rule whose trigger matches a form “(EXPR)” and whose advice is “For readability, use a space after (and before)”.

B. Student development

When students submit the assignment, it is uploaded to WebTA for testing and analysis. Depending on the instructor configurations, student code is compiled, tested against instructor tests, secret instructor tests, the students own tests, and the students test can even be run against an instructor solution to help students develop better coverage in testing. Furthermore, source files uploaded by the student are subjected to textual analysis to provide feedback on their programming style.

In this case, the student submits the following code skeleton, which should fail all tests.

```

public class Fibonacci {
    //Iterative method
    public long fibIterative(int n) {
        return 0;
    }
    //Recursive method
    public long fibRecursive(int n) {
        return 0;
    }
}

```

WebTA provides immediate feedback in the form of a critique report that the student can print. The critique report contains an executive summary of results, as well as a detailed listing of all errors and warnings encountered during

Submit Summary

- Compilation succeeded!
- You failed all the instructor tests.
- You failed all the secret tests.

Fig. 6. First Pass Executive Summary.

1 Compiler Errors:

 **ERROR: compiler.err.expected**
Status: Failed
Line: 5, Column: 17
';' expected

Fig. 7. Second Pass Compile Time Error.

the various kinds of analysis performed (as configured by the instructor.)

Fig. 6 shows that the students skeleton code compiled, but all tests failed as expected. So now the student tackles the *fibIterative* method, which seems like it should be easiest to implement.

```

public class Fibonacci {
    //Iterative method
    public long fibIterative( int n ) {
        long x = 0;
        long y = 1
        for( int i = 0; i < n; i++ ) {
            x = y;
            y = x + y;
        }
        return x;
    }
    //Recursive method
    public long fibRecursive(int n) {
        return 0;
    }
}

```

Oops — the student missed a semicolon on line 17 (Fig. 7). The student makes a quick fix and resubmits the code. This time, WebTA indicates that the test for *fibIterative* failed and a style issue was found (Fig. 8).

The student fixes the style issue by adding a space between the **for** keyword and the opening parenthesis. The test failure is a more difficult matter. The student adds a main method and prints the first ten values. It is evident that the results are

Test: fibIterative Test.
Description: Checks for all values of n from 0 to 9.
Hint: Remember to track the previous two values.
Status: Failed
java.lang.AssertionError: fibIterative(2) = 1. Your method returned 2

 for(int i = 0; i < n; i++) {

Style Critique
Status: Warning
Line: 6 Critique: For readability, use a space after "if", "while", "for", etc. In general, <http://java.sun.com/docs/codeconv/html/CodeConvTOC.doc.html> is good source for Java coding conventions.

Fig. 8. Third Pass: Test failure and style critique.

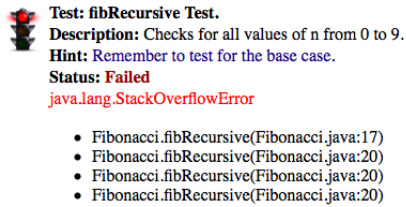

Fig. 9. Student encounters infinite recursion.

not the Fibonacci Sequence. But what is wrong? Fortunately, WebTA has provided a hint, “Remember to track the previous two values”. Taking this into consideration, the student realizes that she did not implement the formula correctly and makes some changes.

```
public class Fibonacci {
    // Iterative method
    public long fibIterative( int n ) {
        long x = 0;
        long y = 1;
        long z = 1;
        for ( int i = 0; i < n; i++ ) {
            x = y; // fib(n)
            y = z; // next fib(n-2)
            z = x + y; // next fib(n-1)
        }
        return x;
    }
    // Recursive method
    public long fibRecursive( int n ) {
        return 0;
    }
    // TEST CODE
    public static void main( String[ ] args ) {
        Fibonacci self = new Fibonacci( );
        System.out.println( "n ITERATIVE RECURSIVE" );
        for( int n = 0; n < 10; n++ ) {
            long fibI = self.fibIterative( n );
            long fibR = self.fibRecursive( n );
            System.out.printf( "
        }
    }
}
```

This time the student passes the *fibIterative* test. Moving on, the student implements and submits the *fibRecursive* method.

```
//Recursive method
public int fibRecursive(int n) {
    if ( n > 0 ) {
        return n;
    }
    return fibRecursive(n - 1) + fibRecursive(n - 2);
}
```

The *fibRecursive* test fails due to infinite recursion (Fig. 9). The student, new to recursive algorithms, spends some time on this before connecting the hint about testing the base to fact that the base case includes 0! That’s a quick fix (post epiphany).

```
//Recursive method
public int fibRecursive(int n) {
    if ( n = 0 || n = 1 ) {
        return n;
    }
    return fibRecursive(n - 1) + fibRecursive(n - 2);
}
```

The student is almost there. All Instructor Tests are passed,

Instructor Unit Tests

Success! All tests passed.

- Number of tests: 2
- Number of passed: 2
- Number of failed: 0
- Number of warnings: 0

Secret Unit Tests

Results Summary:

- Number of tests: 1
- Number of passed: 0
- Number of failed: 1
- Number of warnings: 0

Fig. 10. Student Passes Instructor Tests, But Fails Secret Test.

Submit Summary

- Compilation succeeded!
- You passed all the instructor tests.
- You passed all the secret tests.

[Print](#)

Fig. 11. Student Passes All Tests

but the Secret Test is still failing (Fig. 10). No information is given to guide the student on a secret test so the student has to resort to manual debugging and rereading the specification. In this case, the assignment says that values of n that are out of range should cause the methods to return -1. With a final modification to the code, all tests pass!

Assignment submission. When it comes time to submit an assignment, students can submit to WebTA and get immediate feedback about how well their code compiled and tested via the Assignment Submit tool. When creating an assignment, instructors set the Submission Type to External Tool and select WebTA Assignment Submit. Instructor configuration is similar to the Code Critique tool. Students see the WebTA submit page at the bottom of their assignment.

Upon submitting, students receive an executive summary of how their code performed. This does not indicate a grade. However, a preliminary grade report is saved for a human TA to review before assigning a grade.

C. Instructor evaluates submissions

Through WebTA, the instructor may view student submissions, and select a student to see the students’ code and a preliminary score assigned by WebTA. The instructor then examines the results and the student’s code, providing additional comments and feedback or grade modifications. Once a grade

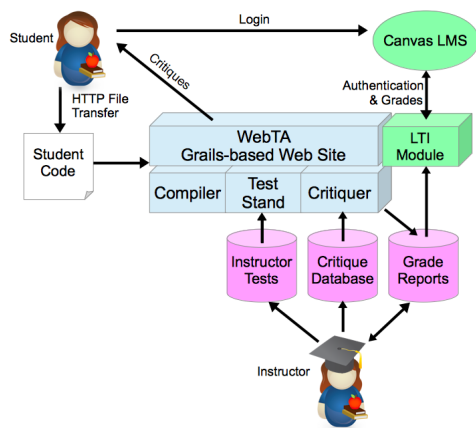

Fig. 12. WebTA architecture.

has been assigned, WebTA sends a grade report to the student.

IV. WEBTA: TOOL DESIGN AND IMPLEMENTATION

As a web application, developed on the popular Grails Framework, WebTA is comprised of several modules, data sources, components, and interaction modes (Fig. 12). At our home institution, the primary form of managing instructional materials is the Canvas Learning Management System (LMS) [9], and our design is intended to fit seamlessly into a Canvas-administered course. At the same time, we plan to furnish a flexible solution not tied to Canvas, in order to make it more broadly useful across other institutions and to satisfy the needs of instructors who do not use learning management systems.

A detachable LTI Module provides web services required for authentication with, and grade reporting back to, the Canvas LMS. In principle, the module can plugin to any other LMS implementing the LTI standard, including Blackboard or Moodle. Furthermore, the LTI Module may be replaced with another component that supports alternative authentication or access control methods, such as `.htaccess`. Indeed, current plans are to develop a web-based authentication module integrating with our institution's Student Account System for courses that do not use Canvas.

Data sources for the system include:

- *Student Code* and *Instructor Tests*, through source files uploaded to WebTA;
- The *Critique Database*, containing instructor-customizable rules for dispensing advice to the students;
- *Grade Reports*, generated by WebTA and updatable by instructors before final grades are recorded.

Our introductory computer science sequence utilizes the Java programming language. Thus our first pass at creating a Critiquer System focused on providing feedback to students on their Java code. The *Compiler*, *Test Stand*, and *Critiquer* components perform general functions specialized on analysis of Java. We plan to develop additional components specialized on C, C++, Racket, and R.

The Compiler component verifies that the submitted student code is legal, constitutes an actual program, and compiles the code. The Test Stand component validates the code by running a series of instructor defined tests against the student program.

The Critiquer uses rules to look for patterns in Errors, Warnings, Console Output, and Source Code to generate advice. Currently, this is done by simple textual analysis using regular expressions, the results of which are applied to rules in the critiquer database.

There are two modes of interacting with the system:

- *Student*. Students login to Canvas, which handles authentication and links to WebTA in a new browser tab. A drag-and-drop field is provided for uploading source code files. Uploaded files are compiled, tested, and critiqued. The student receives feedback in their browser.
- *Instructor*. Canvas is also used to authenticate faculty and graduate TAs, enabling them to access WebTA in their browser. Instructors use WebTA to setup code tests, enter rules into the critique database, and view/modify grade reports before assigning final grades.

These modes of interaction are built-into the web application and are not dictated by Canvas. After authentication, all interactions are through web pages served-up by the WebTA server.

V. PRELIMINARY RESULTS

2014-2015 was our first year of deployment. We beta tested WebTa in two courses (Intro to Programming 1, Data Structures), each with approximately 100 students enrolled. There have been growing pains: some technological, some perceptual.

Technologically, we experienced problems with server load and browser incompatibility. There was a period of time in the fall when several major browsers were pushed security updates and WebTa stopped working with all but the Chrome browser. During crunch periods around midterms and finals week, we experienced severe server lag, making it difficult for students to submit code or for WebTA to execute it within the specified thread time-out parameters. Working with our IT department, we have resolved these issues.

Unfortunately, these issues created perception problems with the students:

- “[WebTA] is also a bit difficult because we can’t access it from our own computers.”

Yet many more students have expressed an appreciation for WebTA:

- “I like [WebTA] because it shows be where my error is or which test is wrong so I can spend more time on fixing it rather than taking forever to search for the error.”
- “[WebTA] gives good input on style and how to fix my errors.”
- “I really enjoyed CanvasTA. Mostly every aspect of it was very helpful. I really loved how quick it was to simply drag and drop my .java file in and simply click to have it run its checks and turn it in. The checks and some of

Course	Semester	Mean	Median	Mode
CS1121	Spring 2015	80.4	95.0	99.8
CS1121	Spring 2014	72.4	77.7	93.2
CS2321	Fall 2014	82.9	86.6	95.4
CS2321	Fall 2013	75.0	80.8	59.4

Fig. 13. Programming project scores.

the style tips it made were also very helpful. There were some bad programming practices I've done that I never realized before until I read through its style suggestions."

WebTA was beta tested in the Fall 2014 Data Structures course and in the Spring 2015 Introduction to Programming course. Programming project scores compared to the previous year were higher (Fig. 13), but more study is required to determine if the difference in scores is solely or in part attributable to WebTA and to identify other influencing factors.

Qualitatively, we have the sense that more effort needs to focus on fading scaffolds and teaching students how to test their code.

Data Structures students were required to submit JUnit test cases with their code during both Fall 2013 and 2014 semesters. WebTA tested their JUnit tests against the assignment API. Over the course of Fall 2014 we saw marked improvement in student conformance to the specified API. However, we also noticed students who, upon failing an attempt to test an edge case, would remove their test method to eliminate the problem, instead of trying to understand the edge case and fixing their test.

A concern is that students are relying on WebTA to test their code. When asked how he used WebTA, one student responded:

- "I mainly used it for testing purposes. It was great that it gave me the results and failures so I could go back and try to figure out what went wrong. On the downside I think it made me put a little less effort in actual testing myself though I ended up having to anyway to fix some of the errors it showed."

Another student said:

- "Whenever I felt that I had working code (i.e. I fixed any bugs I could think of or the bugs pointed out by [CanvasTA]) I would submit my program file to [CanvasTA] to see if it passed or not."

Based on an informal in-class survey, second-year Data Structures students were more accepting and less critical of WebTA while first-year Intro students, who had never used a different system for assignment submission, provided more critical feedback.

VI. PLANS FOR FUTURE DEVELOPMENT

We continue to improve WebTA and are devoting significant resources to expanding its capabilities. We have several ideas for future development. The most pressing features to be worked on include:

- A new web-only authentication module for faculty who do not use Canvas.
- Improved communication between test methods and the critiquer component. One aspect of this is to implement edge case awareness so we can provide students with better feedback.
- Conditional recompilation and testing by graders. Sometimes students have one thing wrong, for example a poorly written constructor, that causes all tests to fail. A simple change to their code and recompilation might allow testing to proceed and provide instructor with a better understanding of the student's progress.
- Code parsing and semantic analysis within the critiquer component. This will enable better critiques and reduce false positives when matching rules compared to the current textual analysis with regular expressions.

We are also planning two larger-scale activities:

- In our targeted courses, we have observed "divergent" student coding behavior that does not reflect good practice despite passing automated tests. Based on these observations, we are formulating common coding antipatterns [8] and devising heuristic triggers within WebTA that detect these behaviors.
- To facilitate enhanced communication, reinforce reflection, and support lab-based pair-programming practices, we are developing an online pair-programming development environment that will be tightly integrated with WebTA. This larger system will enable us to detect and provide feedback on student communication patterns and development practices that we cannot observe by doing a post-facto analysis of code in WebTA.

Furthermore, students have suggested the following improvements:

- Code and data structure visualizations.
- Code to English translation to help them better understand their code.
- The ability to display console output and generate graphs of their data.
- Code repository. Students would like to be able to access previous versions of submitted code and have a rollback facility.

We think these student suggestions are valuable and will help us make WebTA more interactive, make the learning process more engaging, and make the development process more agile for the students.

VII. ACKNOWLEDGEMENTS

This work is supported by the National Science Foundation under Grant #1504860. Additional support comes from a William G. Jackson Blended Learning Grant and the Google CS Engagement Small Awards Program.

Abstract—Embedded System Curriculum at Tsinghua University is target at advanced undergraduate senior students in CS department. At the end of this course, an overall understanding about System is expected to be obtained by students who have gotten perfect software knowledge from software series curriculums and hardware knowledge from hardware series curriculums. Embedded System is unique for its close association with actual application, thus an effective laboratory education is of great importance for embedded system curriculum. In this paper, we are dedicated to reform existing experimental teaching models, methods and laboratory platform to improve system level innovation practice for CS undergraduate students. Firstly, we mainly analyzed the characteristics of embedded laboratory education and current generation students. Based on this analysis, some principles as well as a concept model that guiding the designing of embedded laboratory platform are proposed. And then we present the whole innovative embedded laboratory system in CS department of Tsinghua University. Supported by the system, some typical projects will be presented, include intelligent Greenhouse, Sunflower, intelligence handcart, intelligence spider and rotorcraft.

Keywords—system level practice, embedded laboratory education, teaching models

I. INTRODUCTION

Discussion on embedded laboratory education must considering from two aspects: the characteristics of the development of embedded technology and the role of the embedded course in the teaching system of undergraduates.

Embedded system is now playing increasingly important roles in our lives. From consumer electronics products to aerospace industry, from hot applications as smart phone and tablet computer to relatively unnoticeable applications as artificial satellite, it has impacted nearly every aspect of our lives, directly or indirectly.

The huge potentiality of embedded system has received great concern from educators that discussions about embedded system education have never ceased. Educators from around the world have proposed various kinds of innovate and creative methods and theories to promote the education of embedded system. Among these educators, it is generally accepted that the most conspicuous characteristic of embedded system is its close association with practical application.

The applications of embedded system appears in a broad scope of areas, such as small and single microcontroller applications, control system, distributed embedded control, system-on-chip, networking, embedded PCs, critical systems, robotics, computer peripherals, wireless data system, signal processing, and command and control, while additional cross-cutting skills that also important to embedded system designers include: security, dependability, energy-aware computing, software/system engineering, real-time computing, and human-computer interaction [1].

Students, in order to be a qualified embedded system designer, are expected to have hands on experience in these applications. Thus, it is in great necessity to design a highly effective laboratory system. This laboratory platform is expected to connect the abstract theory to actual applications thus better help the students apprehending the knowledge and skills of embedded system.

On the other hand, embedded laboratory education is an important part of embedded system curriculum, which is also an important part of teaching system of undergraduates. Embedded System Curriculum at Tsinghua University is target at advanced undergraduate senior students in CS department. The students have gotten perfect software knowledge from software series curriculums including Program Design, Compilation Principle, Operating System, and also have gotten perfect hardware knowledge from hardware series curriculums including Digital Logic, Principles of Computer Composition, Computer System Architecture. At the end of this course, an overall understanding about System is expected to be obtained by students. So we emphasize system level innovative practice in embedded laboratory education rather than proof-of-principle experiments taken by other CS specialized basic courses.

In this paper, we will introduce our attempt in trying to improve the embedded system laboratory education in Computer Science department of Tsinghua University. We will first discuss the characteristics of embedded system curriculum in section II, secondly discusses the feature of current generation students in section III, proposed our principles and concept model of designing Embedded System laboratory platform in section IV, finally present the implementation of embedded laboratory education in Tsinghua University in section V and some typical application projects supported by

the principles and concept model will be presented simultaneously.

II. CHARACTERISTIC OF EMBEDDED SYSTEM LABORATORY

Embedded laboratory education is different from other laboratory education in two aspects: the interaction of software and hardware and the rapid updating rate due to technology development, shown as below:

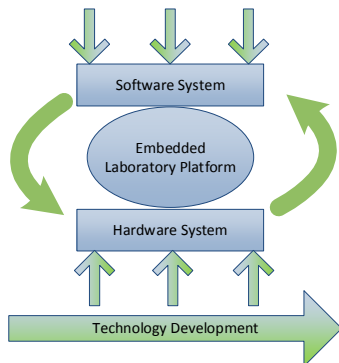

Fig. 1. Characteristic of embedded Laboratory Platform

Embedded system experiments are first characterized by their intense interaction between software and hardware. This is because an integral embedded system necessarily working on the foundation of both of them. In embedded laboratory education, neither of the two parts should be neglected; however, we have made mistakes in the past.

Embedded System at Tsinghua University is target at advanced undergraduate senior students in CS department. An overall understanding about Embedded System is expected to be obtained by students at the end of this course. However, it is discovered that students are generally incapable of designing one integral embedded system, from hardware to software, in a limited 2 credits laboratory curriculum. So we end up taking a compromise approach to require the students developing such open-sourced industrial software driver as mouse and keyboard. However, this approaches proved to be unproductive; students are discovered to comprehend only part of what they should have acquired and subsequently have poor performance in later curriculum. This is so not only because of the commonplace of the experiment task, but also because students are unable to get access to the hardware layer and fail to comprehend the embedded system as a whole.

Another notable feature of embedded laboratory curriculum is the rapid updating rate of knowledge and technology due to the deep-in of embedded system research. As is discussed in section one, sticky attachment to actual application is one critical element in embedded system laboratory education. And since radical change in embedded system technology is taken place every day, the knowledge and skills taught in embedded laboratory curriculum as well as devices and components applied in the platform would soon outdate without timely updating.

In one investigation concerning students' opinion toward the conventional laboratory platform in CS Department of

Tsinghua University, the mainly deficiency, as is revealed in the investigation, is the antiquated device and components applied in the platform. Students find little connection between the experiment platform and the recent technology and feeling no attraction in the laboratory experiments.

In conclusion, in order to design an effective embedded laboratory platform, both the software-hardware interaction and the rapid development of embedded technology should be taken into consideration. System level innovative practice is expected in the embedded laboratory education.

III. CHARACTERISTIC OF CURRENT GENERATION STUDENTS

Except for the embedded laboratory curriculum itself, student is another determinedly factor that should not be neglected. Students are participants of the experiments, how they feel about the experiment will affect the success of laboratory curriculum. However, it is discovered that the traditional laboratory approach has been increasingly unattractive for the new generation students. This is so mainly because the students evolving from one generation to another while the conventional laboratory approach stay ten years or even longer unchanged.

The new generation students, as is pointed out by Yannis Tsividis in Turning the Students On to Circuit [2], different from the older generation students in three aspects that they have been less tinkered, less patient and relied more on software. Furthermore we found the new generation students of China are more innovative and creative than the older generation ones.

Fig. 2. Characteristics of new generation students

First of all, they are less tinkered. Most, if not all, students have growing up in such a social environment that consumerism has becoming increasingly prevalent. They would care more about function rather than the fundamental principles, appearance rather than the architecture. In short, they had little understanding about the principle of embedded system. While on the other hand, most of our laboratory platforms are specifically designed for purpose of demonstrating or verifying the principles on the text book. And thus students are generally unable to connect the over specific-designed experiments to the practical application. This very fact matters because students are much more likely to turn to other areas if they could not see the future application of the studied knowledge. Therefore, it is important to connect the laboratory platform to the updated technologies.

The second characteristic of new generation students is their lack of patience. The wide spread of internet along with the rapid life pace has cultivate the growing impatience of new generation students. They has been so used to seeing the results immediately after starting out, just as they will expect the page showing on the screen right after a mouse click. However, in conventional approaches, curriculums are often started with an overall illustrative analysis classes. It is acknowledged that these illustration are in necessity, since it help the students comprehend the overall knowledge structure of that curriculum, however, these instruction sometime push the students away because of its abstract and dry. In view above, the novel platform should provide the students some interesting and attracting “result”, such as a simple application of embedded system, in the beginning of the curriculum.

Thirdly, they believe and relay more on software. The development of embedded system, radical as it is, is usually taken as granted by the populace. In part, this situation may be due to an evolution in EE toward more intelligent, yet smaller and less visible layers that are often camouflaged by elaborate user interfaces and other icons of what the populate attributes more to computer science than to electrical engineering [3]. However, many universities are unaware of this fact. They often pay more attention on the embedded software designing and less attention on the physical layer introduction. The inappropriate concentration on software in teaching embedded system turns out reinforcing the general impression that software applications are much more important than the physical layer among students. In order to correct this bias, more attention should be placed on the hardware layer in embedded system curriculums.

Furthermore, in China the new generation students are more innovative and creative. With the progress of society and the raise of living material standards, they have unprecedented access to technology and information. Unlike the old generation students, part of which had never haven their own PC before entered the university and were starved for principles of how it works, the new generation students are curious of what new things we can create by it. The knowledge and information in curriculums are both the source material of their innovations. So the embedded laboratory system should provide opportunities to practice innovative projects.

Again, in order to design an effective experimental laboratory platform, the characteristics of current students should not be neglected.

IV. PRINCIPLES OF DESINGING EMBEDDED LABORATORY PLATFORM

In view of the discussion above, we propose several principles in designing embedded system laboratory platform:

- *Integral*: the experimental platform should be relatively complete, which means that students are able to get access not only to software but also to hardware. This principle mainly solve two problems: firstly helps correcting students’ bias that software weights more and then helps attracting the students in the beginning by building a basic but integral system.

- *Open*: this platform should endow the students with appropriate freedom to implement their creative ideas. The platform, whether software system or hardware system, should leave enough interfaces to students, so that they can construct their own embedded system on the basis of which. When applying this principle, more actual-application-related embedded systems are expected to be created by students and their passion will be aroused in the process.

From the teaching perspective, this system should also contain the following characteristics:

- *Updateable*: hardware or software of the system can be extended or updated independently without an overall system modification. As is pointed out in section II, embedded system are characterized by its raid updating rate on especially hardware devices. In order to meet need of frequent updating, the principle of being updateable should be placed in the critical position.
- *Flexible*: the content of the experiment can be tailored according to the curriculum requirement, so that it can be widely adopted. Most specific deigned laboratory platform are weak in their flexibility; their complexity could neither be reduced nor increased and it would soon be discovered that these experiments need to be redesigned in order to accommodate with the change of curriculum length.

In answering to the goals discussed above, we proposed an overall concept model of the system shown as Figure 3:

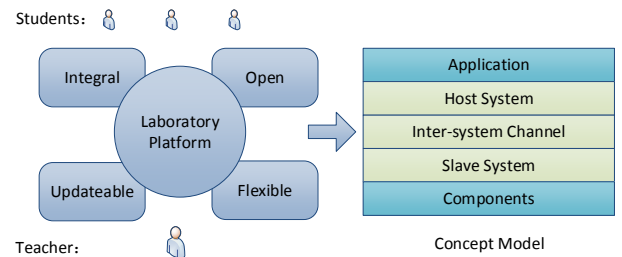

Fig. 3. Conceptual model of target system

This hierarchy concept model consists of three central layers and two peripheral layers. The central layers include host system layer, inter-system channel layer, and slave system layer while the peripheral layers include application layer and components layer. In the following we will explain why this model fulfill the goals we proposed to the best.

Integral Seeing the three central layers as a whole, this basic model consists of the major elements of one typical embedded system, from upper application to lower function components. Students will get access to each components of an integral system.

Open The top layer and bottom layer of this model are opened for students. Designer of the actual laboratory system should provide enough hardware and software interfaces to students in the top application layer and the bottom component level. These interfaces should be complete and user friendly.

Using the hardware interfaces, students are able to construct a creative embedded device by connecting other necessary module to these interfaces; using these software interfaces, students can easily employ correspondent hardware resources that provided.

Updatable The laboratory platform should be modular and layer designed and each layer should provide upper interfaces connecting upper layer and lower layer connecting the lower layer, so that any of these layers can be extended or updated as long as the modified layer interfaces are still compatible with original adjacent ones. The central layer in this model is designed as three-layer structure. This inspiration comes from the design of Phidgets [4] and it will to provide more possibility to the actual devices.

Flexible Each of these layers can be stressed or scant according to the emphasis of the curriculum, so the content and length of this curriculum can be adjusted to the curriculum length. The experimental classes can be arranged as two or more levels. The fundamental experiment may require the students to build up one basic system; in the advanced experiment, students are able to deeply research in layer in the model and thus implement their creativity.

Based on the conceptual model above, an effective embedded laboratory system can be designed without too much difficulty.

V. IMPLEMENTATION OF EMBEDDED LABORATORY EDUCATION

A. Embedded System Curriculum

Embedded System Curriculum is a specialized course for advanced undergraduate senior students in CS department. The teaching goal is to guild the students to master the method and skills of designing embedded applications from the perspective of system level rather than what is the embedded system. The students selected the course must had finished software series curriculums including Program Design, Compilation Principle, Operating System, and hardware series curriculums including Digital Logic, Principles of Computer Composition, Computer System Architecture. In Embedded System Curriculum, the students should finish a system level projects by combining the knowledge of software and hardware.

The curriculum consists 32 credit hours of coursework. Theoretically there are 16 credit hours in class and 16 credit hours in laboratory. Students also can take the experimental equipment home or to the dormitory, practice hours will prolong. Through the investigation on the students of last years, 35 practice hours are expected.

B. Embedded Laboratory Practice

Embedded Laboratory Practice is divided into two parts: the basic experiment and the advanced experiment.

The basic experiment spends 3 credit hours. Each student must finish independently. A serial of detailed experiment

guidebooks help the students to familiar of the experiment equipment and basic development methods rapidly.

The advanced experiment spends about 30 hours. The students are divided into several teams. Each teams contains up to 4 persons and customize their project of interest. The project must be guided and reviewed by the teacher and assistant at first. Every team should design and implement a system application combining with software and hardware. The basic embedded laboratory equipment which we designed must be selected and other components and devices can be added as the team demands.

C. Embedded Laboratory Equipment

In view of the discussion in section IV, we design and implement a set of embedded laboratory equipment which is described in Fig. 4.

Fig. 4. Cortex-M3 based embedded laboratory equipment

We realize the conceptual model mentioned in section IV:

1) *Host System*: We use MB9B506R of FUJITSU SEMICONDUCTOR as Host System. The MB9B500 Series are a highly integrated 32-bit microcontroller that target for high-performance and cost-sensitive embedded control applications. The MB9B500 Series are based on the ARM Cortex-M3 Processor and on-chip Flash memory and SRAM, and peripheral functions, including Motor Control Timers, ADCs and Communication Interfaces (USB, CAN, UART, SIO, I2C, LIN)[5].

Based on MB9B506R, we provide 8 channels of 12 bits A/D converters, 14 channels of PWM, 8 buttons, 16 LED lights, 31 GPIOs and 4 UARTs. One 12V input, four 12V output, eight 3.3V output and four 5V output of power supply can be used by students.

2) *Slave System*: We add CF card, Bluetooth Module and Wi-Fi Module as slave system to the equipment. The CF card is the nonvolatile memory device record the temporary experimental data. With the wireless interface modules we can get the following functions:

- Add a channel to upper monitor: In debug phase, upper monitor can do remote debug to the system. In work phase, the system can upload data to upper monitor.
- Add a channel to Components layer: Some components support Bluetooth or WIFI can be added into the system.

TABLE I. RESOURCES CONSUMPTION OF THE PROJECTS

<i>Projects</i>	<i>Input Components</i>	<i>Output Components</i>	<i>Mechanical device</i>	<i>Slave system</i>
Sunflower	optical sensor	servo motor	sunflower-shaped object	N/A
Intelligent greenhouse	temperature sensor humidity sensor	fans humidifier	heating lamp refrigerator	plastic cloth storage transparent box
Remote controlled astronomical telescope	acceleration sensor	servo motor	astronomical telescope	WIFI module
Intelligence handcart	optical sensor infra-red sensor	ultrasonic sensor motors servo motors	handcart	Bluetooth module
Intelligence spider	optical sensor infra-red sensor	ultrasonic sensor servo motors	spider-shaped object	Bluetooth module
Rotorcraft	gyroscope acceleration sensor	motors servo motors	rotorcraft	Bluetooth module

- Add a channel to peer systems: Students can organize several peer systems as a whole system by Bluetooth or WIFI. The peer can be another Cortex-M3, also can be other systems such as Intel Galileo board [6], Intel Edison board [7] or other microcontroller development board.

3) *Inter-system Channel*: This layer is implicitly included in the system. MB9B506R communicate with Bluetooth Module and WIFI module by one UART channel each. With the update of Host System or Slave System, higher speed bus will be deployed in the Inter-System Channel.

4) *Components*: Students select different combinations of components according to the different choice of projects. Some typical components such as sensors, motors servo motors and mechanical parts will be suggested with supported by well revised guide books. Other components which probably add the challenge also are allowed to adopt. The modules which have well encapsulated interfaces and are easy to program are suggested to use, but sometimes necessary analog signal devices are optional.

5) *Application*: Each team selects to finish a team work project with the application background. The application project contains a system with the combination of hardware and software. Every year we will suggest one or two kinds of embedded applications different from last year. Students must finish some required functions, then improve and perfect the work as well as they can. It is also encouraged when some students will do more challenge work.

D. Embedded Laboratory Projects

Thanks to the “Maker Movement” [8], Internet provides wealth of material of embedded application projects. Sparked by maker network community, especially Intel Maker [9], we designed and reformed the experimental projects to fit the demands of laboratory practice for undergraduate students. The experimental projects should further spur system level innovation and can be controlled in college teaching.

We have finished several interesting projects in the past years. They can all implement in our embedded laboratory

equipment, the projects and resources consumption of that are list in TABLE 1.

1) Projects:

a) *Sunflower*: Use the Cortex-M3 as main controller. Make a sunflower-shaped object always face towards the light. The technical points include: AD sample the light intensity of different directions of the object; Determine the position of the light source; Control the servo motors equipped in the bottom of the object to adjust the direction by PWM.

b) *Intelligent greenhouse*: Use the Cortex-M3 as main controller. Get the data of temperature and humidity in the greenhouse and take steps to make the greenhouse suitable for plant growth. The technical points include: Transform a plastic cloth storage transparent box to a experimental greenhouse; AD sample the temperature and humidity in the greenhouse by sensors; Trig the fans by GPIO when temperature and humidity are too high; Switch the heating lamp by GPIO when temperature is too low; Turn on the humidifier by GPIO when humidity is too low; Optionally wake up the refrigerator by GPIO when temperature is too high.

c) *Remote controlled astronomical telescope*: Use the Cortex-M3 as main controller. Get and adjust the attitude of the astronomical telescope remotely. The technical points include: Adjust the focus of the astronomical telescope by PWM controlled servo motors; Adjust the attitude of the astronomical telescope by PWM controlled servo motors; AD sample the movement of astronomical telescope by acceleration sensors; Transfer the control signal by WIFI module.

d) *Intelligence handcart*: Use the Cortex-M3 as main controller. Control a four wheel driven tracked handcart. It can be remotely controlled by mobile phones, and can search the specified illuminant target in a maze. The technical points include: Control the movement through the motors the servo motors connecting the wheels by PWM and GPIO; Sample the light intensity of different directions of the handcart; Sample the distance to the obstacle by ultrasonic sensors or infra-red sensors; Transfer the control signal by Bluetooth module.

e) *Intelligence spider*: Similar to the handcart. But the movement controll is focus on servo motors arranged in the different joints other than motors besides the wheels.

f) *Rotorcraft*: Flight attitude acquisition and flight control are the key point. Due to the dangers of the propellers and crash, few teams are allowed to do this project. It is a customized project for the students preparing to take part in the embedded competition.

2) Check and examination:

There are two main types of team work evaluations: the exhibition and the competition:

a) *Exhibition*: Some of projects can be showed at the end of the semester such as sunflower and greenhouse. Every team demonstrates their achievement. The teacher and other teams can evaluate and score the teamwork. Of course more functions and delicate operations can earn a better mark.

b) *Competition*: Competition can largely arouse and stimulate creative enthusiasm of the students. We carefully made the game contents and rules for some projects such as intelligence handcart and spider. For example in intelligence handcart project, the game contents include: examine the accuracy to touch the target at a distance of 4 meters in the oblique position ahead; challenge the time to touch the target in a maze by remote controll and challenge the time to touch the illuminant target in a maze by automatic driving.

3) Support Library:

The system developers are all familiar with the datasheet and user manual of hardware components which also are not stranger to the auteur maker. But for the undergraduate students, the situation is not the same. They will be overwhelmed by these documents. So the faculty must prepare the streamlining development resources.

The support library can be gradually richer every year. The typical and guiding valued achievement of upper grade students will be collected by teacher into the support library of next year. The new generation students will get more help from that and will focus on working at new components. With the development of several years, many GPIOs, UART and AD based sensors, wireless communication modules and serval data buses are supported by our support library.

E. Achievements and Future Work

Contras to conventional embedded laboratory education, we stress the system level practice and encourage innovative work. The conventional box-shaped embedded laboratory equipment is difficult to update and deploy in the embedded applications. Some of them are more like micro integrated computers than embedded devices. And the experiment contents repeat with other experimental courses such as Principles of Computer Composition and Interface Technique of Microcomputer.

Compare with the prosperous Arduino [10], we pay more attention to the fusion of computer specialty knowledge. Arduino, also supported by Intel Galileo and Edison, has friendly and easy-to-use program interfaces. The novice, even a

pupil, can build a complex application system in a short time. But too much operate details are encapsulated to a CS undergraduate student. With the update of our system, more powerful architecture is expected to employ to meet the demands of multimedia applications. Then Arduino solutions will have been incompetent.

Besides more projects are developed, we will update the host system with powerful microprocessor. In the slave system layer, FPGA and DSP will be considered to be added in order to do concurrent real-time hardware interrupt processing which are proved inefficient processed by ARM SOC and run multimedia applications which are frequently appear in life but always largely reduce the performance of existing system.

A teaching operating system named Ucore [11] is expected to plant in our system. Ucore is developed by serval Universities of China based on XV6 of MIT. Now it is teaching in Operating System Curriculum and has been planted in the laboratory equipment of other main specialized courses in Dept. CS of Tsinghua. As a link of CS education, the Ucore planted in our embedded system will maintain the continuity and consistency of teaching content.

VI. CONCLUSION

These embedded system designing principles as well as the concept model come from the summarizing of our personal teaching experience. They mainly addressed three problems: arousing students' enthusiasm toward embedded system, doing the system level practice and giving them enough freedom to implement their creative ideas. Also, they overcome the drawback of conventional embedded laboratory education. These principles will help guiding our designing of an effective embedded laboratory platform as well as help enhancing the education of embedded system curriculum. We are expecting and having full confidence that they will play an even greater role in introducing students in to the world of embedded system.

Abstract— The flipped classroom model is gaining increasing attention in higher education, including engineering education. There are various types of models and contexts in which they are applied. Generalized research on the effectiveness of the flipped classroom is emerging, and results have been mixed. One such model is team-based learning (TBL) as originally developed by Larry Michaelsen in the late 1970s. TBL is a structured way to implement a flipped classroom approach, and has been shown to be successful in achieving deeper learning among the students. In this paper, we discuss our experience using the TBL methodology in a graduate computer engineering course on system level design of embedded systems. Specifically, we describe the course design, instructor experience adapting TBL for use in the course, including implementing an asynchronous online TBL process, and instructor reflections and student feedback on what worked well and what did not. We analyze the course content using the Florida Taxonomy of Cognitive Behavior, and assess the effectiveness of our implementation in achieving deeper learning. Additionally, we report on student perception of the new course structure and their experience using TBL.

Keywords— *engineering education, team-based learning, online learning, asynchronous teaming, embedded systems*

I. INTRODUCTION

In the last three decades, engineering institutions have made a large shift from purely lecture based teaching methodologies towards more active learning styles. This is in part due to the initiative of developing higher order cognitive skills, in addition to the technical skills required for the field [5]. Several prior studies in educational research have shown that active and student-centered teaching methodologies enable deep learning, and hence have a higher likelihood of achieving higher order cognitive skills [1, 2]. Although active-learning methodologies, such as problem-based learning (PBL) [6] and project-based learning [7], have become an integral part of several engineering curriculums via hands-on laboratory assignments and term-long projects, they pose several challenges. A few of these challenges include issues with team dynamics, lack of motivation in students for attending class meetings, and difficulty in covering the vast amount of course content that engineering courses typically have [8].

In the last decade, the flipped classroom model has gained increasing attention [9]. There are various types of models, and

contexts in which they are applied. However, the fundamental technique is that the course material is provided before class, freeing class time to apply the concepts to solve problems and interact with other students. Generalized research on the effectiveness of the flipped classroom is emerging, and results have been mixed. A commonly observed concern is related to course structure. Previous studies have reported that students feel overwhelmed when they have to search for the required material themselves and rather prefer a more structured approach [3,10]. One such structured approach to the flipped classroom model is team-based learning (TBL) [11, 31].

When implemented correctly, TBL has been shown to be an effective structure for implementing the flipped classroom model [13]. Developed by Michaelsen in the early 1970's, TBL was first adopted in medical schools [12]. Since then, it has matured and been widely disseminated in other fields, including engineering. Previous implementations in engineering courses have reported an increase in peer-assisted learning, time spent by students on task, and development of higher levels of thinking and lifelong learning skills [14, 15]. TBL is being used by a small but growing community of faculty at Iowa State University. It is promoted through the university teaching and learning center, which has offered workshops for faculty, staff and graduate students [4]. Consequently, TBL has been successfully used in several engineering courses, which served as the motivation to consider using it in a graduate-level embedded systems course in computer engineering.

In this paper we describe the instructor's experiences in implementing the TBL model and the TBL process for online students; and also reflections from the instructional team and students on what worked well and what did not. Additionally, we evaluate the effectiveness of our TBL implementation in achieving higher cognitive levels of thinking using the Florida Taxonomy of Cognitive Behaviors (FTCB). The remainder of the report is organized as follows: Section 2 provides an overview of the course; Section 3 provides details of the TBL implementation; Section 4 evaluates our implementation using FTCB and student feedback; Section 5 discusses related work in the field of TBL in engineering education; and Section 6 provides a summary of the lessons learned through our experience of converting the course structure to a TBL model, and identifies modifications for future implementations.

II. COURSE STRUCTURE AND DESIGN RATIONALE

TBL was implemented in CPRE 588, a graduate-level course in computer engineering at Iowa State University. CPRE 588 is the final course in a series of four courses in the embedded system curriculum at the university [16, 17]. In this section, we provide an overview of the course, the rationale for choosing TBL, and the detailed course structure.

A. The Embedded Systems Curriculum and Design Rationale

The first course in the series (CPRE 288) introduces students to various components of a typical embedded system and basics of embedded systems programming. The course was revitalized in 2001 to use the PBL approach in the laboratory. The second and third courses (CPRE 388 and 488) focus on system design using bottom-up and top-down approaches. They introduce students to system-level design issues and hardware-software codesign methodologies. Similar to CPRE 288, CPRE 488 was redesigned in 2008 by the author to have majority of the focus on laboratory assignments. The 3C5I model was used [17], which incorporated both Bloom's taxonomy [33] and PBL [6].

CPRE 588, the final course in the series, introduces students to Multiprocessor System On Chip (MPSOC) design using system-level design methodologies [18]. It focuses on developing models of embedded systems at different levels of abstraction and a systematic top-down design approach. However, contrary to the first three courses, CPRE 588 is a graduate level course, and is based on new research directions in embedded systems design. The material is varied and mostly referred through academic papers.

The instructor chose to redesign CPRE 588 using the TBL model after experimenting with elements of it in CPRE 388, discussing its benefits with other faculty, and participating in TBL faculty learning community seminars. Key features of TBL address common problems with other methodologies. The essentials of TBL as described by Michaelsen in [11] are:

1. Team formation
2. Student accountability
3. In-class team exercises that motivate students to think at higher cognitive levels
4. Continuous feedback from the instructor and peers.

In section III, we explain these in detail, and describe how they were implemented in our course.

B. Course Structure

The detailed course plan for a 15-week semester is given in Table I. There are two class meetings each week. In addition to TBL related activities, there were two homework assignments, a team project and a final examination. The non-TBL activities contributed to 52.5% of the class grade. The simulation assignments used SpecC, an open source language for system level design [19], and SystemC, an industry standard for designing transaction level models (TLMs) [20].

The content was organized into module as follows:

- 1) **Orientation:** Challenges of state of the art MPSOC design. TBL is introduced via a dummy application exercise.

TABLE I.
COURSE PLAN FOR CPRE 588 (SPRING 2015)

Week	Module	Activity
1	1. Orientation	Team Formation Grading rubric
2	2. System Design Methodologies	RA 2, AE 2A AE2B
3	3. Modeling and Simulation	RA 3, ML AE 3A, ML
4		AE 3A, ML AE 3B
5		AE 3C, ML AE 3C
6		AE 3D, HW 1 assigned AE 3D, RA 4
7		AE 4A AE 4A
8	4. System Synthesis	AE 4B, HW 1 due AE 4B
9	5. Estimation and Exploration	RA 5 AE 5A AE 5B
10		AE 5C, Project overview AE 5C, HW 2 assigned
11		AE 5D, Project updates AE 5D
12		Lecture
13		In-class exercise In-class exercise
14	6. Computation / Communication Synthesis	Lecture, HW 2 due Tool case study talks
15	Student Project Presentations	
16	Final Examination	

*RA: Readiness Assessment Test, AE: Application Exercise
ML: Mini Lecture, HW: Homework Assignment

- 2) **System Design Methodologies:** Abstraction levels of an embedded system, methodologies and steps in design flow.

- 3) **Modeling and Simulation:** Models for embedded systems and their relationship to languages and simulation.

- 4) **System Synthesis:** Models and methodologies for system synthesis, transaction level modeling, and its role in the system design flow. Languages and tool support for system synthesis (e.g. SpecC, SystemC).

- 5) **Estimation and Exploration:** Mapping TLMs to system architectures, the role of estimation in system-level design, metrics associated with system design space exploration, and approaches for evaluation of TLMs.

- 6) **Computation / Communication Refinement:** Refining system models to more complex TLMs. Computation is represented as software code or in a hardware description language, and communication is represented as driver code or hardware interfaces.

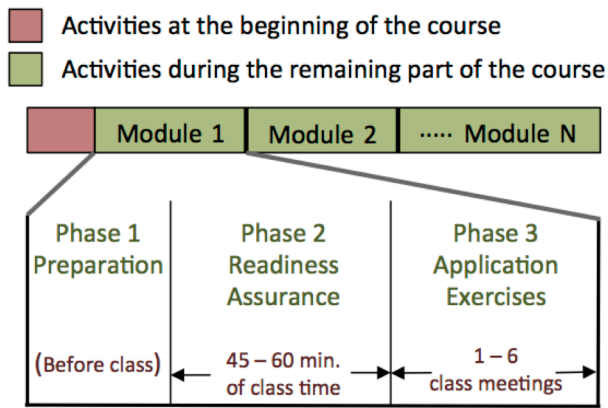

Fig. 1: Depiction of activities performed during a course taught using TBL. Activities performed for each module are broadly categorized into three phases.

III. IMPLEMENTATION OF TEAM-BASED LEARNING

In this section we describe the specifics of TBL in detail and their implementation in CPRE 588. The TBL activities performed by students during the course are depicted in Fig. 1.

A. Activities at the Beginning of the Course

Team Formation: A unique aspect of TBL is the importance given to strategically forming teams. Students were given a survey at the beginning of the course. Teams were formed by the instructor ensuring a fair distribution of students from different backgrounds, both in terms of technical skills and other characteristics. The goal was to ensure that team members bring different perspectives to the team. TBL teams are also permanent throughout a course. Effective group dynamics, such as adapting to and communicating with other members (either similar or different than oneself) and building trust, take time to develop. Essentially, teams in TBL emulate teams found in professional working environments as opposed to groups typically found in academic settings.

Negotiated Grading Scheme: Students participate in a consensus-building process to determine the weights given to selected activities in a TBL course. Each team internally agreed on a grading scheme. Representatives from each team then openly discussed proposed options during a class meeting and reached consensus regarding the grading scheme for the entire class.

B. Activities during Remainder of the Course

The course was partitioned into several modules. As depicted in Fig. 1, activities performed during each module can be broadly categorized into three phases.

Phase 1 – Preparation: At the beginning of each module students were assigned readings. Readings were selected to familiarize students with concepts required to solve the application exercises. Various methodologies like annotated lecture slides, technical publications and recorded video lectures were used, depending on the module.

Phase 2 – Readiness Assurance: As depicted in Fig. 1, each module begins with a Readiness Assurance Process (RAP). The RAP has the following components:

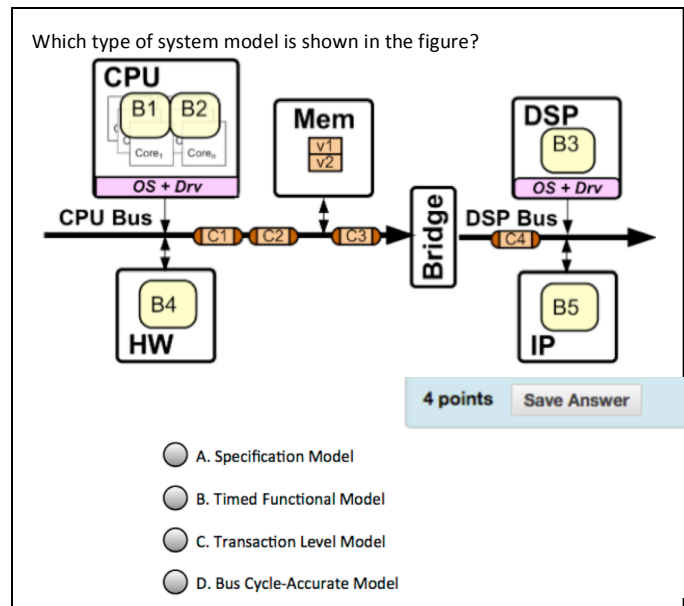

Fig. 2: Example of a Readiness Assessment question. The system model is adapted from [35].

a. Individual Tests: The first in-class activity is the Individual Readiness Assurance Test (iRAT). It is taken independently by each student and is intended to make students accountable for the preparation phase. The iRATs in CPRE 588 consisted of multiple-choice questions administered in class via the Blackboard Learn system. Fig. 2 depicts an example question from the iRAT test knowledge of fundamental concepts. Overall, iRATs contributed towards 7.5% of the course grade.

b. Team Tests: Following the iRAT, students proceed to the Team Readiness Assurance Test (tRAT), where teams take the same test as the iRAT. However, one answer is submitted for the team, and thus team members reach consensus before submitting an answer. Observe in Fig. 2 that points are denoted next to the "Save Answer" button. A team had up to three attempts on a question to obtain the correct answer. Decreasing points are allotted after the first attempt. The tRAT scoring facilitates two goals. First, to arrive at the correct answer, team members go through a process of discussion, agreeing and/or disagreeing with individual answers given during the iRAT. This improves students' ability to communicate with their peers, and thereby aids in team development. Secondly, it provides each student immediate feedback from team members regarding their own understanding of the course concepts.

c. Appeals Process and Feedback: After a tRAT, the instructor provides immediate feedback and clarifies any misunderstandings that students might have about the concepts. At this point, the instructor may choose to give a short lecture. Formal mini-lectures were prepared for modules 3 and 6 in CPRE 588 (refer to Table I). Teams are allowed to submit an appeal to the instructor if they disagree with an answer on a tRAT. A team must provide specific references from the readings. This teaches students to defend their claims using specific and clear evidence.

Below are the specification and architecture models from A. Gerstlauer, "SpecC Modeling Guidelines, Technical Report CECS-02-16, UC Irvine".

Q1. Mark areas in the figure where each of these refinement rules have been applied:

a. Behavior partitioning b. Protocol inlining c. Variable partitioning
d. Protocol insertion e. Scheduling f. Channel partitioning

TBL question: Are all of the rules applied? Why?

Q2. Develop an understanding of the code for the respective models given at the end of exercise.

TBL question: Which lines in the code correspond to the following rules:

Rule	Line number(s)
Behavior partitioning	
Variable partitioning	
Scheduling	

Fig. 3: An example question from application exercise 4A.

Phase 3 – Application Exercises: Students work in teams on application exercises (AEs) for the remaining duration of the module (refer to Fig. 1). The number and complexity of the exercises may vary. AEs consist of problems that simulate real world scenarios, and are the primary instructional tool used in TBL. They provide an opportunity for students to think at higher order cognitive levels, and thereby develop a deeper understanding of the concepts. At the same time, they are also one of the most difficult aspects of designing a TBL based course. Consequently, to facilitate the creation of effective AEs, the TBL methodology recommends using the “4S” rule:

a. Significant Problem: A significant problem creates curiosity and enthusiasm for self-directed learning. To identify significant problems for the exercises in CPRE 588, we used the “backward design” technique [32]. First, the outcomes and associated skills were listed for a given module. Working backwards, the course designers outlined the type of problems that can be solved using the enumerated skills. A few problems were then selected based on the concepts learned in the previous modules. Finally, a real world application was chosen and the selected problems were crafted into an AE.

b. Same Problem: Each team works on the same set of problems. With the same problem, students have a common basis to compare and critique answers across teams and receive feedback from other teams.

c. Specific Choice: Figures 3 and 4 give examples of a question from AEs of module 4. Notice that the “TBL question” in both exercises asks students to make a specific choice. Cognitive research has shown that deep learning is achieved when students are required to make a specific choice. For example, a code snippet was provided in AE 4A (refer to Fig. 3). If students were asked to describe the code functionality, this may result in thinking at cognitive levels 1 (knowledge) or 2 (translation) (look ahead to Table II for levels of cognition and respective indicators). However, the questions asked about specific rules in relation to the code. Thus, students were required to consider alternatives, apply concepts in a practical context, and draw conclusions. This

In the specification model given below, computational code for behaviors B1, B2, B3 and B4 are provided.

You are given the following options of hardware processing elements:

	Freq (MHz)	FP ADD	FP MUL	INT ADD	INT MUL
Proc. 1	1000	16	24	4	8
Proc. 2	850	10	20	4	6
HW	50	1	2	1	2

TBL question 1: Estimate the execution time for the following:

Behavior	On processor 1	On processor2	On Hardware
B1			
B2			
B3			

TBL question 2: If B4 executes in 10 us on both processors, choose a mapping that would result in the shortest execution time for N = 1000.

Fig. 4: An example question from application exercise 4B.

resulted in thinking at higher levels of cognition, such as, interpretation, application, and analysis. Note that while higher order levels are achieved, the low order level of knowledge is implicitly achieved as well. In this example, students would be required to have knowledge of refinement rules and be able to understand the code to solve the problems.

d. Simultaneous Reporting: All teams report out answers at the same time. This ensures that a team’s answers are not influenced by previously reported answers. It also imposes a time limit. In CPRE 588, this was done via white boards provided to each team. As shown in Fig. 4, the questions for AE 4B were complex and required significant work. However, the final answer was concise enough to be simultaneously reported (e.g., execution time, choice of mapping). Each team also recorded details about its solution on a worksheet, which served as a useful tool for the instructor to review after class. Following a report-out, teams explain their answers and feedback is provided by the instructor and other teams. Short lectures are given as needed. Overall the 4S approach supports higher order thinking by students.

C. Team-Based Learning for Online Students

CPRE 588 is part of the department's Embedded Systems Graduate Certificate Online program [26]. In the past, it has been offered in a traditional lecture format using streaming media over the web. During the spring semester of 2015, the course was offered in TBL format to the online students as well. Various tools in Blackboard Learn were used to support asynchronous online procedures for TBL activities, drawing on practices reported in the literature [24, 25].

The primary and most significant difference for the online TBL teams was not having fixed-time, and face-to-face meetings for application exercises. Online students interacted asynchronously over several days via shared web tools, such as a Blackboard Wiki or a Google Drive. Interaction with the instructor and other teams was supported through email and Blackboard discussion forums. Although effective strategies

shown to support online learning were provided [27, 28], the asynchronous mode presented challenges to several essential TBL practices, such as team development, individual accountability, and immediate feedback. Moreover, as online students had greater differences in backgrounds and interests, team members followed the prescribed procedures to varying extents. Dissatisfaction expressed by online students with TBL can be attributed to limitations of the asynchronous format and insufficient use of tools and procedures such as discussion forums. Providing structured opportunities for synchronous interaction should address some of the shortcomings. Additional data has been collected, research in the TBL community is ongoing, and more evaluation of the online approach will be pursued.

IV. EVALUATION

Two aspects of the implementation were of particular interest to the course designers:

1. Cognitive level of student learning, and
2. Student perception of TBL and the application exercises.

A. Cognitive Level of Student Learning

One of the primary reasons for choosing TBL for this course was to create a richer, deeper student learning experience. One way to assess this is by examining the cognitive level of activities in the course, such as application exercises. The Florida Taxonomy of Cognitive Behavior (FTCB) [21, 22] was used for this purpose. FTCB is a modified form of Bloom's taxonomy [33]. It expands the comprehension level of Bloom's taxonomy into translation and interpretation. Specific indicators are used to determine whether a particular cognitive level is achieved. Table II lists the seven levels of cognitive behaviors in FTCB in ascending order, with their respective indicators.

The FTCB has been used in the past to assess cognitive behavior exhibited while teaching a class [22]. Observers check which indicators, among the 55 listed in Table II, are observed during a sampling period. This period, referred to as a recording interval, enables analysis of the cognitive behaviors exhibited periodically over the duration of the class. In this study of CPRE 588, we used FTCB to score the application exercises, and each exercise was divided into recording intervals. Questions from an exercise were grouped into intervals so that the amount of work done by students within each interval was similar. Three faculty members volunteered as observers and scored the application exercises.

A.1 Cognitive Behaviors Observed in Application Exercises

Fig. 5 illustrates the distribution of the observed cognitive behaviors, averaged across the three observers. The knowledge, translations and interpretation levels are referred to as lower order behaviors, while application, analysis, synthesis and evaluation are referred to as higher order behaviors (refer to Table II). We can observe in Fig. 5 that, except application exercise 2A, more than 50% of the observations were of higher-order cognitive behaviors. This was an expected result, as exercise 2A was at the beginning of the course and most of

TABLE II.
THE FLORIDA TAXONOMY OF COGNITIVE BEHAVIOR

Lower Order Cognitive Behaviors	1. Knowledge of specifics
	1. Reads
	2. Spells
	3. Identifies something by name
	4. Defines meaning of a term
	5. Gives a specific fact
	6. Tells about an event
	1.2 Knowledge of ways and means of dealing with specifics
	7. Recognizes symbol
	8. Cites a rule
	9. Gives chronological sequence
	10. Gives steps of process, describes method
	11. Cites trend
	12. Names classification system or standard
	13. Names what fits given class, system or standard
	1.3 Knowledge of universals and abstracts
	14. States generalized concept or idea
	15. States a principle, law, or theory
	16. Tells about organization or structure
	17. Recalls name of principle, law, or theory
	2. Translation
	18. Restates in own words or briefer terms
	19. Gives concrete examples of an abstract idea
	20. Verbalizes from a graphic representation
	21. Translates verbalization into graphic form
	22. Translates fig. statements into lit. statements
	23. Translates foreign lang. into Eng. or vice versa
	3. Interpretation
	24. Gives reason (tells why)
	25. Shows similarities and differences
	26. Summarizes or concludes from obs. of evidence
	27. Shows cause and effect relationship
	28. Gives analogy, simile, metaphor
	29. Performs a directed task or process
	4. Application
Higher Order Cognitive Behaviors	30. Applies previous learning to new situations
	31. Applies principle to new situation
	32. Applies abstract knowledge in a practical situation
	33. Identifies, selects, and carries out a process
	5.0 Analysis
	34. Distinguishes fact from opinion
	35. Distinguishes fact from hypothesis
	36. Distinguishes conc. from supporting statements
	37. Points out unstated assumption
	38. Shows interaction or relation of elements
	39. Points out particulars to justify conclusions
	40. Checks hypotheses with given information
	41. Distinguishes relevant from irrelevant statements
	42. Detects error in thinking
	43. Infers purpose, point of view, thoughts, feelings
	44. Recognizes bias or propaganda
	6.0 Synthesis (Creativity)
	45. Reorganizes ideas, materials, processes
	46. Produces unique communication, divergent idea
	47. Produces a plan, proposed set of operations
	48. Designs an apparatus
	49. Designs a structure
	50. Devises a scheme for classifying information
	51. Formulates hypotheses, intelligent guesses
	52. Makes deductions from abstract symbols, prop.
	53. Draws inductive generalization from specifics
	7.0 Evaluation
	54. Evaluates something from evidence
	55. Evaluates something from criteria

Fig. 5: Distribution of the observed cognitive levels in each of the application exercises.

the questions were designed to test knowledge regarding specific introductory material. Also, notice that 2A is the only exercise without any observations at the evaluation level.

We were expecting to observe that the number of observations of lower order behaviors would reduce in consecutive exercises within a module. A reduction can be observed in exercises from modules 3 and 4. For example, the percentage of lower-order cognitive behaviors reduces from 3A to 3D, and similarly from 4A to 4B. However, the pattern is not distinctive. Also, it does not appear in exercises from module 5. We believe that this could be due to two reasons. One, the instructional team did not designate specific cognitive levels to target while designing the exercises. They were designed to give students problems in real-world scenarios, albeit simplified enough to fit within the timeframe of a class period. Second, due to complexity of the modules, each exercise dealt with a significant amount of new material. Initial questions in an exercise were intended to test basic understanding of the new material. Thus, within an exercise itself, the distribution of lower-order behaviors reduces from first to last recording interval.

Across all exercises, 61% of the observations were of higher-order cognitive behaviors. The two most common behaviors observed were analysis (19%) and synthesis (20%). The least observed higher-order behavior was evaluation (6%). Just under 39% of the observations were of lower-order behaviors, with translation, interpretation, and knowledge having comparable usage at 13%, 13%, and 12%, respectively.

A.2 Cognitive Scores of Application Exercises

The frequencies of observed behaviors (discussed in the previous section) were used to calculate two cognitive measures for each exercise, namely mean cognitive level and total cognitive weighted score.

1) **Mean Cognitive Level:** Each cognitive level from FTCEB was assigned a value from 1 (for knowledge) to 7 (for evaluation). The frequency of observations of each level was

multiplied by the respective value and averaged over all observations. This is the mean cognitive level attained by an exercise. For example, given two observations for an exercise, one each at the synthesis and evaluation levels, the mean cognitive level would be 6.5.

Figure 6 plots the mean cognitive level for the application exercises. Consistent with explanations given in section IV.A.1, slight increases can be observed in the mean cognitive level across exercises within a given module. Notably, exercise 4B, which has the highest mean cognitive level (4.39), has the highest percentage of observations of higher-order behaviors (75%). The mean cognitive level achieved across all exercises was 4.01. A similar score was achieved by laboratory assignments in CPRE 488 [17]. Thus the in-class activities in TBL exhibited a cognitive level comparable to hands-on laboratory work.

2) **Total Cognitive Weighted Score:** A commonly used measure with FTCEB is the total cognitive weighted score [23]. This is calculated as the weighted average of the percentage distribution of observed behaviors, where the weights are 0.10 for knowledge, 0.20 for translation, 0.25 for interpretation, 0.30 for application, 0.40 for analysis, and 0.50 for both synthesis and evaluation. The total cognitive weighted score is considered a more accurate measure of the students' level of cognition compared to the mean cognitive level.

Figure 6 plots the total cognitive weighted score for each application exercise. A pattern similar to the mean cognitive level can be observed. The score increases as we progress further in a module, for modules 2, 3 and 4. An interesting result is that the score of 5A was comparable to that of 5B and 5C. Further analysis showed that the number of observations in 5B and 5C was higher compared to 5A. This resulted in the mean cognitive level for 5B and 5C to be greater than 5A. However, as shown in Fig. 5, the percentage of higher-order behaviors is greater in 5A. Thus, the weighted score of 5A becomes similar to 5B and 5C.

Fig. 6: Cognitive measures for each application exercise.

Fig. 7: Summary of student survey responses.

B. Student Perception of TBL and Application Exercises

As this was the first time CPRE 588 was taught using TBL, we were interested in getting student feedback on the new course structure. A survey was conducted via Blackboard, which consisted of questions in three areas [34]:

1. Opinion of the TBL implementation in the course
2. Perception of the TBL methodology
3. Feedback on application exercises

Sixteen (of 19) students completed the survey. All online students (7) and nine (of 12) on-campus students provided responses.

Fig. 7 summarizes the student feedback in the three areas. Over three-fourths of the responses (76%) indicated that students had a positive experience with the course implementation (refer to Fig. 7(a)). Similarly, 79% of the responses were favorable about the TBL methodology (refer to Fig. 7(b)). 21 % of the responses regarding questions pertaining to the course implementation were negative. Interestingly, only about 11% of responses to general questions on TBL in were negative. This implies that while some aspects of our first-time TBL implementation need improvement, students were receptive in general to the TBL methodology.

Figure 7(c) depicts the feedback received about the application exercises. The questions regarding application exercises received a high percentage of positive responses. Results showed that students liked learning the course concepts through problem solving. Additionally, student responses indicated that the students liked solving complex problems. Negative feedback about application exercises was lower than expected, suggesting that other aspects of the course implementation may need attention. Responses to open-ended questions in the survey pointed to concerns among some students regarding teamwork and communication issues faced by online students. Overall students perceived TBL as an effective methodology for teaching the course.

V. RELATED WORK

This section highlights the use of TBL in engineering courses. Most of the published work pertains to undergraduate courses. A graduate level example is a course on human factors in product design in industrial engineering at Iowa State [36]. It used a version of TBL in which course modules were structured around team projects and emphasized teamwork. Undergraduate examples in the literature have primarily reported on lower division courses. A well-known example of implementing Michaelsen's TBL model in

engineering is that of Hodgson et al. [30]. TBL was extensively used in the second-year engineering curriculum at the University of British Columbia, consisting of four courses. Seventy percent of the students from the TBL-based courses felt that the courses were supported their professional development, compared to only 46% from the lecture-based courses. Similar positive results were reported for learning course content and developing team skills. Students also found the courses more enjoyable.

Connell has used TBL in two sophomore-level courses in electric circuit theory for four semesters at the University of Missouri. [15] He found that freshmen and sophomore students had difficulty with self-directed learning of complex engineering content and with building on concepts learned in earlier modules in TBL. If a student was not comfortable and confident with the material as modules proceeded, enthusiasm for in-class work dropped later in the semester. He modified TBL to address these issues as follows:

1. Created intended learning outcomes (ILO) to guide students: Each module was assigned a list of ILOs. A formative assessment was conducted after each module to get feedback on level of student learning and ensure that the ILOs were achieved.

2. Shortened the readiness cycle: Connell suggested that a shorter module (2-3 class meetings) makes it easier for students to prepare and gives more opportunities for feedback if some aspects are not clear.

With the modified version of TBL, Connell found that only 10% of the students felt learning the technical content was more difficult than in a lecture-based course. Consistent with other studies, a substantial percentage of students felt that the TBL implementation improved their professional (65%) and independent learning skills (50%), while others reported no change. Ninety percent of students reported that TBL helped them develop their problem solving skills, and 85% said it improved their interpersonal skills.

Lamm used TBL in a sophomore chemical engineering problem-solving course and found that students in a TBL section performed as well as students in another section that was taught with an informal active learning approach [37]. She also reported that students developed team-building skills and improved self-study skills. Her work summarizes feedback mechanisms inherent in the TBL method and offers suggestions on the use of feedback.

Demetry used a flipped classroom approach for a large freshman course in materials science and engineering for over a decade [14]. With an unstructured implementation, the author found that all students did not actively participate in class, attendance dropped in the latter part of the semester, and problems did not give explicit attention to development of lifelong learning skills. To mitigate these issues, the author adopted techniques from TBL, including working in teams, in-class readiness assessment tests, and problems involving higher cognitive levels of thinking.

These and other published studies on using TBL in engineering provide evidence of positive results [31].

VI. LESSONS LEARNED AND CONCLUSION

The overarching goal of using TBL was to enhance student learning. We were particularly interested in supporting higher-order thinking skills. This is a common goal, often misconceived, as Felder writes: "All engineering instructors would say that they want their students to master higher-level thinking skills, but in many cases their lectures and homework assignments focus almost exclusively on Level 3. Then, if they put a high-level question on an exam (to see if the students "know how to think") and the students do poorly on it, they blame it on the students' lack of ability or poor study habits. Their criticism is misdirected. The only way people acquire skills is through practice and feedback. If we teach at Level 3, it is unfair for us to require students to figure out for themselves how to work at Levels 4, 5, and 6. The best way to facilitate the development of higher-level skills is to include high-level tasks in learning objectives, share them with the students in study guides for exams, give illustrations and practice in class and more practice on assignments; and then put the high-level questions on the exams" [29].

With this in mind, we used a cognitive behavior taxonomy in the assessment of CPRE 588 to evaluate how well we included high-level tasks in TBL activities. Although we surpassed Bloom's application level in several application exercises, and achieved a cognitive score similar to previously assessed senior-level embedded systems lab exercises, we expected a higher overall cognitive score. There may be several explanations. One may simply be, as Felder notes, the typical instructor is not well-trained to implement high-level tasks in routine class activities. Another may be that the attention of the instructional team was on implementing the TBL process and activities during this initial offering to both on-campus and online students, and less time was available to examine and tune the content to higher levels. However, another explanation is that the expectations for a higher score should be moderated. The score achieved may be relatively good compared to a traditional lecture class. It may also be relatively good if measured on a per time basis compared to labs or projects outside of scheduled class time. This is an open area for research. In any case, we anticipate that more experience with TBL and greater attention during course design to higher-order skills should lead to higher scores. In addition, the TBL community is elaborating on the use of feedback and reflection, and if these become part of the cognitive behavior assessment, the score will also increase.

Our future work includes using our experiences to define design steps for application exercises as high-level tasks in engineering courses. Roberson and Franchini's work will also inform our efforts, as they provide principles and examples for designing tasks. They state that "Course and task design need to be pointing students not toward simply knowing more... . If we want our students to become more expert in our disciplines, we need to structure their encounters with content in ways that change what they can do with knowledge." [38]. We will also provide more support for cooperative learning; more structured interaction for online students; and more reflection for all students.

From the Browser to the Remote Physical Lab: Programming Cyber-physical Systems

Steffen Peter, Farshad Momtaz and Tony Givargis

Center for Embedded and Cyber-physical Systems, University of California, Irvine, USA

Email: {st.peter, fdmomtaz, givargis}@uci.edu

Abstract—Cyber Physical Systems (CPSs) integrate networked embedded computation systems with real-world physical installations. Programming of CPSs is not trivial, since CPSs combine traditional programming challenges and real-world timing, concurrency, and communication. This paper shows how a programming framework that allows students to implement and test CPS control programs in their Internet browsers, can improve both the students' learning experience and learning results. Students model and program a CPS application on a high abstraction level in a web page. This web page, provided by the instructor, invokes the student's code either together with the CPS as functional specification models in a virtual timing environment, or as component in a real-world system that interacts with a real remote physical implementation. Using the provided abstraction, students can incrementally design a CPS and experience challenges such as channel delays, model uncertainties, and real-time behavior, but without the need for complex low level programming or tools. For a CPS example system, we applied the framework in an embedded system design class. Our results show, the ability of a JavaScript-based programming and execution environment to design, program, and run CPSs on different levels of abstraction. Our results also indicate an increased approval from the students and a significantly improved understanding of modeling and programming in the class.

I. INTRODUCTION

Cyber Physical Systems are systems that integrate a networked embedded computation subsystem (the cyber system) with physical subsystems from the mechanic, hydraulic, or electric domain. Examples are as simple as a garage door opener to complex systems such as medical robots, self-driving cars, or the electric grid. Therefore, building cyber-physical systems requires broad interdisciplinary knowledge, including appropriate physical models, precise timing, but also correct programming and implementation skills.

Due to their focus on specific domains, classic domain-specific curriculums do not support the required overview and abstraction. As one example, specific technical implementation details such as memory addresses and port numbers still dominate the embedded systems education, but are alienating for non-computer engineers.

In recent years, a range of new colloquiums and courses were proposed to address the development of cyber-physical systems [1], [2]. Most of the approaches rely on abstract simulations in environments like Ptolemy, Matlab, or in virtual labs that focus on the physical attributes of the system. While these approaches help to educate the concepts of modeling

and physical integration, the abstraction is very high. Important concepts like timing, communication, programming, and event-handling are abstracted away so that an actual real-life implementation is not supported. The problem is not new. Already Vahid [3] described the trade-off between abstraction and implementation detail in embedded system education, and proposed a virtual computer system and a time-oriented programming model, which however only focuses on the embedded system properties.

In this paper we extend Vahid's idea to the programming of CPSs. We propose a framework that allows students to program the control system of a CPS in an abstracted but real-time oriented programming language. The programming and model abstraction is based on Process State Machines (PSMs), which model concurrent processes, communication and timing on a high abstraction level without the need to express low-level implementation details. The student programs are developed in the JavaScript programming language, which is available on most state-of-the-art internet devices. Therefore, students can practically control a virtual or real physical remote system from their laptop, tablet or even mobile phone. While the students' program is implemented and runs in the web browser, the physical system is executed on a remote location – either as virtual plant or on a real physical plant. The architecture facilitates, for instance, to run the program for a simulated virtual plant in a homework assignment, and execute the same program on a real physical system in class.

The benefits of our approach are:

- 1) the availability of a simplified in-browser programming language, which improves the accessibility of CPS programming,
- 2) the support of a experiment-driven systematic transition from PSM models, over abstract simulations and transaction-level models to an actual physical experiment,
- 3) the support for smaller CPS examples that can be addressed in student's homework but also in demonstrations and discussions in class.

In this paper we describe the methodology of our framework and outline the programming model (Section III). In section IV, we discuss the approach in detail for the educational cyber-physical system 'the Falling Ball' [4]. The results originating from a graduate system design class indicate the suitability of our approach to support the education of CPS design, both technically as well as pedagogically.

II. CURRENT CURRICULUMS AND RELATED WORK

The education of CPS has drawn increasing attention in recent years and has been addressed in a range of dedicated workshops at major conferences. Examples are CPS-Ed - Workshop on Cyber-Physical Systems Education along the CPSWeek, and WESE - Workshop on Embedded and Cyber-Physical Systems Education along the ESWeek. The workshops produced a range of compelling approaches and example systems for educational purposes. For instance [5] proposed a focused programming language for dynamic systems. The application scenario is the control of a boat in a sea with currents. The example was discussed and evaluated in a simulation environment. While relatively simple and easily understandable, the example is not trivial and reveals a range of important CPS algorithm challenges, such as the impact of discretization of continuous systems and computation delays to the correctness of the system.

One educational system that can be built in practice is the coupled tank system as discussed by [6] and further applied by [7]. The idea of the system is to balance the levels in coupled tanks with a variable inflow and outflow. [6] proposed a web-based virtual laboratory for the system, but the system can be modeled and build in practice as well, with design kits such as [8].

Another popular teaching instrument for control CPSs – both in practice as well as in simulations – are inverted pendulum systems as for instance discussed by [9]. In those systems a pendulum has to be stabilized with appropriate control mechanisms calculated on a computation platform. The pendulum systems are well-suited for the education of cyber-physical control systems. However, the emphasis on control limits its application as a simple general CPS example.

Other CPS examples include capabilities of mobile phones into the CPS research. For instance [10] applied Android platforms to automatically classify human activities based on models developed in model-based simulation tools. An extended example that facilitates teaching by sensor-driven mobile applications was discussed by [11]. However, such mobile platform is already a complex system for which the integration in a course is not trivial. Other complex use cases include the robotic systems discussed in [12], the amphibious vehicles proposed by [13], or a search and rescue robot outlined in [14]. Such complex examples are exciting and motivating for students and researcher to investigate many interesting details in designing and building CPSs. However, due to their complexity such project usually forbid a complex design analysis, and in-depth discussion of design challenges. In addition, the integration of complex use cases in course frameworks is questionable in most cases.

Recent proposed CPS courses such as the flipped classroom course by [1] or the CPS undergraduate in-class courses introduced in [2] rely on a set of smaller design examples to demonstrate the variety of CPS design challenges. Due to its accessibility is our programming framework and the falling ball example, which is discussed in this paper, a promising contribution for easy integration in such on-class or flipped classroom setups.

From the technological perspective, online submission and assessment tools for programs written by students exist and

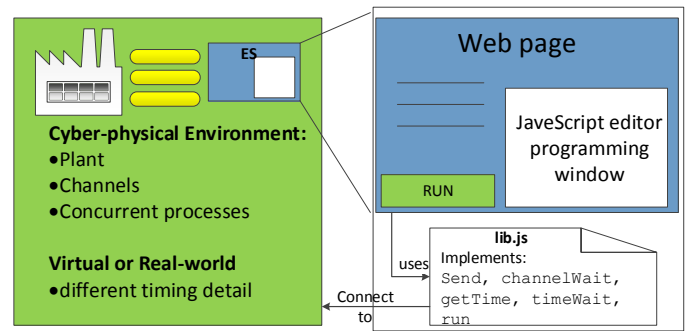

Fig. 1. Architecture of the programming framework: the instructor provides a web page with instructions and a programming window. Students write the application code in this programming window using abstract functions for communication and timing (in lib.js). The run button includes the students program in a cyber-physical run-time environment

have been reviewed in [15]. These tools, however, do not provide an interactive programming and experimentation environment and do not replace the installation of a dedicated development environment on the student's computer. Our approach does not aim at online submission but can be considered as a CPS run-time environment that can be programmed in JavaScript.

JavaScript has already been proposed as language to educate basic programming concepts [16]. The proposed works focus on development for web pages or online games. Our work does not aim for web page programming. Instead we apply the capabilities of modern browsers to directly execute JavaScript code that is typed into the editor window of a web page, which is provided by the instructor of a class.

III. JAVASCRIPT-BASED PROGRAMMING OF CPSS

In this section we discuss the technical background of the applied programming framework. We further outline the student's user experience as well as the required steps for the instructor to set up the educational programming environment.

As introduced, the primary goals of the framework are to provide

- a well-defined and easily understandable programming model,
- a clear abstraction from technical details such as timers or communication channel,
- and the flexibility for instructor to set up the CPS run-time environments ranging from timeless functional abstraction models to real-world experiments.

We realize these goals with our educational programming framework, whose architecture is illustrated in Fig. 1. When students load the instructions web page in their browser, they see a page with instructions, an editor window, and a run button. The editor window allows students to enter their JavaScript program. In this program students are encouraged to use a set of abstract platform-independent functions to access channels and the timing. These abstract high-level functions are provided by the instructor in a library file (lib.js), together with the code to access the run-time environment. Pressing the RUN button, the student's code will be included

Fig. 2. Concurrent Process State Machine as basic model, containing process states (P1, P2, P3), state transitions (arrows between processes), and communication channels (ch1, ch2).

in the run-time environment and the system will be executed. Results of the run will be shown in a text box or graphically.

In the following subsections we discuss the suitability of JavaScript as a lightweight programming language, process state machines as the selected programming abstraction for the students, and the different kinds of cyber-physical environments that can be set up by the instructor.

A. Browser execution with JavaScript

As the underlying programming language we selected JavaScript for a range of reasons: JavaScript is a cross-platform scripting language and is supported by most operating systems and web browsers. Therefore, the execution of JavaScript does not require additional programs, tool chains or plug-ins on most platforms. While JavaScript code is usually embedded into the web page, with the `eval` and `globalEval` functions any use-provided code can be executed just in time. Even though JavaScript is a scripting language with an uncomplicated syntax structure, it is still very powerful, so that classes are available to build online connections or to draw images.

Another advantage of JavaScript is its popularity. According to latest statistics, JavaScript is the most popular programming language in the web [17]. From teaching perspective, the popularity has important benefits, as it results in existing knowledge and interest in the language. The broad availability of material and online support on online platforms like stackoverflow [17] is valuable for instructors and students as well.

The application of JavaScript requires to consider potential drawbacks, too. One disadvantage of the browser programming is the lack of debugging and syntax checking. The interpreter does not evaluate a line of code until this line actually is supposed to be executed, so that errors may stay unnoticed or result in unpredictable behavior. To cope with the syntax issues, we used the ACE editor [18] which provides syntax highlighting and live syntax checking. Another potential disadvantage is the low and non-deterministic performance of today's JavaScript interpreters. Since the intended size of the projects is rather small, we are convinced that the benefits such as good usability and easy understanding outweigh the listed drawbacks.

B. Programming Model and Abstraction

While the browser-based execution environment technically supports a wide range of structured and unstructured programming schemes, in our work we focus on a programming model that is based on the concept of process state machines (PSMs). The construction of a PSM model is widely considered one important first step in the design of embedded

```

if (state == 1) {
    t1 = getTime();
    send("ch1");
    state = 2;
}

if ((state == 2) && waitChannel("ch2")) {
    print("Round trip time="+(getTime()-t1));
}

```

Listing 1. Example JavaScript code for channel timing measurement (for PSM in Fig. 2).

systems [19]. PSMs allow a designer to model concurrent, communicating processes with a very concise semantic, consisting of processes (states), state transitions, and communication channels. As we will discuss later, PSMs are also suitable tools to model the behavior of the physical part and the interfaces of CPSs. As example, the PSM shown in Fig. 2 contains three processes: P1 and P2 are executed in sequential order, and P3 is a concurrent process. Between concurrent processes we allow communication and synchronization with abstract directed channels. In Fig. 2, P1 may send data to P2 via channel ch1, while P3 may send data to P2 via ch2. Due to the importance of timing for CPSs, we explicitly model timing as separate channel. Details such as the underlying platform or timing details of the channel are not considered. However, in the PSM abstraction, the implementation details of timing and channels are not important. As a result, students can use a small set of abstract function hubs to implement the PSM model. Important basic functions are:

- `waitChannel(ch)`: reads from channel ch,
- `send(ch, msg)`: writes optional message msg to channel ch. send without msg works as synchronization mechanism,
- `getTime()`: returns the time in ms,
- `waitTime(t)`: waits until time t.

These basic functions are part of the library (lib.js), provided by the instructor. Using these functions, students can implement the PSM in JavaScript independent from the underlying system.

As an example Alg. 1 shows the JavaScript code for the PSM in Fig. 2, as it can be entered in the editor box of the web page. Alg. 1 implements a round-trip time measurement between process P1-P2 and the concurrent process P3. Visible are the two states, as well as the interaction with the channel (`waitChannel` and `send`) and the time (`getTime`). Alg. 1 may be executed in a virtual environment or in the real world to measure the channel latency to a remote process. The environment is invariant to the students, but set up by the instructor within the instructions web page.

C. Setting up the Environment

One important idea of our architecture is that the application program (programmed by the students) is separated from the cyber-physical environment. Therefore students can use the same application program and apply it to cyber-physical environments on different levels of abstraction.

We consider two general run-time environments: the Virtual timing environment and the Real timing environment.

1) *Virtual timing environments*: A virtual timing environment controls the timing and progress of all system entities within the execution environment. Communication channels and the physical system are simulated. In our experiments, this virtual environment will be set up and executed as embedded JavaScript code in the browser. Both, the physical and the cyber environment are executed in the browser with the same virtual time.

In the virtual timing environment, several abstraction levels are supported. The first is the entirely functional specification model without any timing for computation and communication. More detailed transaction-level models separate communication and computation and facilitate the annotation of timings for each operation.

Benefits of the virtual timing environment are the easy and fast execution, the low organizational overhead, and the reproducible results. Since the timing is virtual, the experiments result in the very same result in every run on every device.

2) *Real timing environments*: The second run-time environment is the real-world, real-time environment. This environment does not simulate the physical part in the browser, but connects the student's program to an external physical system via real communication channels, such as the Internet. The remote physical system may be implemented either as remote virtual lab executed on a server computer, or as a real physical installation. The remote physical lab is an emulation of the real-world system executed on a powerful server. The remote lab can be used when repeated runs of an experiment by many users is not feasible for a real physical installation. The students program works as real-time control program in both cases.

For the Falling Ball example, which we discuss next, we realized both, the virtual plant (Section IV-A5) as well as the real system (IV-A6).

IV. IN-CLASS EXPERIMENT AND RESULTS

We applied the proposed framework in a graduate level course in the school of Electrical Engineering and Computer Science (EECS) at the University of California, Irvine. The basis for the course is the textbook *Embedded System Design* by Daniel Gajski et.al. [19], with extensions towards the design of CPS. The course has been taught in a regular classroom setup and included lectures and homeworks.

One of the CPSs that was modeled, programmed, and analyzed in the class, is the Falling Ball example (FBE) [4], for which we first outline the setup and the implemented models, and then discuss the results and the implications of the experiments.

A. The Falling Ball Experiments

1) *Use Case: The falling ball example*: The architecture of the Falling Ball example is illustrated in Fig. 3 (A). The goal of the system is to take a picture when a falling ball passes a camera mounted on a pole. To determine timings, the system has two motion sensors. The ball is dropped from a height initially unknown to the system, while the height of the sensors and the camera are known. This, in fact simplistic,

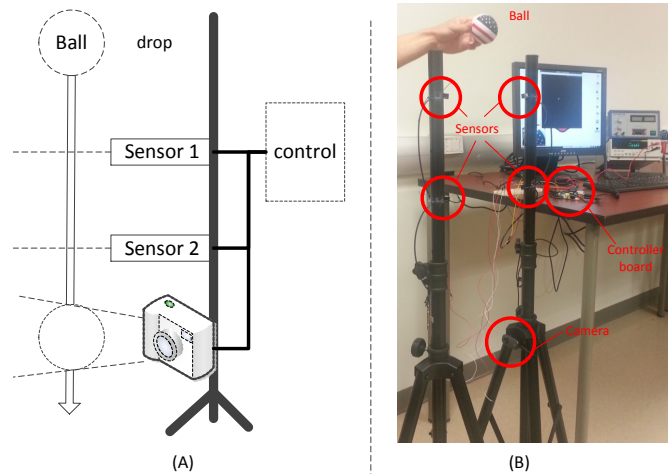

Fig. 3. Setup of the Falling Ball example: (A) as schematics, (B) in practice.

example has some interesting properties of CPSs that refer to the main challenges of CPSs.

The FBE needs exact timing. The timing relates to the physical process, which runs completely independent of any cyber processing. Even though the example can be described in a physical process, which is well understood by the developer and can be expressed in well-known mathematical equations, it is obvious that we will not achieve perfect precision – a fact that interferes with the needed accuracy requirements. The system combines various sensors and the actuator. So their cooperation affects the expected outcome of the system and needs to be regarded as an important factor.

One beneficial attribute of the Falling Ball example is the possibility to implement the system with little manual effort. A practical implementation of the FBE is shown in Fig. 3(B). The system was realized with on a Raspberry Pi Model B Revision 2.0 with Debian Linux. We further used two Honeywell Through Beam Infrared sensors (HOA6299 Series), which work by detecting an interrupt of the line of light from the emitter to the detector. The actuator is the Raspberry Pi Module camera. Two Pyle-Pro Tripod Speaker Stand poles mount sensors and camera.

We used this setting for local tests (written in ANSI C), but also as part of the course to connect the student's JavaScript programs to the real implementation (see Subsection IV-A6). Before the real-world test concluded the series of experiments, we asked the students to model and test the system on different levels of system detail.

2) *PSM modeling*: As first development step, before the control program can be expressed the system has to be modeled as Process State Machine (PSM). In the class, this modeling step was given as homework assignment and was later discussed in class. Fig. 4 shows one correct PSM for the FBE with concurrent processes in the physical and cyber part as well as the interfaces. It can be noticed that the system consists of five concurrent processes: the physical system, the two sensors, the actuator and the embedded system process. In the PSM we can already see the boundary of the embedded system, which eventually should be implemented by the students, and

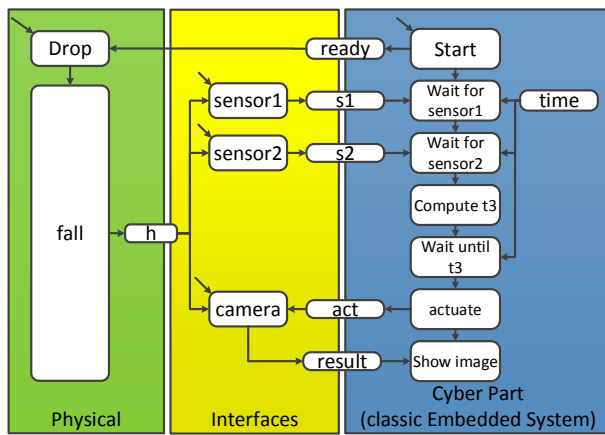

Fig. 4. Process state machine for the falling ball example: the embedded cyber system state machine (blue) interacts with the physical system via sensors and the camera actuator. Communication between the processes is modeled by directed channels.

the environment, which is provided on the web page by the instructor. The embedded system in this case consists of six states, which are implemented next.

3) *Functional Model in the virtual timing environment:* The functional specification model allows the students to implement and test the FBE with ideal (i.e. no) delays and timing uncertainties in computation and communication. The functional models of channel and physical model are executed in a virtual timing environment as invariant JavaScript code in the student's browser. The students had to write the control program, which is an implementation of the 'Cyber Part' state machine of Fig. 4.

In the class, students implemented this program together with an instructor in the editor window of the loaded web page. Alg. 2 shows one complete functional implementation of the control part of the PSM. It can be clearly seen how the program reflects the states, state transition, as well as timing and channel operations of the PSM. The only complex operation is the computation of the expected time. The equation was provided by the instructor. Running the code results in a range of print outputs and a generated graphic of the ball in front of the virtual camera (see Fig. 5).

The result of this first executable simulation is that, first, we successfully translated a PSM into actual code as part of a simulated CPS, and second, that after few milliseconds the ball is always caught slightly below the center of the camera. These observations trigger recommended discussions about the functional and timely determinism of the result (why is it always the same on all devices), about the cause why the ball is caught slightly off center (continuous vs. sampling time), and the difference between real time and simulation time.

4) *Transaction-Level Model in the virtual timing:* The transaction-level model (TLM) extends the functional model with a decoupled channel model. Thus, timing properties of computation and communication can be expressed separately, and can be modeled in more detail. Therefore, in the instruction web page students have the opportunity to parametrize the channels. The channel model uses the same syntax and semantic as the computation model, so that, as example, the

```

if ((state==0) && waitChannel("S1")) {
    t1 = getTime();
    state = 1;
}

if ((state==1) && waitChannel("S2")) {
    t2 = getTime();
    state = 2;
}

if (state==2) {
    t_diff = 0.001*(t2-t1);
    velocity = (h2-h1)/(t_diff) + (g*(t_diff)/2);
    exp = (-V+Math.sqrt((V*V)+(2*g*(h3-h2))))/g*1000;
    state = 3;
}

if ((state==3) && (wait_until(s2+exp))) {
    send("act");
    state = 4;
}

if ((state==4) && (result=waitChannel("result"))) {
    print("result =" + result);
}

```

Listing 2. JavaScript implementation of the FBE (see PSM Fig. 4).

S2 channel with a 2ms delay can be expressed as

```

if (waitChannel("S2.in")) {
    waitTime(2);
    send("S2.out");
}

```

Each computation and communication operation can be annotated with a time this operation needs, by adding the `waitTime` statement. This allows students to express a timed model of the system and experience the effect to the outcome of the simulation and need adaptations of the control program. Students have to understand the source and quantity of delays and anticipate the delays in the control program. Advanced design options include the dynamic measurement of the round trip time of the channel (see Alg. 1).

5) *Remote Virtual Plant Real-world model:* The virtual plant model is a model of the falling ball executed on a remote server. While the actual plant model is still idealistic (i.e. it does not consider air resistance or material), we see two major differences to the previous TLM example: First, real timing, and second, the use a real Internet communication channel.

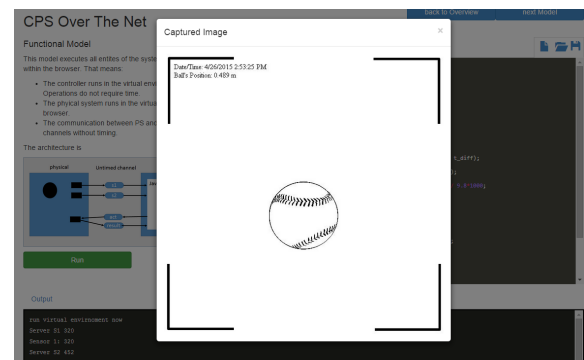

Fig. 5. Result after a successful run in the functional model: The simulated ball is caught by the camera.

Fig. 6. Architecture of the FBE experiment with a virtual plant: the lib.js connects the student's code to a server computer, that emulates the falling ball in real time, via the Internet.

The server was implemented on an Intel Xenon machine running ASP.NET. After the server receives the signal from the 'drop' channel (compare Fig. 4), the simulator waits for a random time before simulating a drop from a random height. We included the randomness to avoid deterministic behavior that could be exploited. In the physical simulation, the server program updates the velocity and position of the ball as fast as possible (tens of microseconds resolution) in real time. Sensor signal s1 and s2 are sent to the controller, which has to process the signals and send the actuation signal at the right time under consideration of the channel delays. After receiving the 'actuate' signal, the server generates a picture of the ball at the simulated position.

While the complexity of the simulation is substantially increased, the student's control program remains unchanged. All platform-dependent code was added in the lib.js, and remains invariant to the students. The actual control program still expresses the small PSM, only with added timing anticipation.

We conducted this experiment in class to control the virtual plant, which runs on a server in another building on campus. Since we use an actual Internet connection, the experiment outcome is less deterministic. In more than half of the cases, the ball could not be caught by the camera. The result is not surprising and motivated discussion on the suitability and the need for detailed modeling of communication channels for reliable CPSs.

6) *Real-world system*: In the final experiment of this series, we replaced the virtual plant with the Raspberry Pi that accesses the sensors and the camera. In the classroom students were able to execute their JavaScript code, expressed in the web page, to control the physical system in the lab, few buildings away from the class room. This experiment required assistance in the lab. We needed to actively drop the ball. The practical part was recorded on video and projected in the class. Due to the nature of the experiment only one student at the time could run the experiment. The outcome was very similar to the virtual plant setup, since in many runs the ball could not be caught. In a successful case, however, the student received a photo of the actual ball, as shown in Fig. 7.

B. Results and Discussions of the Experiments

Admittedly, the organizational and building efforts for the final experiment are considerable. This observation increases the importance of the virtual plant setup, which already

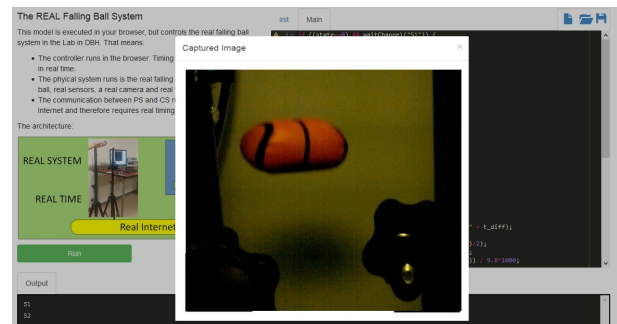

Fig. 7. Resulting picture of the falling ball. The ball appears crushed due to the slow vertical sampling (bottom to top) in the camera sensor.

includes all the timing and programming properties the students are supposed to experience. The virtual remote physical setup contains real timing of control and physical system, communication over the network, and timing uncertainties in computation and communication – all at student's hand in the Internet browser, without additional tools.

However, the practical setup adds additional benefits: First, the real experiment is a special event in usually less eventful programming and design class. In addition, the experiment gave practical closure to the design flow that started with a PSM model and which then developed to a real-world cyber-physical system that can be controlled in real time by a mobile device in the classroom. In this development process, each design step is incremental and seems very little, and therefore, is easy to understand. We studied this hypothesis in a short sentiment study. In the survey 82% of the students agreed that they understand all design steps, while the biggest challenge was the development of the PSM. Even though the real-timing experiments failed in many cases due to the unreliable communication properties, in this survey 86% of the students agreed that this particular misbehavior helped them understand the importance of good modeling and the purpose of the design flow. On a broader question, 96% of students agreed that the falling ball example helped to understand modeling or programming of embedded systems in general.

In addition to the student sentiment, we also analyzed the learning results. We compared the results of weekly graded quizzes to the results of earlier classes on the same subject. Compared to earlier classes without the new programming framework, the amount of correct answers related to model abstraction and the CPS programming improved from 80.7% to 95.3%. One particular result is an improved understanding of abstraction and the impact of channel uncertainties. As comparison, the average percentage of correct answers between the two groups for all other questions increased from 83.0% to 87.5%. The results indicate that the modeling and timing abstraction, which was a relative weakness in earlier years, now is a relative strength of the students.

One additional observation from this class was the increased number of practical student's projects that investigated the effect of communication timing and uncertainties. For instance students applied functional modeling and TLM-based time sensitivity analysis for an electric circuit breaker in the smart grid, the control of a quadcopter drone, and the control of the security and safety system in a smart building.

V. CONCLUSIONS

This paper discussed a browser-integrated development approach for the education of modeling and programming of Cyber-Physical Systems. Following our experiments in an Embedded System Design class, we can draw three conclusions:

First, we got confirmation that teaching techniques that include active programming and experiment-driven analysis are well received by students. The idea to control a real physical system from a mobile phone, a tablet or the laptop in the classroom is appealing to students and instructor. As a result, not only the student's approval improved, but also their results in quizzes on modeling-related questions improved from 80 to 95%.

The second conclusion addresses JavaScript as a suitable programming language for the instructor as well as for the students. JavaScript is a programming language with low organizational and programming overhead, as it does not need the setup of error-prone and platform-dependent tool chains. Applying JavaScript, the proposed framework runs the program, which student enter in a web page, as part of a virtual or real CPS.

Finally we can conclude that the education of CPS programming and design is feasible with smaller examples and just within an Internet browser. On different levels of abstraction and detail, students could run their program, first, as part of a CPS simulation with entirely virtual timing, then, in real-time using a virtual remote physical lab, as part of a real physical setup. The technical interfaces to the environments in all cases are provided by the instructor and hidden from the students, who can concentrate on the modeling, programming and running the experiments.

Based on these results we consider the proposed approach as promising contribution to programming exercises for embedded and cyber-physical systems in traditional class setups, but also to online classes, for which we consider an implementation in near future.

ACKNOWLEDGMENT

This work was supported in part by the National Science Foundation under NSF grant number 1136146.

Abstract—Since 2010 the Universitat Politècnica de València offers the bachelor degrees called “Grados”. The “Grados” follows the guidelines of the European Higher Education Area. Among them are specially relevant those giving students more participation on the education process and incorporating continuous evaluation.

Because of the frustrating results obtained by students of the “Physical Fundamentals of Computer Engineering” course during the 2010-2011 and 2011-2012 academic years, it was decided to examine strategies to overcome the low academic performance, but maintaining the common assessment policy.

The general idea of our proposal is provide students with freedom to prepare their own strategies. To accomplish that, new assessment events were introduced along the term. Thus, students can take a test at the end of each unit, they can also take a midterm exam, combine freely both strategies, or even take a final exam.

After applying the proposed strategies, on the one hand the final grades obtained by the students were better than in previous years, and on the other hand, the teacher observed a greater interest in the subject that leads to improve student engagement.

Keywords- continuous assessment; assessment strategies; student motivation.

I. INTRODUCTION

The Bologna process, launched in 1999, aimed to the creation of the European Higher Education Area (EHEA). As stated in [1] “the EHEA improves transparency between higher education systems, as well as implements tools to facilitate recognition of degrees and academic qualifications, mobility, and exchanges between institutions”.

The common tools includes the “European Credit Transfer and accumulation System” (ECTS) and the diploma supplement. The main goal is to ensure the recognition of study periods abroad.

According to [2]: Qualifications Frameworks are based on learning outcomes. The official Bologna seminar held in Edinburgh described learning outcomes as “the basic building blocks of the Bologna package of educational reforms”, and endorsed the proposition that this methodological approach is at the heart of the paradigm shift from teacher to student-centred learning.

Most of the Spanish Universities started the implementation of the EHEA proposals by the first time during the academic year 2009-2010.

In the “student-centred learning” paradigm the participation and continuous assessment of the students is crucial. Thus, the courses pertaining to the bachelor degree in Computer Engineering (Grado en Ingeniería Informática: GII) had to change not only how the courses were taught but also the learning strategies and the assessment procedures.

A study published by the OECD in 2010 [4] states: “on average among the 23 OECD countries for which data are available, some 30% of students in university-level education do not graduate from the program they enter”. Nevertheless, non-completion rates vary between countries - ranging from less than 10% in Japan to more than 40% in Mexico, New Zealand, Sweden and the United States. This issue is also important in our context, as about 25% of students drop-out our Computer Engineering degree during the two first academic years.

According to Feldman and Zimbler [5], “all beginning college students face enormous challenges, ranging from the academic to the social, and the first year of college marks the period of greatest vulnerability for student attrition”. Therefore, care must be taken in designing a learning environment that motivates by reducing student anxiety and minimizing dropouts. In the case of Computer Engineering degrees, this statement is especially relevant when it refers to Science and Math courses, as they may not be meeting students educational expectations, mainly focused on computer related topics.

In this paper the way how the students of the “Physical Fundamentals of Computer Engineering” course (Fundamentos Físicos de la Informática: FFI) were motivated to achieve better academic performance is presented. The proposed approach has been applied during the last three academic years, and it has evolved based on the obtained outcomes.

The rest of the paper is structured as follows: section II describes the context; section III introduces the syllabus of the FFI course; section IV is dedicated to describe the procedures and strategies used; Section V is devoted to show the results and make some discussion, and finally, in section VI, the conclusions and future work are presented.

II. CONTEXT

FFI is a first-year core subject taught during the fall term (first semester) in the Computer Engineering degree program. In particular, the approach was applied to the students enrolled in the two groups taught in Valencian language (out of 10 offered by the College) as the instructor who proposed the method was the responsible of these two groups. Below it is described the enrolment process just to understand some singularities.

In order to access to the Spanish Universities there are mainly the following options:

- 1) If a student has completed the upper secondary education, level 3 according to the International Standard Classification of Education (ISCED), the standard terminology created by the United Nations [3], he has to take the university admission test (*Prueba de Acceso a la Universidad*, PAU). Each university establishes cut-off grades to access to the degrees that it offers. Depending on the overall grade obtained by averaging the PAU test grades and the upper secondary education grades, students can apply for a particular bachelor programme in a specific university.
- 2) If a student has completed a higher vocational programme (*ciclo formativo de grado superior de formación profesional*), level 4 according to ISCED, he/she does not need to take the PAU test. Each university establishes a number of places in each programme for those having an upper technician diploma.

In our University, students who wish to enroll in any of the offered programmes, they do it according to the obtained overall grade. Thus, students having the highest grades can choose first, not only the programme they wish but also the group that they prefer. It includes the language in which the courses are given: Spanish, English, or Valencian.

In the special case of the GII degree, there are offered places for some 500 students. They are enrolled in 10 groups. Groups are named using letters: Group A, Group B, up to Group J. Groups A and B are given in Valencian, group E is given in English and the remaining groups are given in Spanish.

As stated above, one consequence of the enrollment process is that students with the best grades are gathered in specific groups. For instance, during the academic year 2012-2013, the average overall grade for the students enrolled in the two Valencian groups was 7.99 and 7.06 respectively. However, the average overall grade for the students enrolled in the two best Spanish groups was 9.40 and 8.30 respectively, while in the English group was 9.68. These differences among groups are common year after year.

III. SYLLABUS OF THE FFI COURSE

During the 2010-2011 academic year the GII programme was offered by the first time and teachers adapted the teaching and assessment methods in order to promote students participation and formative assessment.

A. Contents

Table I shows how the course contents is divided in blocks (B0 to B5) and the units (U0 to U13) that corresponds to each block.

TABLE I: Course organization in blocks and units

Blocks	Units
B0. Introduction	U0 Introduction
B1. Electrostatics	U1. Electrostatics fundamentals U2. Electrical properties of semiconductors
B2. Electrokinetics	U3. Direct current and electrical resistance U4. Power and Energy U5. Network analysis
B3. Electromagnetism	U6. Magnetic field. Magnetic forces U7. Magnetic field sources U8. Magnetic materials U9. Electromagnetic induction
B4. Sinusoidal Alternating Current	U10. Sinusoidal Alternating Current
B5. Semiconductor Materials	U11. Semiconductors U12. Conduction in semiconductors U13. The diode and the transistor

Laboratory practices.

1. Introduction to the measure devices
2. Resistance measure. Error analysis
3. The oscilloscope
4. The capacitor
5. Characterization of a direct current engine
6. Analysis of an active linear circuit
7. Resonance and filters
8. Characterization of the diode. Applications

B. Resources

All the resources are available at the institutional Portal.

C. Course organization

The FFI course usually starts on the first week of September and finishes the second week of January (15 weeks).

In each week there are planned two lecture sessions and one laboratory session. Both lectures and lab sessions last 90 minutes.

The first three lectures are devoted to review the main concepts of Calculus. In parallel, during the first week of the semester, two optional seminars of 2 hours each are offered. These seminars were especially prepared for those students coming from the vocational education and training programmes. The seminars are presented as extra sessions.

D. Assessment

FFI instructors agreed to assess students in base of the following items:

- 1) Two midterm written exams. The first one is called “MT1” and the second “MT2”. MT1 assesses blocks 1 and 2, while MT2 assesses blocks 3 to 5.
- 2) The execution of lab skills: scores obtained along the laboratory sessions (LAB)
- 3) Continuous-assessment (CA) over the course of the semester which includes: student class participation, homework assignments, observations, and so on.

Each midterm has two parts: the first part includes multiple choice questions while the second part includes open-ended questions. In the case of the first midterm, the sections are named $MT1_{MC}$ and $MT1_{OE}$ and for the second midterm the sections are named $MT2_{MC}$ and $MT2_{OE}$.

In the rest of the document the first part will be referred to as “multiple choice question part” (MC) and the second part as open-ended (OE), where students have to write and justify the obtained results.

The final grade (FG) is obtained applying the equation (1).

$$FG = 0.2 * \frac{MT1_{MC} + MT2_{MC}}{2} + 0.5 * \frac{MT1_{OE} + MT2_{OE}}{2} + 0.2 * LAB + 0.1 * CA \quad (1)$$

In order to give an extra opportunity to the students, at the end of the term, there was also a common final exam (F) divided in two parts named F1 and F2, according to the previous midterm exams.

In that case the final grade is obtained as indicated in equation (2).

$$FG = 0.2 * \frac{F1_{MC} + F2_{MC}}{2} + 0.5 * \frac{F1_{OE} + F2_{OE}}{2} + 0.2 * LAB + 0.1 * CA \quad (2)$$

At the beginning of the academic year all the common exams (MT1, MT2, F1 and F2) are scheduled.

IV. PROCEDURES AND STRATEGIES

During the academic years 2010-2011 and 2011-2012, the final grade was obtained according to equation (1) in all the groups. The exams were randomly distributed among teachers for grading.

Because of the frustrating grades obtained by students of the FFI course during these academic years (see section V.B for details), since the academic year 2012-2013, it was agreed to allow instructors to try new teaching strategies, but maintaining the common assessment policy.

In order to avoid early drop-outs and aiming at motivate students to be more engaged along the term, the instructor of the Valencian groups tried different strategies. Below are summarised the most successful ones.

- 1) Provide additional course resources to help students in their study. To accomplish that, a web page was created that includes, for each unit, examples of solved exercises and problems, as well as the exam solutions of all the previous academic years, and information about how assessment was made [6].
- 2) For each unit, a questionnaire was posted to the institutional portal. Students were invited to answer the questionnaire as homework and the corresponding score was taken into account in the CA dimension. The initiative aimed at preparing the MC part of the exams.
- 3) By the first time, during the current academic year (2014-2015), students had to answer a brief questionnaire at the beginning of the laboratory session, which was automatically assessed. As the corresponding score was taken into account in the LAB dimension, the initiative encouraged students to prepare the practices at home before attending the lab.
- 4) At the end of each unit, students were invited to take a written exam (unit exam) that follows the same structure (MC + OE) as midterm exams. As it will be explained in detail later on, scores obtained in these unit exams can replace the corresponding ones on midterm exams. See section V for details.
- 5) Students have the opportunity to improve the scores obtained so far, by taken the midterm exams, with the particularity that they can solve just the units that they want.

In order to better understand the strategies 4) and 5), below they are described in detail.

First we have to take into account the structure of midterm exams and the structure of final exam. Such structure is shown in tables II, III and IV. The structure of the MT1 is shown below in table II.

TABLE II: Sections of the MT1 exam.

Unit 1 multiple choice section	MC1
Unit 1 open-ended section	OE1
Unit 2 multiple choice section	MC2
Unit 2 open-ended section	OE2
...	...
Unit 5 multiple choice section	MC5
Unit 5 open-ended section	OE5

While the structure of the MT2 exam is:

TABLE III: Sections of the MT2 exam.

Unit 6 multiple choice section	MC6
Unit 6 open-ended section	OE6
...	...
Unit 13 multiple choice section	MC13
Unit 13 open-ended section	OE13

The nomenclature used for midterm exams is as follows: We will refer to the multiple choice section of the unit X as

MCX, while we will refer to the open-ended section of the unit X as OEX.

The structure of the final exam follows the same philosophy, as shown in Table IV.

TABLE IV: Sections of the final exam.

Midterm 1 multiple choice section	$F1_{MC}$
Midterm 1 open-ended section	$F1_{OE}$
Midterm 2 multiple choice section	$F2_{MC}$
Midterm 2 open-ended section	$F2_{OE}$

Once defined the different sections of the midterm and final exam, we proceed to detail the structure of the Unit-Test(U). Again, $U1_{MC}$ makes reference to the multiple choice section of the U test corresponding to unit 1. $U3_{OE}$ makes reference to the open-ended section of the U test corresponding to Unit 3.

In order to show how the strategies 4) and 5) are implemented, several scenarios are presented.

Note: The *Avg. Grade* of tables V to XII uses a 7-point scale, and is computing according to equation (3).

$$Avg. Grade = \left[\frac{0.2 * \sum_{i=1}^k U_{i_{MC}}}{k} + \frac{0.5 * \sum_{i=1}^k U_{i_{OE}}}{k} \right] \quad (3)$$

Lets start from the assumption that the grades obtained by two different students, in some U tests, are as shown in table V

TABLE V: Grades obtained in the Unit exams.

Student	$U1_{MC}$	$U1_{OE}$	$U2_{MC}$	$U2_{OE}$	$U3_{MC}$	$U3_{OE}$	Avg. Grade
A	10	10	8	8	3	3	4.90
B	4	4	4	4	4	4	2.80

Student A options:

- 1) Does not take the MT1 exam. In this case, table VI shows the student A scores stored for the MT1 exam.

TABLE VI: Student-A MT1 stored data.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
A	10	10	8	8	3	3	4.9

- 2) Takes the MT1 exam.

- a) Student A takes the MT1 but he/she decides to answer only the MC3 part. Then, he/she obtains a better grade than the one obtained in the $U3_{MC}$ exam. Table VII shows the grades obtained by student A in the MT1 exam.

TABLE VII: Student-A MT1 grades obtained.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
A					6		

TABLE VIII: Student-A MT1 grades stored.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
A	10	10	8	8	6	3	5.1

Thus, table VIII shows the MT1 grades stored for student A.

- b) Student-A takes the MT1 but he/she decides to answer only the MC3 part. Now, he/she obtains a lower grade than the one obtained in the $U3_{MC}$ exam. Table IX shows the grades obtained by student A.

TABLE IX: Student-A midterm obtained grades.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
A					1		

In this case it is stored the average of MC3 and $U3_{MC}$. Table X shows the stored grades.

TABLE X: Student-A midterm stored grades.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
A	10	10	8	8	(3+1)/2	3	4.83

Student B options:

- 1) Student-B takes the MT1 exam, and he/she has the option to solve the whole test or only some parts. For instance, he/she solves only the multiple choice parts (MC1, MC2 and MC3), and lets suppose that he/she obtains the grades shown in table XI.

TABLE XI: Student-B midterm MC1 obtained grades.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
B	8		6		2		

Then, the MT1 stored grades are as shown in Table XII.

TABLE XII: Student-B MT1 stored grades.

Student	MC1	OE1	MC2	OE2	MC3	OE3	Avg. Grade
B	8	4	6	4	(2+4)/2	4	3.133

The general idea of our proposal is to provide students with freedom to prepare their own study strategies. They can take a test at the end of each unit, they can also take a midterm exam, combine freely both strategies, or even take a final exam.

V. RESULTS AND DISCUSSION

To help readers to interpret the presented data, we have prepared the results presentations as follows:

Firstly, it is verified that the strictness of the teacher assessing the experimental groups (A and B) is similar to the strictness of the other teachers.

Secondly, the results obtained by the students of the FFI course is compared with another course given during the same term.

A. Teacher assessment strictness

One question that arises when preparing this work was: Given that each teacher prepares the midterm exams and grades his/her own students what happens if the teacher responsible of the experimental groups (A and B) is more or less strict than the others?

To answer such question, it was decided to compare the laboratory results during the academic year 2014-2015, because in that case all the teachers evaluates the laboratory sessions using the same strategies.

Table XIII shows the number of students passing the course in the experimental groups (A and B), and the total number of passing students in the FFI groups (including A and B). It is also shown the percentage of passing students obtained by dividing the number of passing students by the number of students taking the lab exam. Besides, the average and the standard deviation of the final grade (FG) are shown.

TABLE XIII: FFI Statistics per groups.

	Groups A and B	All Groups
#Passing	74	359
%Passing	86.04	88.72
FG average	6.74	6.77
FG std. dev.	1.92	1.69

As we can see the results are very similar.

B. Global results

In order to compare the results obtained by the students of FFI, it will be used the results obtained by the students of the course "Computer Fundamentals" (Fundamentos de los computadores: FCO). The FCO course is given at the same time than FFI.

The results are presented by academic years. The data include: the number of enrolled students in the corresponding course (#Enrolled); the number of students taking the exams (#Taking Exam); the percentage of students taking the exams (%Taking Exam), obtained by dividing the number of students taking the exam by the number of enrolled students; the average and standard deviation of the final grade (FG); the percentage of passing students (%Passing), obtained by dividing the number of passing students by the number of students taking the exam; the success rate (Success rate), obtained by dividing the number of passing students by the number of enrolled students.

It is presented:

- The global grades of FFI students. See table XIV
- The grades of FFI students enrolled in groups A and B. See table XV

- The global grades of FCO students. See table XVI
- The grades of FCO students enrolled in groups A and B. See table XVII

Then the figures with the following data are presented:

- FG. Average (figure 1)
- Percentage of passing (figure 2)
- Percentage of students who presented the exams (figure 3)
- Success rate (figure 4)

TABLE XIV: Global results of course FFI.

	2010	2011	2012	2013	2014
#Enrolled	541	614	539	558	482
#Taking Exam	380	525	425	433	449
% Taking Exam	70.24	74.5	78.85	77.6	93.2
FG. average	4.845	5.132	5.544	5.244	5.251
FG. std. dev.	2.176	1.7866	1.487	1.337	1.47
%Passing	55.53	64.38	71.53	70.67	72.6
Success Rate	39	55.05	56.4	54.8	67.6

Overall results in FFI included in Table XIV shows that percentage of students taking the exams improved after the two first academic years when different initiatives were implemented, and particularly in the last year (2014-2015) when this percentage surpassed 90%. The same applies for the percentage of passing students, above 70% in the last three academic years. However, the average of the final grade (FG) remained quite similar (above 5 in a 10-point scale) along the last four academic years. This fact occurs also when success rate is analysed, although there is an important increase in the last year (2014-2015) mainly due to the high percentage of students taking the exams.

TABLE XV: Results of FFI students enrolled in groups A and B

	2010	2011	2012	2013	2014
#Enrolled	100	NA	84	77	82
#Taking Exam	65	96	70	63	71
% Taking Exam	65	NA	83.33	81.81	86.6
FG. average	4.17	4.586	5	5.316	6.715
FG. std. dev.	2.167	0.219	1.24	1.506	1.807
%Passing	43.1	55.21	67.14	69.84	81.7
Success Rate	28	NA	59.95	57.14	70.7

Related to results obtained in the FFI experimental groups (A and B), Table XV shows that percentage of students taking the exams has also improved after the two first academic years, increasing from 65% in 2010-2011 up to more than 80% in all the remaining cases. An important rise is also observed in the FG average along these years, going to 4.17 in the first year (2010-2011) up to 6.7 in the final year (2014-2015). The same applies both for the percentage of passing students and the success rate.

Conversely, overall results in FCO (Table XVI) show different patterns. For instance, the percentage of students

TABLE XVI: Global results of FCO course

	2010	2011	2012	2013	2014
#Enrolled	547	532	472	508	450
#Taking Exam	482	430	356	404	413
% Taking Exam	88.12	80.83	75.42	79.53	91.78
FG. average	5.67	6.00	6.26	6.44	6.41
FG. std. dev.	2.26	2.11	1.97	2.21	2.09
%Passing	68.88	74.42	77.53	81.68	82.32
Success Rate	60.69	60.15	58.47	64.96	75.56

taking the exams range from 75% in 2012 to about 92% in 2014, although the percentage in 2010 was 88%. There is no a clear tendency in these figures. Concerning the FG average, values are similar although the best results are obtained in the last two years (2013-2014 and 2014-2015). The percentage of passing students improve along the years, going from 69% (2010-2011) to 82% (2014-2015). However, this is not the case for the success rate that has not a clear tendency, although the best results are also obtained in the last year (75%).

TABLE XVII: Results of FCO students enrolled in groups A and B

	2010	2011	2012	2013	2014
#Enrolled	NA	NA	NA	NA	NA
#Taking Exam	94	76	56	72	72
% Taking Exam	NA	NA	NA	NA	NA
FG. average	5.81	5.87	5.66	6.00	5.933
FG. std. dev.	2,04	2.05	1.99	2,14	2.17
%Passing	77.66	72.3	73.21	76.39	80.55
Success Rate	NA	NA	NA	NA	NA

In relation to FCO results in the same analysed groups (A and B), and supposing that students are almost the same as in the experimental groups, there are no clear patterns in the available data (Table XVII). For instance, FG average ranges from 5.66 in 2012-2013 to 6 in 2013-2014. The percentage of passing students ranges from 72% in 2011-2012 to 80% in 2014-2015.

Fig. 1: The average of the final grade.

Concerning Fig. 1, we can see that from the 2010-2011 academic year up to the 2014-2015 academic year, the FG average of FFI students has been lower than the FG average of FCO students.

However, if we consider only the experimental groups A and B, from the 2010-2011 academic year up to the 2013-2014 academic year, the FG average of FFI students has been approaching to the FG average of FCO students, and during the 2014-2015 academic year the FG average of FFI students was higher than the FG average of FCO students.

Fig. 2: Percentage of passing students.

Concerning Fig. 2, we can see that during the 2010-2011, 2011-2012, 2012-2013, and 2013-2014 academic years the percentage of passing students of FCO is always higher than the percentage of passing students of FFI. However, during the 2014-2015 academic year the percentage of passing students of FCO is lower than the percentage of passing students of FFI.

In the case of the experimental groups A and B, we can see that, during the 2010-2011 academic year, the percentage of passing students of FFI was significantly lower than the percentage of passing students of FCO.

During the 2011-2012, 2012-2013, and 2013-2014 academic years the percentage of passing students of FFI has been approaching to the percentage of passing students of FCO. Finally, during the 2014-2015 academic year both percentages are practically the same.

Fig. 3: Percentage of students taking the exams.

As shown in Fig 3 percentages of students taking the exams are very similar except in the 2010-2011 academic year.

Fig. 4: Success rate.

Finally, concerning the success rate, accordingly to Fig. 4, we do not have information about FCO students of groups A and B. So we can say that the overall success rate of the FFI students during the 2010-2011 academic year was quite low (near 40%). During the 2011-2012, 2012-2013, and 2014-2015 academic years the success rate of FFI students was about 55%. However, during the academic year 2014-2015, this success rate increased to nearly 68%.

Since the 2012-2013 academic year the behavior of the experimental groups of FFI (groups A and B) is very similar to the behavior of the remaining FFI groups. An exception is noticed in the 2010-2011 academic year where the success rate of the A and B groups of FFI was really low (near 30%).

In addition to the stated improvements in the quantitative indicators, the teacher has also noticed a greater interest in the subject. For instance, about 90% of the enrolled students made 6 out of 7 unit exams. Only in one of these unit exams the percentage decreased to 70%, and it was related to the scheduling of another midterm examination in the same week. It is important to point out that before each optional exam, the instructor tried to motivate students to take these unit exams as they served them to assess their knowledge.

VI. CONCLUSIONS

To sum up, it was observed that after applying the five strategies described previously, on the one hand the final grades obtained by the students were better than in previous years, and on the other hand, the teacher perception is that students were more comfortable both in the classroom as in the lab, what contributed to reduce early drop-outs.

The key idea of our proposal has been to provide students with freedom to prepare their own study strategies. Depending on the particular student situation, they can take the unit tests, the midterm exams or a mixture. And if they prefer they can take the final exam.

Taking into account that computer engineering students generally are not very motivated to study science and math courses, the presented strategies have allowed the teacher to transmit a positive thinking along the different assessment events. At the same time, students perceive that regardless the initial results, they still have new opportunities to pass the course. Thus, if they get low grades in the unit tests, they can

improve them whether in the midterm exams or even in the final exam, what invite students to keep engaged.

ACKNOWLEDGMENT

The authors would like to thank the “Escuela Técnica Superior de Ingeniería Informática” (ETSINF) and the “Departamento de Informática de Sistemas y Computadores” (DISCA), both in the “Universitat Politècnica de València” (UPV) for their funding.

Qualitative Research on Psychological Experience

A Starting Point for Using Interpretative Phenomenological Analysis

Abstract— This special session invites academic researchers to temporarily adopt the commitments of interpretative phenomenological analysis (IPA) in order to gain insight into psychological experiences in engineering education research. In this session, we will introduce participants to IPA as a methodology that is committed to understanding the lived experience of particular phenomenon while also recognizing that the researcher plays an interpretive role in generating such understanding. The participants will gain an introduction to *doing* IPA to systematically interpret a transcript through multiple iterations of understanding a text. This experiential learning session will be vibrant with focused activities of conducting qualitative analysis and reflecting on the process. Additionally, we will connect the intentional, analytic processes that are practiced to more holistic principles related to quality in interpretive engineering education research. The expected outcome of this session is that participants will have a robust foundation to begin or advance their inquiries using IPA or other forms of qualitative research.

Keywords- *interpretative phenomenological analysis; psychological experience; qualitative research*

I. PURPOSE STATEMENT

We propose a session that guides participants through the process of leveraging intentional techniques to interpret psychological experience in engineering education. A growing body of research is highlighting how engineering education is a process that engages *whole persons* rather than just students who learn concepts and skills (e.g., [4-10]). Consequently, engineering education researchers are increasingly attending to phenomena of embodied, psychological experience, such as emotion (e.g., [6]) and identity development (e.g., [7-10]). This special session leverages the facilitators' background with a study that employed interpretative phenomenological analysis (IPA) [11-12] as a way to gain insight into these experiences.

II. DESCRIPTION OF SESSION CONTENT

The proposed session focuses on three specific areas, which are described as follows.

A. Psychological Experience

The session will focus on psychological experience as a lens to identify under-explored phenomena in the participants' own contexts (e.g., psychological journeys of identity; emotion in engineering education). After the participants engage in an in-depth process of analyzing a common identity journey, based on an excerpt from an interview transcript, we will invite the participants to consider psychological experiences that are often invisible in their own institutional contexts.

B. Interpretative Phenomenological Analysis

The session will introduce participants to IPA as a methodology that is committed to understanding the lived experience of particular phenomenon (e.g., becoming an engineer) while also recognizing that the researcher plays an interpretive role in generating such understanding. Throughout the session, the participants will gain an introduction to *doing* IPA to systematically interpret a transcript through multiple iterations of understanding a text. They will begin by an initial reading for shallow comprehension and end with connecting the transcript to psychological themes.

C. Conducting Quality Research

The session will provide a space for participants to think through how they actually analyze text from a common interview transcript. In order to foster this development for researchers, we will share an excerpt from a transcript in our ongoing investigation related to how students undergo the psychological identity journey to become engineers.

Using this common source of data, we will then guide participants through multiple layers of interpretation of this text, thereby creating an immersive process with multiple iterations of feedback from the co-presenters. Toward the conclusion of the session, we will demonstrate how our exercise relates to the assurance of *quality* in interpretive research, using co-facilitator Walther's quality framework [3], as discussed in the following section.

III. ASSOCIATED PEER-REVIEWED PAPERS

This session is primarily associated with the Huff et al.'s previous work [1], which reflectively analyzed the embodied commitments of conducting qualitative research. Our previous work [1] was presented at the FIE 2014 conference and includes four co-facilitators as authors. In the paper, we detail the transition of one researcher in his journey from attending to the methods of research to identifying and enacting the methodology of interpretative phenomenological analysis (IPA). In the backdrop of this paper was our larger qualitative study that employed IPA to understand a rich picture of how engineering student become engineers, particularly by attending to the fuzzy boundaries between technical and social features of this identity [2]. To ground the discussion of the paper, we drew on a transcript from a single interview in this study conducted with Kevin, a graduating mechanical engineer. We transparently shared a reflexive account of conducting IPA research in order to introduce IPA as an excellent research tool for open areas of engineering education research.

Additionally, we leverage prior work by co-facilitator Walther and his colleagues [3]. Specifically, we draw on their Q3 framework for considering quality in qualitative research. Drawing on the engineering metaphor of quality management, they propose a process-oriented framework of research quality along two dimensions: a process model locates quality strategies throughout the research process, and a typology systemizes fundamental aspects of validation (theoretical, procedural, communicative, and pragmatic) and the concept of process reliability to explicate quality strategies in their fundamental contribution to substantiating knowledge claims.

IV. SESSION AGENDA

In the session, we intend for participants to form small groups of 4-6 persons. The session will incorporate a blend of activities for individual persons, small groups, and the entire assembly. We co-facilitators will divide among multiple groups to provide guidance, as needed, during the structured tasks of the session. The following is a proposed agenda, approximated for the entire 90 minute range (00:00 – 01:30).

A. Welcome and Group Introductions

(00:00 – 00:10): We co-facilitators will introduce ourselves and welcome all to the session. We will then organize the participants into small groups and facilitate introductions within these groups. During this time, we will also hand out all materials related to the session.

B. Defining Terms: Psychological Experience and Interpretative Phenomenological Analysis

(00:10 – 00:15): We will provide a brief explanation of these terms but then quickly immerse them into *doing* IPA to examine psychological experience. This activity corresponds to the steps of analysis detailed in Huff et al. [1]. Our intent here is to foster learning among the participants in IPA through shared experience before considering theoretical

features of these terms. Throughout the activity, co-facilitators will wander the room to provide feedback on the various stages of interpretation.

C. IPA Activity: Reading an Interview Excerpt

(00:15 – 00:20): We will begin by having two facilitators acting out a real interview transcript from our study on identity development. The particular transcript is an authentic account of Charlotte's struggle to transition to her full-time career as a civil engineer. We begin by reading the transcript to discuss how the transcript is a representation of a real event, both for the researcher and the participant.

D. IPA Activity: Individual Reflection of the Transcript

(00:20 – 00:25): After the interview is read, the excerpt will have certainly elicited some personal connections from the individual participants. We will use this time to allow participants to *bracket* off these personal responses by reflectively, writing them down, and then forgetting about them—for the time being.

E. IPA Activity: Descriptive Comments

(00:25 – 00:30): We will give participants the opportunity to individually *describe* what they see in individual copies of transcript. What are significant features of the transcript? What is the play-by-play among the text? Each participant will do so in a designated color of ink in the wide right-hand margin.

F. IPA Activity: Linguistic Comments

(00:30 – 00:35): We then will give participants the opportunity to document how the participant is using *language*. Each participant will do so in a different color of ink in the right-hand margin of the paper.

G. IPA Activity: Conceptual Comments

(00:30 – 00:35): Having considered the description and linguistics of the transcript, the participants will now *ask conceptual questions* of the transcript. This prepares the analysts to consider how the transcript might relate to broader psychological themes from literature.

H. IPA Activity: Connecting to Broader Themes

(00:35 – 00:45): We will close the session by guiding participants to connect sections of the transcript to broader psychological themes (see Huff et al., 2014, for a detailed description of these). Participants will note these in the *left-hand* margin.

I. Group Reflection on Activity

(00:45 – 00:55): After individuals have completed the analysis activity, we will discuss their reflections of the common activity in two layers: first among small groups and then among the entire assembly.

J. How Does Analysis Relate to Knowledge Claims?

(00:55 – 01:05): Following the activity, we will give an overview of how we would use IPA to compare particular findings in the excerpt from Charlotte's interview to

psychological themes in other interviews. Specifically, we will examine how such detailed analysis can result in relevant claims of knowledge.

K. Thinking Through Quality

(01:05 – 01:15): Using the shared analysis activity as a guide, we will walk the participants through the Q3 Framework [3] as a general form of considering quality in their own investigations.

L. Relevance of Psychological Experience

(01:15 – 01:25): We will close the session by inviting participant to consider questions of *psychological experience* that may be relevant investigations in their own institutions (e.g., the identity development of African-American males at HBCUs, the frustration of first-generation college students in an engineering science course). Responses will be written down and shared.

M. Final Group Discussion

(01:25 – 01:30): The session will close with a brief group discussion, which includes time for co-facilitators addressing participant questions.

V. ANTICIPATED AUDIENCE

We anticipate an audience of those interested in qualitative research in engineering education. Such an audience would include researcher that are new to qualitative investigations. It would also include advanced qualitative researchers who are looking to hone their skills or find others with similar interests. We also anticipate that this session will draw those who are interested in examining *experiential* features of engineering education through a psychological lens.

Furthermore, prior to the conference, we will promote the special session among the 200+ persons who have expressed interest in co-presenter Walther's ongoing research with the Q3 Framework [3]. We will also leverage co-presenter Huff's role as a contact-person in the international IPA network in order to advertise the session and conference to beginning IPA researcher across the United States.

VI. EXPECTED OUTCOMES

The expected outcome of this session is, primarily, for participants to have a robust foundation to investigate psychological experience using IPA. We expect that this session will demystify features of interpretive analysis that are seldom made explicit, giving participants confidence to dive further into understanding IPA or other qualitative approaches.

Additionally, we will collect three types of data from the session: participant contact information; the annotated transcripts; and the documented forms psychological experience that are relevant to participants. This data will help inform (1) how multiple analysts might provide various informed interpretations of a common text and (2) develop a

repertoire of topics for the engineering education community related to psychological experience.

VII. PLAN TO DISSEMINATE OUTCOMES

We intend to disseminate outcomes for the proposed session via a full-paper for the 2016 FIE Conference. We will give participants the first viewing of this paper, should they indicate their interest. Additionally, we will provide electronic resources of our own work to participants that indicate interest.

VIII. RATIONALE FOR INCLUSION AS A SPECIAL SESSION

We propose that the session described be included as a special session at FIE 2015. At the heart of this session, we are making interpretive strategies visible in an experiential learning format. Additionally, we are relying on the knowledge of our participants to socially construct the relevance and landscape of psychological experience in engineering education research. A special session at FIE provides the structural space to optimally fulfill these purposes.

IX. ACKNOWLEDGEMENTS

This work was made possible by grants from the National Science Foundation (award no. EEC-1329225; award no. CAREER-1150668). Any opinions, findings, and conclusions or recommendations expressed in the material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Aesthetics and Emotional Engagement

Why it Matters to Our Students, Why it Matters to Our Professions

Jean Hertzberg

Department of Mechanical Engineering
University of Colorado, Boulder
Boulder, CO, USA
Hertzberg@colorado.edu

Katherine Goodman

ATLAS Institute
University of Colorado, Boulder
Boulder, CO, USA
Katherine.goodman@colorado.edu

Abstract— This special session takes the form of a guided discussion, using a hands-on flow visualization exercise as focal point. Our goals are 1) to foster conversation and document ideas about how the aesthetic qualities of engineering topics can be used to deliberately draw the emotional engagement of students; 2) to gauge how the FIE community currently views the aesthetics of engineering, and brainstorm new visions for how aesthetics could be used to improve recruitment and retention of a diverse student population as well as lead to innovative methods for the teaching and learning of core engineering content; 3) to explore the feasibility of viewing aesthetics-driven emotional engagement as a necessity and not an ancillary benefit in course design.

Keywords— *aesthetics, art, affect, design, fluid mechanics, flow visualization, engagement, engineering, physics, education*

I. DESCRIPTION OF SESSION CONTENT

Aesthetics can be defined both as a metric for art (is it art? Is it good art? [1]) and as a psychological measure of affect [2]. With a few pointed exceptions, neither definition has received much consideration in engineering education. Instead, cognitive gains, technical competence, utility, and objectivity are our most highly prized virtues. Despite improvements, the complexity of the problems that remain call for a broader approach; we propose that aesthetics and the attendant emotional engagement as possible solutions to long standing problems in diversity, technical literacy, and retention.

New emphasis is being placed on students' emotional engagement, in works such as *The Whole New Engineer* [3] and in studies relating emotion to cognitive gains [4], [5]. Issues of affect, emotion, and identity are tangled, but certainly overcoming engineering stereotypes, which often highlight being socially awkward or emotionally stunted, requires transformation of our cultural practices in education. Acknowledging that aesthetics is a valid motivation for science and engineering may provide an important avenue for increased inclusion of diverse thinkers; conversely, ignoring the aesthetic dimension of engineering masks the enthusiasm and creativity engineers have for their work. How can we lead more students to Richard Feynman's joyous reaction that, "There are all kinds of interesting questions that come from a knowledge of science, which only adds to the excitement and mystery and awe of a flower. It only adds. I don't understand how it subtracts" [6]?

This line of questioning developed from an intervention in fluid mechanics that improved students' perceptions and attitudes. Flow Visualization, a course in which engineering and art/film students make artistic images of fluid flow, has been shown to improve attitude towards a notoriously difficult topic [7]. However, efforts to extend this success to other subdomains have been only partially successful.

This workshop will generate and collect a wide range of perspectives on what aesthetics means in the context of engineering practice and education, and explore how aesthetics can generate emotional and intellectual engagement.

II. AGENDA

Participants will be in small groups (4-6 people). They will be given a small but beautiful fluid dynamics experiment to perform. This will be used as a discussion starter for the role of aesthetics in comprehending specific physics concepts and improving student engagement. Facilitators will circulate to assist discussion where needed and document report-out using video. See Table 1 for a list of activities.

TABLE I. SESSION ACTIVITIES

Activity	Time, minutes
Pre-readings drawn from EER, PER, art education, psychology and neuropsychology of aesthetics are available for participants interested in digesting contextual information prior to the session [8].	N/A
Introduce the facilitators and goals of the session; settle participants into groups	5
Groups perform Flow Visualization experiment; record results using camera phones. Participants will be asked to reflect on and document personal reactions to the experience as well.	20
Groups report-out reactions to the experiment; whole group discussion	15
Using the Flow Vis. experience as a possible model for aesthetics in their own domains, groups generate other models and discuss possible implementation strategies in formal and informal learning contexts.	20
Groups report-out previous discussion.	15
Whole group discussion on dealing with potential obstacles to these changes; Closing	15

III. BACKGROUND PAPER

A structured summary of the pre-readings and an abbreviated description of the session details is available online [8], and will be distributed to participants in hardcopy. Please note that our preliminary research in this area is being submitted as a work-in-progress to FIE, and will be referenced in the pre-readings.

IV. AUDIENCE

This session is expected to draw from several subsets of FIE attendees:

- Those who value aesthetics already, such as visually creative individuals and artists (being an engineer does not preclude membership in this group).
- Those who are interested a definition of diversity that extends beyond demographics and perspectives defined by demographics.
- Those who are interested in humanistic engineering approaches, including efforts to develop well-rounded students.
- Those who are interested in issues of the affective domain, including attitudes, beliefs, motivation, values, and identity.

V. EXPECTED OUTCOMES WILL BE REPORTED

Within two weeks of the session we will post (on YouTube) preliminary results in the form of the video recordings of the report-outs (Model consent and IRB approval will be secured as needed). Within one year we plan a peer-reviewed journal article placing a summary of the discussions in the context of a review of the appropriate literature.

VI. JUSTIFICATION AND FUTURE WORK

Aesthetics and the resultant emotional engagement are topics that are not well-represented in engineering education

research. In addition, many engineering educators are uncomfortable with these topics. We hope that in the process of facilitating this special session we will begin to establish a community of researchers and practitioners who can help move this area forward. This engagement will be possible only with the degree of interaction afforded by an FIE Special Session. Finally, this discussion, and the video record of it, can be the seed participants take home to begin this conversation at their own institutions.

ACKNOWLEDGMENT

We wish to thank Noah Finkelstein, Tim Curran, and the CU Boulder DBER community for helping us develop this workshop.

Abstract— The Software Engineering sector has been demanding an education model that targets real market practices more and more exactly. This includes bearing in mind that, in the market, a software project is subject to numerous restrictions of time, budget and other resources required for its development. In this context, this article describes the application of a learning methodology based on problems, called *xPBL*. This methodology consists of elements that enable a learning environment to be built that in its essence is practical and contains real learning, and that ensure that this is supported by processes that make it possible to evaluate the effectiveness of the PBL approach from various perspectives: namely, the student's, the teacher's and that of the methodological approach itself. Based on this case study, evidence of the applicability of *xPBL* is demonstrated as is how the behavior should be understood of all stakeholders involved in the process of teaching and learning in one of the most complex disciplines of Software Engineering.

PBL; Project Management, Software Engineering Education.

I. INTRODUCTION

The coining of the term "Software Engineering" in Computer Science has thrown down major challenges for those who teach it. Obviously, the requirements of Software Engineering demand a learning environment that is not only practical but true to the reality of the market. That is, an environment that allows its students to experience in a real way, the software development process, its management constraints (scope, time, cost, risks), technological limitations and conflicts of interest between human resources, whether these are members of a software development team or customers seeking software solutions.

This is the context of what this article sets out to show. By using a teaching methodology centered on the student and on solving real problems in a real work environment, this article describes the experience of applying PBL (Problem-Based Learning) to a Planning and Project Management module which is part of the curriculum of an undergraduate degree in Information Systems (IS).

PBL was applied using a method called *xPBL* developed by the NEXT (*iNnovative Educational eXperience in Technology*) group as described in [1]. The elements of this methodology as well as some of the practical studies that preceded it are discussed briefly in Section II of this article.

It is important to point out that the NEXT group has been making a study of and applying PBL in Computer Science since 2007. Trialing was almost always carried out on post-graduate courses or courses aimed at adding to professional skills, most of which focused on enhancing specific professional skills, for a target-audience of Computer Science graduates, as described in [2], [3], [4] and [5].

Unlike previous research studies, this paper describes and discusses the application of PBL methodology on a course of the 4th semester of a still ongoing 8-semester undergraduate degree in IS, as set out in Section III, in parallel with five other highly relevant course modules, including Software Engineering, Databases and Business Processes Management. In this context, the Project Planning and Management (PPM) course module, the object of this study, competes with the modules of the same semester with respect to the availability, commitment and engagement of the students. This feature reinforces the need for a methodology supported by a real environment and real assessment processes, thereby continuously bringing students to the center of the learning to which they belong.

The application of *xPBL* methodology is described and discussed in Section III, and the evaluation process and its results are presented and discussed in Section IV.

Lastly, Section V draws conclusions and makes some final remarks on this research experience.

II. THE *xPBL* METHODOLOGY

The purpose of the *xPBL* methodology is to align methods and tools to the management of the PBL approach so that the principles that characterize it can be guaranteed when adopted for teaching Computing.

On adopting the PBL approach, characteristics such as flexibility and unpredictability should be considered, especially with regard to their impact on managing the steps and activities associated with the teaching and learning process. According to [6], the essence of PBL is that it is process-oriented. Therefore, as this is one of the main features associated with this approach, it is important to maintain alignment between the stages of the PBL process to ensure its effectiveness. These assumptions led the NEXT group to

conducting research, especially with respect to drawing up processes and metrics to plan and manage PBL. This involves, for example, concepts associated with the 5W2H technique [7], Deming's PDCA (Plan, Do, Check and Act) [8], PBL principles [9] and problem-solving models [10]. It is important to emphasize that the applicability of xPBL in case studies such as in [2], [3], [4] and [5] enabled experience to be obtained of its implementation and the continuous improvement of its processes.

To ensure PBL principles besides its educational goals are adhered to, the xPBL methodology is based on five elements: (1) Problem; (2) Environment; (3) Content; (4) Human capital and (5) Process. These elements reinforce ten principles that were established in [9]. Table I maps the ten principles associated with each element of xPBL.

TABLE I. ELEMENTS OF XPBL AND PBL PRINCIPLES (SOURCE IN: [9]).

Mapping PBL principles and elements of xPBL	
<i>PBL Principles</i>	<i>xPBL Elements</i>
1. All learning activities are anchored on a task or a problem;	Problem
2. The learner should feel he/she owns the problem, and is responsible for his/her own learning;	
3. The problem should be real;	
6. The learning environment should stimulate and at the same time challenge the learner's reasoning;	Environment
4. The task and the learning environment should reflect the reality of the professional market;	
5. The learner needs to own the process used so as to work out the solution to the problem;	Content
7. The learner should be encouraged to test his/her ideas against alternative views and contexts;	
9. The learning is collaborative and multidirectional;	Human Capital
8. The learner should have the opportunity and support to reflect on the content learned and the learning process;	Process
10. PBL is supported by planning processes and continuous monitoring.	

Learning in PBL is directed towards problem solving. The problem is always the central task to be undertaken in this process. As seen in the mapping shown in Table I, Principles 1, 2, 3 and 4 are associated with the 'Problem' element of xPBL. These principles support the idea that problems should be real and complex so that students' interest in solving them is aroused.

Regarding the 'Environment' element of xPBL, Principle 4 supports the need to simulate a real learning environment that reflects actual conditions in the labor market. This means that learning is essentially functional in an environment where students are of a mind to be immersed in practices and activities in a collaborative and multidirectional way (together with their peers, teachers and tutors).

Principles 5 and 7 refer to the "Content" element of xPBL, which reflects the need to align practices to content (whether structure, theory, foundations, model or concept). Although learning is essentially functional, the PBL methodology considers it essential to have the support of content as a

conceptual basis for the problems and that the methodology must not be confused by practical experiments in which the support of theory and monitoring the processes of how solutions are found are not prominent.

Regarding "Human Capital", principle 9 reinforces the idea of collaborative and multi-directional learning being fostered by constantly engaging students, teachers, tutors and customers with each other during the resolution process.

Finally, principles 8 and 10 associated with the element of 'process' emphasize the need to plan and monitor the processes of teaching and learning continuously by having the students reflect on their learning and conducting reviews which are consistent with the paradigm of the method. It is also pointed out that Principles 9 and 10 were defined by the authors of this article in [9].

Therefore, the authors, when defining the xPBL methodology, consider that how its elements are tackled is essential at all stages of the PDCA cycle, above all with regard to planning being aligned to its implementation.

Quality management of the processes in the cycle associated with xPBL elements can also be guaranteed by adopting techniques such as 5W2H. The five aspects associated with W and the two with H presented in the technique match the keywords given in Table II. According to the authors [1], a plan of action guided by the technique sees to it that the 5 elements are defined in a clear and organized way because they obtain answers to questions such as: "What?", "Who?", "Where?" "When?", "Why?", "How?" and "How much?".

TABLE II. 5W2H TECHNIQUE.

5W2H Technique		Questions
5W	What?	What action will be performed?
	Who?	Who will perform the action?
	Where?	Where will the action be performed?
	When?	When will the action be performed?
	Why?	Why will the action be performed?
2H	How?	How will the action be performed?
	How Much?	How much does it cost to perform the action?

As an effective management technique, 5W2H sees to it that activities associated with each xPBL element are broken down, analyzed and summarized during the planning stage. The authors objectively considered information about what should be done and when, or who will conduct a certain activity and when, while they were defining each element.

When considering the 'Problem' element of xPBL, the question "what?" of the technique refers to the set of possible, real and complex problems which are similar to real-world projects and the demands of real customers. The purpose of this element (related to the question "why?", for simplification, "why?") must necessarily be compatible with the educational objectives, with the content to be learned, besides the skills and attitudes needed to solve the problem. As in the real world, problems arise from real customers (who?) and it is they who ask for the activities and evaluate the team's results, when considering their needs. It is up to the students (who?) to select the problem from among different

requests (where?) right at the start of training (when?). This process (how?) allows students to identify and understand requests so that they can thereafter draw up an innovative plan for solving them with relevant arguments, thereby proving the feasibility of the process and its complexity. The aspect of 'how much' is not applicable to this element.

The 'Environment' element refers to definitions of actions set by coordinators, tutors and teachers (who?) before the start of a course (when?). The main actions (what?) refer to the process of forming teams because of the number of aspects and personal aspects and defining the resolution process associated with activities, roles, business models and development models (how?). IT infrastructure and physical infrastructure aspects should also be considered (what?) since the environment should reflect the real conditions of the labor market (why?). The costs for this element (how much?) are related to acquiring resources and licenses. The methodology recommends that small teams (5-7 members) be formed, where aspects such as professional experience and interpersonal skills should be considered.

In the context of Human Capital, roles and responsibilities are defined (what?) during the planning (when?) so that those involved know how to proceed correctly when implementing the PBL approach (why?). Teachers and technical tutors (who?) teach the content, coordinate activities and can be consulted about real experience in projects (how?). The PBL tutor (who?) monitors the entire process of solving the problems of the teams, and records the results of the performance and individual assessments (how?). Students and customers should also be considered in this context (who?). The aspect of 'how much does it cost' is not applicable in this element.

As for the 'content' element, it is known that this is the conceptual basis for the process of problem solving, as well as being responsible for providing the formation of students' knowledge (what?). The flexible learning associated with the PBL approach requires teachers and tutors (who?) to map the contents of different media such as books, magazines, and specialist blogs (where?). The idea is not to follow pre-defined routes, but rather to take up unpredictability as the rhythm of the solution process in practice (why? and how?).

Finally, the last element of the xPBL methodology refers to the assessment process (what?). The reference that the authors [1] stress is the authentic assessment proposed by [3] to evaluate the effectiveness of the approach under different aspects by considering the rigor associated with real practices both individually and collectively (why?). Throughout the training (when?), formative type assessments are conducted to verify that educational goals are being achieved. Summative assessments are carried out at the end of educational units to classify the students' achievement levels as to course content and foundations of the module as well as the interactions and deliveries (when?). Teachers and tutors (who?) evaluate the students (how?) under ways associated with the content, the resolution process, and the performance and development of interpersonal skills in the teaching and learning process. The students (who?) evaluate themselves, their peers, as well as

teachers and tutors and the PBL methodology itself. In the perspective of the students' evaluations, aspects such as results and customers' satisfaction derived from authentic assessment are considered. The level of customer satisfaction refers, above all, to the service provided by the team. The results of each evaluation are consolidated by the teacher in reports with varying levels of visual details using graphics and comments.

The next section describes these elements applied to the undergraduate degree with an emphasis on the management and planning of information system projects.

III. USING xPBL IN PROJECT MANAGEMENT UNDERGRADUATE COURSE

This section describes the application of the xPBL methodology in the Project Management in Information Systems module of the undergraduate course. There is a total of 60 contact hours over 4 months, the educational goal being to train students in good practices in Project Management.

To conduct the course, planning was carried out by the pedagogical team comprising the teacher of the course and four tutors: two technical tutors (with project management experience); and two PBL tutors, responsible for monitoring the learning process throughout the course. This plan followed the guideline proposed by xPBL in [1]. Based on applying the 5W2H technique to the xPBL elements discussed in Section II, the PBL approach was used to structure the module.

A. Environment

The learning environment consisted of 33 students, divided into six teams: 3 teams of 5 students and 3 teams of 6 students. Of the students, 70% of the class were between 19 and 21 years old, and the rest up to 24 years old; 80% of the class were male; and 33% of the group had no professional experience.

The criteria used to distribute the students into teams were: professional experience, age, interest in Project Management, in addition to the student's personal profile (artisan, guardian, idealist and rational), which was identified by applying a simplified version of the MBTI - Myers-Briggs Type Indicator [13]. So as to form the teams in a more balanced way, the following rules were established: (1) Each team consists of a mix of MBTI profiles; (2) At least one profile of "idealist" per team, usually related to creativity and innovation; (3) No team has all members within a single age band; (4) At least one female in each team; (5) At least half the team have some professional experience; (6) Affinities are identified from the initial dynamics.

To support the communication and dissemination of educational materials of the course, the following tools were adopted: Facebook, Dropbox, Google Drive and a WhatsApp group, which enabled greater collaboration among all stakeholders.

To plan and monitor the development of each project, the teams adopted agile management techniques by free choice. All that the teaching team required was that it should be possible to monitor the process remotely and so each team used a web tool that supported the process adopted and allowed the progress of the project to be followed by the team of tutors via

the web, whether by monitoring Tables via document repositories or the project site.

As for the classroom, the students had a whiteboard and a physical space with mobile tables and chairs, which permitted physical configurations to be arranged for groups. This was an environment that was improvised and needed to be reorganized at the start and finish of each class. Unfortunately, the organization does not have appropriate rooms for PBL, which reflect working environments found in the software industry. As to the hardware used, a notebook was made available in the classroom to each team and each team had ample access to the undergraduate laboratories (around five of them and all of which are of high quality and capacity) at the Informatics Center throughout the day.

B. Problem

The objective of the 1st. step of the course was to bring all students to the same level in Project Management concepts thus seeing to it that they could become familiar with the problem- solving approach, which is very different from traditional classes based on presenting content on PMBOK (Project Management Body of Knowledge), version 5.

In the 2nd. step of the course, students were responsible for identifying and formalizing the problem to be investigated, including ensuring the participation of a real client who was external to the academic environment. To ensure that the problems identified by the teams and the proposed solutions would be compatible with the educational objectives and training needs and skills associated with the course, teaching staff guided the teams such that the solutions were designed using WEB2.0 tools or platforms, for example: Salesforce, Content Management Systems, or other environments based on a high-level business component.

To help students understand the problem and propose a solution, a dynamic was conducted, supported by the Delisle problem-solving model [14]. The model sets out four aspects of tackling a problem that should be observed: (1) Ideas, possible solutions for solving the problem; (2) Facts, information about the problem; (3) Hypotheses, raising learning issues to solve the problem and; (4) Action Plan, strategies, resources, information, everything that leads to the solution. On having a clearer understanding of how to find solutions to the problem, the students then move on to the step of formalizing the problem. The problems were defined by each team using a template with questions related to mastering the problem, its causes, complexity, the target public's needs and so forth. To define the proposals, questions guided the students on how to evaluate possible solutions, without overlooking the strategy for achieving them, available resources and the benefits to customers. The definitions of problems were sent to the teaching staff so that they could be evaluated under the criteria of Adequacy, Complexity, Clarity, Relevance and Innovation, thereby determining if they were to be selected or adapted.

C. Human Capital

The teaching staff consisted of the teacher of the course and four tutors. The general function of these tutors was to continually support student learning. Thus, the course received support from: two technical tutors, whose competences and

experience were specific to the subjects of the course and; two PBL tutors, who helped to conduct and implement the xPBL methodology. In conducting the classes, one of the PBL tutors was always present and; at least one technical tutor attended the monitoring meetings of the projects.

Besides the four tutors and the teacher of the course (an expert on Project Management and PBL), there was a team of developers and the Project Manager, who was a student belonging to the team itself and elected by its members. Finally, there was the figure of the real client, a person representing a company or individual entrepreneur, with whom the teams had identified some demand that needed to be satisfied by using information systems.

D. Content

The course was conducted by the teacher and technical tutors for which the main reference was the PMBOK Guide version 5, and speakers on agile management approaches SCRUM [15] and KANBAN [11] were invited. Moreover, a lecture on the PBL approach and a dynamic on the process of problem solving according to Delisle's model were given [14].

The course was run in 3 modules. The 1st module focused on the overview of PMBOK v5, in order to ensure early study of the main concepts of the Project Management area; the 2nd. module focused on the phases of Initiating and Planning the life cycle of projects; and the 3rd. module focused on the phases of implementing, controlling and closing the project life cycle. With reference to the project phases that the teams experienced, the teacher defined the content planned for the course. Based on the difficulties encountered in the evaluation process (detailed in Section IV), the "on demand" content was given to the class, thereby reinforcing the points for improvement identified in the teams.

E. Assessment Process

The evaluation model implemented in this case study was structured into three levels: the first targeted the evaluation of the students according to the authentic assessment model and used five perspectives – *Content, Process, Results, Performance and Client Satisfaction*; the second targeted the degree of maturity of the PBL approach in the students' view; finally, the third focused on the final evaluation of the course, under criteria related to how the teacher planned it and performed. Figure 1 summarizes the evaluation process and the results obtained. The details of each of the levels of Figure 1 will be presented in Section IV.

Fig. 1. Assessment Model used in the module.

IV. ANALYSIS OF RESULTS

A. Results of the Student Assessment

The assessment process was conducted in three modules: the 1st module focused on knowledge and understanding of project management concepts and fundamentals, and only applied the ‘Content’ perspective; the 2nd and 3rd modules focused on planning and project management, and considered all the perspectives of the authentic assessment.

As for the results obtained by the students, Figures 1, 2 and 3 give graphs that show the concentration of the students’ performance in the 1st, 2nd and 3rd modules, respectively, within the value scale of from 0 to 10.

It is worth pointing out that the target set by the course is an average of 7 for a direct pass, and an average of 5 for a pass subject to an evaluation of the cumulative content at the end of the course (final evaluation).

Fig. 2. Concentration of the students’ performance in the 1st module.

Fig. 3. Concentration of the students’ performance in the 2nd module.

Fig. 4. Concentration of the students’ performance in the 3rd module.

Note that the results for the 1st module, reached solely by assessing the Content perspective, show performances with the highest concentration between the values of 5 to 6, unlike the results of the 2nd and 3rd modules, which have a concentration between 7 to 8 and 8 to 9, respectively.

Table III shows the types of assessment conducted within each module, and highlights the instrument used for the assessment: an objective test, based on the PMI (Project Management Institute) standards; the Meeting to start the

Project (Kickoff); the Project monitoring meeting or remote monitoring (Status Report).

TABLE III. TYPES OF ASSESSMENT PER MODULE.

Module	Individual Assessment (Summative)		Group Assessment (Formative)		
	Content	Performance	Process	Output	Client
1	1 st EV	-	-	-	-
2	2 nd EV	1 st EV	Kickoff 1 st SR	Kickoff 1 st SR	Kickoff 1 st SR
3	3 rd EV	2 nd EV	2 nd SR 3 rd SR	2 nd SR 3 rd SR	2 nd SR 3 rd SR

EV – Evaluation | SR – Status Report.

Some reasons for the results of the first module confirm the difficulties of the conventional assessment process, which is summative (a test comprising 20 to 25 questions based on a PMBOK overview) and focuses only on concepts and definitions, given individually without debate or discussion.

To develop the essentials skills that a project manager needs, the authentic assessment, recommended by xPBL methodology [3] was applied in accordance with the five perspectives:

1. *Content*, from objective evidence, aiming at concepts and foundations of the Project Management area, taught by the teacher;
2. *Process*, from assessments led by the teacher and tutors during Status Report meetings;
3. *Results*, from the deliveries made in accordance with the project planning during Status Report meetings, evaluated by the teacher and tutors;
4. *Performance*, based on assessing the 180 degree performance, where each student made a self-assessment and was rated by all members of his/her team, conducted by tutors;
5. *Client satisfaction*, based on the client’s evaluation of solutions during Status Report meetings.

To better understand the performance of the class in the 2nd and 3rd module (Figures 3 and 4, respectively), the following sections describe the performance of the teams within each of the five perspectives of the authentic assessment. To calculate the performance of each student per module, the following formula was used:

$20\% * AA(Content) + 20\% * AA(Process) + 20\% * AA(Output) + 20\% * AA(Performance) + 20\% * AA(Client\ satisfaction)$, where “AA” corresponds to the arithmetic mean of the scores related to each perspective, when there is more than one score.

1) Content perspective:

In the Content perspective, the evaluation was applied individually, based on the content and practices discussed on the course, the main reference being PMBOK version 5, and at sessions led by invited speakers on agile management approaches SCRUM [15] and KANBAN [11]. In this perspective, there were two tests of content, both objective ones, with about 20 to 25 questions: (1) Phases of Starting and Planning the project life cycle; (2) phases of Running, Controlling and Closing the project life cycle. These tests

were conducted at the end of the respective project phases and therefore were of a summative character. The value scale used followed the traditional model of from 0 to 10.

On calculating the overall average of the class, solely under the perspective of Content in the 1st and 2nd modules, we obtained a performance similar to that of the 1st module, the pass rate being about 57%. However, the chief gain from this evaluation was that the results of each objective test enabled to identify the points of most critical difficulty, and thus to work on the content in class with a view to clearing up doubts and mistakes identified in the tests.

Some other matters can be considered regarding the students' difficulty with learning theory and concepts. Unfortunately, for many students, the study habit of reading intensively about concepts and fundamentals has become a rare practice. They are connected to social media based on rapid and short answers. Despite complementary literature being recommended such as presentations, articles and podcasts, the result of the Content evaluations showed that the students did not read the content proposed, even though this is essential for a course based on a reference guide to items of knowledge. Some of the reasons that the students alleged were the competitive demands from other courses of similar complexity and public holidays associated with the World Cup which was held in Brazil in 2014. The tutors recorded these considerations which will be considered when planning future courses. These should include new initiatives to encourage reading, such as debates and discussion sessions.

2) Process perspective:

In the perspective of 'Process', the teams were evaluated by the teacher and the technical tutor who monitored the projects during four meetings: one Kickoff and three Status Report (SR) meetings. At the SR meetings, each team always answered five questions: "What is the objective of your project?"; "What's the plan?"; "What has been done?"; "What are the strengths?"; and "What are the points of improvement?". As criteria for evaluation in this perspective, the following were defined: (1) Clarity in presentation; (2) mastery of the presentation; (3) Completeness when considering the five questions; (4) understanding of Planning. Each indicator could take on one value from a simple scale of five values: "1 - Insufficient; 2 - Regular; 3 - Good; 4 - Very Good; 5 - Excellent". The graph in Figure 5 shows the teams' performance throughout the project.

Fig. 5. Evolution of the perspective of Process.

On analyzing the graph in Figure 5, we see that the performance of most of the teams improved throughout the stages of the life cycle of the project, except team T1 team, whose project manager left the team at the end of the course.

Turning to the performance of teams T2, T3 and T4, we moreover see a significant improvement between the 1st monitoring (Kickoff) meeting and the final delivery in Status Report 3. Another interesting behavior observed in this chart was the natural "relaxation" of the teams that obtain excellent performances. It is common for teams to concentrate on other priorities when they see that the challenges were met in full at that moment, and thus this has an impact on future activities and hence their performance in the following reviews.

3) Output Perspective:

As to the perspective of Output (Figure 6), this was focused on analysis of the content of the presentations of the projects in the monitoring meetings. These analyses were conducted under the following criteria: (1) Overview of the project; (2) Planning activities; (3) Carrying out activities; (4) Strengths; (5) Points for improvement. Once again, the same simple scale of five values was used. These evaluations were conducted by the teacher and technical tutor.

Fig. 6. Evolution of the perspective of Output.

The graph in Figure 6 also shows an upward trend but with slighter variations, thereby proving that, although students have relaxed with the process of planning and monitoring of the project after achieving excellent performances, these continued to be focused on the delivery of results, probably due to the culture of traditional teaching approaches, usually based on delivery artifacts. In addition, teams T2, T3 and T4 continued to stand out.

4) Performance Perspective:

In the perspective of Performance, eight competences were assessed: self-initiative, commitment, collaboration, innovation, communication, learning, planning and analysis. Due to the subjectivity of this analysis, this perspective used a scale of five values, with the following meanings: (1) "did not meet expectations"; (2) "partially met them"; (3) "met them"; (4) "met them very well"; (5) "exceeded expectations". This review was conducted by the PBL tutor and applied in the self-assessment format and evaluation in pairs (known as the 180 degree evaluation), where each member of a team was rated by his/her colleagues, anonymously. Since this was

undertaken by means of an online research tool, sophisticated individual reports could be obtained for each student, which showed the results of the assessment of colleagues in his/her team and his/her own assessment in a consolidated and graphic way, for each assessment criterion, including subjective comments.

On analyzing Table IV, it can be seen that teams T2, T3 and T6 stand out with respect to the performance of their members, in the eight perspectives mapped, as well as the performance of their PMs. On comparing with the perspectives of Process and Output, we see that there is a direct relationship between the best results of Performance of the Project Manager and the teams that stand out in these perspectives show the PM's influence on the conduct of the process of management and deliverables of the project.

TABLE IV. EVALUATIONS IN THE PERSPECTIVE OF PERFORMANCE.

Criteria	T1	T2	T3	T4	T5	T6
SELF-INITIATIVE	3,6 / 3,4	3,7 / 4,1	3,9 / 4,1	3,4 / 3,7	3,6 / 3,4	4,3 / 4,4
COMMITMENT	3,8 / 3,6	3,9 / 3,9	4,2 / 4,2	3,7 / 3,6	3,6 / 3,4	4,5 / 4,6
COLLABORATION	3,7 / 3,6	3,6 / 4	4,1 / 4,4	3,6 / 4	3,9 / 3,6	4,5 / 4,8
INNOVATION	3,3 / 3,3	3,8 / 3,8	4 / 4,2	3,2 / 3,8	3,2 / 3,5	4,3 / 4,5
COMMUNICATION	3,6 / 3,6	3,9 / 4,2	4 / 4,2	3,6 / 3,6	3,5 / 3,7	4,2 / 4,5
LEARNING	3,6 / 3,3	3,9 / 4	4,1 / 4,2	3 / 3,6	3,3 / 3,2	4,3 / 4,5
PLANNING	3,6 / 3,4	3,7 / 4,1	4 / 4,2	3,2 / 3,6	3,7 / 3,4	4,3 / 4,6
ANALYSIS	3,6 / 3,5	3,6 / 4	4 / 4,2	3,4 / 3,6	3,6 / 3,2	4,4 / 4,5
General average of the teams:	3,5	3,8 / 4	4,0 / 4,2	3,4 / 3,7	3,6 / 3,4	4,4 / 4,6
Average of the PM:	3 / 1,5	4 / 4,3	4,3 / 4,3	3,6 / 3,8	3,4 / 4	4,2 / 4,5

It is worth pointing out some important points about teams T1 and T6. The first was strongly impacted by the PM abandoning the project at the 3rd Status Report meeting (final delivery) after his performance had been rated by his team as unsatisfactory in the 2nd evaluation of performance. This result shows the importance of evaluation in pairs to give evidence of the performance of everyone in the team. The second point arose from the team which had high maturity in Performance but a poor performance in content. This impacted the performance of the perspectives of Process, which in this case was associated with planning and monitoring the project, which requires an understanding of PMBOK techniques.

5) Client Perspective:

Finally, the evaluation of client satisfaction was based on the following criteria: projection of confidence in interviews; understanding of the problems; clarity of presentation; quality of the solutions proposed; level of planning. This assessment used the same value scale as the perspectives of Process and Output, and was conducted by the teacher and the PBL tutors together, the client of the solution being present in the monitoring meetings (Status Report). Figure 7 shows the

results of the teams in this perspective. Looking at the graph in Figure 7, we see a direct relationship with the teams' performance in the perspective of Output.

It is worth mentioning, that the involvement of the real customer in the evaluation process is crucial to the PBL approach, given that the stakeholder who will benefit from the solution cannot be left aside. This was one of the points that the teacher most worked on after the kickoff of the project: namely, the need to bring the customer to the center of the project, keeping him/her continuously close to the processes and validating each stage of the project with him. This reinforcement led to greater performances throughout the project in this perspective as shown in Figure 7.

Fig. 7. Evolution of the perspective of Client Satisfaction.

B. PBL Evaluation

To evaluate the degree of PBL maturity in the course, in accordance with the proposal described in [9], the PBL-Test was applied at the end of the 2nd module. The objective of this application was to check for possible deviations from PBL and fix them in time for the 3rd module. The PBL-Test was taken by 28 students, which was therefore a representative total of more than 80% of the class. Table V shows the results of the evaluations.

TABLE V. RESULTS OF THE PBL-TEST.

PBL Principles Evaluated	Average
1. Problem (s) is at the core of the educational proposal.	0.88
2. Learner is the owner of the problem.	0.79
3. Authenticity of the problem or task is evident.	0.93
4. Authenticity of the learning environment is evident.	0.77
5. Solving the problem drives the process.	0.91
6. Complexity of the problem or task reflects the reality of the market.	0.93
7. Evaluation and analysis of how the problem was resolved follows the methodology	0.79
8. Reflexion on the content learned and the learning process is regularly and continuously made.	0.93
9. Collaborative and multidirectional learning takes place continuously.	0.96
10. Continuous Assessment takes place.	0.98
Overall Average:	8.7

In accordance with the proposal of the PBL-Test, each principle evaluated can receive a maximum value of 1.0, so the

total assessment can reach a maximum of 10 points. In [9], the authors define a maturity scale for PBL: *Level 0 - Insufficient* (overall average <7); *Level 1 - Initial* (<= 7 overall average <8); *Level 2 - Satisfactory* (<= 8 overall average > 9); *Level 3 - Good* (<= 9 overall average > 10); *Level 4 - Excellent* (overall average = 10).

From the results of Table V, we found that the PBL maturity reached level 2 in the overall average, representing the satisfactory level. Note that Principles 3, 5, 6, 8, 9 and 10 were very close to the maximum value. It is noteworthy that with regard to the Principles of lower values, little could be exploited by the teacher and tutors because these Principles related to the students' profiles and the limitations of the academic environment. As adopted action, we draw special attention to face-to-face feedback given by the teacher and technical tutors at the end of each monitoring meeting. The objective was to explore the reflection as to the solutions that the teams had adopted.

C. Final Assessment of the course

Finally, at the end of the course, a final assessment with the class was conducted in order to evaluate two aspects: the teacher's performance and the planning of the discipline. We adopted the same value scale as that for the perspectives of Process and Results. In this evaluation, 17 responses were received, representing a little more than 50% of the class.

Regarding the aspect of the Course itself, the following criteria and respective results were considered: Approach of the topic (4.2); Bibliography provided (3.8); Presentation of the Objectives (4.3); Achievement of Objectives (4.1); Contribution to the curriculum (4.2); Contribution to the training of the student (4.5); Development of critical capacity (4.3); General evaluation of the course (4.5). As to the aspect of Teacher, the following criteria and results were obtained: Presentation of ideas (4.3); Coherence of content (4.4); Mastery of Content (4.6); Relationship between theory and practice (4.4); Incentive to students (4.4); Method of Evaluation (4.0); Empathy and ethics (4.7); Teaching methodology (4.4). As a strength, the practical approach of the course which focused on real problems stood out. As points for improvement, the following matters were raised: evaluation centered only on content in the 1st module; extensive content and lack of revision sessions before the tests on content. Both in the evaluation of the course and of the teacher, the results of this evaluation showed that the students considered the course worthwhile, most results being between "Very Good" and "Excellent".

V. CONCLUSIONS

The NEXT group has been working with PBL in teaching software engineering for more than seven years. Given the many challenges of the first PBL applications in a professional master's degree of the area [2], the group's constant concern was to systematize the approach in methodological elements that improve how they are understood and adopted, while being supported by management processes and techniques. Throughout this period, and after the processes had undergone several cycles of evolution, xPBL was applied in a complete PBL cycle (planning, implementation, evaluation and

improvement) in the context of this article, unlike the case study reported in [1], in which the xPBL is formally presented.

It is also pointed out that it is the evaluation procedures that enabled us to prove our objectives were reached. Based on the five perspectives of authentic assessment, the performance of the students could be evaluated in different aspects in the PGP course. The evaluations of Content enabled the concepts and fundamentals which the students had greatest difficulties with to be identified. The Perspectives of Process, Result and Customer Satisfaction allowed the teams to be analyzed, thereby identifying the groups with greatest maturity in the process of planning and project management. The evaluation of performance allowed an individual look under interpersonal skills that, in general, are developed in PBL-based teaching approaches and, to some extent, led to collaboration between members of the same team being perceived. The evaluation of the PBL-Test allowed us to check throughout if we were really heading in the right direction. Finally, the final evaluation showed the students were satisfied with this discipline.

Abstract— When first introducing PBL into a traditional teaching environment, several problems tend to arise. Not changing the structure means that first PBL experiences can only be carried out by a small group of instructors. The use of technology, teamwork methods, and the sharing of individual experiences resulted in some techniques and ideas to introduce PBL successfully in our actual curriculum. This paper presents an experience using this form of active learning in a subject belonging to our Mechanical Engineering degree, which combines three essential aspects in training students: enabling them to be digitally competent according to the European Union considerations, designing and conducting active learning, and analyzing the students' motivation through their educational process. Although the experience was developed in traditional designed environments, ITs were used to ease the collaboration between students.

Keywords—Digital Competence; Problem Based Learning; Hypervideo; Motivation; Educational Innovation

I. INTRODUCTION

Higher education institutions should consider three key factors linked with today society's challenges: Firstly, the role that digital, audiovisual and communicative skills have in the education of future team-working, critical thinking, communicating and knowledge-building individuals. Secondly, the exponential reduction in costs to produce audiovisual contents caused by technological improvements during last decade. And finally, the introduction of active learning methods like Problem Based Learning (PBL) in opposition to traditional learning [1].

As a result of the technological changes occurred in recent years due to the massive use of social networks and Web 2.0 tools, the European guidelines suggested that students must assume an increasingly active role in the generation of knowledge and the exchange of digital contents during their daily communicative processes. This idea is linked to the concept of digital competence [2] and universities, as social and academic institutions should integrate these changes into their educational and communicative practices. Thus, real life learning processes must integrate digital competences.

Some researchers argue that technology can support the building of knowledge if students learn *with* technology rather

than *from* it. Learning *with* technology implies that students acquire knowledge when they are actively engaged in designing, creating and communicating technology-based products. When students learn *with* technology, they change from being learners to designers, and from knowledge users to knowledge builders [3].

In Europe, the Bologna process has been an opportunity to introduce active learning in higher education [4], but this idea is confronted against the difficulties of a change process: the changing of long-established learning processes requires great effort by academic staff and students [5]. In a first step, it is usual to find some interest in problem-based learning. This permits to introduce active learning methods like PBL into individual subjects, even when most of the academic staff simply rejects it. This results that in early stages active learning uses to be adopted with insufficient resources [6]. An important issue when implementing PBL individually is being able to facilitate each group, what usually leads also to adopt a *wandering* facilitation model [7]. This requires the facilitator to rotate between groups, adjusting the time spent with each of the groups according to their needs. In this case, communication processes can be supported and empowered by using digital technologies.

This paper presents a student-centered experience, which is linked to this approach in the adoption of PBL. Starting from challenges and problems, students provide solutions and teamwork creating knowledge. Students use different digital tools not only for searching and filtering information, but also create training materials and present their solutions and conclusions. Interactive audiovisual tools ease the exchange of information between the students and the teacher, and improve motivation and learning quality [8]. This contributes to the development of digital competences as it was established by the guidelines of the European Union [9].

This study is part of a wider study that evaluates the impact that the digital tools has on university teaching and students' motivation by using active learning methods.

II. COMMUNICATION AND CREATION OF KNOWLEDGE

A. Background

The European Union, the Council of Europe and the United Nations (UN) have all invested a great deal of effort in order to move towards an educational model that promotes students'

interactivity. This model should improve the students' critical thinking skills into a collaborative and participatory audiovisual context. It is necessary to go back to 2006 to find the European Union first publication of certain key competences regarding this purpose [10]. The Digital Competence was selected from eight key competences for lifelong learning, and was defined as *the creative, critical and confident use of ICT for the achievement of goals related to work, employability, learning, leisure, the inclusion and/or the participation in society*. The Digital Competence is also a cross competence that eases the acquisition of other competences (e.g. linguistic, mathematic, learning-to-learn, cultural and artistic skills) [2].

B. Digital Competences

The rise of social communities designed to promote the massive exchange of digital information, and the evolution of specific devices that facilitates this task, has created a new communicative scenario [11] where the interaction in the process of creating knowledge is essential, especially to future generations. These new generations will develop a great part of their social skills into these contexts, and will learn at the same time. For a decade, there has been talk of concepts aimed at a new typology of users of these communicative networks: the so-called digital natives [12], or the relatively old label, the NET Generation [13]. There is a clearly defined line where 1982 has marked a milestone in the "natural digital competence" of citizens.

Creating audiovisual contents without a specialized technical and human support was inconceivable just a decade ago. Nowadays, anyone who has access affordable technical resources (computers, mobile telephones, cameras, internet, etc.) is capable of generating audiovisual materials in an autonomous way and of disseminating immediately. This change into social communicative possibilities creates the necessity of audiovisual alphabetization for students. Educational institutions, should assume a more relevant role in this respect [14]. An important concept related to this is self-learning, which emphasizes the idea of students as builders of their own knowledge, based on the importance of their interests, concerns and existing knowledge to build new knowledge, which has been gradually incorporated as an alternative to the classic model of education [15]. This trend is a consequence of the consolidation of the main ideas of the constructivist theory of learning [16], whose fundamental premises were reflected in the Bologna Declaration in 1999. This declaration established an educational model that defines the European education and is based on three essential approaches: the importance of attention in the process of learning against teaching, lifelong learning against terminal learning, and the role of the teacher as a facilitator of competences against broadcaster of contents. In the educational context, interaction determines if the relationship between students, teachers and the environment [11, 17] is more or less active. According to the constructivist theory, it is considered that knowledge is acquired when a person interacts with an object –Piaget–, with other people –Vigotsky–, and when it is significant for the subject –Ausubel–. In short, a higher interaction of students increases their motivation, and therefore creates more significant, detailed and real-world learning [18].

In addition, the rise of the information and communication technologies (ICT), especially the audiovisual promoted educational actions that help students to generate critical thinking skills and not only a certain technical skill. For this reason, in recent years audiovisual alphabetization has been considered from different perspectives regarding several competences [2]: digital competence, informational competence and mediatic competence. Due to the terminological chaos found in literature, these concepts frequently overlap and merge. In this regard, Ferrari [2] tries to give a unifying view to the multiple approaches about competences in the universe of the audiovisual ICT, considering digital competence as a general container for the rest of sub-groups. Therefore, we assume that the concept of digital competence or digital alphabetization covers a great number of meanings and contents and thus, it is a multifaceted definition in constant metamorphosis.

C. The value of the audiovisual content

Nowadays, the tendency is to try to create an audiovisual story to express a specific personal idea, according to the author's intention and linked to creative, demonstrative, educational or informational purposes. This message is enriched with multi-channel, multi-modal and digital dialogue, which is fed by the multiple sender-receiver people who are part of the communicative circuit of the "global audiovisual conversation". In fact, if we observe some of the current participatory communication systems, like Facebook or Twitter, it is seen that all of the audiovisual publications are massive copies that come from an original source, which in many cases are anonymous (mostly disseminated without any selectivity or verification of the authenticity of the message by the users).

There is a need for digital alphabetization, not only in terms of learning techniques or controlling new devices that in most cases can be acquired "naturally", but also for the refinement of the notion of assimilation and creation of audiovisual messages by the new generations of students. One of the challenges of this experience is to provide university students with an expressive and analytic training so they are able to give their own vision.

As mentioned above, the so-called generation of "digital natives" [12] has brought a new communicative scenario in which new generations speak a new language while living –in the academic and familiar environment– with digital immigrants, that is, people who, although can integrate and adapt to the use of these technologies, continue to be "immigrants in a digital world", which differentiates them. This represents an important challenge in the area of education [12], since the current student body is not the same for whom higher education system was designed, nor most of the teacher body is adapted to current communicative languages, "fighting to teach a population who speak a completely new and different language than their own" [14].

Nowadays, communication technologies are progressing rapidly and due to their ubiquity, turn master classes [17] into an obsolete pedagogic practice. Students might wonder why they have to take a master class if the information given by the teacher can be obtained from somewhere else. Therefore, a

new figure of the university professor, closely related to the role of “guide”, facilitator of paths, adviser who provides students with information and awakens their curiosity, but always have in mind their learning interests, existing knowledge, questions and searches. However, students tend to focus on the answer, so the challenge in using digital technologies requires make the students to concentrate in the research process.

Obviously, new training designs have progressively emerged focused on facilitating dynamics of collaborative learning and increasing interaction in classrooms. For example, the teacher, without losing academic rigor, ensures that he introduces the contents and information of his curriculum in an effective, intuitive and playful way. Thus, it is the student who demands the acquisition of knowledge in order to successfully completes certain participatory, autonomous and creative “research”.

In view of the above, it is clearly suggested that there is feedback for students: increase of interaction in the classroom and development of audiovisual, informational and digital languages, in such a way that they train in analysis and educational and communicative expression.

D. Hypervideo as a tool for generating knowledge.

All the didactic resources in video format (knowledge pills, video lessons, videoconference, etc.) have a common denominator: they provide a unidirectional message sent from a transmitting source to multiple recipients. The only difference is the use of distinct means: the spoken or written words change and are transmitted into the audiovisual file recorded with the latest generation digital techniques (HD image, inclusion of recent graphic resources, etc.).

However, from the perspective of audiovisual alphabetization and modern pedagogy, the challenge is different: “The person concerned needs to develop his or her mediatic competence interacting in a critical way with the messages produced by others, and being able to produce and disseminate own messages” [19]. In short, the idea is to transform the creation of contents for education, avoiding the concept of the teacher as the absolute protagonist of the resource, and enabling students to integrate as active actors in the generation of audiovisual contents. From a pedagogical perspective, the hierarchical and vertical structure of the teaching-learning process must be replaced with a model where students increase interaction with their peers and teachers. We find two key factors: on the one hand, the need for collaborative, participatory, digital expression in the new generations provided by the new communicative forms, which have been recognized by their pedagogical efficiency; and on the other hand, the technical potential for entering, cataloguing and recycling audiovisual materials created in the context of the teaching-learning process at universities, which facilitate a closer cooperation between teachers and students. The idea is also to promote audiovisuals through the inclusion of hypervideos during the playback of the original video, enriching the video with written information, web links, graphic files, as well as embedding other videos which begins playing at a specific moment in the original video. The authors refer to this product as hypervideo, a term coming from

hypertext, which allows us to navigate “through a file” by using specific hyperlinks that take the reader, in a customized way according to particular interests, thorough a multidirectional navigation by following the different links [20].

Therefore, the user, spectator or creator becomes the protagonist of the viewing process and decides how, in what order and which elements he or she wants to receive, consume or create. And this interactivity provides an added value that a simple playback of a conventional video in the classroom lacks. On a practical level, different ways of creating hypervideos could emerge. One proposal intends to group together all audiovisual works presented by a group of students into a hypervideo and, at the same time, unify all the groups’ hypervideos of a year into a single group hypervideo. From the pedagogical point of view, it allows the implementation of a number of didactic key factors to any teaching-learning process related to motivation, self-esteem, group identity, teamwork, etc.

III. NEXUS BETWEEN PBL AND TECHNOLOGIES

The use of technological tools is increasingly related to the learning environment. Problem-based learning requires smooth and efficient knowledge sharing in order to boost teamwork, mainly when working with the “wandering tutor model”. Indeed, digital tools facilitate collaboration, and provide access to knowledge, situations or elements that would otherwise be unreachable. This idea has already begun rising over a decade ago with the popularization of wireless devices [21]. Within this approach, the teacher has to propose a number of problems or unstructured challenges that act as threads of the educational process. Regardless of the taken approach –problems or projects– the use of the technological tool catalyzes the learning process, boosting and making easier the exchange of knowledge. This makes it possible to combine the development of critical, communicative and teamwork skills with the acquisition of digital skills. Many university classrooms are not equipped to perform comfortably teamwork, however, digital tools allow the use of this learning model even in this kind of awkward spaces (Fig. 1).

Fig. 1. Working with PBL methodology in a traditional environment.

IV. MANAGING PBL EXPERIENCE

A. Previous experiences

We decided to start our experiences with several randomly selected groups of students, belonging to the Marine Engineering degree at La Laguna University. We mixed different me-

thodologies, which allowed us to create customized active learning environments to suit our needs.

Three experiences were performed by the first semester of 2013-2014 course (the corresponding distribution of students and subjects can be appreciated on Table I). These implementations were different according to the subjects involved:

- For chemistry subjects (experiences 1 and 2 on Table I) there were partial implementations, affecting just one matter and a students' experimental group. The approach for this subject, detailed in Mora et al [22], was based on projects aimed to perform experiments at the laboratory. Students familiarized with the concepts needed to perform the final practice by using challenges where students had to research to find creative answers to several questions related to their subject.
- In the third experience a complete implementation was adopted, affecting all matters and every enrolled student. In this case, the approach was mainly problem-based, as students had to create their own material from problems stated along the course, although smaller projects were also developed. Some seminars were also included as a starting point was required for students to be able to address problems and projects.

In both cases, a collaborative work scheme was followed using every technology available for creating, editing and sharing contents. Lecturers who took part in these experiences adopted the role of the facilitators [23] as wandering tutors [7]. Instead of preparing their classes with theoretical contents for solving predetermined problems later, they generated series of open questions as well as complementary activities that served as a guide to students along the search for solutions to the problems stated. Performance was far more active than in a traditional class as an open approach was undertaken, solving issues, generating debates, revising the student's work, etc.

TABLE I. DISTRIBUTION OF STUDENTS ACCORDING TO SUBJECTS

Experience	Subject	Matter	Course	Semester	Total of students enrolled	Total of students involved
1	Applied Chemistry (morning shift)	Density	1st	1 st	156	9
2	Applied Chemistry (afternoon shift)	Viscosity	1st	1 st	42	7
3	Ship's automation & Control	All	3rd	1st	42	42

The organization required working groups with randomly assigned members, excepting the case of the first experience, where students set themselves up at their own free will. The distribution of working groups and technological tools used for the three experiences is shown on Table II. At the beginning, this kind of setup seemed quite chaotic, as students were not used to this sort of teamwork, especially in the third experience, given the number of students. After one week of work, this initial disorganization become 'order inside chaos': in spite

of certain informality inside the classroom, each student knew his responsibilities inside his working group, allowing a much more dynamic setup.

We had to reconsider the study programs for adaptation to our new needs, designing problems and/or projects, and elaborating a list of challenges, guiding questions, open questions, open issues, presentations, etc., which was associated to each matter to allow the acquisition of the needed knowledge and competences by the students themselves while being oriented by their facilitators. We also considered the setting up of the learning environment defining the infrastructure requirements and the technologies to be used mixed with any chosen methodologies, while choosing the appropriate group dynamics.

TABLE II. NUMBER OF WORKING GROUPS AND TECHNOLOGIES USED FOR EACH EXPERIENCE

Exp.	Subject	Total of groups	Setup	Devices used	Technologies used
1	Applied Chemistry (morning shift)	3	Voluntary	Smartphone/ tablets & netbooks	Augmented Reality, Google Drive, Prezzi, YouTube, Moodle
2	Applied Chemistry (afternoon shift)	2	Random	Smartphone/ tablets & netbooks	Augmented Reality, Google Drive, Prezzi, YouTube, Moodle
3	Ship's automation & Control	8	Random	Smartphone/ tablets & netbooks	Google Drive, Prezzi, YouTube, MindMeister, Moodle, Hangouts, Socrative

Following this approach, real acquired competences were fed back so all previous experiences improve the following ones. Into this loop-process, assessment plays a relevant role as it also may be used for determining if the process to achieve the required competences is adequate or not. This is precisely one of the most complex aspects while adopting this kind of methods, as the acquisition of competences cannot be measured just using a theoretical written exam. Anyway, we opine that assessing requires considering both collaborative work and individual competences.

In experiences 1 and 2, the assessment method was not re-designed, since they were limited to a specific matter inside the subject, meanwhile the students were graded following the same criteria as the rest. In the specific case of experience number 3 required the design of a specific rubric which combining an individual exam with those mentioned competences.

It should be outlined that after the learning environment has been designed and started, facilitators' main task is giving support to the students and assess them continuously by using the appropriate tools.

From a teaching point of view, the experience was quite motivating as students become able to handle concepts by themselves applying knowledge otherwise unthinkable, and also completing a real challenge by lecturers involved in the experience.

B. Objectives

This experience attempts to increase the motivation of students while participating and collaborating by using ICTs, specifically those tools for creating audiovisual contents, va-

luing the students' effort during the learning process and the acquisition of competences:

- Working with Problem Based Learning (PBL) in a traditional classroom, where students solve problems and projects proposed by the teacher working in groups, by using a several ICTs.
- Generating knowledge on the basis of the work developed by the group.
- Developing digital competences by using of multiple web tools to generate data, reports, presentations, communications, meetings, etc., and creating at the end of the experience an introductory hypervideo that explains all the work developed in the subject during the four-months period.

Measuring the motivation of students during the learning process permits checking the success of the experience.

C. Description of the experience

The experience was carried out with fifty-five students enrolled in the subject Technical Office/Projects of the mechanical engineering degree of the University of La Laguna. This subject aims to provide students with skills to develop engineering projects and documents. The learning objectives of the subject are: familiarizing with the professional attributions and types of works of an engineer of this specialty, as well as the structure that the engineering projects should have. Most of the contents refer to the technical regulations that affect the different engineering projects and professional case studies.

Before the beginning of the semester of the subject it was planned the learning strategy. The subject consists of twelve topics. The instructor prepared several learning guides according to PBL.

Each learning guide included one or more topics (in case of topics with complementary aspects). The guide listed the learning objectives that students had to achieve and proposed a series of guiding questions and activities:

- A main question aimed to create discussions and thinking about the topic.
- Several specific questions, challenges or problems to guide the students through their learning process.
- An activity consisting in preparing digital shared contents like diagrams, graphics, presentations or even videos summarizing what they learnt.

D. Description of the process

The teacher introduces the learning guide for fifteen minutes. After this, provides learning contents concerning the topic for consultation, study and research. Students have Wi-Fi network in the classroom and can use tablets, smartphones and laptops to work. All students can have access to Google applications (chat, Hangouts, Drive, Docs, Calendar, YouTube), and several educational web apps that to ease collaborative work.

Students work by teams of five. One of the members of the group acts the "management" or coordinator, and has to assign tasks to each member during an initial meeting. All tasks are carried out in the classroom and, when it is required online by using videoconference tools like Google Hangouts or Trello (<https://trello.com/>) and even WhatsApp. A shared folder in Google Drive is shared for each team to keep information and using collaborative documents. During the class, the teacher/facilitator facilitates from group to group and helps students to search for information and also answers questions that arise during the learning process.

Each team prepares their final task during a last meeting in which discussing and sharing what they learnt. Students have also to check if all members achieved the proposed learning objectives. After that, in the classroom and with the supervision of the teacher, students prepare together a document to present the topic. This document is created by using free available apps on the Internet from their laptops or mobile devices. This document can consist in a poster, a presentation, animation, computer graphics, or video. The teacher proposed the students to use tools like Piktochart, Prezi, PowerPoint, PowToon, Screencast-o-matic, YouTube, Dipity, Pixton, among others. Depending on the topic, a different type of presentation was the most appropriate. Students developed digital competences and also communication skills by creating and presenting information.

Each document was shared to the rest of the students via Moodle. Individually, the teacher asked each student to present a brief report describing his or her. The team manager also had to present the minutes of the first and last meetings and make it available to the teacher using shared folder into Google Docs.

At the end of each topic, the teacher carries out a questionnaire through the online tool *Kahoot.it* to ensure that students have reached their learning objectives. Thus, the teacher is able to provide feedback to the students in real time.

As a final project at the end of the subject, each group presented a hypervideo to explain all their work and what they learnt during the whole course. The video uses links to the contents created in order to obtain an interactive video where users can navigate in a multidirectional way.

The hypervideo was created using Popcorn Maker (<https://popcorn.webmaker.org/es/editor/>), a tool from the Mozilla's WebMaker project (<https://webmaker.org/es/>), which allows to create a hypervideo by combining video, audio and images, and embedded websites, among other many possibilities. In addition, the existing hypervideos can be edited to create derivate videos easily (Fig. 2).

V. RESULTS

At the beginning of the experience, the teacher observed that students were not used to work in groups sharing tasks and discussing topics, so it was necessary to give indications on good practices and teamwork practices. It was also necessary to assist on the part of the teacher at technical tasks related to file sharing (Google Drive). After the third week, students were already familiarized with the working method and the teacher could focus on guiding the learning process by

advising on the information they found and how to organize it. All the work shows that students were able to learn all the necessary information for each of the subject's topics. The computer graphics, presentations, videos and other created files have allowed students to acquire the ability to synthesize a large amount of data learned through efficient presentations that organize the information and effectively structure the contents to remember them.

To measure the students' motivation regarding the active learning model used, we used the questionnaire associated to the MUSIC model [24, 25]. This model of academic motivation consists of five components that the academic staff should consider when designing instruction: eMpowerment, Usefulness, Success, Interest, and Caring [26]. The definitions for each of these constructs are provided in Table III.

The questionnaire consists of 26 items that provide quantitative data that students must rate using a 1-6 Likert scale to give their opinion (1 Strongly disagree-6 Strongly Agree). The instructions to administrate MUSIC, inventory items, and key to use them are provided in the User Guide for Assessing the MUSIC Model Components its authors [27].

TABLE III. THE MUSIC INVENTORY CONSTRUCTS AND THEIR DEFINITIONS TABLE STYLES

Constructs	The degree to which a student believes that:
Empowerment	he or she has control of his or her learning environment in the course
Usefulness	the coursework is useful to his or her future
Success	he or she can succeed at the coursework
Interest (situational)	the instructional methods and coursework are interesting or enjoyable
Caring (academic and personal)	the instructor cares about whether the student succeeds in the coursework and cares about the student's well-being

A. Quantitative aspects

Alpha Cronbach (Table IV) rates from 0.74 to 0.89 indicate good consistency of results and they are considered statistically reliable, despite being a small sample (n=43).

The mean values (all are about 5) indicate that students reported high values for the MUSIC model components. These results provide evidence that most students were, on average, motivated while attending the subject. Standard error values obtained in all cases ($se \approx .10$, $p = .05$) imply that student responses have tended to cluster around the average, which corresponds with the idea that their perceived motivation tends to be uniform. In this regard, the subject based on PBL has apparently succeeded at motivating students. We affirm this because the MUSIC model components have served before to predict students' motivation in higher education courses [24].

TABLE IV. CRONBACH ALPHAS, MEANS, STANDARD DEVIATIONS, AND STANDARD ERROR FOR EACH MUSIC MODEL COMPONENT

MUSIC- Model component	α	Mean (Std. Dev.)	Std. Error
eMpowerment	.84	4.95 (0.68)	.10
Usefulness	.89	5.23 (0.64)	.09
Success	.74	5.05 (0.53)	.08
Interest	.85	4.92 (0.70)	.11
Caring	.77	5.38 (0.53)	.08

The distribution of student responses is showed in the box plots, where the behavior of the medians of each of the measured components (Fig.4) is shown. This diagram shows that 50% of students rated with 5 or more all components of the MUSIC model. The lower limit which encompasses 75% of students is above 4.6 in the sense of empowerment, success and interest, and above 5 for the perceived usefulness and care. Only maximum of 3 students has rated abnormally low the different components compared with the rest of students.

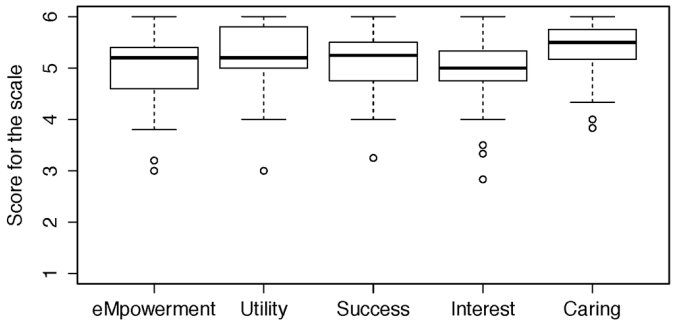

Fig. 3. Box plot. Values for median

The adopted strategy by combining the active learning with intensive use of digital tools has not discouraged students. Although it is not possible to state objectively, in the absence of a preliminary analysis, that it has been the trigger for increased motivation, its effect has been positive as the impressions of teachers. It is possible to affirm from the data that the level of student motivation is high at the end of the course, especially with regard to the feeling of usefulness of learning,

and a sense of satisfaction with the care and attention given by the teacher.

B. Qualitative aspects

The teacher has noted a more pleasant working environment in the classroom compared to the one in traditional methodologies. Students participated in class, and answered correctly the given questions without feeling intimidated. As the course progresses, students tend to work in a more autonomously and require less teacher assistance. Nowadays, the active learning method allows the teacher to have a closer attitude and students see him as a facilitator of learning.

From the analysis of student responses to the open questions given, it has been observed:

- The student feels comfortable working among peers, with his classmates and assigning tasks: "...when you work individually and don't know something, you stay in doubt. But in group, you have the peer support so close".
- The student listens to his or her classmates and learns from them by giving opinions: "...whenever someone did not understand something, we tried to explain among all".
- Students have learnt to discuss and to create the necessary information to obtain knowledge: "...each person brings to the group information that maybe others have not understood or assimilated".
- Students felt comfortable with digital tools to create documents and show information: "Nowadays the use of technology is commonplace and are fun, easy and quick tools for us".
- Students felt free to use smartphones and tablets in the classroom as work tools: "...the technologies are not a *taboo* but a learning method".
- Students and groups shared with each other information and designed ideas using creative tasks: "We used to have small meetings and present our ideas to agree on the different responses to the work".

VI. CONCLUSION

The ability to motivate students is important to achieve the teaching purpose: training students as best as possible. Even if the infrastructure of the classroom is not particularly suited to active learning, fluency in communication achieved with the use of digital tools to facilitate the process. However, digital tools should not be seen as final purpose themselves but as a mean to facilitate communication and creation within learning process.

On the one hand, students have developed their own contents to study the subject using digital tools transversally and transparently. On the other hand, problem-based learning has enabled them to work together so that the final product was not merely a sum of contributions, but the result of work planning, individual effort and an exchange of ideas providing solutions to the challenges and problems proposed.

Students take this combination naturally and, although they needed an initial impulse, they ended up using digital tools transparently embedded in problem-based learning. Despite the initial difficulties, they do not discourage along the course, and maintain a high sense of usefulness of what they learn, feeling supported by teachers.

This type of learning environments allows introducing active learning and working digital skills transparently to the students and teachers. Although it is not the ideal model of active learning, as it is linked to specific subjects and it is not structured along the entire curriculum, it introduces problems based learning into traditional classrooms, and serves as starting point.

Such actions fit with the recommendations of the European Union and the Bologna framework, and are flexible enough to focus the learning process on the students. We hope that the description of this experience will help other teachers and educational consultants to carry out their own educational strategies, and successfully introduce active learning into traditional higher education classrooms.

Abstract—Problem-based learning (PBL) is a well-known active learning approach, and it is becoming increasingly popular in computing. The Computer Engineering undergraduate program at UEFS adopts PBL since 2003. Previous studies thoroughly describe PBL course design and practices, but there is a lack of reports about the teaching experience, i.e., how faculty live the process of teaching PBL courses. Thus, we took advantage of this PBL experience to uncover such issues. We developed an interpretative phenomenological analysis (IPA) to learn the essences of being a PBL teacher, using a qualitative research methodology. Data collection and analysis entailed semi-structured interviews with five UEFS computer engineering professors, interview transcription and memo writing, open coding, code memo writing, code grouping and abstraction, and description of essences. Results led to the following essences: 1) feedback is essential for student success; 2) PBL develops better students and professionals; 3) assessment is complex and multifaceted; 4) developing good problems is a difficult skill; 5) PBL requires strong teacher engagement and background; 6) it is essential to keep a motivating scenario; and 7) good coordination and group dynamics is required. In this paper, we describe the four first essences in detail.

Keywords—PBL, problem-based learning, teaching, essence, interpretative phenomenological analysis.

I. INTRODUCTION

Problem-based learning (PBL) is a student-centered, active learning approach envisioned by physician Howard Barrows, between the 1960s and 1970s [1]. Briefly, PBL is an instructional method that uses a hypothetical case, i.e., problem, to start, guide and motivate learning. In PBL, students are constantly stimulated to learn and take an active role in their learning construction process [2]. The problem is a central element of the approach, motivating study and integrating knowledge. Problems are usually ill-defined: instead of finding one unique correct solution, students understand the problem, retrieve information, build possible solutions, evaluate options, and present results.

Nowadays, problem-based learning (PBL) is an increasingly popular learning approach, adopted not only in medical education, but also in areas such as nursery, engineering, and science [3]. In computing, PBL experience reports have been thoroughly described both in isolated courses and in integrated curricula [4].

Previous studies in computing education thoroughly describe PBL course design and practices on a range of subjects [4], [5]. However, there is a lack of reports delving into the teaching experience. We are especially concerned with a lack of knowledge on teachers' feelings and impressions of the PBL experience, i.e., how they understand, live, and feel the process of teaching PBL courses. Thus, we decided to take advantage of the eleven-year PBL teaching experience in our Computer Engineering program at the State University of Feira de Santana (UEFS) to uncover these issues.

To understand feelings and impressions, the research method of phenomenological interpretative analysis (IPA) analyzes how life experiences make sense to people who live them. In our case, we are particularly interested in the meanings that faculty realize when they live the everyday flow of experience with PBL. Building on this research approach, we decided to investigate how faculty members of Computer Engineering at UEFS live the PBL approach in their everyday lives.

More generally, we developed an interpretative phenomenological analysis (IPA) of what it means to be a teacher in a computer engineering program that is strongly based on a PBL approach. To do so, we used a qualitative research methodology based on a contemporary IPA approach [6]. IPA is useful in this context, since it helps to understand the inter-subjective experience of a small group, reducing their multiple accounts into the essences of the phenomenon. Data collection and analysis was based on Smith's IPA protocol [6].

Results led to the following seven essences: 1) feedback is essential for student success; 2) PBL develops better students and professionals; 3) assessment is complex and multifaceted; 4) developing good problems is a difficult skill; 5) PBL requires strong teacher engagement and background; 6) it is essential to keep a motivating scenario; and 7) good coordination and group dynamics is required. In this paper, for the lack of space needed to describe phenomenological accounts, which are usually deep and thorough, we describe only the four first essences from an IPA standpoint.

This paper is organized as such: Section II provides the background for this work. Section III describes the research methods. Then, Section IV presents our results. Conclusions are derived in Section V together with suggestions for future work.

II. BACKGROUND

Problem-based learning (PBL) is an active learning approach conceived between the 1960s and the 1970s in the Faculty of Medicine of McMaster University, Canada [1]. Idealized by the physician Howard Barrows, it has soon gained widespread adoption in other schools of Medicine around the world. Barrows realized the dissatisfaction of students with traditional lecture-based approaches, in a world driven by an explosion of information resources, new technologies, and growing demands on future physicians and their practices. Later, PBL spread to other educational contexts such as science in higher education [2] and elementary education [7].

In PBL, not only are students constantly encouraged to learn, but also to take an active role in the process of learning construction [2]. A problem in PBL is a trigger to motivate study. It usually follows a learning cycle, repeated for the duration of the problem [1], [2]:

- 1) Students are presented to an ill-defined problem before any preparation or study;
- 2) Students assemble in groups to organize ideas and recall previous knowledge related to the problem;
- 3) Through discussion, students pose questions, known as learning issues, that deal with aspects of the problem they do not understand;
- 4) Learning issues are ranked in order of importance, and students define learning goals for independent and group study;
- 5) Students reconvene to explore previous learning issues, and integrate new knowledge to the context of the problem.

PBL has been adopted in various computing courses throughout the world. A systematic mapping study has found 52 papers that report experiences of PBL in computing. Courses range from software engineering [8], computer programming, software quality [9], and operating systems [10], among other subjects.

In Brazil, the most well-known PBL experience in Computing has been pursued, since 2003, at the State University of Feira de Santana (UEFS). The Computer Engineering undergraduate program at UEFS adopts an integrated curriculum based on PBL [11], [12]. In this program, PBL is adopted in nine integrated courses with core subjects ranging from programming, digital systems and software engineering, to distributed systems, digital signal processing and programming language design [13]. A wide range of experience reports in courses as different as computer architecture [14] and advanced programming [15] have been published in Brazilian conferences on education in computing or engineering¹. Angelo and Bertoni have organized the results of experience reports in the various courses reports in a survey [13].

PBL is an integral part of the pedagogical project of Computer Engineering at UEFS. It is used in a curricular component named integrated study, which takes between 90 and 180 class hours and entails a mix of tutorial groups, lectures, resource meetings, and lab activities [13]. Different subjects are integrated under the integrated study. For instance,

the integrated study of advanced programming joins object-oriented programming, data structures and software design. This structure was implemented in 2003 to reinforce the interaction between theory and practice through a situation–foundation–realization cycle [11].

A tutorial group is formed by a tutor, usually an assistant professor or a teaching assistant that facilitates the learning process, and a group of up to ten students. Two students are initially assigned to work as coordinator and scribe. Sometimes, a whiteboard scribe is also assigned to take notes of group ideas and decisions. Roles are not static, there is usually role rotation between students so that everyone exercises different skills. After receiving the problem, students follow the previously described learning cycle [2], [12].

During the academic term, tutorial groups meet, usually once or twice a week, to perform the activities of a tutorial session. During this session, and following the PBL learning cycle, students read the problem, raise hypotheses and ideas to solve it, describe facts that they know, raise questions about what they do not know, and establish goals for independent study. In the following session, they reconvene to discuss what they have learned, and try to integrate the acquired knowledge to solve the problem. While there are issues still unsolved, students repeat the cycle. The tutor does not provide explanations about the subject. Instead, he or she guides students in their discussion throughout the problem. At UEFS, the PBL learning cycle is explicitly defined by eight steps: starting point, brainstorming, systematizing, question formulation, establishing learning goals, process evaluation, independent study, and follow-up [12].

Student assessment is carried out individually, taking into account both student participation and final product quality, i.e., whether the solution to the problem is appropriate according to established criteria. A final product is usually accompanied by a report. In some cases, after product assessment, tutors may discuss the pros and cons of each student's solution in a feedback session. Later, students return the revised report for a second round of assessment.

The way tutors assess students is continuous and process-based, usually resorting to various types of assessment instruments: diagnostic assessment, formative assessment, summative assessment, peer assessment and self-assessment [12], [13].

PBL has brought various benefits to Computer Engineering at UEFS: students mature both academically and professionally, they gain experience in managing teams, develop abilities of self-criticism, and learn writing and speaking skills [16].

Together with benefits, new challenges arise: the lack of resources dedicated to teachers of computing courses that adopt PBL; difficulties with student participation, especially free riders; difficulties with interpersonal relations between students; difficulties to ensure full participation of each tutor in problem design; and difficulties with administrative support to the PBL approach and curriculum [16]. Nonetheless, regardless of the challenges, most faculty of Computer Engineering at UEFS are enthusiastic advocates of the PBL approach.

¹See the *PBL at UEFS* web site: <http://www2.uefs.br/pbl/>

III. METHODOLOGY

Here we describe the theoretical framework we adopted, research design, participants, and procedures for data collection and analysis.

A. Theoretical framework

This research was developed by means of a qualitative research methodology, which is mostly exploratory in nature. Our goal here is to understand the meanings of lived phenomena in human experience. One qualitative research approach that allows reaching this goal is phenomenological research [6]. Phenomenology allows subjective aspects and implicit or even conscious motivations from individuals' everyday life to emerge in a spontaneous way.

The particular approach of interpretative phenomenological analysis (IPA) and its associated procedures [6] makes it simpler for researchers other than philosophers to reach the essences of a particular lived experience. IPA allows to understand the inter-subjective experience, i.e., how experience lived by some individuals is reduced from their multiple accounts into the essences of the phenomenon. IPA lets the everyday flow of experience lived by individuals be condensed into special meanings to them. In our case, we want to understand what it means to be a PBL teacher in a PBL-based curriculum.

B. Research design

More formally, the main goal of this study was to investigate the essences of the teaching experience for the faculty members of a Computer Engineering undergraduate program that adopts PBL as its main pedagogical approach.

The research questions that guided this study to reach the main goal were:

- 1) How do faculty understand the planning of PBL courses?
- 2) How do faculty perceive the assessment of PBL courses?
- 3) What is the view of faculty about preparing PBL problems/triggers?
- 4) How do faculty understand their conduction of a PBL tutorial group?
- 5) How do faculty provide feedback to students?
- 6) Which perceptions do faculty hold on the advantages and disadvantages of the PBL approach?
- 7) Which difficulties do faculty experience when they offer PBL courses?

C. Participants

The participants of this research were faculty members of the Computer Engineering undergraduate program at the State University of Feira de Santana (UEFS), located in Feira de Santana, Bahia, Brazil. There were five participants: three female, and two male. Participants had from two to eight years of experience with PBL, experience that begun when UEFS hired them. Most of them had previous experience with other traditional teaching approaches (e.g., lecture-lab combinations). Two of them came from the area of electronics, one from networks and systems, and two from software development.

We believe that this moment is appropriate for data collection, since the PBL approach has been used for eleven years in the institution, and it is now routine in faculty's lives. After this period, their feelings about the approach are more consolidated, making it more appropriate to collect information, and providing rich testimonials about their lived experiences.

We limited the number of participants by two criteria: first, we used Smith's IPA protocol of interviewing between five and seven individuals. Phenomenological research requires long and deep interviews, valuing more quality and depth than quantity and breadth; second, after each interview, we asked ourselves whether our questions were sufficiently answered. We ended up with five participants. It is worth noticing that we had two more participants that took part in pilot interviews, but their accounts are not described in the results.

Participants were informed about the purpose of the research, the assurance of confidentiality and anonymity, and their right to participate or not. After these explanations, they agreed to sign an informed consent form. Participants' speeches were identified with codes, starting with the letter R, and followed by sequential numbers from 1 to 5.

D. Procedures for data collection and analysis

We used semi-structured interviews. This choice was made because they are flexible, but still keep important topics in mind. With semi-structured interviews, participants can freely reflect on a theme, object or concept. They let subjective aspects and motivations, either implicit or explicit, emerge. Furthermore, they are also the main data source in interpretative phenomenological analyses.

We started with an interview guide, which was validated in two pilot interviews with two other faculty with PBL experience. Pilot interviews let researchers check whether interviews have: reliability, which is getting similar results, regardless of who interviews; validity, which is examining whether all the needed data is collected and no important data is left out during collection; and operability, which is verifying whether the vocabulary is accessible and the meaning of each question is clear. After the pilot interviews, we updated the interview guide to improve data collection in the next phase.

We scheduled interviews at UEFS, according to participants' choices of data, time and place. This let them at ease to answer the questions without external interference. Respondents answered questions freely in a time interval between 55 minutes and 1 hour and 20 minutes. We let respondents spontaneously express their thoughts and experiences, avoiding interrupting them or intervening in their speech.

The process of data collection, transcription, coding and analysis followed a mix of Smith's protocol and our own experience with qualitative research:

- 1) Perform interviews (ours lasted between 55min and 1h20min);
- 2) Write interview memos right after the end of each interview, to collect first impressions;
- 3) Transcribe interviews;
- 4) Code the interviews with open coding (which led to 440 initial codes, in our case);

- 5) Write code memos, to sketch an initial interpretation of lived experience;
- 6) Abstract codes in a second level, observing relationships between codes and participants' speeches, and group codes by their common features (at this stage, we found 170 categories);
- 7) Abstract the essences of lived experience (in our case, seven relevant themes);
- 8) Report the essences first as draft memos, then as rich accounts after thorough rewriting.

IV. RESULTS

Here we describe the essences of being a PBL teacher in Computer Engineering at UEFS, uncovered by interpretative phenomenological analysis. In short, the essences uncovered were:

- feedback is essential for student success;
- PBL develops better students and professionals;
- assessment is complex and multifaceted;
- developing good problems is a difficult skill;
- PBL requires strong teacher engagement and background;
- it is essential to keep a motivating scenario;
- good coordination and group dynamics is required.

In this section, we thoroughly describe the four first essences, using an IPA reporting approach [6]. We decided to report only four essences mainly for lack of space. The essences presented here were chosen because of their frequency in faculty's accounts. Qualitative research reports demand accounts that are thorough and deep, and it is sometimes better to report less results in deep than more superficial results [17]. It is worth noticing that the interviews were conducted in Portuguese, while accounts are described here in English.

A. Feedback is essential for student success

Feedback is an important tool in the teaching-learning process. Students accept feedback well, as this contributes to their knowledge acquisition. Teachers use some feedback forms, and the most used are: session feedback, performance feedback, report feedback, problem feedback, group feedback, and individual feedback. The timing for feedback is also crucial. Teachers can feel this timing by observing class evolution.

To Hattie and colleagues, effective feedback must answer three questions posed by teachers and students: *Where am I going?* (What are the goals?), *How am I doing?* (Is progress developing toward the goal?), and *Where should I go?* (What activities should be done to improve progress?) [18].

Feedback is an integral part of the teaching-learning process, which guides students to behave and perform according to given requirements, and lets them know how they are being seen and assessed by teachers. Lack of feedback leaves students lost, not knowing which way to follow. Feedback can be seen as a compass, giving the north to achieve the goals. *"I think that feedback is essential[...] for learning.*

The student that takes advantage of this feedback, he has a possibility to learn much more." R2; *"[...] at each session, it is necessary to give feedback and this is important so that they can evolve . [...] from feedback, the student can improve the weak points[...]"* R3; *"If there was no feedback, it is like the problem has not existed, like no knowledge has been produced here [...]"* R4; *"[...] the feedback, I think, is one of the most important things of any approach [...]"* R5; *"[...] read what you wrote, see if a person that reads this text for the first time knows what you're talking about, see if she can understand what you say, then I always bring this feedback [...]"* R1.

Performance feedback is aimed at reorienting or stimulating future behavior. It is also used to maximize the performance of an individual or a group. In the learning environment, feedback is very important because it motivates students to perform their tasks more productively. If a student gets faster feedback on something he or she is doing, accomplishments come earlier. The knowledge acquired by students needs to be consolidated somehow, and this is possible when the tutor situates students, showing where they are hitting or missing.

The feedback that teachers provide gives students a parameter of development. The sooner they are given feedback, suggestions or criticism, the easier students take them more constructively. Generally, students have a good acceptance of feedback provided by the teacher. *"[...]the reactions are varied, then, you know, I think, in general, they accept the feedback well. I keep putting myself in their place, I would accept well because I think everything we receive from criticism even being ... let's say negative, it is being part of our development. Then, in general, apparently yes, but I'm not sure..."* R5; *"I get this feedback from them, and then I later try to analyze what is not going well[...]"* R4.

A technique used by teachers is to hand out an assessment form to students. With the form in hand, students perform self-assessment. At the end of the session, the teacher collects the forms, compares them to the performance grade they had given the student, and provides feedback about it, especially when there are discrepancies.

For the teachers, conveying a correct and assertive feedback requires understanding the student who receives it, the way he or she interprets the message, and also adapting it to particular situations. To assist in this task, teachers use some ways to provide feedback: session, performance, report, problem, group, frequent, generic, individual and technical feedback. In any way, the truth is that feedback is essential for students to produce their results and remain motivated. When the teacher takes a stance of not providing feedback, he or she is depriving students of the opportunity to improve their performance. *"I have been in sessions where some tutors spend three or four sessions... Ask the students: and then? They say: I don't know. How is PBL? I don't know. Because they don't know, like, if it's going well, if it's going bad, if he's learning something, if he's not learning anything, because feedback is not given to them..."* R2.

At the end of each session, the teacher conveys students the issues to be improved. *"[...] session feedback, and then I always prefer doing it at the very end of each session [...] depending on the session, that I need to speak another ten minutes at the end of the session, to give that feedback [...]"*

in general, this session feedback, I try not point issues very individually, unless I can do that with everyone. And if I can't do it with everyone, then I prefer to speak more generally [...]" R1; "You give a negative feedback, in the next session they know what they need to improve, then you can give feedback in each session[...]" I have a feedback snapshot from each session, in each session I know what was his evolution, and then I take notes of his performance at the end of the session [...]" R3.

Session feedback enables students to realize, in time, which aspects they need to improve for better group dynamics. This is done gradually, in each session.

For performance feedback to work well, people involved in the process need to understand the real meaning of the feedback word, which is positive, an information that serves to evaluate paths and results. Feedback should always be rewarding, never punitive. Whenever punitive, it loses its educational condition and mischaracterizes its function. To apply feedback in its entirety, it is important to note the role of communication in the process, because it is through appropriate communication that feedback information flows. *"I have some students, this repeats almost every term, who kind of wait for this feedback, they like to know their performance, because they want to, they try to do something to improve, and they always want to know if I realized that they improved [...]" R1.*

Students look forward to receiving feedback: they want to know their learning progress, and which way to go. To make it work, though, it is important to be open to criticism and understand that criticism is focused on improvement, and that feedback is one of the most important steps of performance assessment. Thus, for those who receive feedback, it is important to learn to listen to criticism, as well as to reply to the teacher whenever something was not made clear or was not fully understood.

Reports are a form of assessment that the teacher uses to determine both the student's writing competence and his or her ownership of ideas in the problem solution. Right after correcting and grading reports, teachers give feedback. Students, then, learn from this feedback. *"I give feedback on the report, I prefer that they deliver me the printed report, because then I take notes, I sit with them, ask for their notes, discuss the notes with them, show the weak points, and the same thing for the presentation of the problem [...]" R3.*

When the teacher provides feedback, also provides students with a metric of their educational development. Reports are assessed for criteria such as text consistency and cohesion. This enables students to mature their writing.

Providing feedback as fast as possible is important in the teaching-learning process. Students need to have enough time to overcome the difficulties pointed out by teachers. *"[...] I tried, if I could not finish the grading, then I would tell them, but I would tell them in the next class, but I think you lose something, the best is when you can finish it in that class [...]" R5; "I give feedback at the end of the problem. When the problem ends, I give this feedback..." R2; "I do it as soon as possible, like, the student gave the final solution, at most one or two weeks after that, I give this feedback..." R4. "What I've been trying to do, and I do it until the end of the term, is: every session I do session feedback, and I always do it [...]" R1.*

It is important to reflect on what students should be told, and to provide concrete arguments when giving feedback. Finally, it is essential that the teacher create room for a frank dialogue and provide the appropriate feedback. That means establishing an environment of trust, discussing the issues, the pros and cons of the student's performance and products. Ideally, feedback should be given in each session, but this is not always possible, since it demands time. Some teachers give feedback at session beginning, which gives students the opportunity to see where they are missing and focus their efforts on their weak points. Some other teachers prefer to give feedback at the end of the problem or at the end of the term. This timing is useful for the teacher to have a broader view of the student's profile, to provide feedback with no influence of the student's behavior in a given session.

B. PBL develops better students and professionals

The PBL approach allows students to develop professional life skills. Skills of written and spoken expression, group management, independent work and learning how to learn: all of them develop a style of entrepreneurship strongly valued by the marketplace, easing the process of graduates adapting to professional life.

Some people develop capabilities of spoken and written expression easily, almost as a gift. Nevertheless, for most people, expression in an adequate professional manner is a constant exercise that involves factors such as role models, environmental stimuli, and, of course, practice. *"I clearly realize their resourcefulness to speak, to participate, this influences in class [...] students will also be more prepared to develop further research without forgetting that side, for example, of an oral presentation, got it?" R1.* When students take part in a PBL tutorial group, they develop their orality, diction, and cognitive abilities, skills considered relevant in a competitive market.

Student skills are stimulated with PBL dynamics. Students fulfill different roles such as coordinator, scribe or participant. Role changing allows fostering latent skills.

Nowadays, information is present in different forms and sources. In an environment of information overload, knowing how to search, interpret and transform information into knowledge is essential. PBL students search information to autonomously solve problems in various spheres. *"[...] I hear of the students who have already graduated, how much they are well regarded in the market for their ability to run after things [...]" R1; "[...] you realize that students... they learn to solve problems or they get better at solving problems [...]" R2; "One of the main advantages is the autonomy to solve problems, I think it shapes a lot the profile of the student who learns through PBL [...]" R4.*

Observing the development of those skills in PBL group sessions leave faculty satisfied and professionally accomplished. *"Look, I feel motivated because sometimes I am surprised by the ability that a student like this has, for example, when he faces an unknown problem, you know? So, sometimes you think the problem is going to be complex, is going to be difficult at first, but then, in the brainstorming of the first session, students already have some very interesting ideas ..." R2.*

Developing a clear, consistent and cohesive prose is a skill better accomplished by stimulating both reading and writing. In PBL, students are encouraged to write most of the time. They constantly write reports at the end of any problem. They deliver their reports to the teacher, who suggests corrections to their written text. Since there is continuous evaluation, students are able to develop or enhance their written expression along the PBL courses. “[...] first report, it may not do very well, but during the work that is being done, in the last one, his result is already better... I believe there is an evolution in the report writing process” R3; “Another interesting issue, I do not know if it is in our PBL here, or if it’s related to PBL in general, but the ability to write better...” R4; “[...] we ask for reports, it can be in the student report format, or in a paper format, so, besides the skills of speaking, clearing doubts, researching, learning on his own [...]” R5.

In tutorial sessions, students choose roles to fulfill (or have roles chosen by their tutors) in the group. The role might be of coordinator, scribe, whiteboard scribe, or simply a regular participant. Those roles also influence skill development. “they are encouraged, and in various forms, including grades, to participate in the discussions all the time, to position themselves” R1; “we can already identify students who have the leader profile ... you realize with the students that he has more of a leadership profile” R3; “exercises a bit of leadership, since he performs activities as the PBL coordinator” R4.

Learning through an approach that lets them experience some issues they will face in their future jobs helps students to develop skills required in the workplace. “[...] you can see students quietly advancing after they leave university and move to the workplace with no issues. [...]” R4.

Teachers feel that the professional accomplishment of most PBL students is a consequence of the approach. With PBL, students are constantly searching for solutions to the problems that teachers propose, which gives them a glimpse and a feeling of being in the workplace. “With regard to learning, and that I hear of students who have finished our program, how much they are well regarded in the marketplace for their ability to run after solutions [...]” R1; “[...] a student that will develop this resourcefulness, I think then he will be more prepared for the workplace[...]

R2. Developing a student’s potential depends on the teacher knowing the right moment to speak or to silence. This balance is usually linked to the teacher’s profile and his or her command of the PBL approach. “When I’m guiding the PBL session, I want to extract the maximum potential of each student” R4; “So the goal is that everyone tries to strive as much as possible in solving that problem” R4; “Sometimes he thinks he did nothing, but did something... Try to explore this knowledge to the maximum, so he produces.” R4.

C. Assessment is complex and multifaceted

Assessment is the process teachers use to better understand the level of competencies (knowledge, skills, and attitudes) acquired by students as well as to perceive the effectiveness of the teaching-learning methods and educational activities performed. Thus, the act of assessment, although complex, is essential. PBL teachers feel that, in the approach, assessment

is fair and thorough. On the other hand, it involves issues that make it difficult for the teacher.

Assessment in PBL is complex because it involves, among other factors, subjective issues. Each student is different, and those differences influence how he or she develops competencies. For such reasons, assessment has a high degree of complexity, and should be done carefully. “What? Assessing is easy? Assessing is so difficult [...] the PBL model is well defined, but the assessment, for being individualized, is a lot of work [...]” R1; “[...] assessment is complicated, it is not so trivial [...]” R4; “[...] the PBL approach, I believe it gives more work than the traditional teaching. If you do the PBL approach as it should be done, it demands more time, but it’s more pleasant, I see you’re really assessing the individual.” R3.

Assessment requires perceptions and sensibility from the teacher that go beyond the classroom. Subjectivity of the assessment makes it a complex task to accomplish. “It is not an easy task [...], because not everyone feels comfortable to be evaluated, [...] is not easy you get to them and say this: you didn’t reach the top. Oh, you didn’t research [...]” R3; “[...] sometimes the student begins very well, then he disappears, then another student gets well, and after a while he disappears as well, then both reappear, then, this way it’s very difficult[...]

R5. If the tutor participates in excess in the tutorial session, it complicates the assessment process, because one does not know whether the students were able to build knowledge or just superficially reproduced what was conveyed by the teacher. “As I told you, I have given PBL courses several times, and I don’t even feel the tutor I’d like to be, and sometimes I have a little trouble with the issue of assessment.” R1; “Excessive tutor intervention makes it difficult to assess.” R3.

Internal and external factors directly influence student learning. Thus, assessing is not a trivial process. Since assessment is a subjective act, every individual has his or her own way to see, feel, and think things out. Fully capturing those factors, making them concrete, and transferring them to objective criteria is a difficult task to accomplish. “[...] however much we try to monitor development, we can’t be sure that that student built that product alone [...]” R1; “[...] So this subjective assessment is hard, and it there has to be some mechanism to try to validate your thinking [...]” R4; “there’s the performance grade, that we try to give every session, but, of course [...], there is the issue of subjectivity ..., of your assessing student performance [...]” R5. “[...] it [assessment] is much more complete, [...] it is, say, a continuous evaluation, it is not a one-time assessment as in traditional approaches [...]” R2.

In an educational context, it is essential to stimulate students. One way to do so is building learning activities by means of challenges. The problem, a motivating element, is an essential tool in knowledge construction. We know that the student’s learning capacity depends on his or her maturity. However, it can be stimulated by means of challenges. “There are goals for every tutorial session, and they know they have to meet them to reach the evolution, the conclusion of the product, you follow the whole process.” R3.

Self-assessment is well regarded by students. It aims to

measure whether teacher assessment is balanced with students' perspectives. "[...] sometimes you can't do it in every session, but I try to assess and ask for self-assessment [...] for they realize from the start where they need to improve [...]" R3; "[...] I prepare a student assessment form, throughout the term this form is with me, and at the end of the sessions, I give my grade and ask them to self-assess [...]" R4.

Continuous assessment allows for a contextualized, flexible and interactive educational practice. The disadvantage of continuous assessment is its subjectivity. It's hard to turn the participation (or lack of) in a tutorial session into something tangible. However, students need to learn their strengths and weaknesses.

Assessment in PBL tends to be fairer than in a lecture-based approach. The fact that classes have fewer students positively influences assessment, because the teacher can monitor students more closely. "[...] I feel that it is an assessment a little more fair [...]" R1; "[...] so they do not discuss much when they see what they did, and if you justify, they don't feel so wronged [...]" R3; "I think that [...] looking at theory and PBL, I think I'm more fair in the PBL grade, because I can get closer to the student, I have more data to assess him, I have his performance [...]" R4; "[...] class of forty is impossible, there is no way you can do it, you could even try, but you couldn't be fair in the assessment [...]" In more traditional teaching, classes are generally composed of a large number of students. This prevents the teacher to make an assessment as fair as in teaching with PBL, which has smaller classes" R5.

Assessment is regarded as one of the most important tools available to teachers to achieve the main goal of the teaching-learning process. In other words, it is important to find ways to assess student learning and offer alternatives for safer student development.

D. Developing good problems is a difficult skill

The problem (or trigger) is the motivating element of PBL approach. However, there are factors that make them hard to develop.

A problem in PBL should be motivating and clear, and should mirror problems found in the marketplace or related to students' daily life. "[...] you think about various aspects related to problems. First, which knowledge will be required of the student for him to evolve [...]" R4. It is important that the teacher estimate the time to solve the problem and relate it to problem goals and content coverage. "[...] measure time against goals that must be met... don't give the solution for free, but don't leave anything too obscure to the point of being awfully unclear, and measure the time for the solution. I think those are the main challenges I see [...]" R1.

The process of developing problems that are motivating and similar to those found in the workplace is a difficult task, even though it is feasible. Teachers usually come together and create situations that subsequently turn into projects or problems, but those problems are not stored in a shared database. "We don't have a problem database, by the way, it was something that a teacher reminded this term, [...] we have so many problems already developed, and maybe we could recycle some old ideas that were good, that worked, and it's a waste we use the same

idea only once..." R1; "[...] each term it's a new problem, there is no problem database. Each session is a new problem..." R3.

Designing problems is not trivial. It requires dedication, knowledge of the topic, and the affinity to write ill-defined problems with the features required by PBL. "There are situations that students interpret in a different way, and it's part of the preparation of the problem, your leaving it a little open, I can't leave the problem completely closed, I have to leave it a bit open..." R3; "...I think I've never been that good to develop these PBL problems, it's a great difficulty [...]" R5; "[...] preparing the problems, I think it's a task that requires a lot of the tutor" R4. The PBL problem is characterized, therefore, as a trigger to encourage students to develop critical thinking and problem solving skills.

Students who are able to finish the activities before the deadline can be bored with tutorial sessions. In this situation, the teacher should motivate them by using methodological devices. "[...] it was a challenge because there is no way they do not get a little discouraged, so I tried to say so – ah, shall we will try to improve your work? How did you do it? Then I tried to bring them into discussion, so that he contributed to those colleagues who hadn't finished, but at the same time they said so – ah, I have to go there just to clear doubts of the others, and mine is already done, so I tried this balance, but it's hard..." R1. Estimating the time students will take to solve the problem is difficult as well. "[...] I had no idea how long students took to advance through each step of the problem. Neither to measure what to ask, how long it would take, and how long they should take to solve the problem... so that was a big challenge to me [...]" R3.

The problem is an integral part of the PBL approach. Since the problems integrate knowledge and are usually multidisciplinary, it is important that at least most of the teachers take part in this task, either writing or reviewing the problem, and discussing how it unfolds in the tutorial groups. "It is important that problems are discussed among tutors before they are submitted [...]" R2; "Because when we prepare the problem, we think about the goals, which contents I must address according to the syllabus, then which contents I should address here, [...] the initial idea, and prepare the problem, and everything together..." R3.

A problem is only considered finished when students receive feedback. This lets them know where they performed well or poorly. "[...] a problem only ends when students receives feedback from the tutor..." R4.

V. CONCLUSIONS

In this work, we performed an interpretative phenomenological analysis (IPA) to learn the essences of being a teacher in a problem-based learning (PBL) approach. Results led to seven essences, related to feedback, professional skills, assessment, problem design, teacher engagement, motivating scenarios, and group dynamics. Here, we described the four first essences in detail.

From the faculty point of view, we could better understand what it means to be a teacher in the active learning approach of PBL. Teachers revealed a strong difference between a lecture-based approach and PBL: instead of valuing content knowledge

and memorization, PBL values critical thinking, logic reasoning, reflection and real-world problem-solving skills.

However, PBL is not a silver bullet for all this illnesses of present-day higher education. It does not offer a satisfactory learning environment for each and every student. Students have different learning styles, and some may not adapt to a collaborative learning approach. Moreover, for being a student-centered approach, PBL requires teacher engagement and training. The approach also requires some extra hours of dedication and this may impair other faculty activities such as research and publications. However, less need to prepare lectures can make up for this additional time.

From the results, we were especially struck about the power of feedback and the value it has for students. It allows better follow-up and interaction with the teacher. With various feedback milestones, PBL lets students reflect on and evaluate their practices.

PBL promotes skills of group work, and it also stimulates individual study, according to students' interests and individual pace. Thus, it develops better students and professionals. PBL actively engages students in a process of teaching and learning, with the knowledge being constructed through collaborative work and discussion.

Results also suggest that PBL contributes to increase faculty satisfaction with teaching activities, stimulating their professional development by means of intellectual challenges posed by students in tutorial groups.

This research provides a reflection on the teaching process in the PBL approach. A major challenge consists of learning to read between the lines, looking at the details of a teaching approach in its everyday practice. We believe that IPA helped to achieve this goal, and that it is a suitable research approach for uncovering the essences of teaching experience.

Further work should deal with additional analysis and reporting of the additional three essences not described in this work: PBL requires strong teacher engagement and background; it is essential to keep a motivating scenario; and good coordination and group dynamics is required. We also intend to perform an IPA with Computer Engineering students that live the PBL experience. It also seems interesting to contrast the essences uncovered in this work with the conclusions of the case reports produced and published by UEFS faculty.

Is Video Feedback More Effective than Written Feedback?

Spencer Hilton, Brian Rague
Department of Computer Science
Weber State University
Ogden, Utah
spencerhilton@weber.edu

Abstract— As online multimedia options grow, instructors have more diverse and interactive choices to deliver feedback for student assignments. In this paper, the authors compare the effectiveness of using screen recording software to provide video feedback on programming assignments versus traditional written feedback.

A Fundamentals of Programming class of 38 students was randomly divided into two groups. Throughout a 15-week semester, one group of students was exclusively given feedback via video and the other was exclusively given feedback via text. For the video feedback, the professor displayed the individual student program and discussed in detail any design or syntactical errors found in the code. For both groups, the authors tracked the scores on each assignment for each student, as well as the time it took to grade each assignment, which included video rendering time for the group receiving video feedback. A survey was also administered at the end of the semester to gather feedback from the students.

The results of this study are analyzed and presented in order to determine which method is more effective. The results from the survey administered to the students who received the video feedback are also included.

Keywords—*grading; feedback; video; written; effective; survey; time*

I. INTRODUCTION

Students often struggle during their first experiences with programming [1][2][3]. Feedback is often ineffective, merely listing what is wrong with the program without explaining why it is wrong or how it might be corrected [4].

Feedback of any kind is traditionally regarded as a major influence in advancing student learning and success [5][6][7]. Written feedback persists as a reliable avenue for instructors to communicate with students about concerns related to course concepts and/or content. As multimedia tools have become more available, investigations into alternative feedback modes have emerged, most notably those using visual recordings [8][9]. In fact, studies and survey results indicate a student preference for visual feedback [10][11].

A visual/audio approach to providing assignment feedback may be especially applicable to certain disciplines. Benefits from non-traditional video feedback have been reported for English composition [12]. Since writing includes both syntactic

and semantic elements, visual/audio feedback allows the instructor to express observations about style and mechanics in a more direct and personable manner. Software engineering in part requires the creation of written programs, graphical user interfaces, and design documents constructed using UML, all of which possess a strong visual component. Feedback commentary that mirrors the visually oriented nature of software design may prove equally or more effective than traditional written feedback [13].

In providing feedback for programming assignments, the instructor is confronted with the challenge of comprehensively and clearly explaining the problems in the submitted program and the strategies necessary to fix these issues [14][15]. Typing out the detailed feedback can be tedious [16].

The authors used the screen recording software package, Camtasia Studio, to record video lectures for their online courses. This software is used by many faculty members in the Computer Science department at Weber State University to record video lectures for their online classes, and the software works very well for that purpose.

The authors realized that they could use the same technology to record video feedback for students on their assignments. This method has the potential to be faster and/or more effective than traditional feedback.

II. METHODOLOGY

The study involved 38 students enrolled in a single CS1 Fundamentals of Programming using Java course during the Summer 2014 semester. The original course enrollment was 45 students, at which time the class was divided randomly into two groups. One group received only normal text feedback (Text group) and the other group exclusively received video feedback (Video group). Seven students subsequently dropped the class throughout the course of the semester, leaving 20 students in the Text group and 18 students in the Video group. The study was completed using only the data from the remaining 38 students that completed the course. The main measures of performance were assignment and exam scores. A sample assignment with associated text feedback and video feedback transcription are provided in Appendices A, B, and C.

The hypothesis was that students who received only video feedback would score better on average in the course than those who received only text feedback.

The time it took to grade each assignment was also recorded in order to determine if one particular method of feedback was more time consuming and to what degree. The dates of the submissions and the penalty for submitting the assignment late were also recorded.

To combat any inherent instructor bias to grade the students in the Text group before those students in the Video group, due to the convenience of being able to provide written feedback as compared to recording a video (where a relatively quiet environment and a microphone are required), assignments were graded in the order they were received.

Data were collected throughout the semester. To establish and maintain consistent modes of student/instructor interaction within each group, responses to student general inquiries about course topics and delivery were exclusively written for the Text group and exclusively visual for the Video group.

III. RESULTS

Fig. 1 shows results from the study:

Fig 1. Average score by week for the Text and Video groups.

Interestingly, the students who received assignment feedback via text generally scored HIGHER on average than students who received assignment feedback via video. The overall assignment score average was 2.79% lower for the Video group. In a paired T-test, this difference proved to be significant, $t(11) = 2.74$, $p \leq .05$, with a p-value of 0.019.

The Video group scored 0.40% and 0.64% higher during Weeks 1 & 2, respectively, and 1.48% higher on average than the Text group on the last assignment. However, the Text group scored higher in each of the other weeks, with Week 4 displaying the largest gap between the two groups at 6.49%.

The Final Exam scores were also compared, with the Video group scoring slightly (0.84%) higher.

Fig. 2. The difference in the average score for the Video group in relation to the Text group.

The first two assignments for the course were both introductory, whereas the Week 3 Assignment marked the point in the course when the relative difficulty of the assignments increased significantly, thus a drop in average score for all students was expected. As shown in Figure 2, it is noteworthy that the Video group closed the relative performance gap over the course of the semester, and eventually scored better on the last assignment, which was a review assignment focused on the concept of Object-Oriented Programming.

It is also interesting to observe the trend for each group.

Fig. 3. Average scoring trends in the Text group versus the Video group.

Using a trend line (Fig. 3), it is easier to see that, while the overall average was lower for the Video group, the scores did not drop at the same rate as the Text group as concepts and assignments increased in difficulty. The slope for the Text group was -0.50, and the slope for the Video group was -0.38. However, the difference in trends was not statistically significant, $t(20) = -0.21$, $p \leq .05$, with a p-value of 0.837.

IV. GRADING TIME INVESTMENT

In terms of grading time, the video feedback took nearly twice as long to produce as the text feedback. Video feedback averaged 5:37 minutes to grade over the course of the semester, while text feedback averaged 2:59 minutes, a difference of 2:38 minutes per assignment. Video feedback included primarily the presentation of student programs in the development environment (Figure 4) coupled with audio commentary (Appendix C) highlighting both the successes and drawbacks associated with the student code.

However, it should be noted that 2:10 minutes of that difference included the wait time required for the video to render and upload. The videos for this course were recorded in

high definition (1024 x 768), therefore the render time could be cut significantly if the videos were recorded at a coarser resolution. The rendering time also varied widely among the work machine, home machine, and multiple laptop computers. Anecdotaly, it appears that the use of a solid-state hard drive had the largest effect on grading times; a future study could be pursued to test that theory and to determine what else might reduce rendering time.

If the rendering/upload time is removed and only the active grading time is considered, the Video grading took slightly longer on average at 3:27 minutes per assignment versus 2:59 minutes per assignment for Text grading, a difference of 28 seconds.

Using only active grading time, the video grading was slightly faster (6-8 secs) when a student scored 90-100% or below 60%. Text feedback was almost a full minute faster (51 secs) when a student scored between 60-80% on the assignment and 28 seconds faster in the 80-90% range.

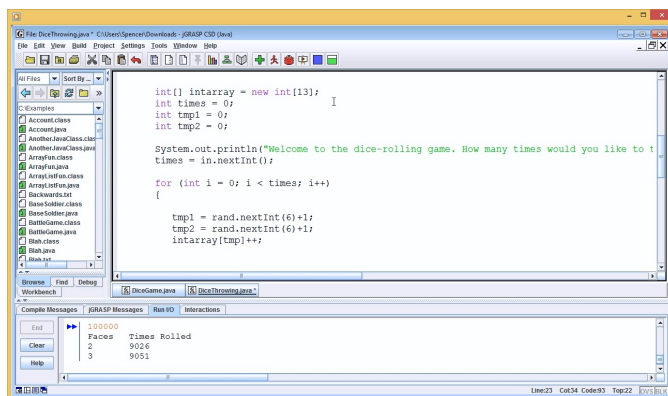

Fig. 4. Screenshot of video feedback.

V. SURVEY

At the conclusion of the course, a survey was given to the students who received video feedback during the semester. A total of 15 out of the 18 students from the Video group responded. While the scoring results were somewhat ambiguous, the survey results revealed that students were clearly in favor of Video feedback.

Question: “Do you prefer receiving assignment feedback through text or video?”

15 out of 15 (100%) of the students chose “Video”.

Question: “Which type of assignment feedback do you feel is more effective for your learning?”

15 out of 15 (100%) responded with “Video”.

Question: “Have you ever received video feedback on your assignments prior to this class?”

15 out of 15 (100%) responded with “This is the first class I have received video feedback in.”

Question: “How often did you watch the video you received as feedback on your assignments?”

10 (67%), “All of the Time”

4 (27%) “Most of the Time”;
1 (7%) “Some of the Time”

Question: “How often do you read written feedback given on assignments?”

4 (27%), “All of the Time”
6 (40%) “Most of the Time”
1 (7%) “Some of the Time”
3 (20%) “Rarely”
1 (7%) “Never”

The most interesting qualitative results were divulged through student comments.

Question: “Why do you prefer the feedback method you chose?”

Here are a sample of the responses:

“It shows me what I did wrong in a visual style with live commentary using my own work. Doesn't really leave room for error.”

“I liked it, just because I got to hear the emotion in your voice on how you really felt about the program! It makes me feel like you actually care rather than you plug it in and just grade it off the outcome and not really even care what is in there.”

“I was able to see what was wrong with my program immediately, and it was like having [the professor] there going over the assignment with me.”

“It was as if the professor was coaching me through each assignment. I really liked hearing his feedback on my assignment, and the tips he gave me that he probably would not have done through text. I loved it!”

“The videos were awesome because unlike in a face to face lecture I was able to get personal feedback on my assignment without having to spend time tracking down the teacher and also I could go back a reference it any time I wanted. I liked hearing the teacher's thoughts and it was a great way to start a conversation about what I did right or wrong and how to fix it.”

Question: “What did you most like about receiving feedback through video?”

Here are a sample of responses:

“Didn't leave room for miscommunications.”

“I didn't have to look back at the assignment to see what the prof was talking about, I could see it right there.”

“Video feedback is a visual learning tool, and I am a visual learner so it helped me to understand what I was doing wrong.”

“I like hearing a teacher's personality as well as I get to see exactly what confuses them in my work, which, in and of itself, is helpful.”

"It seems easier for [the professor] to point out the mistakes that I made and for me to know exactly what you are taking about."

Question: "What did you least like about receiving your feedback through video?"

12 of the 15 (80%) students responded "Nothing.". The other three students responded:

"Sometimes I didn't have time to watch the video and see what you said because in a text it would take me just a second to read rather than download the video and watch it."

"I had to have a fast internet connection to watch the video."

"That I had to download the feedback to my computer."

Question: "Please leave any other comments you have about the video feedback in this course"

Here are a sample of the responses:

"I felt this helped greatly in learning what I was doing wrong. So obviously this helped me move forward quicker and not lag behind in class."

"I found it very helpful. I wish other beginning (intro) programming instructors did this."

"Makes an online course seem much more interactive."

"I have none, other than I wish my other teacher's would have done something like this."

"A short [written] summary to accompany the video would make it perfect."

"I suggest that teachers use video feedback for online and in class formats. I feel that it is very useful at giving the student personal information about their assignments that will improve how they learn the material."

The survey results show unequivocally that the students had an extremely positive response to the video feedback. Over the last several years, students have been increasingly exposed to video instruction as recorded lectures and video conferencing sessions become the norm for both online and hybrid university courses. Majors in the fields of computer science and engineering are receptive to briefer, focused treatments of course topics, typically packaged as 8 to 12 minute presentation videos. Commercial online instructional sites such as Codecademy, Udacity, and Pluralsight have engaged both the aspiring and seasoned programmer with libraries of video courses on learning to code in various languages. Because student experience of the instructional context appears to be trending toward more visual interactions, the overwhelmingly positive survey reaction to video feedback may be more a matter of student expectation rather than novelty.

Although a vast majority of students who received visual feedback (93%) reported watching the videos "All of the time"

or "Most of the time," compared to 67% of text feedback students who did the same, this enthusiasm to absorb instructor commentary did not immediately translate to noticeably better overall performance in the visual feedback group. Improved student assignment results are one key measure to assess video feedback, with one current study showing a positive outcome in this area [13].

However, comments such as *"...this helped me move forward quicker and not lag behind in class"* may point toward a benefit of increased engagement from students who were potentially at risk in falling behind the course schedule, and ultimately withdrawing from the class. Visual learners may be bolstered by feedback that corresponds to their learning modality and thus encouraged to persist in continuing and successfully completing the course. Also, visual feedback might be made more effective from a performance standpoint by employing the student survey recommendation *"A short [written] summary to accompany the video would make it perfect."*

As an anecdotal note, the instructor who taught this experimental section, received the highest average student evaluation score he has ever received teaching this particular course, an outcome which could be in part attributed to the video feedback component.

VI. CONCLUSION

For this particular study, the student performance data is inconclusive. Conflicting trends emerged from this work: the Text students scored slightly higher on average, but the Video students reduced the performance gap over the course of the semester, and eventually scored better on the final assignment. The instructor observed that the first seven submissions for the initial introductory assignment arriving before the due date were Text students. Even though the groups were divided randomly, a number of the top students in the class appeared to fall in the Text group by chance, an observation that held true throughout the semester.

With a sample size of only 38 students, there is greater potential for a few students, exceptional or poor, to skew the results in one direction or the other. It will be necessary to attempt the same study in future courses and aggregate the data to see if the pattern described in this study holds. Perhaps there are reasons that students who receive written feedback perform better overall, and future studies could be aimed at delineating and identifying these specific causes.

Video feedback does take significantly longer to record, due mainly to rendering time. However, straightforward technological solutions as described earlier could significantly reduce this video processing time. If rendering time is ignored, instructor time investment in the visual feedback reports was on average 15.6% greater than instructor time investment in the textual reports. Although assuming a direct correlation between grading time and feedback quality/quantity is problematic because the two modes utilize different communication channels, it is possible that the dynamic, interactive visual format elicited a more substantive review from the instructor.

One critical piece of qualitative data reported here is that students strongly prefer video feedback to written feedback. Video feedback helped students establish a personal connection with the professor and represented an increased level of instructor investment in the process. Performance data aside, grading by video shows initial significant potential in enhancing the positive experience students have with both programming and the course instructor.

VIII. APPENDIX A: SAMPLE ASSIGNMENT

Write a program that simulates the rolling of two dice. Use an Array to keep track of the number of times that each total number is thrown. In other words, keep track of how many times the combination of the two simulated dice is 2, how

many times the combination is 3, and so on, all the way up through 12.

Allow the user to choose how many times the “dice” will be thrown. Then, once the dice have been thrown the specified number of times, print a histogram (using the * character) that shows the total percentage each number was rolled. Each * will represent 1% of the total rolls.

Sample session:

Welcome to the dice throwing simulator!

How many dice rolls would you like to simulate? 100

Dice Rolling Simulation Results

Each "" represents 1% of the total number of rolls.*

Total number of rolls = 100.

```

10: *****
11: *****
12: **

```

Thank you for using the dice throwing simulator. Goodbye!

Submit your .java file containing the source code via WSU Online.

IX. APPENDIX B: TEXT FEEDBACK

“There are a few problems that I spotted. You were close on totaling up the dice, but it doesn't appear to be totaling quite right. I'm not actually quite sure what you're currently doing -- You total up the rolls for one die. And then you total up the rolls for the other die. Then you roll again, and add the total from ‘dt’ and ‘di’, but di will never change. ‘dt’ will change, but then you're not using the other rolls you did at all.

“All we really need is one loop that looks something like this:

```

for (int i = 1; i <= bacon+1; j++)
{
    di = r.nextInt(6) + 1;
    dt = r.nextInt(6) + 1;

    tdice[di + dt]++;
}

```

“That would total up all the rolls correctly. And then for printing the asterisks, if you used the formula for calculating the asterisks in the for loop instead of printing out the number, then I think that would work. You would just need to change the `println()` to be a `print()` so that the asterisks stayed on the same line. And then add a `println()` after you've printed all the asterisks for one line.

“You were on the right track. Hope that helps. Let me know if you have questions.”

X. APPENDIX C: VIDEO FEEDBACK TRANSCRIPTION

“Okay, Quinn. Let's look at Week 7 and see what you've got. OK? We're getting some numbers. Let me try 100. Let me try 100,000. Okay, so I'm already seeing a few problems. Obviously I think one you know. Let's see. [Reading comment from student] “I couldn't figure out to print the asterisks instead of the numbers, but better than nothing I guess.” Good point. It's better than nothing. It looks like you're doing this section correctly. The problem is this. If you... Well, no that's okay because you're doing a 2. If... How can I say this? I'm obviously struggling. [Laughs] If we get a random number out of 11, that's going to give us a number 0 through 10. We add one to it, which is going to give us 1-11. All of those numbers has an equal probability of being rolled. In other words, this: If we took a 12-sided die, if there was such a thing, and rolled it, every side of that die would have equal probability of being rolled, right? There would be a 1 in 12 chance of being rolled. But when we roll two dice, it's not equal probability of any number getting rolled. For example, a 2, you have to roll a 1 and a 1. So you roll one die and you say, “Oh, good. I got it. There's my one. One in six chance, and I got it.” What are the chances you're going to get a 1 on the other die as well? Well, it's still 1 in 6. But what ends up happening is you have to multiply those together to figure out the probability, so it's a 1 in 36 chance because there are two dice. And so what we get is, for a 2, we have to roll a 1 and a 1. That's the only way to roll a 2. Or a 12, you can only roll a 6 and a 6. But for a 7, I can roll a 1 and a 6, or a 2 and a 5, or a 3 and a 4, or a 4 and a 3, or a 5 and a 2, or a 6 and a 1. All of those get me the 7. Any of those combinations. And so there is a much higher probability of rolling a 7 than there is of rolling a 2 or a 12. So anyway, that's a long explanation. But just saying we can't do one simulation. What we needed to do was say, “Give me one die, `nextInt(6) + 1`. Then give me another one out of 6 + 1. Add those together. And then store that number instead.” And that would have gotten you the correct results. It will look more like a sideways pyramid. On the ends, 2 and 12 will be really low. But in the middle, at 7, it will be high. And then the idea of the asterisks. Now, assuming we've done this right. And I think we can even just do it. I probably shouldn't just do it,

but I'm just going to. [Laughs] This is “`tmp1`”, out of 6, plus 1. This is “`tmp2`”, out of 6, plus 1. And we need it out of 13 [in the array] if we're going up to 12. 0 through 12. And then we won't even use 0 or 1. I take the result of that, so instead of just “`tmp`”, I say “`tmp1 + tmp2`”. And that's going to give me my results. And you'll see in the numbers that this works out a lot better. So I roll 100, I got 4, 10, 15, 18, etc. in the numbers. So my middle are the big numbers, and then low numbers on the extremes. Okay? Once I have that, then all I need to do is... right now you're printing this number, which is how many times that particular number was rolled. Well, instead of doing that... I'm going to take that part out, and make this a “`.print()`”, because we're going to finish off this statement. So I start this statement with a “`.print()`”. I say this is the number, and I'll actually just start at 2 and go up through 12. And then I can just say this. I can say, “After I print the number, I need to figure out how many asterisks I'm going to print.” “`int numAsterisks`”, and I'll set it to 0. And then, I can say, “Set the number of asterisks equal to whatever that number it is I'm pulling.” Ok? That's the number. And what do I need to divide that by? Well, I've got to figure out how many times I rolled that number, which is “`times`”. So divide those, and then multiply it by 100 to make it an actual, instead of .3 for 30%, to make it an actual 30. The only problem when I do it this way is that I'm going to get a zero always, because it's integer division, and this number is smaller than this number. So I'm always going to get a 0, with a remainder of this. So, instead, what I'm going to do -- This is a little trick, I think I actually talked about it in the help video actually -- I'm going to multiply it by 100 in the first place. If I roll this 30 times, 30 times 100 is 3000. Divided by 100 rolls will give me 30. And once I have that number of rolls, it's as simple as saying, “Okay, so for an `int “j”`, because I can't use “`i`” – I'm in the middle of a loop, start wherever we want, but I'll start at 0, and go so it equals the number of asterisks. And then “`j++`”. For every single number of asterisks that I have, I'm going to “`.print()`” – Not “`println()`”, just a “`print()`” – One asterisk. Okay? And then after I get done with that line, then I will go to a new line. So do a “`println()`” to go to the next line. And that way, I get this nice pretty histogram, with the numbers looking like we talked about, low on the outside. It doesn't matter if we do 1,000,000 rolls, it still looks super nice. We're missing commenting in the program, so that's a problem. But the rest looks good. You were most of the way there. Just those things we talked about. So hopefully that's helpful to look at it together. Let me know if you have any questions or comments. Thanks.”

New Methodology to Differentiate Instructional Strategies for ESL Learners in the Indian Context

Abstract—Many students struggle with reading when whole group instruction forms the core of the reading program. This is especially true when teaching second language students. The proposed intervention methodology combines multiple proven methods to improve reading skills in students. The study focused on using differentiated instruction and multiple assessments such as Informal Reading Inventory (IRI), Qualitative Spelling Inventory (QSI), Running Records, Dynamic Indicators of Basic Early Literacy Skills (DIBELS), High-frequency words and phonological awareness. After the usage of the said tools, students learnt to follow a firm reading routine, respect classroom procedures, work in teams and solve problems independently. This five-month study examined the benefits of the differentiated instruction with thirty six 5th grade students, who were the second language English learners in a school in the state of Karnataka, India. The key findings from this study indicated that differentiating instruction and using small group instruction assisted and improved students' reading and writing proficiency. With our proposed method, 94% of the students improved their reading comprehension by a minimum of three grade levels. An unexpected benefit was a positive change in attitude and behavior of the students along with increased confidence.

Keywords— *Informal Reading Inventory (IRI), Qualitative Spelling Inventory (QSI), Running Records, Dynamic Indicators of Basic Early Literacy Skills (DIBELS), High-frequency words*

I. INTRODUCTION

Teaching English in India as a second language is indeed a challenge. Often teachers are neither proficient in spoken English, nor are they trained in classroom management skills, the skills that teachers require to have in order to manage a large group of multi-leveled students.

To be an effective English teacher for second language learners, Echevarria, Frey, and Fisher state that a teacher has to be aware of four sections - access, climate, expectations and language instruction [1]. The word 'climate' here refers to the conditions that are present in classrooms. It is said that the effective teachers create a positive climate in the classrooms using a variety of ways. To say, they show respect and patience towards the students [1]. A widely used adage in educational circles says that the teachers should first examine their own educational practices and make changes when the

students are not successful. A change in the teachers will lead to change in the students.

Also, many years of research has shown that a teacher's expectations directly influence the performances of the students [1]. Therefore, it is important to first state specific instructional objectives to the students before a lesson is being taught. This would provide a framework for the students. Without this framework, it is easy for English language learners to be distracted while the lesson is being taught [1]. Although vocabulary development is a significant part of language acquisition, oral language, grammar, and other literacy skills also play a major part. Teachers use phonemic awareness to help students understand many layers of language acquisition.

Our intervention methodology combined several methods to improve reading skills in students. The students learnt classroom routines, rules, procedures and guidelines for five months, the duration of the entire research. Students practiced the classroom procedures, learnt how to work in teams and solved problems independently.

The various assessments used in this study include an Individual Reading Inventory (IRI), Running Records, Qualitative Spelling Inventory (QSI), High-frequency word list and Dynamic Indicators of Basic Early Literacy Skills (DIBELS). All these practices were new to the participants of the research, including teachers, students, administration and parents. This paper will show how the assessments were administered among students, elevated their reading levels and motivated them to perform better.

II. BACKGROUND

The current educational system encourages students to use rote-learning techniques to memorize the chapters and also to prepare for the examinations. This is a widely accepted method, and teachers instruct students using whole group instruction with a focus on rote memorization. There have been several studies to show that the obsolete practice of rote memorization is inappropriate for many subjects and may not prove beneficial in all the circumstances [2]. In her research, Fata-Hartley [2] pointed out that the rote learning does not induce actual learning in students. Rather, for the actual learning to take place, there should be active engagement from the part of the students.

In another research, Vygotsky and Bruner too encourage students to acquire knowledge through active participation. The backbone of the curriculum in US schools is Vygotsky's Zone of Proximal Development, popularly known as ZPD. The ZPD concept states that the students can learn to do independent works when an adult or a more competent peer assists them [3]. A teacher or an educator can recognize a child's ZPD, the area between what a child can do by himself and where the child will require assistance, through his/her watchful eyes or by testing through asking questions, and by determining a student's individual learning techniques.

In addition, it is important to provide a calm classroom atmosphere for the effective learning to take place. Good classroom management strategies can provide this effective learning environment for students. Calm environment in classrooms proves productive because it enables the teachers to take a proactive approach to classroom misbehaviors, a key factor in good classroom management. Behavioral learning theories state that the misbehaviors persist over time if maintained by some 'reinforcer' such as a teacher or a peer group, or by both [4]. Therefore, it is necessary to identify the 'reinforcers' to reduce the misbehaviors. Praise is usually a powerful motivator for many students to reduce misbehaviors. That is, to appreciate students when doing the right things. To say, if students often move away from their seats without permission, praising them when they sit back and get to work can reduce this misbehavior.

III. METHODOLOGY

A. Assessments used in the Method

The research applied a set of assessments to align students to their correct grade level. They were as follows:

- The QSI put the students in the preliminary reading group.
- The IRI assessed reading comprehension level of students.
- The Running Records checked if the words the students read were correctly/incorrectly pronounced.
- The DIBELS assessed each student's reading fluency.
- The High-frequency words list tested students at three separate junctures of the research - at the beginning, mid-level and post research.

Qualitative Spelling Inventory (QSI), a similar method like spelling test, also considered to be the baseline or pre-assessment test was first initiated for the assessment. The QSI assessment consisted of a list of 25 words, where each word represented different spelling patterns that were progressively more difficult. Among the several levels of inventories, primary, elementary and upper level that exists for QSI, this research undertook an Elementary Spelling Inventory (ESI) for students as they belong to elementary school. Subsequently, each student was administered with a bi-monthly test, a method to examine their mastery of the studied attributes of the words.

Conducting such tests helped our researchers to examine the retention capability of students, which in turn helped gear instruction. Thus, using the original QSI that each child had done at the beginning of the study (in October 2014), the researchers conducted mini-lessons and taught students several word sorting games which in turn helped them understand word patterns.

Mini-lessons

The researchers spent five to fifteen minutes teaching mini-lessons on various topics such as reading comprehension strategies, English grammar or other text related factors. Sometimes mini-lessons were taught to the whole class, and at other times the students were taught in small groups. In our research, we used mini-lessons to correct grammatical errors that students consistently made in their writing. We also conducted mini-lessons, when we felt the students needed extra help to comprehend a reading lesson we had taught. We used questioning strategies to help the students. For example, we started the lesson by talking about why people ask questions. Then, we used this strategy to ask them questions about the stories that they were reading about. We made a list of questions, then evaluated the questions, choosing the ones that focused on the big ideas that helped students understand the story better. [16].

A. Quantitative Spelling Inventory

The QSI test enabled the placement of students into four reading groups and revealed the spelling deficiencies of each student. Students generally moved on a continuum through the various spelling stages, namely; Emergent, Letter-Name, Within-Word, Syllables and Affixes, and Derivational Relations Spelling^[7]. This research ceased at the Syllables and Affixes stage and administered the inventory, resulting in four reading groups.

The intervention for each reading group was varied. For example, the Within-Word Spelling group differentiated between short vowel and long vowel words, as it was their area of deficiency. The group required training on short and long vowels, hence, a few rules to differentiate between cut-cute, hat-hate, slid-slide etc. were taught to the students. While teaching, students were initially made to pronounce the words in the list, following which several word sorts were used to teach the concepts. The students were also made to write down the words in their spelling notebooks. Word sorts are word study to assist students to focus on conceptual and phonological features of words and to identify recurring patterns they possess. For example, students sort words (written on cards) such as *stopping*, *bugging*, and *running* they discovered the rule for doubling the final consonant in short vowel words before adding the *ing* at the end of the word. [15].

The whole class was also deficient about the concept of blends, digraphs, and diphthongs. Blends are two or more consonants, when combined together makes a single sound. (for example *br*, *cl*, *sp*, etc.). Digraphs are two or more consonants combined together make a single sound. (for example *ch*, *sh*, etc). Lastly, diphthongs which are two vowels when combined make a certain sound and the sound of neither

vowel is heard. (for example *oi* as in *foil* etc). [7]. They also required training to sort the words into categories. Such trainings were provided. Vowel patterns were taught using 'word sorting', a process of separating a group of words into piles with similar features. For example, we taught them to sort pictures using the same beginning consonant sounds or medial vowel sounds. This format of teaching was followed for the entire class for the entire duration of the research.

Assessments have become a necessity in the 21st century classrooms. The present education system analyzes the achievement level of students through annual tests, administered by school districts and federal education agencies. To better this system, a number of teachers use Quantitative Spelling Inventory (QSI), published in the book 'Words Their Way: Word Study for Phonics, Vocabulary and Spelling Instruction' (Bear et. al., 2008). The legitimacy and dependability of this spelling inventory are indisputable. Also, they are easy and quick to administer in any classroom environment.

There are several different levels of the spelling inventory, Primary, Elementary and Upper Spelling Inventories. This research has used Elementary Spelling Inventory (ESI) which is specifically used for elementary school grades from 1st to 6th grade. Generally, there exists co-relation between the spelling test score and standardized reading scores (Bear, et. al., 2008). Thus, from the researchers' past and the current experience, when students attempt and achieve a high score at this spelling inventory, they are also counted as good readers.

In conclusion, using the Guttman Scalogram analysis, it had been noted that the coefficient of reproducibility had an average of 0.91 (Bear, 1982, 1992).

A. Running Records and Informal Reading Inventory

Running Records and IRIs are primarily used to document the development of the students with suitable academic (leveled) reading material. Running Records enable the teachers to analyze the oral reading skill of the students. It would also help to understand their ability to solve reading problems.

During this research, Running Records were collected at three different periods:

- 1) Prior to beginning the research to get a baseline score
- 2) At the mid-point of the research (November 2014)
- 3) At the end of the research (February 2015)

The book used for narrative reading is Flynt & Cooter's *Reading Inventory for the Classroom (RIC)*. Alongside, reading inventory was also administered. The below methodology is used to implement the Running Records and IRI on the same day to the student:

Initially, the Running Record was introduced to each student. They were then tested for their oral reading competency right outside their classroom. The duration of these tests (running records and IRIs) took the researchers approximately 15-20 minutes per child. The students read

aloud a narrative passage to the researchers, during which, the running records were documented. Documentation involved penning down the words that the students read correctly and the type of errors they made while they read. Students repeated the read passage as the next step.

The assessment of comprehension was also taken by asking students questions from the reading. Comprehension is measured by the student's ability to recap the passage they read and to answer questions about the passage. The questions were both evaluative and inferential, to examine student's ability to use literal and higher level thinking. They also tested their knowledge of vocabulary. The IRI chose for the purpose was *Reading Inventory for the Classroom (RIC)*, written by Flynt and Cooter. The book was chosen as it contains a miscue analysis grid for each passage and focuses on vocabulary building.

IRI and Running Records diagnose various difficulties students face in word identification, fluency and comprehension [8]. They help students with higher-level thinking like synthesis, evaluation and analysis. For enhancement of comprehension of higher-level concepts, graphic organizers were also used. Constructivists like Vygotsky and Bruner has advocated this type of learning within school systems (used in the U.S.A) [9]. The experience of hearing ideas from peers, experiment them and obtaining feedbacks are ways to advance the cognitive scaffold and to maintain the higher-order of learning [10].

B. Dynamic Indicators of Basic Early Literacy Skills

DIBELS is another tool that is used to evaluate the students' reading fluency and provides oral passages that measure the reading speed for each grade level. Usually this test is individually administered to each student. However, we administered the test in small groups. For the first 10 days, the test was supervised once in a day, thereafter, once in a week until the 8th week. As the days passed, a better motivation to perform well was seen among the students. They also showed an improved competition with each other and compared each other's scores on a regular basis.

C. High-frequency Words

High-frequency words are the words that are most frequently used in the English language. Example: 'who', 'and' or 'the'. School districts across the US require students to study high-frequency words for each grade level. Thus, students in the US have to know 500-600 words by the time they are in 5th grade. Many of these words are difficult for non-English speakers to learn because they are not easily decodable, i.e., difficult to extract the true meaning of the word [8]. The other complicating factor is that these words do not individually carry any meaning. So, for example, it is easier to explain what a 'spider' is, rather than words such as 'what' and 'how'.

D. Phonological Awareness

Early phonological awareness helps a student understand the structure of spoken language, that it consists of sentences and that those sentences are further made up of individual sounds called phonemic awareness. Acquiring this

phonological awareness is important because it later builds the foundation for success in phonics and spelling^[11]. We showed students how to 'chunk' words. We started teaching students this concept by explaining the common features that words have. For instance, by adding a consonant 'h' or 'm' to long vowel words that end in 'ike', or short vowel words that end in 'en', we arrive at words such as 'hike' and 'mike' or 'hen' and 'men' respectively.

IV. STRATEGIES

The first author taught the students various strategies during the entire duration of the research. These strategies worked well in the study and the students made great progress.

In the beginning of the research, the lessons included scaffolds, giving the students the structure that they were used to. Currently, the teachers structure their classroom using whole group instruction. Therefore, at the beginning, the whole group instruction was maintained and eased the students slowly into small group instruction before commencing differentiated instruction in the class. This process took over seven weeks. Rigorous and firm classroom rules were implemented in order to achieve the necessary structure. This structure was the backbone of the classroom, hence, the rules were firmly followed and the students accepted the consequences that were set in place at the beginning of the research.

Implementation of classroom jobs was another factor that contributed towards daily and weekly form of positive reinforcement. For instance, only students who listened, and adhered to our classroom rules, and were who exhibited on task behavior, were assigned weekly jobs. They were taught clearly that this is the scenario in the real world, where only people who work hard and do their jobs properly are able to maintain their jobs. During the early part of our research, as a move to teach students on framing questions, we structured questions that students might ask and modeled various questions for them. As the weeks passed, the students themselves began generating the questions^[12]. This was one among the many scaffolding strategies taught to the students.

Also, every time a book was read or taught a lesson, we stopped and thought out aloud. In his studies, Wilhelm^[13] have shown that teachers who follow this routine, make children aware of the thinking style of capable readers and the way they process the information read. This approach motivated the students to ask more questions, thereby, encouraging more learning. According to educational psychologists, there are two different types of motivation — intrinsic and extrinsic. Intrinsically motivated are those activities people perform, and find fulfillment and joy from the activities itself. They require no external encouragement^[14]. Extrinsic motivations demand external rewards, by praise, prizes, grades, recognition et cetera. We used both types of motivations and the students thrived with the attention, praise and other academic rewards such as better grades during the research study.

V. THE STUDY

A. Participants

Our study was done with 36 fifth grade students over a period of five months.

The study offered supplementary English language classroom instruction to Kannada (language spoken in the state of Karnataka in India) speaking students, many of whom had low reading comprehension and vocabulary levels.

Of the 36 students selected to participate in the study, 21 were male (58%) and 15 were female (42%) students.

B. Procedure

The study was divided into three phases — pre-testing, mid-level and post-testing. The methods used to test the students' knowledge are detailed below:

During pre-testing (or testing prior to actually beginning the study), the researchers gave the students a list of over 480 words. The parameters of fluency, accuracy, and the speed with which the students were able to pronounce each word on this list were tested. In the beginning of the study, during October 2014, each student was tested for fifteen to twenty minutes in order to get a baseline score. This process took three days of testing for all the students. This method was again repeated in November 2014 to obtain a mid-point reading score and then again in February 2015 to obtain the final score. Based on the results obtained, the class was divided into four reading groups.

During the mid-level testing, in addition to the method used during the pre-testing, the list of words was included as a game that the students could play during their literacy rotation time. The students were allowed to practice the list of high-frequency words at home. As the weeks went by, researchers coached the students on gaining automaticity, accuracy and speed. This in turn, improved the students' reading comprehension. The children looked forward to the reading classes and waited anxiously for the lessons we had planned. They were required to work within their assigned reading groups for 20 minutes each day for the duration of the study. Using leveled books, they were tested for 'reading fluency' and were taught phonological awareness and comprehension skills. In school, children are taught to pronounce the speech sounds in English. As they learn to pronounce these sounds, they learn to talk and they also learn to associate these sounds with letters as they learn to read and write^[5]. As stated earlier in this paper, the phonological system is important for both reading and writing.

The post-testing was conducted in the same manner as the pre-testing. The test enabled us to analyze the students reading comprehension skills after completing the previous two levels. Responses of the students reading comprehension score were statistically analyzed using the SPSS software and R.

C. Results

We conducted a repeated measure ANOVA to analyze the improvement in the reading comprehension skills of the students learning, which was tested within the duration of five

months. Table 1 shows the means and standard deviations (SD) for improvement in reading comprehension.

TABLE I. DESCRIPTIVE STATISTICS

Time points	mean	sd	n
Pre-Test	2.17	1.73	36
Mid-Test	4.92	2.39	36
Post-Test	6.44	1.97	36

Table 2 shows the overall significant difference between the means at different time points. A repeated measures ANOVA done with a Greenhouse-Geisser correction determined that mean, reading comprehension score differed significantly between the time points ($F(1.92, 67.11) = 143.866, P < 0.05$). The results presented in table 2 show an overall significant difference in the mean score.

TABLE II. TESTS OF WITHIN-SUBJECTS EFFECTS

Source		df	F	Sig.	Partial Eta Squared
Time	Greenhouse-Geisser	1.92	143.866	.000	0.804
Error (Time)	Greenhouse-Geisser	67.11			

The table 3 presents the results of the Bonferroni post hoc test, which allows us to discover which specific means differed.

TABLE III. PAIR-WISE COMPARISONS TABLE

(I) Time	(J) Time	Mean Difference (I-J)	Std. Error	Sig.
Pre-Test	Mid-Test	-2.750*	.277	.000
	Post-Test	-4.278*	.231	.000
Mid-Test	Pre-Test	2.750*	.277	.000
	Post-Test	-1.528*	.257	.000
Post-Test	Pre-Test	4.278*	.231	.000
	Mid-Test	1.528*	.257	.000

Post hoc tests using the Bonferroni correction revealed a significant improvement from pre-test to mid-test ($P < 0.05$) and between mid-test to post-test ($p < 0.05$). The post-test score showed a remarkable improvement in reading comprehension skills among the students. Specifically, the results suggest that the integrated method implemented elicits a statistically significant improvement in reading comprehension.

Fig. 1 shows the estimated marginal means of students' reading comprehension score over a period of time. Before conducting the treatment, the students' mean score was lower.

Their mean score improved significantly after the students followed the learning process in the mid-test. This progress continued until the post-test, subsequently the students' means score increased.

Fig. 1. Estimated marginal mean of student's reading comprehension score

VI. DISCUSSION

The assessments were a huge motivational factor and encouraged all the students towards higher achievement levels. Perhaps due to cultural factors, none of the students in the study wanted to be associated with the lower reading group. This motivated the children. The other factor that played into students' motivation was classroom rules and consequences.

With our proposed method of Differentiated Instruction, students increased their grade levels by an average of 4.3. In the initial measurement, 86% of the 5th grade students were reading below grade level. At the end of five month, all the students in the research study had improved his/her reading level by at least three grade levels. There were many factors that played into the success of this research however a large portion was due to the motivation of each student. 66.6% of the students were assessed at Grade 6 or above and 16.6% at a 9th Grade level in the final measurement.

The final result of the high-frequency word tests revealed that the new methodologies used influenced the students positively, though on an average, the overall increase in percentage was only 1.6%. These small increases of high-frequency words had a big influence on reading comprehension with most of the large increases coming from students who tested initially at Grade 0, 1, or 2 levels.

The fluency test (DIBELS) not only motivated students, but also increased their fluency scores where 66% of the students doubled their reading fluency score. It was seen that overall, the class scores increased by 2.1 grade levels in five months. At the beginning of the test, only 14% of the class was at grade level 5 or higher, but at the end of the five months, 75% of the class was at least at grade level 5. Note that it is possible that the grade levels attained were higher, but the researchers only had reading fluency measurements up to 6th grade level.

On average, 94.4% of the students in our study improved their reading comprehension by a minimum of three grade levels or more. We found that the mistakes the Indian students made differed greatly from the mistakes made by students of the same age in the U.S.A. For example, the Indian children had a difficult time understanding prepositions and prepositional phrases. We implemented a much more rigorous classroom management system than the existing one, supplemented existing text books with leveled books, taught grammar in context using mini-lessons and worked on common errors to help improve learning English as a second language.

Generally, reading and writing go hand-in-hand and this was also the case in this research. In the research, a writing rubric was implemented and we were able to perform the initial baseline and the mid-level (7 weeks) reading. However, the final reading could not be collected due to time constraints in the study. The mid-level readings after just seven weeks showed an average overall improvement of 45 percent, an impressive overall result.

VII. CONCLUSION

To sum up the research:

- 94% of the students improved their reading comprehension by three grade levels or more.
- 80% of the students in the research improved in the high-frequency knowledge and automaticity by an average of 1.6%.
- The reading fluency of students scoring 5th grade or higher was improved from 25% to 75% by the end of five months.
- The writing skills of students improved by 45% in seven weeks.

To explain our research metaphorically, just as the electricity charges an electric fan and rotates its blades, the assessments and classroom rules stimulated the various reading groups in the classroom. The assessments, classroom rules and consequences energized the students in the class, encouraging them to learn, enhancing their enthusiasm. The students moved into higher reading groups as the weeks passed, and they engaged with their own learning at their own developmental level. Individual conferences permitted us to outline expectations to the students.

At the end of the study, parent-teacher conferences were conducted. Majority of parents commented that there is an overall improvement for their children in both reading comprehension and fluency. Besides, they stated that there is an improvement in children's social behavior. In short, they were very pleased with the outcome of the research.

When considering the scenarios of Indian students, it has to be noted that they do not practice spoken English in the universities. Many of these students hail from rural backgrounds, where English is hardly spoken and considered a novelty. Consequently, these students are accepted into university, where the language of communication (both

written and spoken) are in English. Naturally, they will encounter a difficulty in understanding their professors and the text books.

However, if IRIs and QSIs were administered on a regular basis to each incoming student, it would remove students' difficulty in dealing with English language. Perhaps, students who fail at the university level may actually be failing due to their lack of skills in English language.

These key findings from this study, thus conclude that the differentiating instruction and using small group instruction assist and improve students reading and writing proficiency.

ACKNOWLEDGMENT

This work derives its inspiration and direction from the Chancellor of Amrita University, Sri Mata Amritanandamayi Devi. We are grateful for the support of our colleagues at Amrita CREATE and the staff at Amrita University.

Starting From Scratch

Developing a Pre-Service Teacher Training Program in Computational Thinking

Abstract—This paper details a series of pre-professional development interventions to assist teachers in utilizing computational thinking and programming as an instructional tool within other subject areas (i.e. music, language arts, mathematics, and science). It describes the lessons utilized in the interventions along with the instruments used to evaluate them, and offers some preliminary findings.

Keywords—Computational Thinking, K-12, teacher professional development, Scratch

I. INTRODUCTION

The inclusion of Computational Thinking (CT; a problem-solving approach associated with the field of Computer Science) into a student's K-12 experience has been gaining ground in recent years. Bolstered by inexpensive, ubiquitous computing technology and associated with changing strategies for answering questions and solving problems in a wide range of science and engineering fields [1], CT has been identified among the critical 21st century skills all students should develop [2], and has even been incorporated into the latest emerging national educational standards in the United States: the Common Core State Standards [3] and the Next-Generation Science Standards [4]. Underlying this thematic push are arguments derived from growing market demands, concerns about national security, and a desire for social equity.

Yet bringing CT into the K-12 realm is also rife with challenges which must be addressed – as was demonstrated by the earlier CT integration movements like that associated with the LOGO programming language emerging in the 80's [5]. Chief amongst these is preparing future K-12 teachers to tackle the challenge of teaching CT. This paper describes one approach to tackling this problem piloted at Kansas State University as a partnership between the Department of Computing and Information Sciences and the Department of Curriculum & Instruction. This approach was derived from both the literature and practical experiences emerging from our NSF-supported GK-12 Program, INSIGHT. In addition to the discussion of the professional development approach, we provide some evidence supporting its efficacy and suggestions for future directions.

II. RELATED WORK

With the increasing popularity of tools like Scratch, Snap, Alice, Blockly, TouchDevelop, and other introductory programming tools, computer science outreach has expanded significantly. Code.org, The Hour of Code, and Computer Science Education Week have exposed numerous K-12 students and teachers. Some workshops focus on K-12 students, such as [6], but provide research and advice for best practices like curriculum, content delivery, interfacing with schools, and even classroom layout. Other workshops tend to not only focus on the students, but also to directly train teachers, so that they be able to blend CT and CS into their classrooms. CS4HS has funded face-to-face workshops, like [7, 8, 9], that have shown to not only increase participants understanding of CT and CS, but also how to integrate it as a part of their curriculum. CS4HS has also began introducing MOOCs targeted for training K-12 teachers [10]. While reaching a significantly larger audience, this particular MOOC is still in its infancy stage; however, it has shown promise in delivering CT and CS training to K-12 teachers with a broader impact than traditional workshops. Other workshops include CSbots [11], which has worked alongside CS4HS to also develop introductory CS curricula for K-12.

While these interventions have helped develop curricula and approaches for teaching CS at the K-12 level, they have targeted in-service teachers and have been delivered as supplemental programs. Participants for these programs therefore embody a degree of self-selection: they have an interest in CT and have chosen to pursue it, which likely means they have a stronger degree of interest and confidence than the general body of teachers. If CT is truly to be integrated into the K-12 educational system, then it must also be addressed in *pre-service* teacher education, with future teachers who are less enthusiastic about CT. Our intervention targets this broader pre-service teacher audience, and seeks to develop methods for approaching them that can overcome fears and concerns they may hold about CT and CS.

III. INTERVENTION DESIGN

A challenge that emerges in trying to bring computational thinking into the current standards-driven K-12 educational system is finding time where it can be taught. The importance of high-stakes testing to school funding has had the practical

effect of increasing scrutiny on all activities students and teachers engage in. In most cases, this has the practical effect of aligning classroom teaching with test-taking norms: concentrating instructional time on tested content, teaching content in fragmentary pieces, and utilizing teacher-dominated pedagogical techniques [12].

Thus, to provide both a motivation and justification for using CT tools in the classroom, we chose to develop our example lessons which tied directly to these three subject areas. Hence, each lesson we employed needed to directly support not only CT instruction, but instructional efforts within the subject area it was embedded. This approach comes with additional benefits: it emphasizes the nature of CT as a *process* to be utilized rather than an end unto itself while also grounding the use of CT within the student's pre-existing sphere of experiences.

In designing our intervention, we drew upon Social Cognitive Theory and its concept of self-efficacy – an individual's belief that they can accomplish a particular task requiring a particular skill – which in turn shapes the learner's efforts and attitude towards the learning. Under this theory, self-efficacy can be improved in the following ways, listed in order of effectiveness [13]:

1. *Enactive Attainment* (mastery experiences) happens when the individual personally and successfully carries out a task requiring the skill in question, establishing that they can, indeed, accomplish it. Such experiences must be carefully balanced in terms of difficulty – tasks that are too easy are dismissed as trivial, and tasks that are too hard can lead to frustration and lowered self-efficacy.
2. *Vicarious Experiences* occur when the learner observes a peer carrying out the activity successfully, which leads the learner to believe that they should be able to accomplish it as well. It is critical that the learner consider the person they are observing a peer *in relation to the task*, simply being in the same cohort is not enough.
3. *Verbal Persuasion* occurs when the teacher (or other person) talks the learner into believing they are capable of carrying out the task.
4. *Psychological State* refers to the need for the learner to be in a receptive state for learning – calm, relaxed, and rested. Agitated, anxious, or self-conscious emotional states can short-circuit the learning process, countering the benefits of the above approaches.

Our intervention approach was built around all four of these factors. We carefully selected experiences that would be both attainable and challenging, and arranged them in increasing complexity. Our intervention was carried out in a classroom where students sat together in small groups around tables, and could observe one another succeeding at the task. Throughout the presentation we emphasized how the tools and approach we were using was appropriate for even elementary students (and thus, should be approachable for college students). Finally, we carefully structured the exercises to build from comfortable domains of knowledge to the pre-service teachers, and made

sure they knew success or failure in this intervention was not tied to a grade, only their participation.

IV. THE EXERCISES

For our two-hour intervention we designed three exercises. For each exercise, we opened with a brief discussion of what we were going to accomplish, followed by a brief follow-me demonstration using an overhead projector where we introduced the programming concepts as we used their related blocks, and then we let the students continue on their own, while instructors circulated through the classroom to address questions as they arose. We believe scaffolding the experiences in this way helps reduce the students' anxiety, ensures they have encountered and used all the skills needed to complete the task, yet it also leaves them to carry out the bulk of this work personally, leading to a sense of personal mastery. Once the class completed the task, we held a brief class discussion about how this introductory experience could be used and expanded upon in the classroom, as well as identifying specific CCSS and NGSS standards that mapped to it. Full exercise lesson plans and associated materials can be found on our website [14].

A. Scratch Music

The first exercise was selected from the domain of music education for several reasons: the domain was familiar to all of our students and it is also very far from their conception of what programming is. Nonetheless, both musical notation and programming are forms of symbolic representation, and sheet music, as a representation of notes to be played in a sequence, maps very well to imperative styles of programming like that embraced by Scratch.

The exercise itself consisted of transcribing notes from sheet music into Scratch "play note (n) for (b) beats" blocks. We demonstrated starting the program with a "When Green Flag is Clicked" block, and attaching the first few notes, then the students were turned loose to continue transcribing the music. As only a single Scratch block was required for the bulk of the program, this allowed students to focus on the physical act of connecting the blocks in sequence, and the mental act of applying the correct meaning to that block (by selecting the right note and duration). The task also offered immediate and ongoing feedback, as the students could click the green flag and hear the program play through all they had completed – and the choice of a familiar song, Beethoven's "Ode to Joy," ensured they would recognize any mistakes.

While the task was repetitive, it bore clear purpose and reward in that the students could hear the song coming together. Moreover, it remained mentally challenging throughout, without becoming overwhelming. Our approach was also open to inquiry: many students asked if (1) they could speed the music up, and (2) change the instrument playing. Rather than telling them how, we shared that there were blocks for both, and encouraged them to try to figure out how. Similarly, many students were able to realize how to play the bass line by starting a second script on their own. We would then have one of the first adopters of these techniques demonstrate what they had learned to the class; this ensured the students had all seen these blocks in use the end of the lesson.

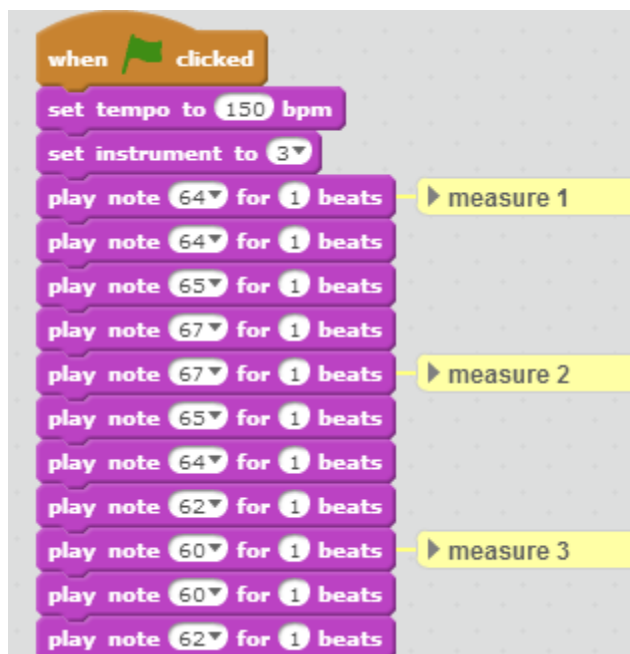

Fig. 1. Fragment of a music program written in Scratch; note how the commands snap together like puzzle pieces emphasizing the sequence of execution.

Before the discussion, we also introduced the use of operators to calculate the number of measures to wait before playing the second and third notes in the bass clef chords.

In this way, we quickly built the students' concept of *sequences*, as well as setting the conceptual foundations for *events*, *operators*, and *parallelism*. Moreover, the practice of playing the song as the students were building it firmly established the practice of *testing and debugging* early on. In addition, the song was short enough that all students were able to finish it in the allocated time, leading to both a definite sense of mastery and a diffusion of anxiety associated with programming.

B. Scratch Play

The second activity consisted of adapting a one-page script into what we called a *Scratch Play* – a multimedia animation carried out by a Scratch program. This exercise expanded considerably on the first one, introducing many features of Scratch including the *stage* – the area where multimedia actions unfold, *backdrops* – different images that can appear as the background of the stage, *sprites* – animated characters that appear on the stage and can be programmed with blocks, and *costumes* – different images the sprite can take on as their appearance. It also made use of many blocks from the *looks*, *motion*, *control*, and *events* palettes, a considerable departure from the first program which only used the *sound* palette.

Here we began by discussing the script and what challenges it posed. It involved three parts: the *dramatis personae* – the characters of the play, *stage directions* which indicated what those characters were physically doing, and the *dialogue* – what the characters were saying. After this brief discussion, we walked the students through choosing a backdrop and sprites to play the roles in the play. The students were invited

Fig. 2. The completed Scratch Play unfolding on the stage.

to choose any sprites and backdrops from Scratch's built in library, not just the ones we were using, and many did so – helping them to establish the program as “their own” and also embodying the perspective of *expressing*.

We then led the class through programming the first part of the script – demonstrating the blocks needed to get a sprite to speak, and rapidly switching costumes to create animations. We also introduced two ways of controlling timing – the use of “broadcast message” and “when I receive message” blocks, as well as “wait (n) seconds” blocks. Once all the necessary blocks and techniques had been introduced, we allowed the students to finish the exercise on their own, again circulating through the classroom to address questions.

This exercise delved much deeper into computational thinking concepts, including: *loops* (for creating animations from repeated costume changes), *events* (for coordinating different sprite's activities), and *parallelism* (as each sprite operates independently, at the same time). It also reinforced the practice of *testing and debugging*, as well as *being incremental and iterative*, and *abstracting and modularizing*. While this exercise required far fewer blocks than the music one, the variety and interaction of these blocks and multiple sprites made it more challenging, and in some ways, more rewarding.

C. Drawing Shapes

Our third exercise brought us into a more traditional programming area – using Scratch's turtle graphics functionality to draw shapes. In Scratch, each sprite can be equipped with a “pen” which, when “down,” draws lines on the stage as the sprite moves across it. By moving the sprite a set distance, rotating, and then repeating, a variety of shapes can be drawn. We focused on drawing regular polygons, starting with a triangle, for which we walked the students through the entire process. Once students had the triangle working, we challenged them to draw a square, and circulated through the classroom assisting students with questions. Students who finished quickly were challenged to draw more challenging

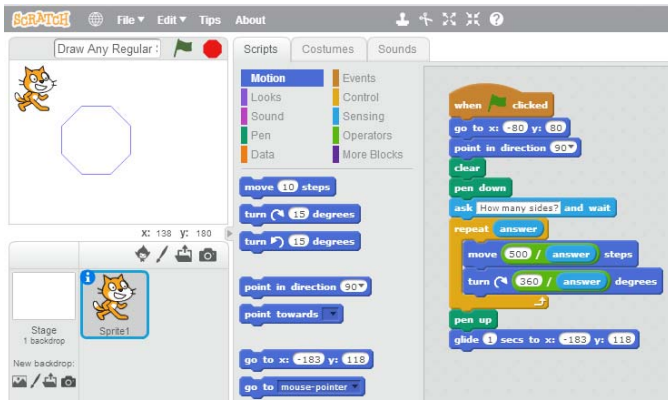

Fig. 3. Completed Scratch program for drawing any regular polygon, showing both the stage and programming area of the editor.

shapes, until everybody had drawn at least two regular polygons successfully.

At this point, we had students demonstrate drawing their different shapes, and compared the programs to see the similarities and differences, drawing out the observation that programs only differed in the number of sides drawn, the angle the sprite turned, and the distance it traveled between turns. From this, we suggested creating a general solution to draw any regular polygon, and introduced Scratch's "ask" and "answer" blocks as a way of implementing this. Working from student suggestions, we programmed and tested a general solution on the overhead.

This exercise led to some very fruitful discussion about how using Scratch can enhance learning. For example, when discussing how to calculate the angle the sprite needs to turn in the general solution, nearly every class suggested using the formula $180/\text{sides}$, drawing from their well-established understanding that the sum of the interior angles of a triangle is 180 degrees. However, the angles the Scratch sprite was turning were exterior angles – as such they add up to 360 degrees. Thus, students quickly saw that the exercise could lead to deeper theorizing and conceptualization of concepts introduced elsewhere. Moreover, nearly every student, once equipped with a general solution, tried to draw a shape with hundreds or even thousands of sides, resulting in a circle. We were able to capitalize on this curiosity pointing out that this is one way computers render circles – as an approximation formed by line segments or even points. Moreover, we pointed out that this process of approximation is the foundation of calculus, and by giving their students experiences with it now, they were laying the groundwork for future mathematics learning.

D. Closing Demonstrations and Discussion

To wrap up the intervention, we demonstrated several other Scratch projects we had developed for simulating a simple ecosystem in a drop of water (complete with a simplified representation of the chemical reactions involved in photosynthesis and respiration), and an engineering simulation to determine the optimal launch angle of a catapult (involving the transformation and transferal of energy from potential spring energy through rotational inertia and into ballistic motion). We then led a brief class discussion where students

suggested other ways Scratch could be used as part of their future teaching endeavors.

V. EVALUATION

To evaluate our approach, we developed a simple survey instrument – Teachers' Self-Efficacy in Computational Thinking (TSECT) – intended to capture a sense of the student's self-efficacy in utilizing programming and computational thinking within their future teaching endeavors. This survey was given as a pre- and post-test before and after the intervention; as this would consume part of our available time, it was kept short. A second, more nuanced version of the TSECT instrument was developed for our second iteration of the intervention, more closely based on Bandura's suggestions for measuring self-efficacy.

A. First Intervention

For the first intervention a series of ten items were adapted from existing self-efficacy instruments found in the literature, using a five-point Likert scale. The instrument's face validity was considered in the selection of items by the authors, who are all computer scientists with teaching experience. Item wording for this instrument can be found in table 1 below.

While the intervention was experienced by all students in the class, participation in the study was voluntary. Of the 126 students who began the survey, 2 answered no questions, and 8 did not answer any questions in the post-assessment; these students were left out of the analysis. Of the remaining 116 surveys, 9 contained missing values (0.3%) with no discernable pattern; these were classified as MCAR by the researchers and addressed with multiple imputations with five sets of imputed values, performed with SPSS 22.

A principal components factor analysis suggested the first

TABLE I. ITEM WORDING FOR FIRST TSECT INSTRUMENT

Item	Wording
1	I feel confident using computer technology.*
2	I feel confident writing simple programs for the computer.
3	I know how to teach programming concepts effectively.
4	I can promote a positive attitude towards programming in my students.
5	I can guide students in using programming as a tool while we explore other topics.
6	I feel confident using programming as an instructional tool within my classroom.
7	I can adapt lesson plans incorporating programming as an instructional tool.
8	I can create original lesson plans incorporating programming as an instructional tool.
9	I can identify how programming concepts relate to Common Core Standards
10	I can identify how programming concepts relate to Next Generation Science Standards.
Note: All items used a five-point Likert scale with options of: Strongly Agree, Agree, Neither Agree nor Disagree, Disagree, Strongly Disagree.	

* Item excluded from TSECT scale measure

item “I am comfortable with computer technology” was too general to contribute meaningfully to the TSECT construct. Accordingly, a scale for TSECT was constructed by summing items 2 through 10. These nine items loaded onto one factor that accounted for 66% of the variance in TSECT. Chronbach’s Alpha was 0.935; the scale had good reliability.

A t-test of the pre and post-survey TSECT scale revealed a statistically significant increase in TSECT from pre ($M = 21.50$, $SD = 8.16$) to post ($M = 31.75$, $SD = 6.45$), $t(107) = 13.613$, $p < .0001$. Cohen’s effect size ($d = 1.316$) indicated a large positive effect.

This corresponded well to the researchers’ informal observations during the intervention – when the subject for the class session – the use of programming in education – was introduced, there was a palpable sense of rising anxiety on the part of the students. Yet by the conclusion of the session, the students were deeply engrossed with the activities, joking with one another, and eager to discuss other ways they might use programming in their future classrooms.

B. Second Intervention

For our second intervention, the instrument was significantly revised based on Bandura’s recommendations, which included focusing on specific skills and asking participants to rate their confidence on a 0-100 scale. We aligned items to lessons used in the intervention and content and practices identified in the Scratch assessment framework. We further separated the instrument into two theoretical constructs: Self-Efficacy for Computational Thinking (SECT) and Teaching Self-Efficacy and for Computational Thinking (TSECT). This instrument was again evaluated for face validity by the authors, who are all computer scientists with teaching experience. The item wording of these new instruments are found in Table II and III below.

Unlike the first intervention, the second intervention was plagued with technical difficulties, mostly arising from the switch in platforms from laptops to iPads (the College of Education had undergone a 1:1 adoption program between the first and second interventions, and had specifically requested the intervention be run on these newly-adopted iPads). Scratch is programmed on Adobe Flash, which is not natively supported on iOS. The intervention was accordingly adjusted to use Scratch Jr. (a native iOS app created by the Scratch team targeting younger students), and Scratch run in the Puffin browser. Unfortunately, while Puffin/Scratch had worked in the researchers’ tests, a new version of both was released days before the intervention, and the results of the interaction were buggy at best. We were also concerned that the interaction between Scratch and the Puffin browser would not allow for Scratch to play music (and Scratch Jr. lacks music blocks), so we struck the first exercise from the lineup and replaced it with an overview of Hopscotch, a similar but more limited and proprietary block-based programming framework.

Much like the first cohort, participation was voluntary, but even though the class sizes were comparable, far fewer

TABLE II. ITEM WORDING FOR THE SECOND TSECT INSTRUMENT

Item	Wording
<i>Items Aligned with CT Concepts</i>	
I can teach students to write programs that ...	
1	execute a step-by-step sequence of commands
2	uses loops to repeat commands
3	respond to events like pressing a key on the keyboard
4	do more than one thing at the same time
5	only execute some commands when a specific condition is met
6	perform arithmetic operations like addition and subtraction
7	can store, update, and retrieve values
8	can ask the user a question
<i>Items Adopted from earlier TSECT Instrument</i>	
With my future classes, I can ...	
9	promote a positive attitude towards programming
10	guide students in using programming as a tool as we explore other topics
11	use programming as an instructional tool
12	adapt lesson plans incorporating programming to meet my students’ learning level
13	Create original lesson plans using programming as an instructional tool
14	Recognize how programming relates to the Common Core State Standards
15	Recognize how programming relates to the Next Generation Science Standards
Note: All items used a 100-point scale where 0 = cannot do 50 = moderately I can do 100 = highly certain I can do	

submitted survey results. Of the 33 surveys entered, 7 contained no responses, and 4 did not contain post-survey results. These were left out of the analysis. Of the remaining 22 surveys, 17 contained missing values (77%). There was a clear pattern – missing items were concentrated in the pre-assessment; when only the post-assessment was considered, only 9 contained missing values (40%) and no discernable pattern was found. Surveys with less than 75% of items answered were left out of the analysis, and case-wise deletion was used for missing values.

TABLE III. ITEM WORDING FOR THE SECT INSTRUMENT

Item	Wording
<i>Items Aligned with Intervention Activities</i>	
I can write a computer program to ...	
1	draw shapes
2	animate characters
3	tell a story
4	play music
5	model plant growth
<i>Items Aligned with CT Concepts</i>	
I can create a computer program which ...	
6	executes a step-by-step sequence of commands
7	uses loops to repeat commands
8	responds to events like pressing a key on the keyboard
9	does more than one thing at the same time
10	only executes some commands when a specific condition is met
11	perform arithmetic operations like addition and subtraction
12	can store, update, and retrieve values
13	can ask the user a question
<i>Items Aligned with CT Practices</i>	
When creating a computer program I ...	
14	make improvements one step at a time, and incorporate new ideas as I have them
15	run my program frequently to make sure it does what I want, and fix any problems I find
16	share my programs with others and look at others' programs for ideas
17	break my program into multiple parts to carry out different actions
Note: All items used a 100-point scale where 0 = cannot do 50 = moderately I can do 100 = highly certain I can do	

The survey tool used by the researchers was designed for a mouse, and proved problematic when using the touch functionality of iPad and many participants reported issues with setting their response level. The researchers suspect this was the cause for much of the missing data – especially as it was concentrated in the pre-survey; as participants worked out how to correctly manipulate the interface they shared the techniques with their peers. Nonetheless, this pattern could also be due to participants being uncertain how to answer

TABLE IV. STATISTICAL ANALYSIS FOR THE SECT AND TSECT INSTRUMENTS

SECT Instrument			TSECT Instrument		
Item	P-Value	Cohen's Effect Size (d)	Item	P-Value	Cohen's Effect Size (d)
<i>Items Aligned with Intervention Activities</i>			<i>Items Aligned with CT Concepts</i>		
1	.001	1.65	1	.0001	2.42
2	.001	2.23	2	.00003	2.68
3	.01	1.57	3	.0002	2.32
4	.02	1.08	4	.0000008	4.17
5	.01	0.99	5	.0005	2.02
<i>Items Aligned with CT Concepts</i>			6	.0006	1.19
6	.02	1.09	7	.01	1.00
7	.001	1.81	8	.01	1.16
8	.01	0.79	<i>Items Adopted from earlier TSECT Instrument</i>		
9	.0004	1.59	9	.0001	2.09
10	.01	1.37	10	.00007	2.04
11	.009	0.78	11	.0002	1.82
12	.01	0.86	12	.0001	1.83
13	.02	0.78	13	.0001	1.98
<i>Items Aligned with CT Practices</i>			14	.002	1.80
14	.0005	1.79	15	.007	1.36
15	.001	1.59			
16	.00002	3.20			
17	.0001	2.08			

questions addressing specific CT constructs before encountering them in the intervention. Given this concern, along with the small sample size, the results of this analysis should be taken with a degree of caution.

After data cleaning as described above, responses of 11 students were analyzed. A one tailed, paired t-test was performed which revealed that the intervention had a statistically significant impact on both SECT and TSECT where $p < .05$, and a positive growth ranging from medium-to-large Cohen's effect size ($d > 0.75$). A Cronbach's Alpha of .96 indicates an internally consistent and reliable instrument.

The benefit of the re-worked instrument allows further investigation of how the students own understanding of computer programming and how they can integrate those computational concepts into their future classrooms.

As seen in Table IV, the intervention had considerable success in increasing pre-teacher computer science self-efficacy. Moreover, the re-worked instrument gives measures aligned to specific CT concepts, allowing specific intervention design questions to be addressed. For example, items 6, 7, 9, 10 show large effect sizes ($d > 10$) – an expected outcome of the intervention, as sequences, loops, parallelism, and conditionals were explicitly targeted in the intervention activities. Item 13, targeting the use of user input (ask and answer blocks in Scratch), had a much lower gain, even though it was a part of the generalized shape-drawing solution, suggesting this area may need more focus in future interventions.

While the CT constructs show to be meaningful in the SECT instrument, the TSECT instrument reveals a higher impact on the students' confidence in teaching CT in their future classrooms. This further suggests the accuracy of the instrument as the intervention emphasized on linking the computational thinking and programming concepts to potential integrations in the classroom. Another observation that leads to the students' confidence in teaching the CT constructs is their method of programming during the intervention. Students are able to employ computational thinking in a natural way, much like problem solving, while programming and the SECT items aligned with CT practices measures their confidence without directly asking them about programming practices, design, or principles.

VI. CONCLUSIONS

The intervention strategy of providing pre-service teachers with mastery experiences of using CT embedded within other subject areas was clearly successful in increasing their self-efficacy with CT. Both sets of evaluation data show a large effect. This was also reflected in students' end-of semester blog posts in comments like this one referencing the intervention:

I found a lot of value in learning about something that intimidated me, and learning to actually enjoy it. That feeling will be good to remember as I go into the classroom and teach students about things that they may be intimidated by.

Moreover, many students indicated their intent to use Scratch in their future teaching, recognizing that embedding Scratch programming into other areas can "[...] actually enhance lessons," and that "I really felt like I could apply this to my high school classroom which is something that I honestly did not feel for many of the other projects that we completed throughout the semester."

This growth is likely the result of directly confronting and breaking down students' preconceptions about programming – that it is difficult, only suited to a small portion of the population. Through mastery experiences, the students learn that they can indeed program, and may even enjoy it, even though they previously did not consider it a possibility. This

may trigger a similar shift in thinking about students' programming abilities. As one participant observes, "the students can create games, animations, art and anything they can think to make, all they have to do is drag and drop blocks."

VII. FUTURE WORK

While convenient for a pilot study, the limited duration of the intervention and tight bracketing of the pre- and post-instrument leaves long-term effects open to questions. A longer duration intervention, with repeated measures of instruments would give far richer data as well as support theory development about CT learning. Further, the authors believe that repeated use of CT throughout a pre-service teacher's training, especially integrated into their methods courses, will lead to both stronger self-efficacy and future adoption. Longitudinal studies to investigate this, along with the effect on those teachers' future pupils, are critically needed.

In considering the difficulty faced in carrying out the second intervention, and given the current penetration of the iPad platform into K-12 education, the authors have come to believe an iOS-friendly version of Scratch is necessary. The most attractive approach is to build a version of Scratch completely based on W3C standard technologies – i.e. HTML5, JavaScript, and Canvas or SVG – as this would ensure high cross-platform viability; as any platform equipped with a W3C compliant browser would be able to host it.

GK-12 DISSECT: Incorporating Computational Thinking with K-12 Science without Computer Access

R. Folk, G. Lee, A. Michalenko, A. Peel, E. Pontelli
Depts. of Computer Science and Biology
New Mexico State University
Las Cruces, NM, USA

Abstract—Computational Thinking (CT) introduces computing concepts and demonstrates their usefulness in many other disciplines. CT principles such as algorithmic problem solving, abstraction, modeling and simulation, are integrated into existing STEM (Science, Technology, Engineering, Mathematics) curricula by DISSECT (DIScover SciEnce through Computational Thinking). By pairing a local K-12 teacher with a graduate fellow, DISSECT provides instruction and resources as instruments that are pertinent to each specific discipline. These skills in problem-solving and abstract reasoning are necessary for students to be able to compete in the modern and future job markets.

DISSECT works to provide these skill-sets to students and classrooms that lack access to computers. The K-12 teachers and graduate fellows work together to develop modules that are capable of teaching CT concepts that are directly tied to their current curriculum while removing the need for access to computer systems. This paper will focus on the modules developed and executed in middle and high school classrooms, emphasizing the creative ways explored to operate in a computer-free environment discussing the strengths and weaknesses of different approaches, while qualitatively assessing student engagement, learning, and interaction which is gathered through teacher interviews, observations and informal talks with students.

Keywords—Computational Thinking, K-12, Graduate Fellows

I. INTRODUCTION

Computational technology is becoming more prevalent as the world evolves and its needs for technologically literate individuals increase. Computational thinking (CT) introduces concepts that are used in computing which are applicable in many other disciplines, especially scientific pursuits [1]. Individuals worldwide must have an understanding of these CT principles if they are to succeed in modern careers. According to the US Bureau of Labor Statistics careers in fields related to computer science are anticipated to grow between 15% [2] and 22% faster [3] than non-technical jobs through 2022 with an expected 4.2 million jobs available. Unfortunately as of 2010, there were 25 states that did not qualify CS courses as either a math or science course that a student could use towards their high school graduation. Furthermore there is a shortage of math and science instructors equipped with the experience and training necessary to teach these essential skills to students in K-12 education. This shortage of teachers is evident in the fact that there has been a 17% drop in computer science courses being offered in K-12 education since 2005 [4].

With the importance of CT skills in individuals it is critical that these skills be learned by students early in their education. The earlier these skills are taught, the stronger and more developed they will become as the student ages giving them an advantage in their future careers. Further, these skills are not only relevant to students practicing computer science but rather to any pursuit or area where critical thinking and problem solving abilities are required [5]. In contrast according to the Advanced Placement Data there were less than 30,000 students who attempted the AP CS test in 2013 [4]. Compound this with the declining interest in completing undergraduate degrees, especially among women and underrepresented minorities, in computer science and there is a responsibility to change these trends.

The DISSECT (DIScover SciEnce through Computational Thinking) program aims to combat these trends with an innovative technique of introducing CT into existing K-12 classroom courses. By integrating fundamental CT principles outside of traditional computer science courses, DISSECT is able to impact a much larger portion of students. DISSECT has chosen to focus on algorithmic thinking and problem solving abilities over the 2014-2015 school year which allows for easily combination with courses such as chemistry, biology, forensics, and literature. As only one course operating with DISSECT is a dedicated computer science course, this joint venture is enhancing far more students than traditional teaching methods would allow.

DISSECT operates by recruiting graduate fellows who are selected from graduate programs in the areas of Computer Science, Electrical & Computer Engineering, and applied computing such as Biology and partnering them to local K-12 instructors. The instructors are respected professionals working within the area who are selected by a panel of NMSU faculty and offer their expertise in the area of pedagogy to the fellows. In return the fellows bring their respective computing background to the table and together produce learning modules which introduce CT principles into the classrooms. Being a low-income area, though, many of the classrooms are unable to offer continued access to computer resources for these lessons and as such the fellows and teachers work together to ensure that their lesson plans are able to account for these limited resources and still provide an environment wherein learning ensues. DISSECT uses these limitations to investigate previously unexplored techniques in teaching CT. By approaching their current classroom curricula from

Fig. 1. Roles of Teachers and Fellows

a computing perspective, fellows and instructors are able to illuminate the underlying CT principles such as algorithms and problem solving that the students are already tasked to learn and provide them a fuller experience.

Throughout the remainder of this paper we will explain the approaches and methods that the graduate fellows and K-12 instructors are using to prepare their modules, their deployment, the techniques used to analyze their delivery, and an evaluation of the effectiveness thus far, placing particular emphasis on the pedagogical activities that expose CT skills with the use of actual computing technologies.

II. DISSECT

A. Concept and Design

Scientific computational thinking is the core concept in the DISSECT program. Even though computational thinking abilities are critical to all scientific pursuits ("All Science is Computer Science" [6]), the resources available in existing STEM courses and K-12 curricula are constrained and instructors have difficulties in providing the necessary environment for their students. DISSECT helps to provide these resources by recruiting graduate fellows with strong backgrounds in computational studies to be fellows in the program. This recruitment grants the fellows many opportunities they may not otherwise have including that of gaining an outside perspective towards their research area, training in pedagogy and communication of complex theories to people of limited experience and background, as well as leadership, team-building, and collaboration skills necessary to function in a group environment. The goals of the DISSECT program therefore are threefold, (i) to create more effective scientists in the recruited graduate fellows, (ii) to increase the levels of interest and future enrollment in STEM+C (science, technology, engineering, and math plus computer science) studies in future generations, and (iii) to help provide the recruited K-12 instructors with the necessary materials and background education to be able to continue creating CT enhanced modules and lesson plans in their classrooms.

By aiding the graduate fellows in becoming better scientists as a whole, the DISSECT program hopes to enhance the fields in which the fellows operate. As new discoveries and breakthroughs in computing have been forthcoming their applicability is not only to the domain of computer science but all sciences. By exposing the fellows to areas of research and topics outside of computer science, DISSECT hopes to inspire them to not limit their interests and efforts to this one domain but use this domain to further both computer science and other related areas as well. Furthermore, the training that the

fellows will receive in communication of advanced technical information to individuals of other backgrounds is vital in the workforce and academia where proposals and explanations must be given and understood by those around them.

The excitement that the graduate fellows have in their own areas of expertise is a factor that DISSECT leverages to inspire excitement in the fields of science and computing in the K-12 classrooms. As the fellows work with the instructors to create effective lesson plans and modules that introduce CT principles the students are able to experience these principles outside of the direct influence of computer science and apply them to many different areas of their academic pursuits. This direct application gives the students an understanding that areas of computing need not limit their options to working behind a desk always but instead can be combined with other interests they may have such as literature, forensics, biology, math, chemistry or physics.

B. Origins and History

The DISSECT program is funded by the National Science Foundation NSF under the Graduate STEM Fellows in K-12 Education (GK-12) program. One of the purposes of this program is for graduate fellows to integrate components of their research into K-12 classrooms. DISSECT believes that this is best accomplished by joining fellows with a K-12 instructor and having them collaborate to create modules that highlight CT concepts in their existing curriculum.

DISSECT utilizes the research and findings of both the Computer Science Teachers Association [7] and Computer Science Principles (CSPinciples) by CollegeBoard [8] in their efforts. The latter influence especially has served as an inspiration and guide to create modules that are completely integrated into the existing classroom curricula while exposing standardized CT principles in the K-12 classroom.

Since 2010, DISSECT has engaged 25 graduate fellows from the fields of Computer Science, Electrical & Computer Engineering, and applied computing (Biology, Psychology, Astronomy) and 16 middle school and high school instructors throughout the Gadsden Independent School District and the Las Cruces Public Schools District. The instructors have primarily been focused in science with a wide variety of subjects including middle school general science, forensics, zoology, biology, chemistry, as well as literature, history, and social studies.

C. Structure

The DISSECT program, as of the 2014-2015 school year, is comprised of 10 graduate fellows, 9 K-12 instructors from the Las Cruces Public School District, members of the New Mexico State University faculty from the departments of Computer Science and NMSU STEM Outreach Center, 1 program coordinator, and 1 external evaluator. The fellows work in conjunction with the instructors in classrooms around the Las Cruces, New Mexico, area to provide CT enriched lesson plans that are integrated directly into the existing curriculum. The fellows spend each week in the classroom presenting these lessons and directly communicating with and assessing the learning of the students with whom they are working. The instructors monitor and coach the fellows in the art of pedagogy

to help the fellows flourish as presenters and instructors under their tutelage. The fellows and instructors need to combine the existing K-12 curriculum, CT concepts, and the fellow's own research into the modules presented and are tasked with determining the appropriate blend of topics to be covered. The fellows as a whole meet regularly throughout the school year to brainstorm and devise techniques to better present the CT topics to their classrooms. Examples are detailed in Section V.

At the start of the academic school year DISSECT hosts an orientation meeting which allows all members of the program to be introduced to the goals and expectations of the current school year. Instructors and Fellows are required to meet at least an hour per week to plan for the classroom activities and module deployment. These meetings allow for cross-training between fellow and teacher in the arts of pedagogy and CT principles. K-12 instructors meet monthly with the program coordinator to discuss the status of the program, areas that need improvements, and ways to increase the benefits for their students. Graduate Fellows, the program coordinator, and NMSU faculty meet weekly to discuss modules that have been introduced or are in development, challenges encountered in the classroom and the ways to overcome them, and share their successes with each other.

All activities throughout the program are thoroughly documented so as to review and improve upon the success of the program. Weekly journals are required from the fellows and instructors that detail in length the preparation that went into the module presented this week, the activities undertaken in the classroom, and the evaluation of the benefits experienced by the students. Modules that are deemed extremely effective are documented in detail by the fellow and instructor so that all materials required are outlined and a step-by-step instruction for carrying out the module is presented. This is to give other instructors the opportunity to present the module in their own classroom without the benefit of the original fellow or original instructor being present. These modules are often repeated by the fellows in following semesters or the instructors in classrooms that the graduate fellow is unable to attend.

D. Components

The three components that comprise the DISSECT program are the graduate fellows from NMSU, the K-12 teachers in the schools, and the K-12 students who are affected by the CT instruction. The fellows benefit heavily from the program by becoming better researchers and educators. They learn how to communicate advanced technical information to a potentially non-technical audience in a way that is beneficial and relatable. The teachers benefit from the expertise of their graduate fellow and are able to learn how best to infuse their curricula with CT teachings. Finally the students benefit by being able to experience CT, even if they are unable to participate in a class that is dedicated to computing.

By participating in the GK-12 DISSECT program fellows obtain a deeper understanding of CT in order to demonstrate the underlying concepts present in the K-12 curricula and increase their presentation skills accordingly. Teachers discover that they need not disrupt their classroom or sacrifice valuable time in order to teach these skills to their students and as such are more likely to continue after their time with the fellow

is at an end. The students realize that CT is a concept that exists outside of computers and hopefully begin to understand the importance of learning these problem solving and critical thinking skills and begin to apply them throughout their lives.

III. CONTRIBUTION TO INOVATIVE PRACTICE

The work of DISSECT is innovative in that we are trying to find alternative methods to successfully teach CT to students without the use of computers. While many educators and researchers have already started integrating CT concepts into K-12 classrooms, most use programs such as Scratch [9] or App Inventor [10] or NetLogo [11] to facilitate teaching. For example, two schools in Connecticut investigated using App Inventor to introduce CT principles in the K-12 classroom for both students and teachers during a summer program. They created lesson plans that introduced App Inventor and gave activities for students and teachers to complete throughout the summer. At the end of the program they found that they were successful in promoting CT and STEM-C by using computer technology such as Android phones and tablets [12]. Other researchers from John Hopkins and Purdue focused their efforts on introducing CT principles to undergraduate students studying engineering. They found that by teaching these engineering students of all grade levels using Matlab that both the students' abilities in solving equations increased and their confidence in their abilities. Again, the influence of presenting computing in the engineering students' curricula provided positive results but relied on computer technologies to accomplish this [1].

A study from Purdue took an approach similar to what DISSECT has done to better prepare teachers and education majors with CT knowledge. For their study they created two 50 minute modules to be covered during one week which introduced CT in real-world applications in hopes of the educators being able to introduce this new knowledge to their own classrooms. After this week, participants were quizzed in their thoughts about CT and were able to distinguish CT from general computing activities versus the control group where most could not distinguish CT from computer related activities. Further, most of the participants saw the opportunity for integration and planned to implement it throughout their own curricula [13]. Using these results as a model, DISSECT has worked to integrate CT principles into K-12 classrooms by modeling the underlying algorithms that are present in the existing curriculum. This direct tie in allows students to gain an understanding of CT as well as a deeper understanding of the original curriculum.

IV. METHOD

As the goal of DISSECT is to incorporate CT into the teachers' current curricula, fellows and instructors work to showcase both the explicit and implicit ways CT is active in their daily lives. To accomplish the instructor-fellow team works together to create lesson plans for modules that integrate into the current curriculum. Modules are customized for a specific classroom subject, however, being that they are focused on the subject of algorithms most can be adapted to fit the requirements of other classrooms.

When creating modules, teachers and fellows utilize the inquiry based learning model [14] because it best captures

the computational thinking applications in the real world. The modules focus on asking students to develop their own methods for solving problems which implements the design-based learning aspect of the inquiry based learning model. For example, in the weather tool algorithm, students are asked to design an algorithm to create a weather tool such as a barometer. Having students create the algorithms themselves allows them to be innovative in their design while learning about the properties of temperature and weather.

When designing modules, fellows focused on the area of algorithms and the accompanying CT concepts. DISSECT has chosen algorithms as our key area for the 2014-2015 school year because algorithms are at the heart of CT concepts with every other concept stemming, either directly or indirectly, from them. The objective is for the fellows to demonstrate that algorithms are used, whether realized or not, in all subjects and that, when given thought, they can be optimized to produce more accurate or more efficient results. This is particularly easy in science classrooms where experiments are conducted and a specific algorithm must be followed.

Because DISSECT focuses its efforts in low-income areas [15], most of the schools the fellows and teachers are working in have neither immediate access nor continuous access to computers. This has proven to be a challenge for the graduate fellows and the teachers to teach computational thinking concepts to students in a straightforward manner. Rather, fellows are tasked to create modules that teach students these concepts without using computers or similar technological advances. A lot of the modules created focus on the design of the underlying algorithms. This is equivalent to the brainstorming a programmer does before starting to implement working code. For example, in the fingerprint search module discussed in detail in Section V, students are asked to write the steps needed to complete a fingerprint search. In this module, students write their answers in English, rather than a specific programming language or pseudocode, a theme that is prevalent in most of the modules used.

Algorithmic logic that are the focus of a couple of modules are abstraction and branching. Again, in these modules inquiry based learning is used but the implementation is through problem-based learning. Fellows design modules that have a problem statement or an article for students to read where students then have to extract the necessary information to answer questions and/or solve problems. This technique is demonstrated in the middle schools modules and again mimics real world environments in technical areas.

V. MODULES

The DISSECT fellows work with teachers in a variety of classrooms. The subjects that fellows are integrating CT modules that do not use computers in are Forensic Science, Computer Science, and 6th grade science. In the 6th grade classroom fellows integrate their modules in the areas of scientific practice, and meteorology. In the following section we will go over the vocabulary that DISSECT has deemed important for teaching CT and sample modules from the classrooms.

Fig. 2. Example of End Result of Image Reconstruction

A. CT Terms

The DISSECT fellows developed a set of 10 concepts that reflect our goal for teaching CT in the classrooms. *Computational Thinking* is a problem solving technique that uses methods from Computer Science. *Algorithm* is a step-by-step process for solving a problem. A *sequence of steps* is a list of steps to perform an action. *Branching* is making a choice that leads to different steps. *Iteration* is repeating steps until a condition holds. A *variable* is a named location that can hold a changeable value. *Abstraction* is a process of removing information from an idea in order to keep only the parts that are relevant to a problem. *Clarity* is a qualitative measurement of how easy an algorithm is to understand its function. *Correctness* is a measure of ability of an algorithm to solve the problem it is intended to. *Efficiency* is a measure of the resources an algorithm uses while solving a problem.

B. Example Modules

1) *Image Reconstruction Module*: This module is used in a forensic science class to show how the techniques are used in the real world. The students were engaged in a game to reconstruct images printed from USC image database [16]. Preparation for this activity includes selecting several images, mounting them on paperboard, and cutting each apart. The activity starts by distributing a piece of the image to each student. The students then need to ask other students questions to see if they have pieces of the same image. When a match is found the students form a group and continue looking for more pieces together. Example questions include asking about the color, shape or edges in the image. The students should gain an understanding of branching and iteration within an algorithm. An example image that is obtained after the activity is shown in Figure 2.

2) *Fingerprint Generation Algorithm Module*: This module is used in a forensic science class to teach students the importance of clarity in an algorithm. Students are expected to have experience in creating a 10-Print Fingerprint Card and are separated into groups of 2 or 3 and tasked with creating an algorithm that a person without any previous experience may follow to generate a successful 10-Print Fingerprint Card. The students must incorporate branching to determine if prints

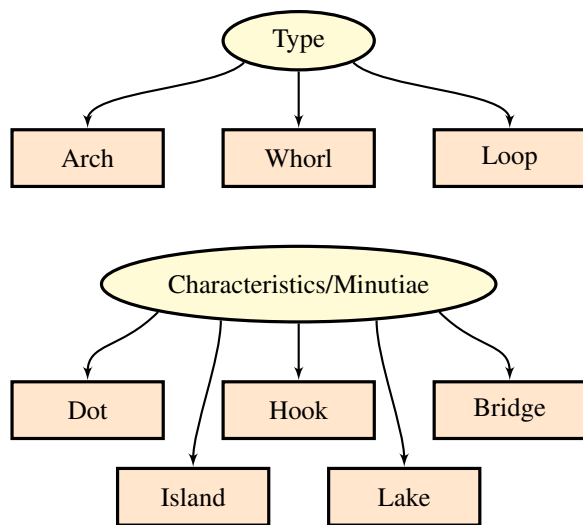

Fig. 3. Example of a Fingerprint Classification Algorithm

are successful and iteration to instruct the user in each finger. After the algorithms are generated they are collected and then administered to people outside the classroom to follow and the results are collected. At this point the results are returned to the students and a discussion ensues about why the results vary from what they expected. After this module, students have a better understanding of how to use iteration and branching to simplify a sequence of steps and a greater respect for the importance of clarity and correctness in an algorithm.

3) *Fingerprint Search Algorithm Module*: This module is designed to have the students create an algorithm to search fingerprints as well as review terms used in fingerprint identification. An example algorithm to search fingerprints is given in Figure 3. To prepare the module, a list of terms are written on index cards with a single term on each. The index cards are taped to the board in a random order. The students are instructed to create an algorithm to search for a fingerprint based on the characteristics listed, starting from most general to most specific. Students are called individually to select the next characteristic to search for. The CT concepts the students should learn about are algorithms and branching.

4) *Weather Tool Algorithm Module*: This module has the students building a weather measurement instrument and writing instructions for others to replicate their work. This module is divided into several days of instruction. On the first day the students are given a crossword puzzle with CT terms. This is followed by developing algorithms to draw shapes, first as an entire class then in smaller groups. On the second day, a warm-up involving writing an algorithm to draw a shape again is used. The class is divided into groups with two or three students. Each group designates a writer and supplier. The writers and suppliers are separated and given the supplies to build either a barometer or a weather vane as well as a picture of the completed tool. The students build and write instructions to build the pictured measurement instrument. On the final day, the groups are again split up and given instructions written by someone in the other group. This module is designed to introduce the ideas of clarity, correctness, and efficiency.

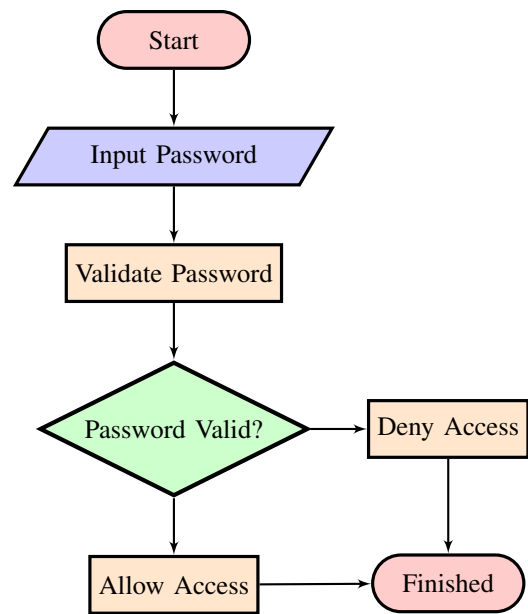

Fig. 4. Example of a Branching Diagram. The branch occurs at the green diagram, the 2 paths are represented by the "yes" and "no" arrows. Notice that both path lead to the finish.

5) *Rocket Branching Module*: This module introduces students to branching and abstraction by following true/false statements taken from an article about an event. In preparation for this module, an article on an event related to the subject in the class is obtained. Next, make a handout that contains true/false statements about the contents of the article. Based on the truth of the statement, there are directions given to move either North, South, East, or West a number of tiles. The students learn branching by following the true/false statements and ending up at the correct final location.

6) *Diagramming Modules*: This module teaches students how to plan out an algorithm through diagramming. Students work in groups to design a board game by diagramming out the rules. Students start by cutting out different shapes from colored construction paper. These shapes are labeled for different actions. Students then post the shapes in order on the wall to show a series of steps with arrows between shapes to show direction. A sample algorithm for checking a password is shown in Figure 4. This module introduces students to algorithm development and gives them a clear understanding of how branches and loops are used in algorithms.

7) *Binary Search Module*: This module has students writing instructions and following others on searching for an unknown page within a book. Students are grouped and given a large book and a secret page number for their group. Each group writes instructions that others can use to find a page within another book. The written instructions are shuffled between the groups and groups follow new instructions. After this an algorithm for searching the book based on a binary search is given to all groups. This module introduces students to algorithms and designing them. Also, clarity, correctness and efficiency are highlighted by discussing the instructions the students wrote and comparing the number of pages that need to be looked at.

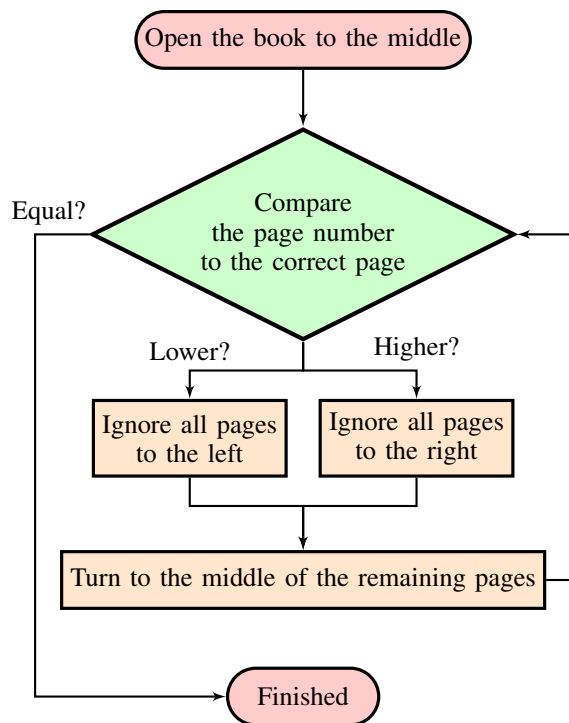

Fig. 5. A Binary Search Algorithm for a Book

TABLE I. RECOGNITION AND DEFINITIONS PAIRED T TEST RESULTS. THE T VALUE WAS TESTED FOR SIGNIFICANCE USING AN ALPHA OF 0.05. (* = $0.01 < p \leq 0.05$; ** = $0.001 < p \leq 0.01$; *** = $p \leq 0.001$).

Test	t Value	P Value	Significance
Recognition Fall	10.22	< 0.0001	***
Definitions Fall	9.02	< 0.0001	***
Recognition Spring	9.95	< 0.0001	***
Definitions Spring	12.28	< 0.0001	***

VI. EVALUATION AND RESULTS

A. Quantitative Evaluations

Students involved in the GK-12 DISSECT program were given a pre-test at the beginning of each semester and a post-test at the end of each semester. The students had continuous training in CT throughout the entirety of both semesters, consisting of a combination of modules taught with and without computers. The overall results can be seen in Table I. A combination of all of the classes showed a statistically significant increase in CT term definitions and recognition over the course of the semester.

More detailed module descriptions can be viewed at http://www.cs.nmsu.edu/gk-12/?page_id=460.

B. Individual Module Qualitative Evaluations

1) *Image Reconstruction Module*: Students seemed to understand what they needed to do to get a complete picture. The only challenge presented by this module was time; about 15 minutes were used to complete the module, and it most likely would be more successful if done in 20-25 minutes. Students liked moving around the classroom for the activity, and they were able to clearly see how iteration and branching

were used in the questions. Students appeared to enjoy the module, and they were quite vocal during the discussion of the concepts presented. This module successfully taught 11th and 12th grade forensic science students about how iteration and branching are used in image reconstruction without the use of computers.

2) *Fingerprint Generation Algorithm Module*: Students were initially surprised by the vast difference between what they believed their algorithm should generate and what the algorithm actually generated. As we discussed where deviations occurred, students were able to see how a lack of clarity and false assumptions led to incorrect results. After about 15-20 minutes of discussion the students then looked again at correcting their algorithms and were able to produce a clear and concise algorithm that generated the results they required.

Overall the students enjoyed this module and were amused by the results they received from their original algorithm and engaged in the process of improving the algorithm. This module successfully taught high school grade forensic science students about the importance of clarity and the use of iteration and branching used in algorithm creation.

3) *Fingerprint Search Algorithm Module*: In order to attempt to involve all of the students, the fellow and teacher tried to make enough terms on index cards so that each student could physically participate. For future modules of this sort, it may be more successful if students are put in groups. The module as a whole, however, was successful. Most students understood that they should look for general characteristics first, and follow with more specific characteristics. Students were able to understand how branching was incorporated in searching for a fingerprint. Students also learned what an algorithm is and how an algorithms can be depicted in psuedocode. Students were nervous at beginning of the module, but as it continued students became more confident in their choices and receptive to solving the problem of how to search for fingerprints based on characteristics. This module successfully introduced algorithms and branching as a method to search for fingerprints without the use of computers to an 11th and 12th grade forensic science class.

4) *Weather Tool Algorithm Module*: When rating each other's algorithms, the students often got confused between correctness and clarity; many gave a low correctness score because it was hard to understand. Also, they gave low efficiency scores because it took them a longer time to understand what they were supposed to do, which made the algorithm take longer, instead of evaluating the number of steps. There were no algorithms that were 100% correct, though some were close, while others were completely wrong. Most of the students were very confused by their partner's algorithms, which was the point of the module. This module demonstrated how in depth they had to go with their algorithms to make them clear, correct, and efficient. They really liked actually building something, and the kids who usually aren't engaged when doing writing exercises were very involved in the building process. This module successfully demonstrated how writing correct, clear, and efficient algorithms can be used to build weather tools in a sixth grade science class.

5) *Rocket Branching Module*: In this module, students had a lot of difficulty with remembering directions and abstracting

information. A lot of them had to do the activity multiple times before they got it right because they walked in the wrong direction, or didn't choose the correct answer. Students enjoyed physically exploring branching statements and getting out of the classroom. By the end of the module, students had a good foundation for understanding if/then branching statements. To improve this module, more time can be spent on practicing abstracting information after reading it. The module would be more successful and would take less time with older students. As a whole, this module successfully introduced branching statements and using abstraction to simplify a scientific article in a sixth grade science classroom.

6) *Diagramming Module*: Students were slow in understanding the concept of diagramming and its importance in problem solving. Because of this it is recommended that this module be presented over several class periods to give students the opportunity to better retain knowledge. Once students understood the idea and purpose of diagramming they greatly enjoyed working on this module and were proud of their work. They were able to create diagrams that were easily read and understood by others. This clearly demonstrates knowledge of clarity and correctness in algorithms. This module successfully introduced the idea of diagramming algorithms and using branching and iteration to problem solve in an 11/12th grade computer science classroom.

7) *Binary Search Module*: The students exclusively wrote a linear search for finding a page within a book. (e.g. "Look through the book, page by page, until you get to your page.") There was a wide range of success when the students followed directions provided by another student. Several students had incorrect instructions that stated to turn to the wrong page. Some of the instructions tried to make the search faster by opening the book to a random place to start as this would tend to be closer to the correct page. The algorithm given in Figure 5 checks few pages and doesn't rely on moving to the exact middle at each step.

VII. CONCLUSION

One of the goals of DISSECT is to teach CT principles to K-12 students while increasing interest in STEM+C. One of the obstacles of teaching CT in a traditional manner is the lack of continuous computer access in the classroom. This paper clearly demonstrates how DISSECT approached this problem and successfully incorporated algorithmic thinking and CT principles for problem solving into existing STEM classrooms. This success is demonstrated through both qualitative and quantitative analysis of the K-12 students by both the fellows and classroom instructor.

In order to develop modules fellows needed to pull out the underlying algorithms from classroom activities and curriculum lesson plans. Using this information the fellows, with instructor guidance, could then create modules to teach about developing algorithms and have students design their own algorithms, implementing the inquiry based learning module. Other times, the fellows focused on teaching individual portions of an algorithm such as branching, abstraction, and iteration, rather than a complete algorithm. Focusing specifically on a certain aspect of an algorithm has proven effective in helping students be able to better understand and apply the principle in other modules and classroom activities.

The modules developed by DISSECT were used in several disciplines from middle school general science through core and elective science classes taught throughout high school including graduating seniors and can easily be adapted for use in different settings. The modules are designed to be incorporated into the teacher's current curriculum, allowing them to supplement their current lesson plans in a way that allows them to achieve their goals while simultaneously incorporating CT principles. Algorithm design was the main concept focused upon in the modules because it is the center of most CT problem solving techniques. DISSECT felt that by teaching students the root of algorithm design the students would be able to have a strong foundation in applying these techniques to their future endeavors.

As seen in our results we had a statistical increase in CT knowledge after deploying these modules. The qualitative evaluation also shows that our modules were successful in the classroom. Most students understood the concepts we were trying to teach and had fun. This further engages students to participate in CT activities in the future.

In the future we would like to strengthen our methodology for creating modules for classrooms without computer use and better assess their effectiveness in the classroom.. Possibilities for better assessing CT knowledge is through the use of critical thinking questions. By adapting our pre- and post-test questionnaire to incorporate such questions we will be able to measure not only a taxonomic understanding of CT principles but also a conceptual and applied understanding. CT principles are applicable beyond the realm of computer science because they are skills that strengthen critical thinking, therefore by testing these skills directly DISSECT will be better able to assess the impact that the fellows and instructors are making in the classroom. Further, we will focus on ways to reach to students other environments than strictly those of a middle school and high school classroom. As the focus of DISSECT is to promote scientific computational thinking and we are innovating ways to achieve this goal without the use of computer technologies it is not necessary that we limit our reach to traditional areas of instruction.

ACKNOWLEDGMENT

We would like to thank Raena Cota with the overall organization of the DISSECT program and research, and her help in editing this paper; Dr. Sara Hug and Dr. Susan Brown for their help with the research, evaluation, and organization of the DISSECT program; and Professor Robert Steiner of the New Mexico State University Statistics Department for help designing the statistical analyses. The data presented in this paper was collected under the approval of the NMSU IRB-11201. The research presented has been supported by NSF grant DGE-0947465.

Abstract — Jeannette Wing's seminal computational thinking (CT) paper, published in 2006, set forth CT as not just a way of looking at *computational* problems, but as an alternative approach to solving everyday problems. We strongly support Wing's assertion. Accordingly, we report the results of our meta-analysis of CT curricular implementations since 2006. Our principle interest is in CT framings and implementations for K-12 audiences in disciplines other than computer science, thus fulfilling the broad appeal and utility originally prescribed by Wing. We break CT down into its constituent characteristics, and split these characteristics into two principle groups: mechanistic (inextricably tied to and limited by computer science) and humanistic (separable from and adaptable beyond computer science). We use this conceptual bifurcation as a basis for selecting and analyzing implementations of CT for subsequent reporting. We summarize our CT meta-analytical results by distributional themes including grades, disciplinary foci, equity groups, and programming paradigms. In conclusion, we make recommendations for improving K-12 CT curricular implementations. Our hope is that utilization of CT characteristics and principles will become more commonplace in public education, be utilized more continuously through primary and secondary grades, and be inventively applied across a more inclusive range of academic disciplines.

Keywords — education, pedagogy, computational thinking, K-12, science education, computer science

I. INTRODUCTION

Jeannette Wing described computational thinking (CT) as "...solving problems, designing systems, and understanding human behavior, by drawing on the concepts fundamental to computer science." (p. 33) [9]. The principle purpose of her seminal paper was to foster general application of thought processes and data/knowledge organizations that had been typically confined to computer science and computing technology. Wing supported broadening the applicability of CT in her statement, "One can major in computer science and do anything. One can major in English or mathematics and go on to a multitude of different careers. Ditto computer science." (p. 35) [9]. However, while Wing's paper has received significant attention from the computer science (CS) education community since its publication, we were aware of little application of CT beyond CS.

Therefore, in this paper we discuss our meta-analysis of the diversity and depth of academic studies related to CT *exclusive* of pure CS contexts. Our goal is to assess the extent to which

CT has been framed and implemented in K-12 and informal educational settings. To our knowledge, no one has published a similar meta-analysis of CT. A meta-analysis of this emerging field is warranted by virtue of its potential contributions to general education. The benefits include identification of characteristics of superior implementations, and illumination of pedagogical and developmental gaps among implementations. More broadly, this meta-analysis may contribute to increased discussions among CT stakeholders, which can do nothing but broaden and improve the state of CT research, and help to determine the limits of its efficacy.

II. COMPUTATIONAL THINKING DEFINED

A. Definition of CT from Wing (2006)

Given that our main purpose with this paper is to assess the evidence of CT in general K-12 education, it is essential that we settle on a definition of CT. Can we be sure that Wing [9] is the right starting point? Clearly, this is the case. Prior to Wing, Web of Science lists only four papers using the phrase, "computational thinking", in their topic descriptions. These papers, all of which precede Wing by at least seven years, are typically disjoint from her description of CT. From 2006 through 2014, Web of Science catalogs 167 papers that use the phrase in their topic descriptions. The vast majority of these papers clearly exhibit basic conceptual alignment with CT as described by Wing. In addition, 188 papers from Web of Science explicitly reference Wing. Among the combined pools of papers that use CT as a phrase in their description, and those that cite Wing, 115 of 240 papers (48%) do both.

Wing [9] frames CT by discussing aspects including who should use it ("...everyone, not just computer scientists". (p. 33) [9]), what kinds of problems are well suited to it (complex tasks or systems of tasks), the nature of answers it yields (degrees of precision), and how it consists of sub- and super-tasks (e.g. parallel processing, recursive routines, "...planning, learning, and scheduling in the presence of uncertainty" (p. 34) [9])

The characteristics of CT that Wing [9] discusses are presented in Table 1 in two categories. The white cells indicate *humanistic CT characteristics* that are related to thought processes such as formulating problems, weighing alternatives, and designing systems. The gray cells are *mechanistic CT characteristics* that are inextricably tied to computer science, traditional programming, and computer engineering. These

include operating system constraints, type checking, and aliasing. It is the set of eighteen humanistic characteristics that is the focus of this paper, as they embody the inclusivity for individuals and implementations that is a main thrust of Wing's paper. We decided to remove Wing's mechanistic characteristics from further consideration in the scope of this paper.

TABLE 1 - Elements of Computational Thinking from Wing (2006)

<i>Humanistic CT elements</i>	<i>Mechanistic CT elements</i>
problem solving	fundamental concepts of CS
designing systems	considering the OS
understanding human behavior	considering the machine's instruction set
considering resource constraints	interpreting data as code and code as data
reformulating problems by reduction, embedding, transformation, or simulation	generalization of dimensional analysis through type checking
thinking recursively	using aliasing appropriately
thinking in parallel	cost of indirect addressing or procedure call
decomposition and abstraction of large tasks	judging programs for aesthetics in addition to correctness and efficiency
suitable representations	suitable use of invariants
modularization	confidence of safe use of systems without intimate details
prefetching and caching	appropriate technical language
strategies for error correction and recovery	avoiding race conditions
heuristic reasoning	
planning, learning, and scheduling	
searching	
game theory	
using massive amounts of data	
choosing among tradeoffs	

B. Definition of CT from CSTA/ISTE

While the historical majority of CT research has been aligned with Wing's [9] articulation, we considered the possibility that Wing may no longer be considered the *de facto* definition. We found a couple additional definitions to consider in this regard. After analyzing these alternative definitions, we concluded that Wing's articulation should retain its status, but with a caveat, courtesy of several organizations involved in science and technical education.

From 2008 to 2010, the National Science Foundation's Directorate for Computer & Information Science & Engineering, then with Jeannette Wing as its assistant director, awarded three grants. The first was to the National Academy of Sciences to "...hold two workshops to explore the nature of computational thinking and its cognitive and educational dimensions." [6] This was followed by two grants to the International Society for Technology in Education (ISTE) and Computer Science Teachers Association (CSTA) to "...serv[e] as a national convener and consensus builder around defining a common language surrounding computational thinking..." and "...build [...] a shared understanding of computational thinking and prioritizing the strategies and resources that need to be developed to implement computational thinking in K-12 education.", respectively. [7] [8] The final product of these three grants was the Operational Definition of Computational Thinking for K-12 Education [2].

We note, and appreciate, that the Operational Definition [2] includes five habits of mind (such as tolerance for ambiguity) that are important for utilizing its six CT characteristics. These habits of mind are not mentioned in Wing's set of characteristics. While these habits of mind rationalize much about the design of the Operational Definition's set of characteristics, they did not factor into our meta-analysis.

C. Definition of CT from Google

Google's web sub-tree, called "Exploring Computational Thinking", is a component of Google for Education [4]. Google breaks down CT into four techniques: decomposition, pattern recognition, pattern generalization and abstraction, and algorithm design.

We found this articulation of CT problematic. For example, we consider pattern recognition to be a type of algorithm. Furthermore, we consider pattern generalization to be a product of the pattern recognition process...the ability to see commonality and generalize across sets of patterns *by virtue of* an abstraction of an algorithmic solution. In general, we consider the Google articulation of CT confusing because of hierarchical, cyclic, and overlapping constructs.

D. Choosing among the alternative definitions

Of the three CT alternative definitions, we viewed Wing's [9] and the Operational Definition's [2] articulations to be superior to Google's [4], so we proceeded to consider just the first two alternatives.

The Operational Definition [2] consists of six general characteristics compared to Wing's [9] eighteen more narrowly focused characteristics. In some cases, an Operational Definition characteristic is approximated only by aggregating several of Wing's characteristics. For example, automation of solutions through algorithmic thinking, combines several of Wing's characteristics including heuristic reasoning, planning, learning, and scheduling. Formulating problems in computational terms combines multiple characteristics from Wing including reduction, embedding, parallelism, recursion and modularization. The Operational Definition includes the important aspect of intelligent data organization, a characteristic notably absent from Wing (2006). Computer scientists often consider the various usage cases of data when

designing structures to contain them. Only one of the Operational Definition's CT characteristics specifically mentions computing ("Formulating problems in a way that enables us to use a computer and other tools to help solve them."). Even here, the characteristic is cast in terms that are not exclusively computational. All of the other Operational Definition characteristics are cast in terms that are agnostic with regard to computing.

We constructed a conceptual map relating Wing's [9] CT characteristics to those of the Operational Definition [2]. This exercise was instructive in that it illustrated the complexity of the interrelationships between the characteristics. In a number of cases, one author's characteristic was split into multiple characteristics by the other author. In other cases, separate characteristics from one author were combined by the other. Only three characteristics (consideration of resource constraints, decomposition and abstraction of large tasks, and modularization) were linked to a single characteristic from the other definition. At the other extreme, eleven of Wing's characteristics mapped to the tool-appropriate problem formulation characteristic of the Operational Definition, Eight of Wing's characteristics mapped to the automated algorithmic thinking characteristic from the Operational Definition.

Though the per-characteristic interrelationships between Wing [9] and the Operational Definition [2] were convoluted, the respective conceptual breadths of the sets of characteristics were very similar. This realization informed us to consider a superset of CT characteristics formed by combining Wing's articulation and that of the Operational Definition. From this superset, we eliminated three characteristics of Wing that, to us, seemed to be inapplicable based on their generality (solving problems, designing systems), or their inappropriateness for K-12 audiences (using massive quantities of data). However, aside of these exceptions, we considered Wing and the Operational Definition to be conceptually and functionally similar, though at two different levels of granularity.

III. METHODOLOGY

The purpose of this paper is not to expand the wealth of writing about computational thinking, but rather to attempt a meta-analysis of all writing on the topic and distill tangible evidence of educational impacts outside of computer science from the body of work. To our knowledge, a similarly focused meta-analysis has not previously been conducted.

Consistent with our purpose, we searched for CT-related academic writings using four sources: the Web of Science (WOS), the digital library of the Association for Computing Machinery (ACM), the digital library of the Institute for Electrical and Electronics Engineers (IEEE xPlore), and Wiley Online Library. The first and last sources are general repositories of academic writing. The second and third sources are, respectively, specific to computing, and generally focused on technology.

The first stage of searching sought to capture all writings that were possibly influenced by Wing [9]. As much as possible, we searched the four digital libraries similarly. We searched for "computational thinking" in the title, abstract, and topic text, except for the ACM digital library, which does not

offer topic metadata searching. An additional first round search of WOS was performed for all publications that referenced Wing.

TABLE 2 - Literature Search Stages by Source

Stage	Criteria for selection	Sources				
		WoS	IEEE	ACM	Wiley	total
1a	abstract contains topical word string	167	70	177	148	
1b	paper references Wing (2006)	188				750
2	paper is unique	240	67	177	148	632
3	title of paper indicates a plausible fit	230	65	174	52	521
4	abstract clearly meets topical criteria	45	9	47	1	102
5	full paper clearly meets topical criteria	17	4	20	0	41

The second stage of literature selection eliminated duplicates occurring between databases or between different searches of the same database. Duplicates were identified by matching title, author, and year of publication. As might be imagined, there was significant overlap between the two types of WOS searches (115 duplicates, Table 2). However, the degree of mutual exclusivity of the respective databases, with respect to CT, was surprising to us. Of the 395 non-WOS papers, only three were found in WOS. No papers whatsoever were found in common between the non-WOS databases.

The third stage of literature selection eliminated papers that seemed to only be related to traditional forms of programming (e.g. programming with the C language rather than assigned-function physical blocks). We also eliminated papers that were not related to education, learning, or cognitive processes. The vast majority of the Wiley writings were eliminated in this stage because they focused on professional biosciences where traditional computing was used as a simulation or analysis tool.

The fourth stage of literature selection involved reading the abstracts to explicitly evaluate the relevance of the related writings. Abstracts had to clearly meet the following criteria.

- Pedagogical or curricular implementations must have been completed. Implementations that were merely proposed, but not classroom tested, were eliminated.
- Implementations must have targeted a subset of grades K-16. Though this paper ultimately focuses on K-12, we thought that extending the literature search range into college would, potentially, identify implementations that could be *adapted* to high school or younger audiences.
- Implementations that abstracted programming functionality in non-traditional ways were accepted even if it was mixed with traditional programming.

- Implementations must have included non-CS majors and focused on disciplines and majors outside CS.

Table 2 shows that the fourth literature selection stage was the most discriminating, eliminating 80% of papers from further consideration. Web of Science papers were retained at a 20% rate, and IEEE xPlore papers were retained at a 14% rate. Only one Wiley paper was retained in this stage. By contrast, the ACM digital library papers had the best retention rate (27%).

The fifth and final literature selection stage involved full readings of the papers that passed stage four. Sixty percent of the remaining papers were culled out of this stage, with the principle reasons for rejection being...

- proposed or in-process implementations, rather than completed implementations
- reports on teacher workshops about CT implementations
- implementations for teachers only
- implementations for CS students only
- implementations based on conceptions of CT that did not fit the descriptions found in Wing [9] or the Operational Definition [2]

Forty-one (<6%) of the original set of 750 (632 unique) papers remained at the completion of our literature selection process. We then completely scanned (visually and electronically) for text strings or text string stubs (e.g. parallel*, abstract*, algorithm*) matching any of the characteristics of CT as articulated by either Wing [9] or the Operational Definition [2]. We reasoned that authentic implementations of CT were likely to mention the specific characteristics they utilized. We now present the results of our search for specific CT characteristics in the final group of CT candidate papers.

IV. IMPLEMENTATIONS USAGE OF CT CHARACTERISTICS

A. Wing's CT characteristics

Two concepts, decomposition of large tasks and abstraction of data representations, were used in sixteen and fifteen implementations, respectively. Beyond this, as can be readily seen in Table 3, the usage of Wing's [9] characteristics dropped precipitously. Eight of Wing's 15 characteristics were referenced by one or zero implementations. Modularization was mentioned only twice, which struck us as inconsistent with the frequent mentions of large task decomposition. Searching, one of the most basic and essential algorithm classes, was mentioned by only one implementation.

B. The Operational Definition's CT characteristics

Sixteen papers mentioned abstraction of methods or data representations from the Operational Definition [2] in their implementations. In four of the papers, this was the only CT characteristic they mentioned. Automation or algorithmic development was mentioned by nine of the implementations. Aspects of problem formulation were mentioned by six of the implementations. Only three (19%) implementations cited a majority of the characteristics identified in the Operational

Definition. Two of these implementations are discussed in more detail later in this paper.

TABLE 3 - Selected implementations' usage of Wing's CT characteristics

<i>Humanistic CT characteristics from Wing (2006)</i>	<i># of imps. using (max 41)</i>	<i>% of imps. using</i>
decomposition and abstraction of large tasks	16	39.0%
suitable representations	15	36.6%
planning, learning, and scheduling	5	12.2%
reformulating problems by reduction, embedding, transformation, or simulation	4	9.8%
thinking in parallel	4	9.8%
choosing among tradeoffs (optimization)	3	7.3%
modularization	2	4.9%
strategies for error correction and recovery	1	2.4%
heuristic reasoning	1	2.4%
searching	1	2.4%
understanding human behavior	0	0.0%
considering resource constraints	0	0.0%
thinking recursively	0	0.0%
prefetching and caching	0	0.0%
game theory	0	0.0%

TABLE 4 - Selected implementations' usage of Operational Definition's CT characteristics

<i>CT Characteristics from Operational Definition (2011)</i>	<i># of imps. using (max 41)</i>	<i>% of imps. using</i>
represent data (and methods) abstractly through models and simulations	16	39.0%
automate solutions through algorithmic thinking	9	22.0%
formulate problems that enables us to use a computer and other tools to help solve them	6	14.6%
logically organize and analyze data	4	9.8%
optimize a solution among competing solutions	4	9.8%
generalize and transfer problem solving process to other problems	1	2.4%

In the next section of our meta-analysis, we focus on identifying themes among the 41 implementation papers that passed all stages of our literature selection process.

V. DISTRIBUTION THEMES IN CT IMPLEMENTATIONS

Here we present a few of the dimensions along which our select group of papers can be considered.

A. Distribution by publication year

Figure 1 shows the frequency of selected implementations by publication year. After several years of none to few papers that fulfilled our selection criteria, a significant increase started in 2010, proceeded into 2011, slightly declined in 2012, and finally declined significantly in 2013. There were somewhat more implementations in 2014.

FIGURE 1 - Selected Humanistic CT Implementations Per Year

B. Distribution by educational grade level

Table 5 shows the frequency of CT implementations per grade from kindergarten through senior year of college (note: two implementations did not clarify their grade applicability and were therefore eliminated from the table). Dark colors represent relatively small numbers, indicating a lack of implementations for some grade levels. Light colors represent relatively large numbers and an abundance of implementations for that grade. Very few implementations applied to elementary grades. Significantly more implementations applied to middle school grades. Fewer applied to high school, and college grades had another relative abundance of implementations. The reason college freshman had more implementations than either high school seniors or college sophomores, was two freshman-only implementations.

TABLE 5 - Computational Thinking Implementation Frequency by Grade (dark gray is least; white is most)

Primary					Middle			High				College				
K	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
4	3	4	5	5	4	14	14	14	9	8	8	8	17	15	13	13

While Table 5 is a summary by grade, Table 6 shows grade level details of the selected implementations. The shaded rows to the right of the publication year indicate the grade ranges for each implementation. The shading of the row is determined by the span of years (grade range) of the implementation. For example, some CT implementations spanned K-12, a range of 13 grades. This was the widest range and is colored dark gray. At the opposite extreme, single year implementations are shown in light gray. The vast majority of implementations were confined to only one school level (e.g. only to elementary school). However, Table 6 shows nine implementations spanned school levels. Three implementations spanned three

school levels. Twenty-seven implementations covered four or more grades. Of these, twelve implementations were restricted to the college level.

TABLE 6 - Computational Thinking Implementations by Author, Year, and Implementation Grade Range (light gray is most grade focused; dark gray is least grade focused)

C. Distribution by disciplinary focus

Twenty-two (54%) of the selected implementations applied to general studies. Twelve (29%) were non-CS STEM oriented, and 7 (17%) were humanities focused.

D. Distribution by equity group

Thirteen implementations (32%) were designed with one or more equity groups in mind. Of these, girls were the most frequently targeted (six) equity group. Hispanic and Latino students were specifically mentioned in four implementations. African-American students were explicitly mentioned in three implementations. Other specifically mentioned equity groups were underachieving students (two), and students with disabilities (one).

E. Distribution by approach to programming

To reiterate, implementations that completely depended on traditional languages such as C, C++, and Python, were

dropped by our literature selection process. We considered these to be more typical of CS-specific implementations of CT and therefore outside the scope of this paper.

Thirteen (32%) implementations did not program at all, and instead used puzzles, creative writing, visualization, and interactive and online systems, as tools to teach characteristics of CT.

The remainder (68%) of the implementations used one or more game-development frameworks or visual language tools to teach CT skills. These tools included Alice, a program developed at Carnegie Mellon University for building virtual environment worlds; AgentSheets, a visual programming environment designed by researchers at the University of Colorado at Boulder; Scratch, a visual logic simulator from the Massachusetts Institute of Technology; VPython, a 3D graphics development system based on Python; Lego Mindstorms, for programming customized robot behaviors; and Kodu, a game development environment from Microsoft Research

VI. OBSERVATIONS ON META-ANALYTIC DATA

Here we list some observations regarding the data offered in the sections on literature selection, implementations' usage of CT characteristics, and distribution themes.

Only one paper from the Wiley database search made it through the fourth selection round. In fact, the titles of papers from the Wiley search indicated significantly less topical fit with our conception of computational thinking than other databases. Considering that the Wiley database encompasses a number of top education journals, this was very surprising to us. To corroborate this finding, we conducted several mini-searches of top education journals. These searches supported our initial interpretation of the Wiley database search result: educational research and computing-at-large seem to have little commonality in research literature.

The grade distribution of selected implementations from Table 5 was interesting in that there were fewer high school implementations than middle school. We expected either a more uniform distribution or gradual escalation of implementations from middle school, on to high school, and through to college.

Table 6 shows that nine implementations spanned multiple school levels (e.g. middle into high school) and six implementations spanned seven or more grade levels.

The extent to which our 41 selected implementations utilized CT characteristics in a piecemeal fashion surprised us. Not only were the majority of characteristics used little or not at all, a significant number of the authors cited CT characteristics which are not mentioned in either Wing or the Operational Definition.

VII. CONCLUSIONS

The Operational Definition's [2] CT characteristics provide a very useful adjunct to Wing [9]. Together, these two sets of characteristics provide different levels of detail yet have a high degree of conceptual overlap. Taken collectively, they help

explain CT more broadly and more effectively to a wider range of audiences than either does individually.

The degree to which Wing's [9] ideas about computational thinking have been implemented for disciplines other than computer science is small. Of 632 unique papers related to computational thinking, less than 7% met our selection criteria. This surprised us and led us to consider root causes for the lack of generalized application of CT.

Of papers implementing CT according to our selection guidelines, less than half utilized any characteristics of computational thinking as articulated by Wing [9] or the Operational Definition [2]. Further, among this subset of selected implementations, only one offered a complete set of CT characteristics. The typical implementation utilized three of fifteen characteristics from Wing, and two of six characteristics from the Operational Definition. As a result, we weighed the positive and negative impacts of less-than-complete CT implementations.

The distribution of the selected implementations, as a function of grade level, was uneven. The average number of implementations for elementary grades was four, while the average number for middle school grades was fourteen. High school grades averaged eight implementations. For several reasons, we considered this to be less than ideal for advancing students' use of CT as they progress from kindergarten through high school. We think the broad range of grades for some of the implementations may hinder their effectiveness by diluting their age-specific pedagogical criteria. In addition, the uneven distribution of implementations may mirror uneven scholarship connecting technical education to cognitive development. Finally, in terms of building academic momentum, especially for students interested in technical fields, we considered distributions that are flat or increasing over the grade range preferable to the low-high-low-high pattern we observed.

A couple excellent examples of CT implementations for non-CS students emerged from our selection process. Basawapatna et al.'s [1] implementation incorporates aspects of all Operational Definition characteristics. Using a game development and prototyping environment, 6th grade students associate agents with behaviors (an example of abstraction) that are simultaneously applicable to physical world phenomena (e.g. absorption) and games (e.g. predator/prey). Varying the parameters of the behaviors (an example of competing solutions), students pick the optimal parameter set for a given phenomenon, analogous to optimization for game play. Chaining outcomes of agents' behaviors fosters students' algorithmic thinking and planning.

Dierbach et al.'s [3] college-level implementation addressed four of the six Operational Definition characteristics. The authors initiated interest in computational thinking through a freshman seminar class and subsequently developed individual CT implementations for the humanities, music, kinesiology, and sociology departments. Common course goals included modeling, algorithm development, assessment of problem solvability and tool selection, and algorithm assessment. Additionally, faculty developed domain-specific CT-oriented goals for each of the implementations. For example, one of the goals for the CT music course was

“Demonstrate understanding of how sonic and visual information can be modeled through analysis, decomposition, abstraction, and alternate forms of representation in computational systems” (p. 260) [3]. Post implementation data indicated that more than 75% of students successfully applied CT characteristics within their respective domains. However, 45% of students reported having some confusion about CT. An overwhelming majority of administrators associated with the four implementations recommended using CT in diverse curricular settings beyond CS, math, and science.

We believe CT characteristics are confusing to educational researchers and educators alike, outside of CS circles, and our study identified a number of symptoms of this confusion. The symptoms included implementers citing CT characteristics that were not mentioned in Wing [9] or the Operational Definition [2], the dearth of non-CS implementations of CT, the lack of implementations’ use of CT characteristics excepting abstraction and algorithmic thinking, and students and teachers alike expressions of confusion about using CT in classroom implementations.

VIII. RECOMMENDATIONS

To answer the question begged by this paper’s title, “Does Computational Thinking impact K-12 science education?”, we respond, “No, but it could and should.”, and, to paraphrase Wing, “Ditto, non-science education, where it makes sense to do so.” At this point, not enough evidence exists to assess the limits of CT’s utility. Until this evidence exists, all efforts should be made to try CT in as diverse a collection of pedagogical circumstances as possible.

We recommend that educators wanting to incorporate CT into their teaching, and computer scientists wanting to get CT out of the computer lab, start talking and keep talking...together. Educators need to articulate what it is about CT that they don’t understand. Computer scientists, ironically, need to think abstractly (e.g. traditional programming is but *an instance of abstraction*) about elements of their craft and be ready to answer educators in non-CS terms. The bottom line is that conversations between computer scientists, educators, educational researchers, and non-CS scientists are invaluable, but happen all too infrequently. All of these groups were represented at the second NSF workshop on computational thinking. The report from that workshop contained significant contributions from educators and education researchers, and played no small role in the creation of the Operational Definition.

We also recommend that the Operational Definition for Computational Thinking [2] be considered as much a cornerstone document of CT as Wing’s 2006 paper [9]. Though the Operational Definition is more general than Wing, we judge it to be more readable by non-CS audiences. Furthermore, the section on dispositions and attitudes is wonderfully clear in depicting the right mindset for any application of CT, and the nature of the problems to which CT is best suited.

We recommend that classroom CT implementations be informed by educational psychology. Students’ cognitive abilities should determine the pedagogical CT mechanisms that are used to teach the topic at hand. Here again, more data from classroom CT implementations are needed to help determine what pedagogical CT mechanisms are effective for students at different levels of cognitive development. This is but one aspect of personalizing CT. As Roy Pea said in the first NSF workshop, “Connecting computational thinking in a personally meaningful way is at the heart of tackling the problem of how everyone can be brought into a pathway for developing and using computational thinking in their everyday lives.” (p. 6) [5]

Finally, once data of sufficient breadth and depth has been collected on CT implementations, educators and computer scientists should reconvene to discuss assessment. As it stands, the absence of a standardized assessment instrument to measure learning outcomes makes it harder for scholars to measure the effectiveness of current K-12 CT implementations. However, any effort to produce CT assessments at this point would be sorely under-informed by the present state (low volume and high variability) of CT classroom implementation data.

DISSECT: An Experiment in Infusing Computational Thinking in a Sixth Grade Classroom

A. Peel, J. Fulton, E. Pontelli

Depts. of Computer Science, Molecular Biology, and Plant and Environmental Sciences
New Mexico State University
Las Cruces, NM, USA

Abstract—This paper summarizes the successes and challenges encountered during the incorporation of the New Mexico State University DISSECT (DIScovering SciEnce through Computational Thinking) Fellowship program into a 6th grade classroom. Graduate student fellows work with experienced K-12 teachers to create and deploy interactive computational thinking (CT) modules in middle and high school classrooms that promote active learning through the use of technology and cutting edge scientific research. One of the main objectives of the DISSECT program is to facilitate the professional development of graduate students in computing-rich fields, such as engineering, computer science, and biology, through leadership development, public speaking experience, and an enhanced vision of how CT is vital to in all scientific disciplines. The alliances formed between K-12 teachers and their fellows provide an opportunity for teachers to attain knowledge of CT principles and equips them with the ability to develop and continue their own future lesson plans integrating CT. This paper thoroughly describes specific modules that integrate CT concepts into the traditional 6th grade science curriculum, the statistical results of assessments gauging the development of CT skills and knowledge during the course of one academic year, and suggestions for improvements and incorporation into other curricula.

Keywords—Computational Thinking, K-12, Interdisciplinary, graduate fellows

I. INTRODUCTION

As is widely reported in the United States, economic recession has led to a rocky employment landscape over the past decade. Employment opportunities and salary rates have greatly expanded within the disciplines of Science, Technology, Engineering, Mathematics, and Computing (STEM+C) while growth has severely slowed or become stagnant within more traditional disciplines such as manufacturing, services, and sales [1]. In 2014, there were nearly 8.2 million Science, Technology, Engineering, and Mathematics and Computing (STEM+C) jobs, with computer occupations making 44% of those jobs [2]. In fact, the number of STEM+C careers are expected to rise by 17% by 2018, while non STEM+C careers are expected to increase by only 9.8% [3] while wages within these STEM+C careers are approaching nearly twice the US average [4].

Consequently, a strong background in scientific and computing principles is key to future financial success, especially for youth [5]. Instruction in computational thinking (CT), a pedagogy incorporating science and computing into classrooms, is becoming more prominent. Wing, 2006 defines computational thinking as "taking an approach to solving problems, designing systems and understanding human behaviour that

draws on concepts fundamental to computing". Through this teaching style, students are coached to think in an inductive, logical manner that strives for efficient solutions to challenging problems. Furthermore, through improved capacities for abstraction, students' ability to creatively solve problems grows as they are able to simplify complex problems into manageable components they can be addressed [6].

CT concepts and terminology was selected from CS Principles, the proposed AP Computer Science Curriculum Framework [7]. The CT terms used in module development were algorithm, clarity, correctness, efficiency, iteration, abstraction, branching, variable, and sequence of steps. The definitions given in the CS principles are described below, and they were simplified for optimal 6th grade understanding.

An algorithm is defined as precise sequences of instructions for processes that can be executed by a computer and are implemented using programming languages to solve a problem (simplified to a sequence of steps to solve a problem). Clarity is described as the language used to express an algorithm can affect characteristics such as clarity or readability but not whether an algorithmic solution exists (the readability of an algorithm). Correctness is described as the correctness, usability, functionality, and suitability of computational artifacts (how well the algorithm produce the desired outcome or answer). Efficiency is described as including both execution time and memory usage (the speed, or number of steps in an algorithm). Iteration is defined as the repetition of part of an algorithm until a condition is met or for a specified number of times (repeating a sequence of steps). Abstraction is described as reducing information and detail to facilitate focus on relevant concepts (simplifying information to solve a problem). Branching is defined as a decision point that affects the resulting steps of an algorithm (choosing a path). Variables are used in programs and initialized and updated, read, and written (a value that can change). Sequence of steps is a simple linear algorithm without a solution (a simple algorithm).

An education grounded in science augmented with CT introduces students to an essential body of knowledge and lays a solid foundation for future learning. Middle school is an appropriate age to introduce these computing concepts in order to facilitate their incorporation into the lives of these youth and form a foundation for their future careers. By being acquainted with CT, students can find the transition into STEM+C careers easier and more fulfilling. Furthermore, the underlying belief is that career choices are often formed during the transition of middle school, and the impact of early awareness to computing opportunities could influence students'

decision towards STEM+C careers [8]. Middle school students learn best when they are actively engaged, which is often a result of hands-on and inquiry based activities [9]. Studies in middle school classrooms have shown increased student engagement and enthusiasm when technology was used to implement lessons [9]. Implementing this new curriculum as a supplement to traditional science in order to improve subject comprehension and engagement is a primary objective of New Mexico State University's DISSECT program. To achieve this aim, graduate student fellows work in coordination with an experienced K-12 teacher to create and deploy interactive CT modules in middle and high school classrooms that promote active learning through the use of technology and cutting edge scientific research. Another main objective of the DISSECT program is to facilitate the professional development of university graduate students in computing-rich fields, such as engineering, biology, and computer science, through leadership development, public speaking experience, and an enhanced vision as to how CT is vital to in all scientific and social disciplines. The alliances formed between K-12 teachers and their fellows provide an opportunity for teachers to attain knowledge of CT principles and equips them with the ability to develop and continue their own future lesson plans integrating CT. The hypotheses underlying these objectives, and constituting DISSECT's philosophy are: (1) Several components of CT are already implicitly present and used in many traditional scientific disciplines (e.g., Physics, Biology) - thus, it is important to make them explicit and bring them forward to enable students to recognize them and reuse them across domains and disciplines; (2) CT provides principles, tools and models that can be effectively used to enhance the learning of traditional sciences, making the learning process more dynamic, interactive and engaging. The following sections of this paper describe methods for incorporating CT into the 6th grade science curriculum. The qualitative results for each developed CT module are reported, and suggestions for module improvement are discussed. The overall quantitative results based on pre and post-test evaluations are described and their implications discussed.

II. MODULES

Modules discussed in this paper were primarily created by Amanda Peel, a graduate fellow, with the guidance of Mrs. Kathleen Guitart, a Las Cruces Public Schools sixth grade science teacher, and were created to incorporate CT concepts into the existing curriculum. The sixth grade science curriculum consists of 7 concepts: scientific practice, matter, geology, meteorology, inventions, astronomy, and energy. The following modules have been selected to demonstrate CT concepts, algorithm skills (following and writing), branching, abstraction, visual programming, and iteration. Further details pertaining to the described modules, and other modules can be seen on the NMSU GK-12 DISSECT program website (<http://www.cs.nmsu.edu/gk-12/>).

A. CT Terms: Vocabulary Introduction Module

The learning goal of this module was to have students learn the definitions of the CT concepts, and how to identify examples of each. During the first and second class, students wrote the CT terms and their definitions with the assistance

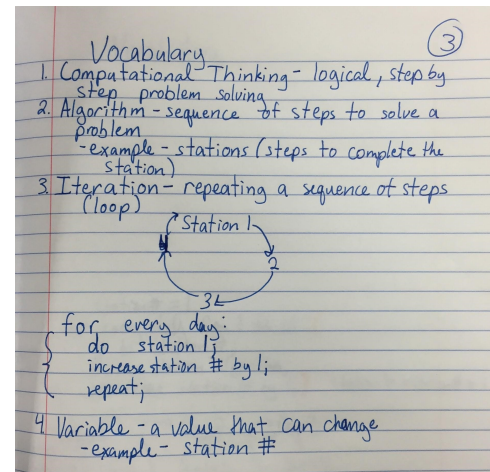

Fig. 1. CT Vocabulary Example

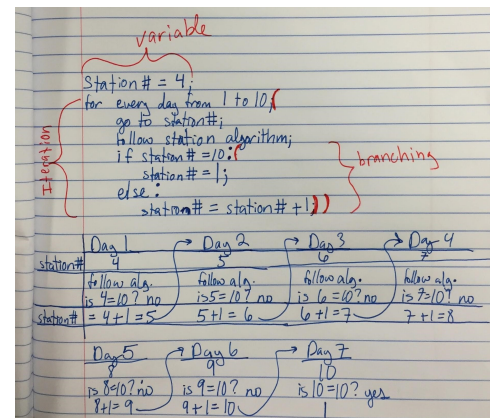

Fig. 2. Geologic Stations Algorithm

of the GK-12 fellow. After writing each definition, they talked about what each term meant and they were given real world examples of each (Fig. 1). At the end of defining all the words, the fellow and students wrote an algorithm together, describing how to go through their geologic stations (Fig. 2). In class, they were working on 10 stations, in which they would work in groups on one station per day learning about different geologic concepts. During the third class, students played CT Jeopardy (jeopardylabs.com/play/computational-thinking-vocabulary), which allowed the students to test their vocabulary understanding.

B. Metric Measurement: Following Algorithms Module

The learning goal of this module was to teach students how to measure in metric. Another goal was to introduce students to algorithms, and to evaluate how well they followed algorithms. Prior to module deployment, students should be taught how to measure in centimeters and millimeters. Students were given the handout with an algorithm of how to cover a composition notebook. The notebooks were called their computational thinking notebooks, and were used for the CT activities throughout the semester. They were instructed to follow the algorithm by themselves and only ask for help if they couldn't figure it out on their own. Once they finished covering their notebooks, they wrote down if they followed

the algorithm, didn't follow the algorithm, or had to ask for help. Next they were given a CT vocabulary words sheet, and they cut and glued them onto their notebooks.

C. Weather Tool Algorithm: Writing Algorithms Module

The purpose of this module was to get students comfortable with clarity, correctness, and efficiency of algorithms. They learned what the terms mean and how to score algorithms in each. Next, they practiced writing clear, correct, and efficient algorithms multiple times, which culminated in writing a weather tool algorithm. The fellow and teacher demonstrated the importance of correctness, clarity, and efficiency by writing an algorithm with the entire class on how to draw a chosen shape, or shapes. The fellow went in the hallway, while the class wrote the algorithm, and came back in when they were finished and followed their algorithm. The drawings were usually way off, so they saw how important these CT concepts were to algorithm development. Next, students paired up and they each chose a shape from an envelope and made their own algorithms to draw it. They switched notebooks with their partners and they followed each other's algorithms. They each rated the algorithms on a scale of 1 to 3 (3 being the best) for clarity, correctness, and efficiency. Next, students were split into groups of two or three. There were usually ten groups per class, so five groups went in the hallway and five groups stayed in the classroom. One student from each group got a brown paper bag with the materials needed for the project. The groups in the classroom got supplies to build a weather vane, and the groups in the hallway got supplies to make a barometer. Each group was given a picture of the final product, but no instructions. They had to build the tool based on the picture, and then write an algorithm for how to build it. In the next class period, they switched either to the hallway, or to the classroom from the last activity. As before, the groups in the classroom got supplies to build a weather vane, and the groups in the hallway got supplies to make a barometer. Each group was given an algorithm to make the product, which was written by a different group from the last class. They had to build the tool based on the algorithm. Once they were finished, they were shown the correct final products, and they rated the algorithms on correctness, efficiency, and clarity on a 1 to 3 scale, with 3 being the best score.

D. Rocket Branching Module

The learning goal of this module was to teach students how to use abstraction to solve a problem. Another learning goal was to have students learn how to execute if/then branching statements. Students read an article about a rocket launch at WSMR. Students all started by standing on a paper rocket we taped to the floor in the hallway. Next, they followed the branching statements the fellow and teacher wrote about the article. For example, "If the rocket took images of the sun, then move 4 squares west, else move 4 squares east." They had to abstract information from the article to decide if the statement was true or false, then move a certain amount of tiles N, E, S, or W. Once they completed the statements, they were given a key card with two more movements. If they chose the right paths for all four steps, they ended up on the rocket they started on after following the key card. To relate the module article to class content, after they were done with the branching exercise

they researched the different layers of the sun. This module can be adapted to any content, as long as there is an article or something to read with information to be abstracted.

E. The Case of the Bungled Bovine Bales: Abstraction Module

The purpose of this module was to get students comfortable with the measurement and calculation of density, which was the lesson unit for that week. This module also introduced the students to the world of genetically modified plants. Students were given an informative handout, density cubes, and measurement tools. The handout described a situation where a farmer was delivering four types of bales of hay, one made of organic alfalfa, and the other three made of different types of genetically modified alfalfa. On his way to deliver the bales, he hits something in the road, and the bales get mixed up. He knows that the densities of the bales are ranked in descending order, as follows: GS/SPS, SPS, GS, organic. In order to figure out which bales are which, students had to measure their densities and rank them. The handout was read together in class and students were told to highlight the important information needed to solve the problem of mixed up bales of hay. The fellow and teacher had to discuss the problem with the students in order to reinforce their understanding. Students measured and calculated the densities then solve the problem with the knowledge given in the handout.

F. Scratch Introduction: Visual Programming Module

The purpose of this module was to get students comfortable with the basics of Scratch, a visual programming language, while reinforcing the geologic Mesozoic Era, specifically the Jurassic Period, which was the lesson unit for that week. This module introduced the students to iteration, and using variables to make programs universal. The first class was used to introduce Scratch to the students. Students were given Scratch handouts with the element info program and the steps with formulas and vocabulary (Fig. 3). Students labeled the different parts of the program and filled out a worksheet with the sequence of steps of the element program. The computer screen was projected while building the program, so the students could see how to make an algorithm. To introduce iteration, the fellow built the Dancing Penguin algorithm in Scratch (Fig. 3). As each vocabulary word came up, students wrote it and its definition on their worksheet or in their journals. For the second class, students used Scratch on computers connected to the internet at www.scratch.mit.edu. Before this class, an account for each class was set up on the Scratch website. This allowed teachers and students to access their Scratch programs from any computer with internet connection. Students signed into the Scratch account, and began creating. The classes were studying the Mesozoic Era, they had to change the sprite to an organism from the Jurassic Period and change the backdrop to an accurate habitat for their Jurassic sprite. The subject matter can be adapted to the subject matter being studied. It is important to have students change the title to their name and the project title. For example, we used FirstLastJurassicPeriod. Once they finished the task, they explored Scratch by either adding to their program, or starting a new program.

G. Web Ad Iteration: Iteration module

The purpose of this module was to get students comfortable with iteration in algorithms using Scratch. Students had just

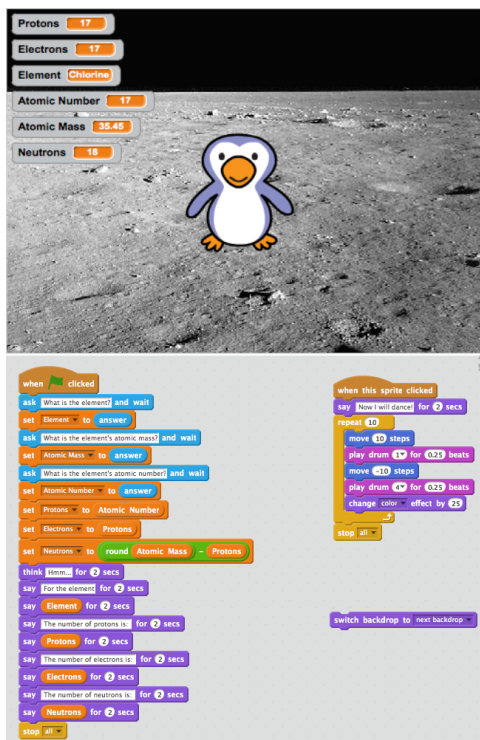

Fig. 3. Element Info Program with Dancing Penguin Iteration

made inventions for a class project, and were then learning how to make a webpage to advertise them. First, the fellow presented different examples of web ads made using Scratch and showed them how to use iterative structures in three different ways to catch people's attention (Fig. 4). Next, students wrote down the steps of one of the algorithms so they would have an example to base theirs on. Students then created their Scratch ads for their inventions using iteration. Screenshots were taken of their ads and glued to the poster of the web pages they designed for their inventions. This module took three class periods to complete.

III. RESULTS

A. CT Terms: Vocabulary Introduction Module

During this module, students were attentive and responsive while we went over the terms. Students enjoyed playing Jeopardy, however, they did not do very well the first time we played, but progressed as we played it through the semester. This module successfully introduced students to CT concepts.

B. Metric Measurement: Following Algorithms Module

This module helped the kids develop their measuring skills. By the end of the module most of them improved in measurement. They seemed to understand that an algorithm is a sequence of steps used to solve a problem and most of them tried to follow it. The students were engaged and excited to cover their notebooks. They were very excited to be given a notebook of their own and they were excited to decorate them. They were eager to measure and cut and glue things, but many of them became frustrated when they couldn't ask for help without trying it on their own first. Some were very slow

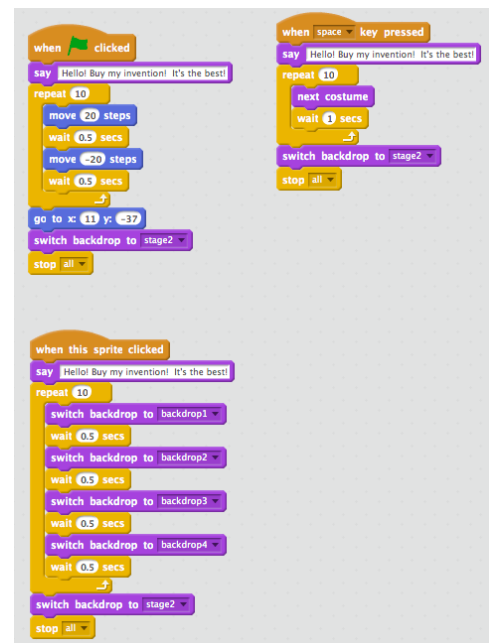

Fig. 4. Web Ad Iteration Examples

executing directions. A lot of the kids had to ask for help, but most could figure it out just by reading it together out loud. Almost all of the kids had difficulty measuring. Sometimes they would try and use inches and some kids didn't measure at all. They were not confident in their own problem solving skills; most kids were doing the right thing, but still asked for help with, and/or confirmation of what they were doing. This module successfully utilized algorithms and reinforced metric measurement.

C. Weather Tool Algorithm: Writing Algorithms Module

The students that did not look at their partner's shape were often very confused by their partner's algorithms, which was the point of the module. The kids were working on inventions for a multiple week project. In this project they had to write instructions on how to use and make their inventions. This module demonstrates how precise they had to be with their algorithms to make them clear, correct, and efficient. They really liked actually building something, and I noticed that the kids who usually aren't engaged when we do writing exercises were very involved in the building process. This gave opportunities to the students who like to write as well as the students who like to be more hands on. Scores were expected to be higher because they had practiced so much, but they still needed to work on their correctness and clarity. It was very challenging getting the kids not to show each other their shapes. One partner went outside and the other stayed in the classroom, but they still shared their shapes with the other students, which made it much easier for some of them to guess what their partner's algorithm was describing, rather than following the algorithm. When rating each other's algorithms, the kids often got confused between correctness and clarity; many gave a low correctness score because it was hard to understand. Also, they gave low efficiency scores because it took them a longer time to understand what they were supposed to do, which made the algorithm take longer,

Fig. 5. Weather Tool Algorithm Module Results

instead of evaluating the number of steps. There were no weather tool algorithms that were 100% correct, though some were close (Fig. 5). Some were completely off, which was a little discouraging. The students really enjoyed this module because they were able to do more hands-on work and were able to work on their teamwork skills. Students really liked seeing how incorrect their algorithms were and many kids liked writing them. It was definitely challenging for them, but they enjoyed it. This module successfully demonstrated how important clarity, correctness, and efficiency are in algorithm writing. Students, however, did not completely grasp the individual concepts in terms of algorithms. This module can be improved by possibly splitting the three concepts into their own activities, and then combining them in this module.

D. Rocket Branching Module

During this module, students enjoyed getting up, and out of the classroom. They also began to understand if/then/else statements. They had a lot of difficulty with directions and abstracting information. A lot of them had to do the if/then/else activity multiple times before they got it right. The students enjoyed physically exploring branching statements. Although it took students longer than expected to complete the activity, this module successfully taught students about branching in the context of the classroom curriculum.

E. The Case of the Bungled Bovine Bales: Abstraction Module

The practice with density in this module was successful and really helped solidify their measuring skills. Most students were engaged and understood the concept of organic versus genetically modified alfalfa. They also understood that in order to be an organic dairy farmer the cows had to be fed organic hay. Some kids were still very slow executing directions. Almost all of the kids were comfortable with measuring mass, while most of them had difficulties with measuring volume. They thought that since the measurements for length, width, and height were the same that they could just multiply that value by three when it should have been raised to the third power. Some kids had trouble making the connection between density and bale identity even though it was clearly stated in

the introductory paragraph. Most students did not effectively abstract the data; they either highlighted way too much, or not enough information. There was an error in the handout because we did not specify the difference in densities between GS and GS-SPS hay bales. We accepted correct answers as long as the highest density and lowest density were correct. Most students assumed GS-SPS was more dense than GS alone, which is a correct assumption, indicating their comprehension of the subject. The students were engaged and excited to figure out the identity of the hay bales in order to deliver the correct bales to the correct farmers. They were very excited when they identified them correctly. This module was successful in teaching students about density, and although students seemed interested in abstraction they did not fully grasp the concept; more practice was needed.

F. Scratch Introduction: Visual Programming Module

The students were very excited to see programming, and they understood the CT concepts introduced and reviewed. The students were very enthusiastic about using computers and Scratch. All of the kids finished their assignment and many went on to explore more in depth Scratch concepts. Most students were very creative and liked making their sprites move and talk. During the first class, we really didn't have any challenges with the students, but we did run out of time trying to get through the programs and vocabulary thoroughly. This module can be challenging if the internet connection is bad, or if the computers are slow. The students loved this module; the next time I went into the classroom, they were asking me if we were going to do more Scratch. Some students even told me that they went home and used Scratch on their own time. This module successfully introduced the students to visual programming.

G. Web Ad Iteration: Iteration module

At the completion of this modules, there was significant improvement on the understanding of CT vocabulary words. The kids loved working with Scratch and some kids really got into it and understood iteration. The kids' projects that had both iteration and advertising were very impressive. The biggest challenge was getting the computers set up. Another challenge was getting all the students to change the name of their projects. Even after four weeks, there were still untitled projects. I noticed that the projects were mostly either very good with iteration or very good with advertising; it was rare to find a project with both iteration and advertising (Fig. 6). Providing more time may improve student incorporation of both iteration and advertising. The students seemed to enjoy working with Scratch and I noticed that the kids who are usually not engaged were enthusiastic and working hard when using Scratch. This module successfully allowed students to use visual programming to demonstrate their knowledge of iteration and advertising.

H. Statistical Results Fall 2014 Semester

Pre-tests were given to students before any CT instruction was given, and post-tests were given at the end of the semester. Assessments of the tests were split into two categories: CT term recognition, and CT term definitions. The data shown in this section was collected during the Fall 2014 semester.

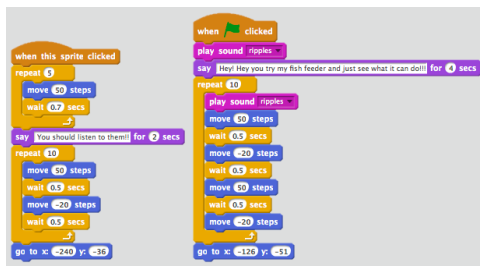

Fig. 6. A Student Example of a Scratch Web Ad Iteration Program

TABLE I. FALL 2014 RECOGNITION DIFFERENCES PAIRED T TEST. THE T VALUE WAS TESTED FOR SIGNIFICANCE USING AN ALPHA OF 0.05. (* = $0.01 < p \leq 0.05$; ** = $0.001 < p \leq 0.01$; *** = $p \leq 0.001$).

Mean	Std Dev	t Value	p Value	Significance
3.1582278	2.2681523	12.38	< 0.0001	***

Fig. 7. Number of CT Terms Recognized. All class subjects, with the exception of 6th Grade Science, were high school classes.

The number of words recognized in the pre-test was subtracted from the number of words recognized in the post-test, and a paired t test was done using Statistical Analysis System (SAS) software (Table I). The amount of CT terms the students recognized significantly increased at the end of the semester, indicating that the modules successfully introduced the students to the CT terms. When compared to the high school students scores, Fig. 7, the mean recognition was comparable in the 6th grade students. This suggests that 6th grade students had a relatively equal recognition of CT terms to high school students at the end of the semester.

The pre-test definition score was subtracted from the post-test definition score, and a paired t test was done (Table II). The amount of CT terms correctly defined significantly increased at the end of the semester, indicating that the modules successfully taught the students how to define the CT terms. When compared to the high school students scores, Fig. 8, the mean correct definitions was comparable in the 6th grade students. The max score was highest in the 6th grade class, which suggests that 6th grade students have the same capacity to learn complex concepts, such as computational thinking, as high school students at the basic definition level.

I. Statistical Results Spring 2015 Semester

Pre-tests were given to students again in January, and post-tests were given at the end of the semester. Assessments of

TABLE II. FALL 2014 DEFINITIONS DIFFERENCES PAIRED T TEST. THE T VALUE WAS TESTED FOR SIGNIFICANCE USING AN ALPHA OF 0.05. (* = $0.01 < p \leq 0.05$; ** = $0.001 < p \leq 0.01$; *** = $p \leq 0.001$).

Mean	Std Dev	t Value	p Value	Significance
1.47468354	1.16821893	11.22	< 0.0001	***

Fig. 8. Number of CT Terms Correctly Defined. All class subjects, with the exception of 6th Grade Science, were high school classes.

the tests were split into two categories: CT term recognition, and CT term definitions. The data shown in this section was collected during the Spring 2015 semester.

The number of words recognized in the pre-test was subtracted from the number of words recognized in the post-test, and a paired t test was done using Statistical Analysis System (SAS) software (Table III). As seen in the fall semester, the amount of CT terms the students recognized significantly increased at the end of the spring semester, indicating that the modules successfully further introduced the students to CT terms. When compared to the high school students' average scores, Fig. 9, the mean recognition difference was significantly higher in the 6th grade students. This suggests that 6th grade students had a higher recognition of CT terms than high school students over the course of both semesters.

TABLE III. SPRING 2015 RECOGNITION DIFFERENCES PAIRED T TEST. THE T VALUE WAS TESTED FOR SIGNIFICANCE USING AN ALPHA OF 0.05. (* = $0.01 < p \leq 0.05$; ** = $0.001 < p \leq 0.01$; *** = $p \leq 0.001$).

Mean	Std Dev	t Value	p Value	Significance
3.84507042	2.31546285	13.99	< 0.0001	***

Fig. 9. Number of CT Terms Recognized. All class subjects, with the exception of 6th Grade Science, were high school classes.

TABLE IV. SPRING 2015 DEFINITIONS DIFFERENCES PAIRED T TEST. THE T VALUE WAS TESTED FOR SIGNIFICANCE USING AN ALPHA OF 0.05. (* = $0.01 < p \leq 0.05$; ** = $0.001 < p \leq 0.01$; *** = $p \leq 0.001$).

Mean	Std Dev	t Value	p Value	Significance
3.88571429	2.18554445	14.88	< 0.0001	***

Fig. 10. Number of CT Terms Correctly Defined. All class subjects, with the exception of 6th Grade Science, were high school classes.

The spring 2015 pre-test definition score was subtracted from the post-test definition score, and a paired t test was done (Table IV). The amount of CT terms correctly defined significantly increased at the end of the semester, indicating that the modules continued to successfully teach the students how to define the CT terms. When compared to the high school students' scores, Fig. 10, the mean correct definitions was significantly higher in the 6th grade students. This suggests that 6th grade students have the capacity to learn complex concepts, such as computational thinking, at a the foundational level, which could supplement further in depth CT learning in their educational futures.

IV. CONCLUSION AND FUTURE WORK

Taken together, the qualitative and quantitative results indicate that the developed modules successfully increased CT term recognition and meanings over the course of one semester. The qualitative results and module development have confirmed DISSECT's hypotheses: (1) Several components of CT are already implicitly present and used in many traditional scientific disciplines (e.g., Physics, Biology) thus, it is important to make them explicit and bring them forward to enable students to recognize them and reuse them across domains and disciplines; (2) CT provides principles, tools and models that can be effectively used to enhance the learning of traditional sciences, making the learning process more dynamic, interactive and engaging. Quantitative analyses showed that students significantly increased in their level of CT term recognition, suggesting that they should be able to recognize these terms in other contexts. The increase in correct CT term definitions indicates that students understand complex CT concepts at a foundational level, which should provide adequate framework for future encounters with these concepts. Qualitative assessments indicate a more thorough understanding of the concepts that surpasses the foundational definition in some students, suggesting that these students may be able to not only recognize CT concepts, but also reuse CT concepts across subjects and disciplines. Although these results

are positive indicators that the modules work in achieving the desired goals, future modules should be geared towards creating specific challenges requiring algorithmic and parallel processing thought processes [10]. Qualitative analyses indicate that the level of engagement and learning in the 6th grade science curriculum concepts incorporated in the CT modules was higher. The use of CT concept modules provided hands-on and inquiry-based learning environments that could have contributed to increased student interaction and engagement. The developed modules successfully used CT concepts to enhance the learning of traditional 6th science, resulting in more student interaction and engagement. The comparison of the mean scores seen at the end of the fall 2014 semester between high school classes and the 6th grade class showed that the 6th grade students had similar scores to the high school students. Before data collection began, there was concern that younger students would have difficulty understanding the concepts, but the fall 2014 results indicate that 6th grade students have the capacity to learn complex concepts, such as computational thinking, at a the basic definition level. Some students demonstrated the ability to recognize and create their own examples of the CT terms, which suggests a much more thorough understanding of the concepts that surpasses that of simple definitions. As seen in the fall 2014 data, the sixth grade students scored significantly higher than the high school students. This indicates that the continued participation over the course of a second semester resulted in more CT term recognition and correct CT definitions in 6th grade students than high school students. It is important to note that this was the only fellow/teacher combination working with 6th grade students, so the success of the modules could be due to other contributing factors, such as teacher and fellow teaching styles, and school and classroom atmosphere. Regardless, the data presented suggests that middle school students can benefit more from CT modules than high school students. In conclusion, the results clearly indicate that the created CT modules are effective in increasing the interest, motivation, and knowledge of computer science in 6th grade middle school students. It is, however, important that future studies be directed towards exploration of concept mastery. Future research will indicate whether students are developing concept mastery beyond foundational understanding and recognition of covered topics.

ACKNOWLEDGEMENTS

The activities presented in this paper were funded by NSF grant DGE-0947465. The data presented in this paper was collected under the approval of the NMSU IRB-11201. Thank you to Kathleen Guitar, the 6th grade science teacher involved in the study. Professor Robert Steiner of the New Mexico State University Statistics Department was involved with designing the statistical analyses. Dr. Sarah Hug and Dr. Susan Brown were involved in the research, evaluation, and organization of the program. Raena Cota was involved with the overall organization of the program and its research, and was very involved in editing this paper. Gregory Lee formatted and put the final touches on the paper.

DISSECT: Analysis of Pedagogical Techniques to Integrate Computational Thinking into K-12 Curricula

T. Burgett, R. Folk, J. Fulton, A. Peel, E. Pontelli, and V. Szczepanski

Depts. of Biology, Computer Science, Electrical Engineering, New Mexico State University Las Cruces, NM, USA

Abstract—This paper analyzes the efforts of DISSECT (DIScover SciEnce through Computational Thinking) to introduce computer science theories into K-12 Curricula. This is accomplished by teaching computational thinking (CT) problem solving techniques in existing STEM+C courses in select middle and high school classrooms in Las Cruces, New Mexico, USA. Data collected over the course of the fall 2014 and spring 2015 semesters involving 10 graduate fellows, 9 teachers, and over 200 K-12 students has been analyzed. A single assessment was issued at the beginning and end of each semester in order to track metrics about fellow-teacher pairings, student understanding of CT concepts, and student interest in STEM+C areas. Using statistical analysis software to evaluate the data, we were able to determine the efficacy of the DISSECT program. In particular, we use descriptive statistics to evaluate the trends in CT vocabulary recognition and overall interest in computing, and we compare trends across courses and grade levels.

Index Terms—Computer science, computational thinking, K-12, graduate fellows, statistical analysis, stem+c.

I. INTRODUCTION

Integrating computational thinking into the K-12 curriculum has been a long standing goal of the New Mexico State University DISSECT (DIScover SciEnce through Computational Thinking) program. Computational Thinking (CT) is an important component of all STEM+C activities, but CT is traditionally underrepresented in the K-12 curricula. CT is not to be confused with computer programming but is instead the art of thinking in a similar manner to a computer scientist. Before being able to program a solution, a computer scientist must conceptualize the problem and abstract the required information before crafting the appropriate algorithm with which to solve the problem. These problem solving abilities are what Wing originally referred to as CT and is one of the cornerstones of the research that DISSECT performs [1]. This is especially important as computer science becomes more important in the workforce. In fact, the number of careers in fields related to computer science are expected to grow by as much as 22% faster than non-technical careers [2]. We also believe that fields that do not directly apply computer science can benefit from training in CT. Consequently, one of DISSECT's objectives is to infuse CT into standard K-12 curricula and how to leverage CT in a variety of subjects ranging from chemistry to literature.

The DISSECT program operates out of New Mexico State University's Computer Science Department and pairs graduate students in Computer Science or applied computing fields such as Electrical and Computer Engineering and Biology with K-12 teachers around Las Cruces, New Mexico. The graduate students (fellows) offer expert knowledge in CT while the teachers provide their skills in pedagogy.

Together, the fellow-teacher pair create modules that integrate the teacher's current curriculum and important CT concepts. The fellows do not create these modules in a vacuum - modules are designed to teach CT concepts while directly tying them to the current coursework. By keeping the modules closely tied to what the students are learning, any disruption to the teacher's schedule is minimized while maximizing instruction in CT principles. DISSECT's aim is to illustrate that CT is inherent in the subjects the students are learning, rather than an extracurricular activity or supplement. Furthermore, by illuminating that CT concepts form the foundations for the subjects currently being taught in the classroom, students will be able to apply their skills in CT across all disciplines.

In the 2014-2015 school year, DISSECT had ten fellows in nine classrooms, and we focused instruction on the process of algorithmic thinking. To assess our effectiveness analytically, we have designed an assessment to be administered as a pre-test at the beginning of DISSECT's instruction in the classroom and after the winter holiday for single semester courses. This same assessment was used as a post-test at the conclusion of the calendar year (December 2014) for single semester courses and the academic year (May 2015) for year-long and single semester courses. The test assesses students on their ability to recognize and define CT concepts, and further includes a section of Likert questions to assess students' attitude towards CT and computer science. We have performed statistical analysis on the data collected for the fall 2014 and spring 2015 semesters and present our findings in this paper. In particular, we directly compared pre- and post-test scores within the same class, between a control Computer Science course without a fellow (only for the fall semester) and courses including fellows, and we compared post-test scores between semester-long and year-long courses. We also describe DISSECT's general techniques in the classroom and explain in detail how we collected our data. Finally, we

interpret our results, describe our findings, and discuss our plans for future research.

II. EXISTING RESEARCH

Several researchers have been working to develop methods to integrate CT into K-12 education. Several visual programming environments have been developed that are useful in this regard such as Scratch [3], App Inventor for Android [4], and NetLogo [5]. For example, in Connecticut, the Computer Science Department of Trinity College developed a summer program where they first began investigating the effectiveness of App Inventor as a teaching method to instill CT principles in K-12 education [6]. By working with college students with varying backgrounds in computing and K-12 teachers with a background in computer science instruction, the team worked to develop a curriculum that would impart CT knowledge by developing applications for Android smartphones. The rapid development cycle offered by App Inventor allowed students to quickly learn the techniques needed to create apps that could be shown to friends and colleagues. This led to an enthusiastic learning environment that helped the students improve their abilities to solve problems and overcome new challenges.

Purdue used another approach to prepare K-12 teachers and college students majoring in education to be able to infuse CT principles into their curricula [7]. Purdue researchers introduced CT into the existing topics involving critical thinking and problem solving in an educational psychology course. Their program was deployed during one week of instruction and was comprised of two 50 minute sessions. During this week long module, the researchers introduced one group of the class to a CT infused curriculum while the curriculum of the other group remained unaltered. The first session involved defining the chosen CT concepts and illustrating how these concepts are integral to their daily lives and exploring their applicability to problem solving and strengthening critical thinking. The second session involved applying these principles in solving problems that were not well defined or required convoluted solutions. By using CT concepts, the students were better equipped to solve these challenging problems. The researchers demonstrated how CT could be infused in other curriculum areas with concrete examples in science and social science scenarios.

During the 2013-2014 school year, DISSECT worked with students from 6th grade and 9th grade through 12 grade in subjects including general science, biology, and forensics to investigate the integration of CT into K-12 science curricula [9]. This involved pairing graduate fellows from New Mexico State University (NMSU) with K-12 teachers around Las Cruces, NM. The pairs would then work together to create modules that infused the teacher's current curriculum with CT concepts that were derived from the fellows CT background and current research topics. These modules followed an inquiry-based learning style and often incorporated a hands-on approach to illustrate the underlying CT concepts in the science and forensics classes. The modules that were created covered a broad variety of CT concepts spanning the use of programs

for animating subject matter to developing algorithms to solve problems in the given classroom subject. These modules also included various programming environments including the MIT Scratch environment and Python programming language to model and demonstrate levels of understanding of both CT concepts and classroom material [10]. When qualitatively evaluated by their paired teachers, the fellows were acclaimed for challenging the students' critical thinking in the subject matter of their assigned class, relating CT principles to the students' daily lives, and successfully infusing CT concepts into their respective classroom's curriculum.

III. DISSECT METHODS AND ASSESSMENT

Continuing the strides made last academic year (2013-2014), DISSECT again paired graduate fellows with K-12 teachers to work to integrate CT into the teacher's current curriculum by demonstrating its presence in the students daily lives. Receiving invaluable instruction in pedagogy from the teachers, the fellows developed their modules following the inquiry-based learning model. Fellows focused the modules on the theme of algorithms and all the CT concepts that tie into it such as branching, iteration, clarity, and sequence-of-steps. Fellows were encouraged to be creative in their module development because resources, especially computational technology, are limited due to the low-income areas in which DISSECT operates [9]. Due to this, the fellows investigated numerous ways to incorporate CT in their lesson plans utilizing both the use of computer technology and a lack of access to advanced technology. For classrooms with access to computer technologies, several fellows decided to incorporate the MIT Scratch environment as an instruction tool, using it in a variety of ways to demonstrate materials from the curricula. For example, in a forensic science class one fellow teacher pair had the students develop a program that modeled a crime scene from one of three vantage points: criminal, victim, or investigator. Another fellow used ToonDoo [12] in a high school English class to have the students plan and implement a scene from the story Macbeth. For classes without access to computers fellows looked towards the classroom curricula and sought to illuminate the underlying algorithms that were being taught. In one class the fellow developed a module that covered image reconstruction in which case different groups of students were issued a part of different images that had been cut up. The student groups would then attempt to find the other pieces of their images by inquiring among the other groups for characteristics similar to their own image. The goal of this module was to demonstrate iteration in going from group to group making the same inquiries each time and branching by determining from the answers obtained what their next course of action should be. To accurately assess the efficacy of the DISSECT program, the fellows issued a pre and post test to measure the change in understanding over the course of the semester. The test was composed of one page of CT concepts and two pages of Likert questions which focused on the students feelings concerning a job in computing and their general interest in computing. The assessment asks for

recognition, definition, and usage of ten concepts which are tightly integrated into the modules and applicable to each of the curricula that the fellows are integrating CT into. DISSECT defined the given terms as such.

- *Computational Thinking* is defined as using methods from Computer Science as a technique for problem solving.
- A *variable* is a piece of data that is assigned a name and has a specific value that can be changed.
- An *algorithm* is a step-by-step process that, when followed from start to finish, will result in a solution.
- A *sequence of steps* is merely a list of steps that must be followed.
- *Branching* is defined as the need to make a choice where each decision will have unique outcomes.
- *Iteration* is repeating a set of instructions until a certain condition is met; one common condition is a predetermined number of times.
- Simplifying the problem with *abstraction* is to remove information from the idea until the only parts left are those that are relevant and necessary to the problem.
- *Clarity* is a qualitative measurement of how easy the program or algorithm is to understand.
- A measure of the ability of the program or algorithm to correctly solve the intended problem is defined as *correctness*.
- *Efficiency* measures the resources used by the program or algorithm to solve a given problem with respect to energy exerted, be it time, space, and power.

IV. DATA COLLECTION TECHNIQUES

The data collection performed by DISSECT was based upon the assessment form outlined in Section III which was approved according to NMSU IRB-11201. This IRB allows us to collect data centered around a specific pre- and post-assessment created by DISSECT to be used in the classroom. This IRB does not allow collecting data outside of this assessment which includes a student's course grades, performance from other courses, or external opportunities that may influence a student's learning of CT principals. Around the city of Las Cruces, NM, there are many opportunities to indirectly learn various CT principals including MESA, Project GUTS, and YWIC, but our program does not track if any students are involved in these programs. DISSECT does not track this data because these programs teach CT principals in a computer science aspect while DISSECT teaches CT as a discipline that can be tightly integrated into any K-12 curricula as a problem solving method. Tracking this information is an area that is being considered for future research.

The fellows were to issue the assessment as a pre-test at the beginning of the fall 2014 semester before beginning instruction in CT principles had begun. The pre-tests were to be labeled with a unique identification number to each student and not include a name or other method of identification in order to respect the student's privacy. The fellows would then collect the test and keep them through the remainder of the semester. Prior to the pre-test being administered the only

contact with the students had with the fellows was to be an introductory period in which the fellow would introduce herself or himself as well as the GK-12 DISSECT program to their respective classrooms. After a semester of instruction in which the fellows had been actively attending the classroom between 5 and 8 hours a week teaching CT concepts, the fellows would issue a post-test. This post-test was to be given during the final or penultimate week of instruction and was identical to the pre-test given at the beginning of the semester.

The students would identify themselves on the post-test using the same unique identification number they had used on their pre-test. The fellows then used the statistical analysis techniques which will be outlined in Section V to evaluate the differences between the pre- and post-tests. Unfortunately, some of the data was collected outside of the methods outlined and the exemptions are stated as follows. One fellow was unable to collect the pre-tests personally which meant the teacher paired with the fellow collected the tests for the fellow. The fellow received the tests from the teacher at a later date and retained them throughout the semester. One fellow was unable to administer the post-test and had their teacher administer it. However, no identifying number was present on the test and the data had to be discarded and the results are not present in this paper. Several of the fellows gave either pre- or post-tests that were missing one or both pages with the Likert questions. In these cases, DISSECT ignored the direct comparison of missing datasets between the students. DISSECT did however incorporate the remaining data that contained successful pre- and post-test pairs. Two fellows that shared a classroom administered one set of pre- and post-tests to the students in the classroom instead of a set per fellow. Two fellows instructing at the same school administered the pre- and post-tests via Google Forms. The students were assigned a random identification number which they used to enter their answers. There were cases of missing data, be it pre- or post-test, due to student absences when the tests were administered. In these cases, the students collected data is used but no direct comparisons are made when one set of data is not available.

Despite the anomalies in data collection outlined above, DISSECT has maintained student confidentiality and have used data only where it is both permissible and applicable. Our analysis of the data indicates that these issues had no effect upon our results.

V. RESULTS - FALL 2014

The results of the pre and post-tests were categorized into four assessments: (1) CT term recognition, (2) CT term definitions, (3) Likert job questions: Getting a job in computing would allow me to..., (4) Likert interest questions: How much interest do you have in the following? The difference between pre and post-test values were subjected to paired t tests using the Statistical Analysis System (SAS) [13]. Table I describes information collected in addition to the pre and post-test data for each fellow/teacher combination.

As seen in Table I, the change in CT term recognition and the number of correct CT term definitions were statis-

teaching style, class dynamics, and class time, there is large variability between fellow/teacher combinations. The mean difference of CT terms recognized increased, or was greater than zero, for every fellow/teacher combination (FT) except FT 5, suggesting that the modules successfully introduced students to CT terms, and they were able to recognize more terms at a basic level at the end of the fall semester. The average difference of CT terms correctly defined increased, or was greater than zero, in all fellow/teacher combinations except FT 5 and FT 10, indicating that, in most cases, students increased in their foundational knowledge of CT concepts after

one semester of participating in CT learning modules.

For each Likert subject areas, each of the student's answers were averaged first by individual student then by pre and post-test, and the difference between pre and post-tests were tested for statistical significance (Table III). The increase in differences was statistically significant for both sections of Likert response questions, indicating that students' views about computing jobs and their interest in computing increased over the course of one semester. As depicted in Figures 3 and 4, the mean differences in both Likert subject areas

Fig. 6. Difference of CT Term Recognition Over the Course of One Semester.

increased over the course of the semester, with the exception of FT 1. These results demonstrate that high school students who participated in DISSECT modules for one semester were more interested in computing and had higher expectations for computing jobs.

For the fellow/teacher combination in the computer science classes, the same teacher taught another section of the same computer science class and deployed the same modules without the fellow. This class acted as a control so that the effectiveness of the teachers CT training and their ability to teach CT concepts without the fellow could be evaluated. As seen in Table IV, there were no significant differences in the averages of the pre to post-test differences, which indicates that the computer science teacher successfully de-

Fig. 7. Difference of CT Term Correct Definitions Over the Course of One Semester.

Fig. 8. Differences of Likert Job Questions Over the Course of One Semester.

ployed the CT modules without the fellow. This solidifies one of the primary goals of the DISSECT program to train teachers to effectively deploy CT modules on their own. This teacher was already trained in computer science, so it would be more informative to deploy this evaluation with teachers of different subject matters. The modules that were developed through the DISSECT program available for use at http://www.cs.nmsu.edu/gk-12/?page_id=460.

To further explore students CT learning, the differences between class subject, core class versus elective class, and yearlong class versus semester class were examined using the post-test averages for all four categories. There were no significant differences in the means for class subject in CT term recognition, or CT term definitions (Table V). This indicates that over the course of one semester, the class subject that CT was incorporated into did not influence the students' ability to recognize or define CT concepts. There were significant differences between class subject area in both Likert questions (Table V). A similar trend in means is seen in each category

Fig. 9. Differences of Likert Interest Questions Over the Course of One Semester.

Fig. 11. Comparison of Number of Correct CT Definitions in Core and Elective Classes.

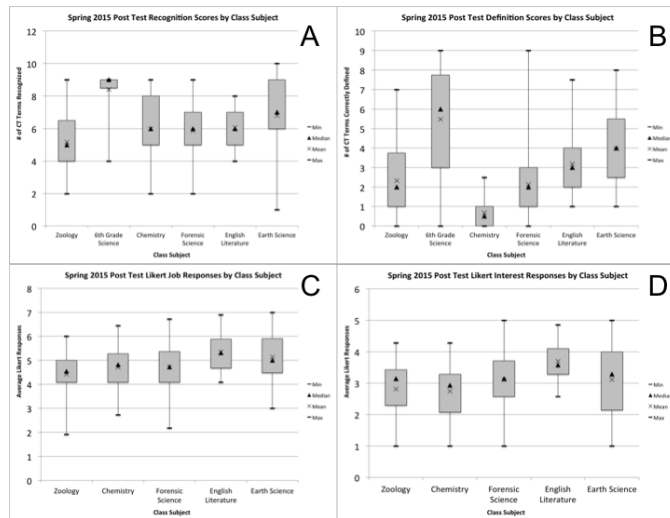

Fig. 10. Class Subject Comparisons for CT Term Recognition, CT Term Definitions, and Likert Questions.

(Figure 5). The computer science classes means were the highest in correct definitions and both likert questions (Figure 5B,C,D). This trend is expected because computer science is an elective course, and its curriculum already includes CT concepts. The students in those classes chose to take the class, which may suggest that their scores were higher because they were already interested in computing, and they learned CT concepts as part of their curriculum for the course. The sample sizes were small in the chemistry, physics, and english literature subjects, which contributes to the smaller variation seen in these subjects compared to others (Table V). The small sample sizes also make it difficult to make statistical conclusions on the comparison of class subjects. The overall trends show that CT term recognition was high in all subjects except for chemistry, and the number of correct CT term definitions was highest in computer science and physics and all other subjects had similar means (Figure 5). It is important to note that, in most cases, the class subject is confounded with fellow/teacher combination, so the differences described could be attributed to the differences in fellow/teacher combination teaching styles rather than subject. For future studies, efforts

will be made to have multiple fellows within a class subject.

When comparing core classes to elective classes, there was no significant difference in the post-test means for CT term recognition, CT term definitions, or Likert questions. From this, it can be concluded that the modules being taught in both types of classes are successful in teaching students fundamental CT concepts. When comparing yearlong classes versus semester classes, there was no significant difference in the post-test means for CT term recognition, CT term definitions, or Likert questions. A difference at this stage in data was not collection was not expected because fellows had only been deploying modules for one semester. It is important to note that there were not enough data combinations to test interactions between class subject, core, elective, year long, and semester long classes. Fellow/teacher combination and class subject may influence the data compared at the core vs elective and year vs semester levels.

VI. RESULTS - SPRING 2015

Spring 2015 data was collected and analyzed in the same manner as the fall 2014 data. Table I shows the information collected for each fellow/teacher pair. The post minus pre-test difference significantly increased over the course of the spring 2015 semester for CT term recognition and CT concept definitions (Table VII), indicating that students were able to recognize more CT concepts and correctly define more CT concepts at the end of the semester than at the beginning of the semester. This also implies that the fellows in the year long courses continued to increase knowledge over the course of the second semester. As seen in Figures 6 and 7, there is a large amount of variability between fellow/teacher combinations, which can be attributed to outside factors, such as teaching method, class time of day, and number of students. Overall, the mean differences for CT term recognition and correct definitions were greater than zero, indicating that students increased in their foundational CT knowledge with every fellow/teacher combination, especially in combinations 2, 3, and 7. This data enforces the DISSECT goal of successful CT incorporation into K-12 curricula.

The difference of Likert responses for computing interest and jobs were also investigated for the spring 2015 semester. The average responses were subjected to a paired t test to detect significant changes over the course of the semester (Table VIII). The responses for computing jobs showed a significant increase, while the responses for CT interest did not show a significant difference. This illustrates that the CT modules increased students' understanding of computing jobs, but did not change their interest in computing in general. This is in contrast to the results from the fall semester, which could be due to the year long courses. The students in the year long courses already displayed an increase in interest in the fall semester, so it is possible that their spring pre-test average was high to begin with, which would result in a small or undetectable difference over the course of the spring semester. Figures 8 and 9 depict the differences of the Likert responses, showing that the fellow/teacher combination 6, which was a semester long course, had the highest difference in both Likert responses.

The differences between class subject, core class versus elective class, and yearlong class versus semester class were examined using the spring post-test averages for all four categories (Table IX). The fellow/teacher combinations were used to account for the variability of the model. There were no significant changes in CT term recognition, correct CT definitions, or Likert responses (Figure 10). This demonstrates that subject matter does not influence the students' ability to learn CT or their interest in and understanding of computing, which correlates with the fall semester data.

There were also no significant changes in recognition, definitions, or Likert responses when comparing year long classes to semester long classes. This was unexpected because it was assumed that the more time students had with CT modules, the more they would learn, and thus, they would have had increased in CT term recognition and correct CT definitions. This data demonstrates that CT incorporation was equally effective in year long and semester long courses.

There was, however, a significant increase in the number of correct CT definitions in the core classes when compared to the elective classes (Figure 11), which resulted in a p value of 0.0296. This indicates that the CT modules delivered in the English literature, 6th grade science, and earth science courses resulted in higher CT term recognition and number of correct CT definitions. As with the fall semester data, it is important to note that there were not enough data combinations to test interactions between class subject, core, elective, year long, and semester long classes. Fellow/teacher combinations and class subject may influence the data compared at the core vs elective and year vs semester levels.

VII. CONCLUSION AND FUTURE WORK

This paper discussed the intentions of the DISSECT program and the efforts to equip the students with essential skills in CT and increase their abilities in problem solving and critical thinking. The fellows imparted these skills by creating

and deploying modules in the classroom with the students on average between 5 and 8 hours a week for two semesters.

The modules were evaluated by issuing an assessment before instruction in CT begins and issuing the same assessment at the end of the semester. The results of the assessments were compared and analyzed to determine the differences between their before and after scores. The intention was that the efforts of DISSECT and the graduate fellows working in the classrooms had a positive impact on the students recognition and integration of CT principles in their daily lives. In addition to increasing the students' CT knowledge, DISSECT intended to increase their interest in pursuing a career in computing or involving computing and their interest in computing in general.

According to our generalized method of assessment, the results clearly indicate that the modules developed and used by DISSECT fellows were effective in increasing the interest, motivation, and knowledge of computer science in secondary education students. The analysis was robust in its ability to assess improvements in knowledge of, attitude towards, and interest in computer science and computing in general, with the results being favorable in this regard. It is important, however, that future studies be directed towards finer exploration of concept mastery.

Future research will need to indicate whether students are developing concept mastery beyond rote memorization and recognition of covered topics. It is essential that students not only recognize examples of the terms and concepts discussed, but also show a creative process of concept use. DISSECT's ultimate goal is the improvement of analytical thinking, strategic organization, and planning. The program aims to test the organization's underlying hypothesis that participation in DISSECT modules will improve these intellectual qualities beyond those of nonparticipants.

In future semesters, DISSECT fellows plan to extend and expand assessment to include questions that test the critical thinking skills of the students. It is the goal of the DISSECT program to characterize the improvements made by students in their understanding of CT concepts and their ability to apply those concepts to both real-world and computer science problems. By providing students with several thought provoking challenges fellows aim to show a marked improvement in students' analytical abilities. As the program progresses it evolves and data collection techniques are refined. There are many uncontrollable variables when collecting data across many schools, grades, subjects, teachers, and fellows. Then NMSU DISSECT team held one summer camp in 2014 and plans to continue camps in the future since they provide an opportunity to evaluate the productiveness of CT modules in a more controlled environment. Additionally, expanding the assessments to include more questions will provide more insight into each student's depth of understanding of specific CT concepts and effectiveness between individual modules.

ACKNOWLEDGMENT

The activities presented in this paper were funded by NSF grant DGE-0947465. The data presented in this paper

was collected under the approval of the NMSU IRB-11201. Thank you to the teachers involved in the study: Lorraine Bridges, Bryan Gabitzsch, Kathleen Guitar, Melody Hagaman, Jeri McDowell, Tammy Miller-Dwake, Beth Rewalt, Christin Slaughter, and Timothy Staley. Professor Robert Steiner of the New Mexico State University Statistics Department was very involved with designing the statistical analyses. Dr. Sarah Hug and Dr. Susan Brown were involved in the research, evaluation, and organization of the program. Raena Cota was involved with the overall organization of the program and its research, and was very involved in editing this paper.

Young Women in Computing: Creating a Successful and Sustainable Pipeline

N. Nesiba, J. Dana-Farley, N. Muhyi, J. Chen, N. Ray, E. Pontelli

Department of Computer Science
New Mexico State University
Las Cruces, NM, USA

Abstract—Young Women in Computing (YWiC) is an outreach initiative housed in the Department of Computer Science at New Mexico State University (NMSU). The program is designed to increase the number of women introduced to computer science; promote the role and presence of women in the field of computing; improve the retention of female students in computing programs; establish a permanent infrastructure (i.e., pipeline) to promote the participation of women, especially of Hispanic heritage, in computing activities; and, serve as a model of effective computer science outreach practices to reach young women. Since 2006, YWiC programming has reached over 10,200 students. By enhancing interest in computing among student populations, YWiC has successfully created a pipeline into Computer Science and Science, Technology, Engineering, and Mathematics (STEM-C) undergraduate programs, particularly at NMSU; among the 366 non-repeated summer campers, 99% of the 98 high school graduates attended college in the fall term immediately following their graduation, with 61% declaring a major in a STEM-C field. This paper will present quality practices and lessons that YWiC has learned in order to become a successful and sustainable outreach program in southern New Mexico.

Keywords— *Computer science; Computer science education; Outreach; K-12; Curriculum development*

I. INTRODUCTION

Female presence in the field of computer science (CS) is dramatically underrepresented; the problem is compounded when observing the presence of Hispanic females. Research suggests that the gender gap and lack of interest in CS among female students can be traced to high school [1, 2]. College Board's 10th Annual AP Report to the Nation analyzes each state's effort to "provide opportunities to demonstrate college-level skills and knowledge in high school" for low-income and traditionally underserved minority students [3]. At 46.7%, New Mexico (NM) was the state with the highest number of Hispanic Advanced Placement (AP) test-takers. However, Hispanic students only made up 18.8% of the entire pool of test-takers [4]. The supplemental report for the AP CS exam [5] stated that out of the 22,273 AP CS test-takers in 2013, women made up 19%, and Hispanic students made up only 9%; the report did not include the percentage of test-takers that were both female and Hispanic.

This has a direct impact on CS degrees awarded to women in general, and, more specifically, Hispanic women. Several studies conducted to track the graduation rates of women show that the number of women graduating with CS degrees, while slowly increasing, is not on track to fill the Department of Labor's projected 15% growth in Computer and Information Research Scientist jobs by 2022 [6]. The 2011-12 CRA Taulbee Survey reported the fraction of women awarded bachelor degrees in CS increased to 12.9%, compared to 11.7% in the previous year [7]. An infographic compiled by the National Center for Women and Information Technology (NCWIT) explores the disparity of women in tech in 2013: women earned 57% of undergraduate degrees in the US, while 18% of undergraduate computer information and sciences degrees [8]. The increase from 12.9% to 18% may be attributed to the increase in diversity recruitment efforts to hire and retain women and Hispanics in computing. Yet, in 2013 women still made up only 26% of the computing workforce, 2% of which were both female and Hispanic [9].

The Southern Education Foundation has published a Research Bulletin that detailed the nation's poverty rates in 2013 [10]. The bulletin explained that 51% of students were living in poverty or near-poverty, qualifying for free or reduced-price lunches; NM is ranked second in the nation with a 67.7% poverty rate. Additionally, NM holds a 50.4% female and 22% Hispanic female population, on trend with projections for the United States female population (50.2%) and Hispanic population (28%) in 2060 [11-13]. The increase in demand for computing services and the diverse and representative population within NM establishes a prime environment for bringing CS to one of the most underrepresented and underserved populations within the industry, who can potentially have a tremendous long-term impact. This problem has prompted the creation of numerous K-12 outreach initiatives (e.g., [14-21]) that aim to introduce female and other underserved student groups to CS and other STEM disciplines (STEM-C) earlier in their academic careers in NM. The Young Women in Computing (YWiC) program is one such initiative that was created in 2006 under a National Science Foundation's Broadening Participation in Computing grant [22].

YWiC, in partnership with the Department of Computer Science at New Mexico State University (NMSU), is committed to promoting the role and presence of women in computing at all levels across the educational pipeline, with particular focus on girls and Hispanic students from the south-central region of NM. Specific goals and objectives of YWiC are to:

- 1) Increase the number of girls being exposed to CS through initiatives geared towards introducing computing in fun and interactive ways.
- 2) Increase the presence of women in college CS programs.
- 3) Improve the retention of female CS students, and ultimately improve female CS graduation rates.
- 4) Provide a space to develop mentor-mentee relationships to support women in their work.
- 5) Establish a permanent infrastructure (i.e., pipeline) that unites regional school systems with NMSU to promote the participation of women, especially of Hispanic heritage, in a 4-year CS program.
- 6) Create a base of expertise to train K-12 instructors in computing and in best practices to motivate young women to study CS.
- 7) Serve as a model of effective computer science outreach practices to reach young women.

II. PROGRAM DESIGN

A. Program Overview

Established in 2006, YWiC has become a multi-faceted and sustainable outreach program, reaching over 10,200 students through outreach initiatives across southern NM. YWiC initiatives are implemented year-round and strategically occur at key points to efficiently introduce CS to the most female students; outreach initiatives, which are designed to build upon one another, include competitions, clubs, conferences, classroom workshops (roadshows), and summer camps. Figure 1 provides an overview of YWiC's outreach components throughout the school year. YWiC is designed to introduce students to CS via roadshows, give students a deeper understanding of CS with after-school programming clubs and competitions, and give students a broader perspective of CS through conferences. The goal is for the more committed students who participated in YWiC activities during the school year to attend YWiC summer camps, where students have the opportunity to learn and apply more advanced CS skills through project-, problem-, and inquiry-based curriculum.

B. Curriculum Design

Acknowledging that the current challenge is to continuously engage female students in CS activities as they progress through their education, YWiC offers extensive interdisciplinary year-round opportunities for elementary, middle, and high school girls in computing. The structure of YWiC's curricula is a series of integrated modules that span across all outreach initiatives and multiple stages of the pipeline to generate an interest in CS for all students. Each unique module offers opportunities for students to learn

Fig. 1. Annual Outreach Timeline

computing and algorithmic thinking concepts through either a programming language, programming platform, or an interdisciplinary context. Overall, YWiC modules are taught with three pedagogical approaches: 1) project-based; 2) problem-based modules present students with a problem that can be solved after acquiring knowledge; and, 3) inquiry-based modules provide an active questioning, critical thinking, and problem-solving approach. These modules are designed to encourage continued learning after a module is complete by utilizing platforms and languages that are open-source, address student needs and interests by covering a wide range of interdisciplinary content, and meet student programming experience level by offering instruction with both visual and textual programming platforms. Note, visual programming platforms implement a simple drag-and-drop programming interface (e.g., Scratch [23]), while textual programming platforms represent traditional programming languages (e.g., Python, HTML).

It is vital to find a proper balance between challenging and overwhelming students [24]. Each cohort of students brings a unique set of skills, so the difficulty of material and the style of the presentation is dynamically adjusted to meet the needs of students. Unchallenged students tend to quickly lose interest, while presenting too many concepts leads to frustration. Another important component is to ensure that the material is always presented in a way that puts "computing in context", in order to make the subject matter relevant to the students' interests.

C. Personnel

YWiC currently staffs one full-time coordinator and five part-time Undergraduate Research Assistants (URA); in the past, YWiC has employed up to seven URAs. The choice of instructors and team members is critical for success. They not only have to be prepared and skilled, but they should also demonstrate enthusiasm and a willingness to establish a bond with the student participants. YWiC experience has demonstrated that students engage more with instructors from similar backgrounds; the URAs are highly motivated female undergraduate students majoring and/or minoring in STEM-C fields at NMSU and are the technical experts associated with each element of YWiC's outreach initiatives. Integral to the success and sustainability of the program, the URAs are responsible for the implementation, from idea to instruction, of innovative platforms and projects that enhance YWiC summer camps, roadshows, and competition curricula.

III. PIPELINE STRUCTURE

Multidimensional program components such as classroom workshops, summer programs, conferences, after-school clubs, and competitions graft together to facilitate the pipeline: elementary school, middle school, high school, and college. An overarching goal of YWiC is to create a structure that successfully integrates the five program components to retain female CS students from elementary school through college graduation. Figure 2 depicts the structure of YWiC's pipeline by illustrating the outreach avenues implemented at each level of the pipeline. YWiC collaborates with the Las Cruces Public Schools (LCPS) District and surrounding districts for all outreach practices. Due to the scope of this paper, the following sections expand on only the most successful and effective outreach activities conducted to each group of students.

A. Elementary School

The elementary school phase of the pipeline was first implemented in 2011, and was a strategic move in an attempt to increase the number of students continuing the pipeline in middle school. Effectively put by the J.B. School of Engineering, adding elementary students to the pipeline serves to "enlarge the funnel" of interested and prepared students that pursue STEM studies later in their education [25]. Other research [26] shows that such pursuits are worthwhile, as "STEM initiatives and activities positively impact elementary students' perceptions and dispositions", and may better motivate and prepare students to undertake STEM-C careers.

Roadshows (i.e., informal hands-on classroom-style workshops) range in duration from 45 minutes to 1.5 hours and are the foundation for elementary outreach. At the elementary school level, roadshow curriculum is designed to introduce students to CS through a short discussion followed by an engaging project. The discussion is a 10-minute interactive presentation focused on the definition of CS and the well-known exciting job opportunities (i.e., game programming, industry software engineering at Google, Apple, Facebook, etc., and government jobs with NASA and White Sands Missile Range). Students are encouraged to take active roles in the discussion; small prizes are awarded to provide an incentive for shy students. To retain interest, YWiC instructors complete the presentation as quickly as possible; students are usually more excited to play with robots or make their own computer games.

The emphasis of these roadshows is the hands-on project component, where students are led through an example program and are tasked with modifying the sample program or creating one of their own. Because roadshows vary in structure (duration, number of students, student age, location, and resources), YWiC has utilized a range of platforms as the basis for roadshow projects. Each platform determines the student project to be completed and has its own limitations.

B. Middle School

Middle school outreach began in 2009. Early on, YWiC understood the phenomena that elementary school girls and boys show equal interest in STEM until middle school and

Fig. 2. Pipeline Structure

recognized that if girls do not develop the correct perceptions of their strengths and weaknesses in specific subjects during this crucial time, their interest in STEM begins to fade [27, 28]. YWiC has continued to introduce young students to technical fields and provide encouragement at the middle school level to make it more likely for students to pursue STEM-C fields in their post-secondary education. It should be acknowledged and celebrated that the LCPS system has invested significant effort in the creation of programs to train and motivate all students; at the middle school level, three schools offer magnet programs to attract students to specific areas of interest (i.e., media, science, music technology, and engineering). However, although most programs include a technology component, they do not specifically teach students CS or its relation to the program content. YWiC works to address this problem by providing these students, and all other students who do not attend magnet schools, CS learning opportunities to supplement the curricula they are taught in school. Specific CS learning opportunities for middle school students include summer camps, roadshows, conferences, clubs, and competitions.

In response to the increased interest of the students who participated in YWiC's first after-school club, middle school summer camps were created in 2010. The majority of the 2010 "campers" were club members, and, therefore, the curriculum was designed to build upon their existing knowledge. Since the pilot year, the summer program has evolved significantly: the length of camp has increased from one week to two; recruitment is open to all area students; and, the curriculum provided is more extensive. Each summer YWiC instructors guide campers through an action-packed curriculum that is designed to show students that CS is a rewarding field. The camps are designed to achieve three major goals: 1) generate and sustain girls' knowledge and interest in CS; 2) drastically increase students' confidence in CS and CS-related disciplines; and, 3) build a community among camp participants. Each goal is achieved through specific sets of activities implemented in the summer camp.

CS Knowledge and Interest: The central focus of each summer camp is the instruction of the underlying computational thinking skills and CS concepts needed to succeed in CS courses. Each Spring, YWiC chooses the summer camp curricula by determining the best combination of modules that are interactive, hands-on, exploratory, and relevant for 10- to 13-year-old girls. Figure 3 depicts the history of YWiC's middle school summer camp modules

integrated into the curriculum. In particular, it portrays YWiC's increased flexibility and wide range of module instruction.

The majority of the summer camp modules are project-based and challenge campers to implement a solution to a problem through the use of interactive software platforms; many modules implement visual programming platforms to meet the needs and experience-level of middle school students. YWiC research has shown that visual programming platforms are more enticing to the middle school population.

Confidence: The second objective of the summer camp is to build the students' confidence in CS endeavors. This is done through a variety of methods. First, the curriculum is taught in a fun, engaging atmosphere, where successful outcomes are frequent and celebrated. Second, self-efficacy is developed by challenging students to step out of their comfort zone in a non-threatening environment to solve a problem, interact with their peers, and present their project. Finally, YWiC instructors pose discussions that aim to break down the stereotypes and perceptions students have about CS.

Community: Not only do the students learn technical CS skills, but YWiC also emphasizes soft skills – such as leadership, teamwork, and communication. Campers should experience CS as a social and collaborative profession. Thus, every summer camp is composed of community building components that aim to reduce any sense of isolation. Campers use pair-programming to complete projects; participate in daily ice breakers and small team-building activities; and are invited to weekly social events including game nights and movie nights.

C. High School

High school is when students spend the majority of their time determining what they want to study in college. Most often, students will choose careers that they are familiar with (e.g., careers held by family members, related to elective courses, etc.). However, the rigidity of curricula in school systems does not easily allow the introduction of new courses, such as CS courses. This presents a problem because high school course selection is one of the factors that contributes to the lack of female interest in information technology (IT), as noted by Bartol and Aspray [29]. According to their research on the underrepresentation of women in IT, other contributing factors include confidence with computers, female role models, perceptions of IT careers, and knowledge about career options. Thus, if students are not presented with the opportunity to take a CS class in high school, the chances of them pursuing a CS career are low. On the other hand, when CS courses are offered, the majority of students do not have any incentive to take them; only 25 states offer graduation credit for CS classes [30], and many female students perceive CS as a man's pursuit [31]. Hence, it is critical for YWiC to reach out to the high school students who are interested and have the potential to do well in CS, but are either intimidated by CS, can't fit it in their schedule, or do not have access to CS courses. YWiC first addressed this problem in 2006 by offering a summer camp for female students. The program has now expanded to provide additional year-round CS learning opportunities such as roadshows, conference opportunities, competitions, and clubs.

Fig. 3. Middle School Summer Camp Module Instruction

Fig. 4. High School Summer Camp Module Instruction

Summer camps have been the cornerstone of YWiC's outreach initiatives to generate interest in CS among young women. The nine years of summer camp have reached 438 aggregate participants. A net total of 232 high school females have participated: single year students amount 115, two-year attendees total 42, and the number of campers who participated in three or more camps is 11. The goals of the high school camps encompass those of the middle school camp with one additional goal: 1) generate and sustain girls' knowledge and interest in CS; 2) drastically increase students' confidence in CS and CS-related disciplines; 3) build a community among camp participants; and, 4) introduce students to the plentiful, diverse, and multidisciplinary nature of CS career opportunities.

CS Knowledge and Interest: At the high school level, the camp curricula focuses on building competency in CS concepts to prepare students to excel in introductory-level CS courses in college, should they decide to study CS. Figure 4 represents the progression of YWiC's high school summer camp module instruction.

Specifically, YWiC's camp curriculum has evolved to include more modules that feature textual programming platforms, as opposed to visual programming platforms. Again, this tactical decision was to ready high school students for the CS concepts and programming style they would face in college; the AP CS exam also requires knowledge of the Java programming language, so test-takers would benefit from being

comfortable with textual programming platforms. Furthermore, students leave camp with a comprehensive understanding of CS topics including, but not limited to, animation, robotics, and mobile development.

Confidence & Community: The methods to increase student confidence in CS and to build a community among campers in high school are similar to those in middle school. Please reference section 3B for explanation.

CS Career Opportunities: To some high school students, the concept of going to college can be intimidating; it is difficult for these students to picture themselves getting a degree, and even more difficult to see themselves pursuing a tough technical degree like CS. To remedy this, students are given three presentations: the college admissions process, financial aid options, and benefits of a CS career. The general feedback from campers about the presentations has been consistently positive. Campers report that they were previously unaware of the many scholarship opportunities available, and would be less intimidated to meet with an NMSU Advisor after the presentation. Students are also surprised to learn that they could potentially contribute to products that billions of people use every day (e.g., Facebook, Google, etc.), or even invent the next new tech fad themselves.

D. College

The college stage of the pipeline exists to retain the female students that have matriculated from high school into college. YWiC gives female college students the chance to travel to conferences, join the YWiC team as URAs and conduct research, and be a part of a friendly undergraduate community within the CS department at NMSU.

Beginning in 2009, in conjunction with NMSU, the CS Department, and other partners, YWiC began to offer support for the URAs and other undergraduate students to attend local, regional, and national conferences. YWiC encourages the URAs and all conference attendees to take full advantage of the conference experience by actively participating in conference activities. The URAs have not only attended conferences, but have served as student panelists, keynote speakers, poster presenters, and career fair interviewees. Notable accomplishments include the 2010 New Mexico Celebration of Women in Computing Undergraduate Student Poster Award, 85 industry-sponsored conference scholarships, and 7 internship/job securements as a direct result of conference attendance. In total, YWiC has assisted 162 students to attend 23 conferences.

IV. PROGRAM EVALUATION

The ultimate goal of YWiC is to create a pipeline structure that: increases exposure to and interest of young women in CS; attracts them to four-year CS programs; and, effectively prepares them for academic success. These goals are broad and general, and address the problem with a long-term solution. This section presents metrics that measure the short-term and estimated long-term effectiveness of YWiC, including program growth, curricula impact, and college success.

Fig. 5. Program Growth

A. Program Growth

In an effort to increase the number of women being introduced to CS, YWiC has provided a plethora of CS learning opportunities for the students of southern NM, and has experienced considerable growth in the process. Figure 5 depicts the number of students reached per year via outreach initiatives and the cumulative total of students reached. Overall, YWiC's outreach trend has been positive, as the program has continued to engage an increasing number of students every year. YWiC reached the following number of students each year from 2006 - 2014, respectively: 12; 71; 113; 160; 456; 1,956; 2,108; 2,583; and 2,756.

As of January 2015, the organization has reached over 10,200 students through: 53 weeks of summer camps, 315 roadshows, 15 teams mentored in competitions, hosting 5 conferences, and sponsoring 45 women to professional conferences. It is important to note that the 10,200+ students were not all female; the nature of roadshows and competitions provide opportunities for both female and male students to engage in a supportive introductory CS learning experience. Although gender-specific data was not collected from each outreach avenue, YWiC has reached female students at all levels of the pipeline, successfully meeting its goal to introduce female students to computer science.

B. Curricula Impact

In large part, YWiC research has been centered on evaluating the effectiveness of interdisciplinary modules to teach CS concepts and encourage students to pursue STEM-C degrees. YWiC roadshows and summer camps have yielded quantitative and qualitative data via student questionnaires and interviews, which have attempted to: 1) gauge student perceptions of and interest in STEM-C, and 2) provide feedback to evaluate the effectiveness of summer camp and roadshow modules across the curriculum. The research objectives for each year directly affect the questions that students are asked in the pre- and post-camp questionnaires and interviews. Likert-scale questions allow students to respond to questions on a scale from 1-5 (e.g., 1: Strongly Disagree through 5: Strongly Agree); open-ended questions allow students to elaborate on their camp experiences.

One question that has remained consistent across the nine years of camp is: "I have basic knowledge of computer science". Figure 6 presents data for the high school students who selected a 4 or a 5 on a scale from 1-5 to this question

from 2006 – 2014. As expected, pre- to post-camp knowledge of CS increased substantially each year of camp. The largest increase observed was in 2009; 46% of campers reported previous knowledge of CS, while 93% of the campers reported knowledge of CS after the completion of camp. The smallest increase occurred in 2008 when the pre- to post-responses were 71% and 100%, respectively. There were no pre-surveys administered in 2006, but the 100% post-camp responses showed that all campers acquired knowledge of CS during camp. Data from 2011 is missing.

Figure 7 displays the most recent data available for student responses to the questions: 1) “I want to major in Computer Science”; 2) “I would like a job that uses Computer Science”; and, 3) “I want to be a Computer Scientist”. The chart represents those students who selected a 4 or 5 on a scale from 1-5. Interestingly, the 2013 middle school group reported the largest percentage of students most interested in majoring in CS, and the 2013 high school group contained the highest percentage of students that wanted a job utilizing CS, and, specifically, wanted to be a computer scientist.

At the conclusion of the 2014 middle school summer camp, after being exposed to visual and textual programming environments, students were surveyed to determine what was their favorite programming style and which programming style they felt taught them more about CS. Figure 8 shows that the students’ favorite programming styles correlated with their perceptions of the programming style they felt taught them the most about CS. From this study, YWiC concluded that middle school students are more comfortable with visual programming platforms.

In 2013, YWiC conducted a two-week study during the high school summer camp to determine which module, LilyPad Arduino [32], a textual programming platform, or App Inventor [33], a visual programming platform, was most effective at teaching students programming skills. Students were asked to indicate which software approach best instructed them in the fundamental concepts of CS; Figure 9 shows the percentage of students that indicated which modules successfully taught them each CS concept. The results were as follows: compared to App Inventor, LilyPad was more effective in teaching variables (75%), loops (69%), functions (81%), and properties (63%). Conversely, App Inventor was more effective than LilyPad Arduino at instructing if-else statements (81%), input/output (81%), and events (69%). Both tools were equally successful in teaching the concepts of objects (81%) and parameters (56%). The study concluded that if time permitted, a combination of both platform types (textual and visual) is ideal to teach the specified CS concepts.

The study also measured student interest in a number of STEM-C-related domains. Figure 10 presents the percentage of students that became interested (or more interested) in mobile applications, electronics, math, CS, programming, and technology as a result of learning LilyPad and App Inventor. Students reported an overall increase of interest in all categories as a result of their work with LilyPad and App Inventor: App Inventor was most successful in increasing student interest in mobile applications (86%); LilyPad was most successful in increasing student interest in technology

Fig. 6. High School Summer Camp Understanding of CS

Fig. 7. Middle School and High School Post-Camp CS Aspirations

Fig. 8. 2014 Middle School Summer Camp Programming Preferences

Fig. 9. Concepts Learned Through LilyPad Arduino and App Inventor

(85%). In particular, reported interest in CS reached 76% and 52% as a result of working with LilyPad Arduino and App Inventor, respectively. YWiC hypothesizes that LilyPad Arduino generated more interest in CS, programming, and technology than App Inventor because of the textual-based programming environment that gives students a more intimate and challenging programming experience; LilyPad Arduino also has a hardware component to the module, which creates a tangible connection to CS.

In 2013, YWiC also initiated a survey study to see the factors impacting student interest in CS during roadshows. The modules used for these roadshows were PicoCricket [34] and Storytelling Alice [35]. Over a four-month period, 18 sets of pre- and post-surveys were administered to students during roadshows. Due to roadshow time constraints, it was impractical to administer both pre- and post-surveys to all students; 9 groups received pre-surveys and 9 groups received post-surveys. A total of 295 responses were recorded: 157 (53%) were pre-survey responses and 138 (47%) were post-survey responses. Figure 11 shows the responses to the question: “How interested are you in Computer Science?” Between the pre- and post-survey groups there was a 4%, 19%, and 9% decrease in the not interested, a little interested, and pretty interested responses, respectively; there was a 66% percent increase in the number of students that reported being super interested in CS. The significant increase in “Super Interested” responses justifies that roadshows are effective tools for increasing student interest in CS.

C. College Success

The obvious metric to measure the increase of presence and retention of female students in CS is the number of women in the NMSU CS program and other STEM-C programs. Because this is a long-term metric, data in this section is only available for the 98 summer camp alumnae that have graduated high school since their participation in YWiC camp in 2006, and the student-base in the CS program at NMSU. It is important to note that many of the students in YWiC’s pipeline are currently in the elementary and middle school stages, far from graduation. Further, at this time it is infeasible to track every student that YWiC reaches through various outreach activities.

YWiC encourages every student to pursue a college degree, and has seen a high matriculation rate for high school summer camp students. Of the 98 high school graduates, 97 chose to attend college the semester immediately following graduation. Among them, 63.2% are STEM-C majors, and 76.5% chose to attend NMSU. Figure 12 shows the distribution of majors that were chosen by the 97 students upon entry into college. Although only 16% of camp alumni chose to pursue a CS degree, YWiC deems the fact that 63.2% of students selected STEM-C majors a success. CS is interdisciplinary in nature, and many recent advances have been motivated and guided by the interaction between CS and other scientific domains. Various research suggests that women do not perceive CS as a self-sustaining discipline, but as a tool to serve the needs of other disciplines, (e.g., education, medicine, etc.) and recognize its potential to address societal needs. This allows young women to pursue CS careers where they feel like an active part of the solution; this interdisciplinary perspective also stresses the role of collaboration, teamwork, and communication, factors that have been recognized to be of great importance to enhance success of Hispanic students.

D. Lessons Learned

YWiC has encountered many challenges and successes throughout its nine years of outreach. Post-experience reflection and analyses have yielded interesting insights, with many valuable lessons learned.

Fig. 10. Interest Generated by LilyPad Arduino and App Inventor

Fig. 11. Roadshows Survey Question: “How interested are you in CS?”

Fig. 12. Chosen College Major

Curriculum Design: The retention of student interest in CS relies on the relevance, engagement, and uniqueness of the YWiC curriculum. The curriculum has been effective at generating interest in CS among students at all stages of the pipeline; the challenge that remains is keeping repeat students interested. Many students participate in more than one YWiC program, and so it is imperative to continuously update and redesign curricula with both challenging and engaging content. This includes the creation of new modules when cutting-edge programming platforms are introduced.

Data Collection: Collecting data regarding student experiences with CS in YWiC-sponsored events is essential to the development of relevant and successful program curricula. YWiC has found it challenging to keep questionnaires consistent. The fluctuations in management and URA positions have complicated data collection at times, specifically in relation to the consistency of the types of questions and methods for student questionnaires and interviews. Survey questions reflect the different research initiatives, innovative modules and platforms, outreach avenues, YWiC staff, etc.

Instructors and Student Assistants: Camp instructors and student assistants are critical to the success of all outreach practices. Each activity offered by YWiC is taught by

undergraduate and/or graduate students and staffed by student assistants. Hiring student assistants promotes the continued engagement of past students who have participated in YWiC programming; they engage in mentor-mentee relationships with camp instructors and help teach material to students in ways that are applicable, meaningful, and relevant to their own age group. It is important to train all instructors and student assistants in topic and substance, and also in the overall goals and mission of the program for maximum student participation, engagement, and retention. With community outreach, the desired effects include recruiting students for future participation in outreach initiatives through activities that promote confidence, positive self-image, and create bridges for building communities and social networking.

Leveraging Partnerships: Expanding the collaborations with school districts, as well as with local, state-wide, and national girl-serving programs helps to ensure a larger pool of talented students from the under-served areas of NM and the survivability of the program. Specific to summer camps, YWiC has partnered with organizations including, but not limited to: GUTS y Girls, AAUW, DataOne, and NCWIT.

Parental Involvement: Direct communication with parents/guardians via phone calls, emails, Facebook, website postings, text messages, and informational sessions assists YWiC in reaching out and communicating about upcoming opportunities. Parents learn they have a direct link with the university, the department, and the programming available for their children. This increases response rates, participation rates, and interest for new, upcoming activities. In addition, as families become more familiar with the campus community, they become less intimidated by the transition between secondary and postsecondary education and more vocal when questions and/or concerns arise.

Student Involvement With Other Programs: YWiC's outreach initiatives are limited to the students who are able to participate in them. This is challenging because many students participate in additional extra-curricular activities that conflict with YWiC programs and opportunities. To overcome this challenge, YWiC has learned to promote opportunities in advance to allow interested students to plan accordingly. YWiC has also learned that to retain interested students it is important to be flexible and, if possible, adapt to student schedules as best as possible.

Target Schools: Expanding collaborations with local schools is crucial to the expansion and success of the program. YWiC began targeting three local public schools, and later expanded to local private high schools, home schools, and other school districts. Targeting a wider range of schools has led to greater diversity of students from the under-served areas of NM.

Team Building: YWiC has learned that it is essential to provide exciting team building exercises for students in order to foster a successful cohort. Students increase satisfaction and connection with instruction sessions as their cohort generates greater familiarity and comfort with one another. This also raises creativity levels and overall design output for each participant.

V. CONCLUSION AND FUTURE WORK

To address the underrepresentation of women and minorities in computing fields, YWiC has created a permanent infrastructure (i.e., pipeline) that ensures the participation of girls and women in CS. YWiC's broad student base, engaging curricula, unique pedagogical approaches, and ability to learn from and adapt to a changing landscape of technology and student abilities have enabled the program to be successful in recruiting and retaining females in STEM-C post-secondary programs at NMSU and other universities. Specifically, YWiC research initiatives show that summer camp and roadshow curricula have a positive effect on student perceptions and abilities in CS, with 63.2% of YWiC summer camp alumnae having selected STEM-C majors. Additionally, since the introduction of YWiC in 2006, the NMSU CS Department has seen an increase from 8% to 23% of female undergraduate students, and YWiC experiences have been instrumental in the design and addition of a Bachelor of Arts degree in CS, which facilitates the interdisciplinary study of CS.

YWiC has reached a level of reputation and maturity to fill a bigger role within NM by coordinating state-wide initiatives and acting as an entity that will lead to integration and growth for existing programs. Looking to the future, YWiC aspires to fully develop each stage of the pipeline (i.e., conduct more outreach for elementary and college students) and expand its role to serve as an information and outreach portal for other similar STEM-C outreach programs on a regional scale. YWiC will continue to connect organizations, individuals, universities, and industries, both public and private, to further engage students in their STEM-C journeys.

ACKNOWLEDGMENT

The authors acknowledge the contributions provided by all YWiC URAs, Rebecca Galves, and Raena Cota. This work has been partially supported by NSF grant CNS-1440911.

A Community of Practice to Develop, Teach, and Disseminate Learning in Engineering Design

Matthew D. Lammi, Cameron D. Denson, Nathan Stevens

College of Education

NC State University

Raleigh, USA

mdlammi@ncsu.edu, cddenson@ncsu.edu, ncstevens@ncsu.edu

Abstract—This work-in-progress paper describes the initial efforts and findings from the development of a pedagogical approach to prepare pre-service teachers for teaching engineering and engaging with the community mediated through an online portal. This project incorporates the latest research on inverted classrooms and best practices for online learning in an effort to build the VILLA Community of Practice. VILLA has been designed in a manner that makes it unique in the area of instructional technology and web-based learning. This project recognizes the importance of engaging community in the teaching and learning of engineering-based content. Where VILLA is able to distinguish itself from other service-learning projects is the use of an inverted classroom format to facilitate instruction and the emphasis on modeling artifacts as a representation of student learning.

Keywords—communities of practice, design education, pre-service teachers, teaching

I. INTRODUCTION

This work-in-progress paper describes the initial efforts of VILLA, a Community of Design and Creation, in preparing pre-service teachers for teaching engineering and engaging in and with the community mediated by an online portal. Education is constantly debated and evolving as it relates to technology. With the printing press, the computer, the world-wide-web, and social media educators and students have questioned how technology might best be employed for learning. Technology not only influences how curriculum is developed and delivered, but also impacts nearly every aspect of teaching and learning.

II. MAKERS IN A FLIPPED CLASSROOM

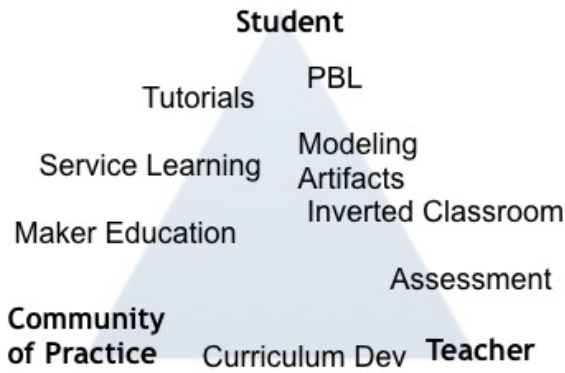

A mismatch between teacher's pedagogies and students' learning preferences has precipitated the need for introducing technologies to improve students' opportunities to learn. One such approach is "inverting" the classroom where traditional instruction and lecture that normally occur inside the classroom are flipped and these events occur outside of the classroom [1]. In inverted classroom settings teachers focus mainly on student outcomes whereby the student is expected to take more responsibility for deciding the best method to reach said outcome [1]. One drawback is the amount of time and commitment needed from the instructor on the front end to facilitate this kind of instruction. Inverted classrooms also require students to take more responsibility for their learning

and the delivery of course content. In the inverted classroom lectures and similar content are not covered in class, instead students are expected to review tutorials and other pre-packaged content and class time is used to do get students involved in active work [2].

In order to build effective online learning environments there needs to be consideration for the necessary elements needed to develop a learner-focused, active-learning community. Pallof and Pratt [3] developed a framework for the development of effective learning communities that include: *people, purpose, policies, computer systems, collaborative learning and reflective practice*. This model evolved into three categories: *people, purpose, and processes* wherein the outcomes of an effective online learning environment would be *reflective/ transformative learning*.

This project incorporates the latest research on inverted classrooms and best practices for online learning in an effort to build the VILLA Community of Practice. VILLA has been designed in a manner that makes it unique in the area of instructional technology and web-based learning. This project recognizes the importance of engaging community in the teaching and learning of engineering-based content. Service learning projects provide students, in this case pre-service teachers, with authentic real-world experiences which helps secure buy in from the student, teacher, and community of practice [4]. Where VILLA is able to distinguish itself from other service-learning projects is the use of an inverted classroom format to facilitate instruction and the emphasis on modeling artifacts as a representation of student learning [5]. Furthermore, the students not only publish what they have made and learned, but also are able to receive feedback from the community of practice as well. Students learn from resources on the web and in turn develop their own resources and share them as tutorials and videos. The learning then is truly student driven, Figure 1.

FIG. I. THE COMPONENTS OF VILLA.

III. GETTING OFF THE GROUND

The majority of teachers create activities that are either deskwork or have a singular focus on a certain tool. Most educators are accustomed to being the single source of information in the class and control the flow of learning. The more advanced students typically wait for other students to finish or be remediated. This creates a pause in learning for the students who want to learn more and delve deeper into the activity.

In this project the research-practitioners had to look at making the class more student-driven and inclusive to a majority of learning preferences. Realizing that technology is rapidly changing, the research-practitioners had to assume the role of co-learners in the classroom. There are times when a student knows more about subject than the instructor. Some students have a parent that work with them on a home project that is above and beyond what is being covered in the classroom. Having a student-driven classroom allows motivated and advanced learners continue to progress at their pace.

It can be a little disconcerting to the students and instructor to walk into a classroom and say, “Let’s explore.” Even though there was a class learning management space to guide the students, the primary medium for student work and interaction with the community was a wiki. The students typically published tutorials from the projects they developed on the wiki. Other students, teachers, and anyone from the community were able to leave comments on the tutorials.

In order to help students become familiar with online successful tutorial authoring, they were to find existing tutorials on mechatronic systems, critique them, and eventually make them better. From there, the students were to begin their own projects. The students documented their process with multi media, photos, videos, slides shows, etc. Now it was the students’ turn to create a new tutorial and publish them. As the students were encouraged to reflect and justify their designs, they shared not only what they had done but also why they were doing it.

IV. COMMUNITY AND PARTNERS PERSPECTIVE

The maker and open source movements have always focused on developing knowledge bases that help others learn. Some examples of these knowledge bases are Instructables, various

company websites, Youtube channels, and personal websites of individuals. Quality can sometimes vary. For educators who need to know what items are needed to complete a project or judging how long it will take students to complete, community knowledge bases need to be developed with pedagogy in mind.

Several educators have been developing lesson plans and posting them online. Few of these postings have become vetted tutorials. College faculty create excellent tutorials on innovative ideas, yet these pages are usually hidden behind a learning management system. This model does not help the student as they progress through their programs. It also does not help the current educators to know what other tools are available to improve their student’s learning. Institutions of higher learning are starting to use public platforms to share work to interested parties. These platforms allow for others in the community to add to the posts.

A. Lessons Learned

As educators we want to ultimately impact student learning. Having students publish what they did and why they did it compels them to reflect on their designs and furthermore provides an outlet for dissemination. The students were instructed to write to a middle school audience, thus ensuring the students understood what they were doing.

B. Modeling

The students posted what they did and why they did it, engaging in reflective practice. The modeling artifacts produced were conceptual, graphical, mathematical, and working models. Figures II and III are screenshots of the recycled robot tutorial with graphical (code) and working models.

FIG. II SCREENSHOT OF CODE DEVELOPED FOR ROBODOG

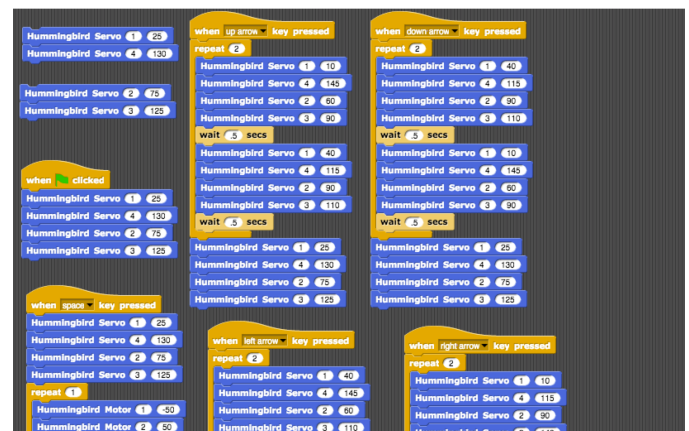

FIG. III PHOTO OF WORKING MODEL OF ROBODOG

C. Format

Although a wiki was chosen as the medium for sharing tutorials, the format is still a challenge. As of now, there has to be restrictions on who can post and edit on the wiki. The students typically needed feedback to improve the tutorial so that it was actually helpful and informative. Copyright and privacy issues are continual concerns. From their experiences, the students did come up with a list of “best practices” for developing a successful tutorial, Table 1. This also served as a standard for the students’ work.

TABLE 1. ELEMENTS OF A SUCCESSFUL TUTORIAL

- Written like they were speaking to you
- Shows how to put project together with steps that are detailed and readable
- Explain why it works or what the different parts do
- Provide an overview and explanation and then provide details
- Know why your are doing the steps
- Inspires you to create
- Quality multimedia
- No fluff
- Shows finished product
- Clear formatting, spelling, and grammar
- Links to resources, both needed and supplementary

D. Assessment

The modeling artifacts not only served as a medium for communication to the community of practices, but also facilitated assessment, formatively and summatively. However, there is a learning curve for using a technology to disseminate tutorials. For some students the learning curve was steeper than others. Students come in at different levels of

publishing on the web. It is not certain how novice students would participate, especially at the k-5 levels. Furthermore, it was easier to assess the teams’ work, but not as simple to assess an individual’s work. One clear advantage was the opportunity for feedback from the community. They are the real users and want vetted resources for themselves and their students.

V. MOVING FORWARD

The overarching goal of VILLA is to provide a central space for creating, editing, and accessing vetted learning resources. Additionally, it aids in collaborative development (professional development) for learners and co-learners (practitioners, instructors, teachers, parents, administrators, mentors, et.c). It is hoped that this resource will help bridge formal STEM learning through informal activities. It is anticipated that the results from this study will lead to pedagogical improvements in teaching engineering design, community engagement, and innovative ways of developing curriculum.

ACKNOWLEDGMENT

We would like to acknowledge the help of Corey White and Nolan Farher on this project.

TIES to STEM: University Outreach Model for Teachers in K-12 STEM Schools to be Trained in Engineering Skills

Ramakrishnan Sundaram
Gannon University, sundaram@gannon.edu

Abstract - This paper discusses plans to establish the 'TIES to STEM' outreach program for K-12 STEM school teachers at our University. TIES denotes Training in Engineering Skills and comprises the engineering education program, the pre-engineering curriculum, and the cyber-instructional networks to integrate the K-12 STEM education programs with the engineering disciplines at institutes of higher education. The engineering education program creates the opportunity for K-12 school teachers to learn and apply the engineering design process, engineering technology, and skills in the products approved and used by the engineering industry. The teachers will be better prepared to (a) teach STEM concepts to the K-12 students (b) revise the content and delivery of the K-12 STEM curriculum (c) advance their STEM careers in engineering and engineering technology. The pre-engineering curriculum for the middle school and high school students (a) improves the STEM preparation of the students (b) motivates and encourages the students to pursue degree programs in engineering and/or engineering technology at institutes of higher education. The networks based on cyber-instruction facilitate the widespread dissemination of course content, involve the teachers from widespread K-12 schools and school districts, and promote cohort identification and professional collaboration among the educators.

Keywords – STEM engineering education, cyber-instruction

INTRODUCTION

The 'TIES to STEM' outreach program for K-12 STEM teachers is viewed as the partnership between the engineering departments at the University and the K-12 schools with science, technology, engineering, and mathematics (STEM) curricula to enhance the content and improve the delivery of critical teaching and learning components of K-12 STEM education. Unfortunately, factors that contribute to the high drop-out rates of students from the STEM school systems and the low enrollment of school graduates in the STEM colleges and universities across the U.S. include (a) inadequate preparation and the lack of technological resources available to the K-12 STEM teachers to effectively deliver STEM teaching (b) STEM curricula which fail to inspire the students to develop a life-

long passion for STEM learning (c) lack of awareness of the promising careers after the successful completion of STEM-based school and college education. The partnership between K-12 schools with STEM curricula and the engineering departments at the University which offers the ABET-accredited baccalaureate degrees in engineering disciplines [1], [2] can address the critical issues facing STEM learning and teaching in the following areas.

(1) Introduce revisions to K-12 STEM courses and curricula

The K-12 curriculum will include new and revised STEM courses which introduce the engineering design process and teach students how to use engineering technology to solve engineering problems with design and cost constraints. These courses will incorporate project-based and goal-oriented STEM learning experiences to supplement the traditional STEM curriculum.

(2) Raise student motivation and desire to learn STEM

The engineering education program and the pre-engineering curriculum integrate the teaching of concepts with hands-on project activities to train the K-12 teachers. This approach will equip the teachers with the knowledge and skills required to sustain the STEM learning experience for the students. The adoption of the pre-engineering curriculum by the teachers will motivate the students to advance their understanding of basic and advanced STEM concepts.

(3) Improve the retention of STEM concepts by the students

The training of K-12 STEM teachers in the engineering education program will lead to revised K-12 STEM courses across the K-12 curriculum. The pre-engineering curriculum for the K-12 students will deliver critical STEM learning competencies and improve the retention of STEM concepts by the students.

(4) ACT-48 compliant course work

ACT-48 is the statewide recognized pathway for educators in our state to earn course credit toward professional growth. The courses offered by the 'TIES to STEM' program will allow the teachers to gain or sustain continuous professional development through ACT-48 compliant credit hours assigned to each course. This will serve as the incentive to motivate K-12 STEM teachers across a wide range of schools and school districts to enroll.

This paper reports work-in-progress to create the ‘TIES to STEM’ program comprising (a) the engineering education program for high school teachers (b) the pre-engineering curriculum for middle and high school students (c) the dissemination of educational content through networks based on cyber-instruction (d) the teacher induction, teacher residency, and cohort identification criteria. Section 2 discusses the engineering education program. Section 3 outlines the pre-engineering curriculum. Section 4 documents the set up of cyber-instruction. Section 5 identifies the evaluation and dissemination plan for the program. Conclusions and future work are in Section 6.

SECTION 2: ENGINEERING EDUCATION PROGRAM

The engineering education program will comprise engineering courses offered to STEM-based K-12 high school teachers. These courses will be written to conform to the EC2000 guidelines of the accreditation board for engineering education (ABET). The courses will focus on solutions to engineering problems with products and tools approved by the engineering industry and will be offered through training institutes and professional development workshops.

The proposed initiative adopts the model displayed in Figure 1. In this model, centralized engineering projects whose scope and breadth encompass most engineering disciplines and STEM teaching/learning are identified. For example, the solar-powered home and the electric car are engineering projects with broad engineering coverage and significant STEM components related to engineering design and validation. Each project is a complex engineering system made up of subsystems with engineering design specifications and requirements, and capable of reliable operation upon integration. The assembly, test, and validation require the understanding of engineering concepts and their applications from several engineering disciplines.

Figure 1. Model for STEM teaching and learning.

The centralized engineering projects create the environment for active engagement in real-world engineering design. Thus, the participants gain measurable knowledge and the tangible sense of accomplishment. In addition, the projects help structure the content of the STEM-based courses offered in both the engineering education program and the pre-engineering curriculum through course objectives which are measured by hands-on STEM project activities related to the subsystems of the project. Each course has clearly defined STEM goals which

relate the STEM teaching and learning to engineering design and practice in the context of the chosen projects.

The engineering education program will comprise course work which emphasizes the application of fundamental and advanced concepts to the engineering projects. The courses will comprise modules whose focus will be to understand and implement the design of subsystems required by each project. The modules will be either discipline-specific (i.e. ECE, ENV-SE) or cross-discipline integrative (i.e. EEE) in nature. The broad topical areas covered in each module are shown in Table I.

TABLE I
COURSE MODULES

Category	Module #	Theme of Module
ECE	1	Electronic Circuits and Electromagnetic Fields
	2	Microprocessors and Embedded Systems
	3	Signal Analysis and Communications
ENV-SE	1	Fundamentals of Environmental Science & Engineering
	2	Emissions Control and Environmental Regulations
EEE	1	Smart Sensors and Actuators
	2	Alternate and Renewable Energy
	3	Climate Control and Prediction

The courses will be offered to K-12 teachers as workshops and seminars during the three months of the summer session (June to August). Each course module will run for four weeks (one month). For each course module, there will be three sessions each week. The duration of each session will be three hours. The total contact time for each course module will be 36 hours over 12 sessions. Table II displays the schedule for the course modules.

TABLE II
SCHEDULE FOR COURSE MODULES

Month	Course module
June	ECE #1, ENV-SE #1, EEE #1
July	ECE #2, ENV-SE #2, EEE #2
August	ECE #3, EEE #3

The K-12 teachers will pay a nominal tuition fee per course module. They will receive a stipend to cover the expenses (e.g. board and lodge, course supplies) incurred as part of their enrollment in the course modules of the program. They will receive a certificate upon successful completion of the course modules in the program.

The goals of the engineering education program are to create the environment for STEM-based K-12 high school teachers to (a) understand the application of engineering concepts to solving problems at the component, subsystem and system level as related to the chosen engineering projects (b) gain proficiency with the engineering products and tools necessary to solve the engineering problems associated with the projects (c) develop the infrastructure to design and offer new courses to K-12 students through the pre-engineering curriculum (d) apply the learning and

training to incorporate revisions to their K-12 STEM curriculum.

SECTION 3: PRE-ENGINEERING CURRICULUM

The pre-engineering curriculum comprises STEM-based engineering courses for the K-12 teachers to adopt at the middle school (grades six through eight) and high school (grades nine through twelve) level. These courses use the platform of the centralized engineering projects to emphasize the critical aspects, issues, and constraints to be understood for successful engineering design and practice.

The K-12 teachers who have successfully completed course credits from the engineering education program are qualified to choose courses from the pre-engineering curriculum as part of their K-12 STEM teaching. These qualified teachers in turn engage their K-12 STEM students as active participants in the centralized engineering projects. The knowledge gained by these teachers through the course modules of the engineering education program will prepare them to deliver the critical STEM learning to the K-12 students.

The courses for the middle school students will focus on engineering technology and the understanding of engineering principles through laboratory activities. The laboratory activities will consist of experiments which stimulate the interest, enthusiasm, and energy of the students to tackle the engineering design issues as they relate to subsystems of the centralized engineering projects.

The activities are categorized into three levels (1) basic (2) intermediate (3) advanced. For middle school students (grades six to eight), the K-12 teachers can introduce the applications of STEM concepts to solve problems related to the centralized engineering projects. Each course focuses on the development of the solution to simple and complex engineering problems through hands-on experiments and laboratory activities. The course activities will take place over 9 weeks during the summer months from June through August. Table III displays the duration of each course, the course activity level and the theme of the course activity as it relates to the centralized engineering project.

In each session, the students will apply the principles of engineering design and the concepts of STEM to build and test simple and complex engineering systems. The students will also become familiar with industry standards and practices, as well as gain proficiency in the use of engineering tools.

The courses for the high school students are identified in three categories - *core/fundamental*, *elective/specialized*, and *capstone/design*. The *core/fundamental* courses will teach the engineering design process, the principles of engineering, and the design of engineering systems.

TABLE III
CONTENT AND SCHEDULE - PRE-ENGINEERING, MIDDLE SCHOOL

Course Activity Level (Duration)	Theme of Course Activity	
	Centralized Project: Electric car	Centralized Project: Solar-powered home
Basic (Two weeks)	Battery charging & test	Energy sources
	DC signals & circuits	Energy conversion
	AC signals & circuits	Solar cell test
Intermediate (Three weeks)	Sensor design	Solar cell design
	Sensor calibration	Solar cell calibration
	Energy & Power	Solar water heater
Advanced (Four weeks)	DC motor test	Solar panel test
	AC motor test	Solar pump design
	Smart sensor design	Solar pump test

The *elective/specialized* courses will focus on strengthening the mathematics and science required by the students to understand and interpret the subsystems of the centralized engineering projects. The *capstone/design* course will comprise integrated design, development, and implementation of one or more subsystems of the centralized engineering projects.

The pre-engineering courses for the high school students (grades nine to twelve) are project-driven activities taught at three levels as shown in Table IV. At the *Core or Fundamental level*, the students are first introduced to the principles and practices of engineering system design. Thereafter, case studies are used to illustrate the components of a project: specifications, requirements, preliminary design, schedule, and the steps leading to the final design, test, validation, and technical documentation.

TABLE IV
CONTENT AND SCHEDULE - PRE-ENGINEERING, HIGH SCHOOL

Course Level (Duration)	Theme of Course Work	
	Centralized Project: Electric car	Centralized Project: Solar-powered home
Core/Fundamental (Two weeks)	Engineering Project Design Principles	Engineering Project Design Principles
	Case study: Project Specifications & Requirements	Case study: Project Specifications & Requirements
	Case study: Preliminary Design & Schedule	Case study: Preliminary Design & Schedule
Elective/Specialized (Three weeks)	Motor Subsystem	Inverter Subsystem
	Hydrogen Fuel Cell	Solar-powered Laptop
	Smart Sensor System	Off-grid Solar System
Capstone/Design (Four weeks)	Project Identification: Scope, Prelim. Design	Project Identification: Scope, Prelim. Design
	Build & Test Prototype	Build & Test Prototype
	Technical Documentation	Technical Documentation

The proposed pre-engineering curriculum will (a) improve the STEM preparation of the students by

introducing and re-enforcing the importance of STEM learning in engineering project design and practice (b) create more options for the students to pursue degree programs in the fields of engineering and engineering technology at colleges and universities across the country.

The course work at each level will take place over nine weeks during the summer months from June through August. The total contact time for the entire schedule is 81 hours across 27 sessions with three sessions per week and three hours per session.

SECTION 4: CYBER-INSTRUCTION

Cyber-instruction is an effective means to deliver the STEM teaching and learning for the model described in Figure 1. This creates the *virtual* classroom experience to complement the hands-on training and leads to curriculum development and integration with positive impacts on (a) program and course enrollment (b) digital storage of and access to teaching and learning materials (c) dissemination of learning outcomes. Figure 2 illustrates the set up for cyber instruction. The content of each course is accessible to K-12 teachers and students on secure internet sites. The K-12 teachers and students can obtain instructional material or engage in interactive sessions with the engineering faculty responsible for the course content.

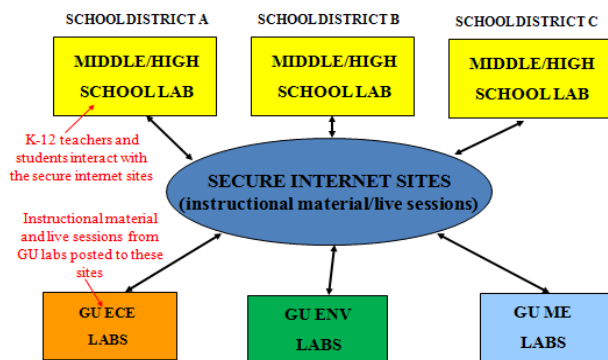

Figure 2. Cyber-instruction

Cyber-instruction offers the following benefits to K-12 teachers across schools and school districts (a) opportunity to interact with the engineering faculty to enhance the STEM teaching and learning experiences (b) engage in discussion and curriculum development with the K-12 teachers and students from remote school districts (c) reduce or eliminate scheduling conflicts within the regular day by organizing the laboratory session(s) after school hours.

SECTION 5: PROGRAM EVALUATION AND DISSEMINATION

Program evaluation will consist of the following components:

(a) *Project, course, and instructor evaluation*

This component of the project evaluation relates to the assessment of the chosen project platform, course

curriculum, and course instruction by the engineering faculty teaching in the engineering education program. The external evaluator will be identified from the list of nationally recognized STEM program evaluators. The external evaluator will employ surveys as well as other indicators of program success. The assessment of the course content and delivery will be separately conducted by (a) the external evaluator, and (b) the course attendees i.e. the high school teachers enrolled in the course.

(b) *K-12 STEM course and instructor evaluation*

This component comprises evaluation of course instruction by the high school teacher or counselor trained through the engineering education program. This evaluation will determine methods to improve their ability to effectively use the material learned from courses of the engineering education program in their K-12 curriculum and classrooms. This evaluation is separately conducted by (a) the external evaluator, and (b) the K-12 students attending the pre-engineering courses taught by the teachers who have been trained through the engineering education program.

(c) *Pre-engineering course-level learning outcomes*

This component comprises assessment of the learning outcomes of the K-12 students enrolled in the pre-engineering courses taught by the high school teachers trained through the engineering education program. This evaluation will have formative and summative assessment techniques to measure the student learning of the course outcomes for each pre-engineering course [3] based on surveys created for each course.

SECTION 6: CONCLUSIONS AND FUTURE WORK

The 'TIES to STEM' program delivered through the engineering education program for K-12 teachers, the pre-engineering curriculum for K-12 students, and the networks for cyber-instruction will exploit the synergy between the K-12 environment and baccalaureate engineering degree institutions to develop new or revised course material and instructional practices to reinforce the learning of K-12 STEM concepts through the application of mathematics and science in engineering design and practice. In the future, the program will be expanded to incorporate teacher residency, cohort identification, and professional collaboration.

Comparing Students' Mathematics Achievement by Their School Types

Inclusive STEM Schools that implemented PLTW curriculum with Inclusive STEM Schools that did not Implement PLTW

Abstract— Inclusive STEM high schools (ISHSs) are increasingly emerging in the research literature and have yielded promising effects on students' science and mathematics achievement [1; 2; 3]. ISHSs emphasized STEM preparation for underrepresented subpopulations and offered open enrollment. In the present study, we selected 17 ISHSs in Texas and divided those schools into two groups. Of these schools, seven ($n=1,682$) implemented Project Lead the Way (PLTW) curriculum and 10 ($n=3,070$) did not implement the PLTW curriculum. PLTW was an engineering curriculum and professional development program intended to increase K-12 students' interest in the fields of science and engineering [4]. Results from the present study showed that students who attended ISHSs increased their mathematics score regardless of the curriculum used. Results also showed that the mathematics achievement of students over time did not differ ($p>.05$) between STEM schools that implemented PLTW and those that did not. In fact, given the effect sizes, it is arguable that schools in which PLTW was not implemented had greater gains in mathematics.

Keywords—STEM schools, and PLTW.

I. LITERATURE REVIEW

The United States was a global leader in science and technology, but the present trends among students do not look promising [5]. International comparisons in mathematics and science performance ranked U.S. school students below students from many other industrializing and industrialized countries [6; 7]. The National Assessment of Educational Progress (NAEP) has also stated that the proficiency of students in mathematics and science was inadequate. One result of the poor performance in mathematics and science by young people in the United States has been the decline in the number of science, technology, engineering, and mathematics (STEM) graduates, creating a shortage of skilled domestic workers [8]. This shortage has forced employers to rely heavily on a foreign workforce to meet labor demands [9]. In a world dominated by technology, employers need people with basic

STEM knowledge and problem-solving skills even for non-STEM related jobs [10], making the existence of a domestic STEM proficient workforce even more critical. In order to retain a position of technological and innovative leadership, the United States must improve the domestic labor force by emphasizing STEM subjects in K-12 education [11]. The shortage of a domestic STEM workforce was attributed to a lack of interest in STEM among K-12 students and a low retention rate of students majoring in STEM fields in college [12]. Increasing student exposure to STEM concepts and practical applications at the K-12 level may help engage more students in STEM pursuits. Historically, this has been attempted in many ways as a response to international labor and innovative competition.

Though the distinctive term STEM emerged in the 21st century, the concept of schools dedicated to supporting student interest in STEM is not recent [13]. Specialized STEM schools first appeared in the early 1900s with the purpose of catering to the needs of gifted or talented students in addition to developing a technically skilled workforce for the nation [14]. As the launch of the Soviet Union's Sputnik threatened the scientific superiority of the United States, the government emphasized improving mathematics and science achievement among students [15]. This STEM emphasis resulted in initiatives that were the forerunner to modern STEM programs. Students were encouraged to participate in programs such as early college entrance, STEM summer camps, STEM schools, after school STEM activities, internships, and mentorship programs [16]. Specialized STEM schools were considered one of the most effective ways to prepare and motivate students in STEM fields as they provide adequate time, guidance, and authentic learning environments for students [17].

STEM schools were classified into three categories: (1) selective STEM schools, (2) inclusive STEM schools, and (3) schools with STEM-focused career and technical education [18]. Reference [18] pointed out key differences between the types of STEM schools. Selective STEM schools admitted

students who meet certain criteria, such as achievement on standardized tests or interviews. Inclusive STEM schools admitted students regardless of academic ability but required at least 50% of the student body to consist of student subpopulations that were underrepresented in STEM fields. Schools with a STEM-focused career and technical education emphasis offered programs and classes within a traditional school format to engage students in STEM related learning activities. Even though the three types of STEM schools had differences, they served the common goal of introducing students to STEM subjects and motivating them to pursue STEM related careers.

STEM schools, in their various forms, were developed to address national achievement issues and have done so with success. STEM schools were successful at a) narrowing the achievement gap between students of different socioeconomic statuses [19], ethnicities, and genders; and b) motivating students to pursue STEM disciplines [1; 20]. Students of subpopulations who were underrepresented in STEM fields, such as Hispanics, saw improvements in their performance when they were enrolled in a STEM school [21; 22]. A consistent aspect of STEM schools was an emphasis on STEM throughout a child's academic career. Research has shown that students who have positive experiences with STEM subjects early in their education are more likely to choose a STEM major [23]. Students exposed to STEM content in traditional high schools were not as motivated as the students from STEM high schools to take up a STEM related career [24; 25]. A notable improvement in student mathematics performance was shown when a non-STEM school transitioned into a STEM school [22]. STEM schools differ from traditional schools in their teaching methods and curriculum. STEM schools generally employ a student centered and inquiry-based instructional approach to actively involve students in the learning process. Problem-based, project-based, and activity based learning were some inquiry-based teaching strategies used in STEM classrooms. Project-based learning allowed the student to learn the subject while producing a well-defined end product [26]. Students developed the ability to conduct research, think critically, and apply their knowledge practically [27]. Project-based learning allowed students to learn while solving multiple problems in context [28]. Additionally, it helps students to understand the subject and recall information better than students taught using traditional methods [29]. Activity based learning allows groups of students to work together on various activities to gain knowledge [30]. Inquiry-based instructional strategies were found to be effective in improving students' content knowledge and their ability to actively think to arrive at solutions [31]. There have been several different curriculums that utilize these teaching strategies at STEM schools, but one in particular is the focus of investigation for the current study.

Project Lead the Way (PLTW) was a STEM curriculum that was implemented extensively in STEM programs in elementary, middle, and high schools across the United States [32]. The PLTW program was first established in 1986 by a high school teacher named Richard Blais. The program grew out of his efforts to teach basic engineering skills to his students. The Charitable Leadership Foundation in 1997

financially supported the expansion and development of his teaching method into a more rigorous engineering curriculum. It was designed to allow high school students to explore technology related career options in New York State [33]. The program grew and offered various curricular options for different grade levels, involving subjects such as mathematics, science, biology, robotics, health, and computer science. PLTW incorporated activity, problem-based learning, and project-based learning into classrooms along with professional development and support for teachers [32]. Teacher training and professional development were an integral part of the PLTW program. Teachers received constant support from master teachers and university professors either through online sources or through meetings and workshops. Due to the flexibility of PLTW courses, many schools had incorporated PLTW courses either to complement the existing courses or as the core curriculum.

PLTW was shown to be effective at increasing student performance in STEM subjects as well as increasing interest in STEM pursuits. It was claimed that students who learned using the PLTW curriculum could efficiently understand, analyze, and solve problems under time-constraints, similarly to an engineer's approach to problem solving [34]. Proper implementation of the PLTW curriculum was successful in improving students' academic performance, critical thinking, and problem solving skills, and it narrowed the performance gap between students from different sections of the population [32]. Students in PLTW courses a) were exposed to more rigorous and engaging science and mathematics classes, b) had richer experiences in engineering and technology subjects, and c) were more likely to take up and complete four-year university courses [35]. PLTW had a positive impact on students' self-efficacy and interest in an engineering career [36]. These positive gains made PLTW appear to be a viable solution for addressing many of the problems in the United States and specifically in STEM schools.

II. RESEARCH QUESTIONS

- 1) Is there a statistically significant change in the mathematics TAKS test scores from 10th grade to 11th grade of all the students who attended T-STEM academies?
- 2) Is there a statistically significant change between students who attended STEM schools with PLTW and students who attended STEM schools without PLTW on their mathematics TAKS test scores?

III. METHODOLOGY

A. Project Lead the Way (PLTW) Curriculum as an Intervention

Project Lead The Way (PLTW) was a STEM-focused engineering curriculum and professional development program aimed to increase middle and high school students' mathematics and science competencies [4]. Reference [37] also described PLTW as "an instructional project designed to prepare students to be successful in post secondary engineering and engineering technology programs" (p. 15). The PLTW program was multifaceted and included curriculum,

professional development, and innovative instructional practices [32].

One of the goals of the PLTW curriculum was to strengthen the problem solving, critical thinking, and innovation skills of all students who took the courses, meeting the need of the United States for a more STEM proficient population. Another long-term goal was to inspire K-12 students to specifically follow an engineering related career pathway in college, thus increasing the domestic STEM workforce. PLTW was later implemented by several STEM schools, and was of specific interest to inclusive STEM high schools. As of this writing, PLTW was the largest nonprofit provider of STEM programs, providing 6,000 PLTW programs to more than 5,000 K-12 teachers in all 50 states and the District of Colombia [32].

B. Data Sources

In this quantitative study, student and school-level data of students who attended inclusive stand-alone Texas STEM (T-STEM) academies were obtained from the Texas Education Agency (TEA). This study was based upon 17 selected T-STEM academies out of a possible 75. These 17 were comprised of seven that implemented the PLTW engineering curriculum in conjunction with their regular STEM school curriculum and 10 that implemented the mainstream STEM school curriculum.

The sample consisted of two years of the Texas Assessment of Knowledge and Skills (TAKS) test data for a total of 4,752 students. These students either attended a T-STEM academy that utilized the PLTW curriculum (n=1,682) or a T-STEM academy that implemented a typical, non-PLTW curriculum (n=3,070). The participants took the first TAKS examination in 2010 at the end of 10th grade and took the second examination at the end of 11th grade in 2011.

In the present study, only ISHSs that started implementing STEM or PLTW curriculum before 2009 were selected. This was done to ensure that these schools and teachers had fully adopted the new curriculum and instructional approaches associated with ISHSs. Also, selecting schools that had already implemented these programs for consecutive years ensured that the student population had received at least three years of STEM school curriculum. We examined all students' mathematics growth from 2010 to 2011. We also observed how students' mathematics scores changed by their school types (STEM high schools with PLTW and STEM high schools without PLTW).

Students were excluded from the study if they did not take the TAKS test in 2010. Students were also excluded if they (1) left a T-STEM school with PLTW and transferred to a T-STEM school without PLTW, (2) left a T-STEM school without PLTW and transferred to a T-STEM school with PLTW, or (3) transferred to a T-STEM school from a non-STEM school. These exclusions ensured that the students who attended T-STEM academies could accurately display the impact of attending STEM schools with and without the PLTW curriculum.

C. Analysis

In order to understand how students' mathematics scores changed overall and by their school types, repeated measures ANOVA was employed. Hierarchical Linear Model would be an appropriate analytic method if the number of schools was larger. Due to a limited number of schools in this study, repeated measures ANOVA was the preferred analytic method. Eta-squared effect sizes and confidence intervals (See Figure 1), along with descriptive statistics (See Table 1), were provided.

TABLE I. DESCRIPTIVE STATISTICS

Grade	School Type	Mean	SD	N	d
10 th	nonPLTW	2240.47	194.479	3070	
	PLTW	2228.32	181.532	1682	
	Total	2236.17	190.067	4752	-.064 ^a
11 th	nonPLTW	2300.36	183.630	3070	.316 ^b
	PLTW	2290.16	199.614	1682	.253 ^c
	Total	2296.75	189.484	4752	-.052 ^d

^a. Note. a= The effect for 10th grade with PLTW as the treatment group; b= The effect for nonPLTW comparing from 11th grade to 10th grade; c=The effect for PLTW comparing from 11th grade to 10th grade; and d= The effect for 11th grade with PLTW as the treatment and nonPLTW as control.

Fig. 2. 95% Confidence Intervals for both STEM high schools with PLTW and without PLTW.

IV. RESULTS

Before investigating results, five assumptions were checked to make sure the results were accurate and differences were not due to violation of statistical assumptions. First, the dependent variable was continuous. Second, the independent variable was nominal with at least two categories (STEM with PLTW and STEM without PLTW). Third and fourth, there were no outliers in the data, as assessed by the inspection of a boxplot, and the data was normally distributed. Fifth, the sphericity assumption was not violated because the variances of the differences of each pair of groups were not statistically significantly different from one another ($p > .05$). Descriptive statistics (see Table 1) and 95% confidence intervals (see Figure 1 & Figure 2) were provided.

Repeated measures ANOVA was used to answer the first question concerning the possible existence of a statistically significant change in students' mathematics scores from 10th to 11th grade. The results from the present study yielded that regardless of school types, students who attended STEM high schools statistically significantly ($p < .05$) increased their mathematics scores with an eta-squared effect size of ($\eta^2 = .137$).

To answer the second question concerning whether the change in students' mathematics scores was statistically significantly different based on the use of PLTW curriculum or a typical STEM school curriculum, the interaction effect of time and school type (math X PLTW curriculum) was also added into the model as a between factor. The results from this step showed that the improvement in student scores was not statistically significantly different ($p > .05$) from 10th to 11th grade by their school types as STEM schools with PLTW and STEM schools without PLTW. The eta-squared effect size was calculated to be 0.0004, which was negligible. This effect size implies that the implementation of PLTW curriculum in STEM schools was not an effective means of improving students' mathematics scores.

V. DISCUSSION

There is a great deal of interest in STEM, so much so that schools search for innovative solutions whether or not there is a sufficient research base underlying those innovations. In this study a curriculum, Project Lead the Way, was examined. This curriculum requires a heavy school commitment in budget allocation and a huge time commitment from teachers [32]. This sizeable commitment can create a psychological dependence on the part of teachers and school administrators. It is reasonable to believe that when anyone commits a sizeable portion of school funds and teacher time during the summer for training, decision makers do not want to be wrong. This psychological dependence can yield to persistence with a program even though the obtained results are no better than the results obtained through traditional methods. It is important to note that this is a limited study with a relatively small sample of schools. Additionally, there was no check on fidelity of implementation, so it is not known how well PLTW was implemented in the schools. We do hope that given the time required by the teacher to invest in the summer before implementation and the schools' financial commitment, that

the enactment would be typical of PLTW implemented anywhere. One has to wonder what the economic effect size would be for any STEM centric program. Unfortunately, schools are reluctant to reveal how much they spend on PLTW so it is difficult to determine the gain students realize per dollar spent, which is needed to understand if the money is being spent wisely.

There are many challenges facing STEM education and its successful implementation, none of which is greater than the ill-informed and self-proclaimed STEM curriculum by STEM enthusiasts. When the National Science Foundation transformed the arrangement of the starting letters for mathematics, engineering, technology, and science into the ubiquitous STEM – it created a void. What we know from science is that nature abhors a void. That void created by the NSF became the destination into which many sprinted. Some transformed from business, some from law, and some from various education disciplines. All these are potentially damaging to the education mission. There was no credential to proclaim one's expertise in STEM curriculum design or implementation than to add four simple letters arranged into a now meaningful and pronounceable acronym, "STEM" to their business card. While the void metaphor works, consider evolution and the work of Darwin – species voids are filled. But not always as elegantly as the one who vacated it.

Abstract—The availability of low-cost sensors and environmental monitoring technologies is growing rapidly. While researchers are making use of these technologies and validating their results, there is also enormous potential for their use in education and outreach. Through the North Fork Valley (NFV) Project, we are bringing next-generation air quality monitors into the classroom and developing necessary resources to support student-driven research projects. This project is a collaboration between the University of Colorado at Boulder, community partners, and educational partners (Delta County School District 50, and St Vrain Valley School District) and is funded by the NSF-funded AirWaterGas (AWG) Sustainability Research Network Education and Outreach (E&O) efforts. During year two, we are formalizing the curriculum, implementing it in multiple school districts, and conducting assessment activities. This paper will discuss the curriculum, the results of our assessments thus far, and our vision for the project. The work completed during year two will help ensure we are building a sustainable project. Additionally, we intend to make the curriculum public with hopes that other research groups working with low-cost air quality sensors can utilize our materials and possibly our model for their own education and outreach.

Keywords—project-based learning; low-cost sensors; air quality education and research

I. INTRODUCTION

For the past two years our team has implemented a project that brings together innovative research and K-12 education. The North Fork Valley (NFV) Air Monitoring Project takes a low-cost, next-generation air quality monitoring instrument, still undergoing the research and development process, and explores its place in education and outreach. Partnerships like these provide a unique opportunity beneficial to both researchers and K-12 students. Researchers are able to learn about their work from a different perspective; in our case how the public would like to use our technology, and how well it can be adapted for this purpose. Students in these K-12/university partnerships are able to work in a hands-on way with a technology that is not a black-box and learn about university-level research and the possibility of pursuing a

degree or career in STEM. This program provides students with an introduction to disciplines like environmental and mechanical engineering, as well as the problem-solving that goes into investigating complex questions. Teaching students about air quality is not our final goal, but rather we hope to use air quality research as the vehicle by which students can learn more about the skills specific to STEM fields, both technical and professional. This paper will describe the project's evolution, the technology that makes this project possible, and our efforts to build a sustainable outreach program.

A. The Communities

Our initial school district partner was Delta County School District 50 (DCSD) located on the Western Slope of Colorado in the North Fork Valley. During the second year we have expanded to the St Vrain Valley School District (SVVSD) on Colorado's Front Range. Delta County is a rural and primarily agricultural community with several coal mines that have been in operation for over 30 years. However, the recent collapse of the local coal industry [1] and the continual loss of jobs due to mechanization in agriculture is putting stress on the local economy. During the 2013-2014 school year, 50.1% of the students were eligible for free or reduced lunch [2]. In terms of the perceived value of higher education, 10%-20% of residents have a college degree [3]. DCSD is also more than a four hour drive from Colorado's large state schools located on the Front Range, which makes K-12/university partnerships difficult to initiate and sustain.

By contrast, SVVSD is a mixture of rural and suburban. This part of Colorado has experienced significant growth over the past few years due to the expansion of the oil and gas industry [4]. During the 2013-2014 school year, 37.4% of the students in SVVSD were eligible for free or reduced lunch [2]. Additionally, the area is well served with university outreach programs as the schools in this district are less than an hour drive from the Denver Metro area and several major Colorado universities. The districts also differ demographically, with DCSD made up of a 10-20% minority population and SVVSD made up of 20-40% minority population [3]. Working with these two districts during year two of the project is helping our team to build a program that meets the needs of a variety of

groups, especially underserved rural communities. We hope to build a curriculum both accessible to and suitable for the diverse geography and socio-economic demographics of Colorado.

B. NFV Project, Year 1

The North Fork Valley Air Monitoring Project began as a collaboration between the Western Slope Conservation Center (WSCC) in Paonia, CO, the University of Colorado, Boulder's Office of Outreach and Engagement, and the Hannigan Air Quality Research Lab (Mechanical Engineering, CU Boulder). Delta County lacks detailed historic air quality data, and the WSCC was interested in understanding current air quality in the area in light of proposed increased oil and gas development in the NFV. The original objectives of the project were to pilot low-cost tools for baseline air quality data collection and engage the community in citizen science.

During year one we engaged local high school students in assisting with the project, but found that they were more interested in asking their own questions than helping with the collection of baseline data. The project naturally grew into two parts: (1) the long-term, continuous collection of air quality data using a stationary network of monitors, and (2) student-driven air quality research projects. After seeing the benefits of this experience to students, particularly in a rural and underserved community [5], we decided to continue for a second year in an attempt to build a sustainable outreach program.

C. NFV Project, Year 2

During year two, the project is continuing through the NSF funded AirWaterGas (AWG) Sustainability Research Network, specifically with the help of the AWG Education and Outreach (E&O) team [6]. AWG is a large-scale interdisciplinary research project including teams studying air quality, water quality, water treatment, water quantity, natural gas infrastructure, social-economic systems, health effects, practices and policies, and E&O. Together all of these teams are examining the benefits, risks, and challenges associated with unconventional oil and gas development. Year two activities for the NFV Project included continued data collection in the NFV, curriculum development, implementation in multiple school districts, and overall project/curriculum assessment. Although the title of the program has not changed, we have expanded to an additional school district in an area of Colorado outside of the North Fork Valley.

Working with school districts affected by current and proposed oil and gas development helps us build bridges to facilitate the sharing of results from the larger AWG Project. For example, these communities may have specific questions regarding risks to local air/water quality, and because we have built trust between the community and our University, they may feel comfortable coming to us for information. Using this program to build relationships has the potential to help us get up-to-date, relevant research to these communities to inform decision making on the local level. Finally, air quality serves as a vehicle to initiate conversations on complex issues surrounding energy development and use.

II. THE TECHNOLOGY: U-PODS

Developments in sensor technology are making environmental monitoring tools more accessible, and ideal for supporting STEM learning opportunities. Researchers at the University of Maine demonstrated through the GK-12 Sensors! Program that using sensors in secondary schools is beneficial to students, teachers, and graduate teaching fellows [7]. For several years, our research group has been developing and using an air quality monitor that utilizes low-cost sensors for our own research. Our monitor (the U-Pod, shown in Fig. 1) is an open-source design and can be constructed for under \$1000 per monitor [8]. The U-Pod is capable of measuring multiple pollutants (e.g., carbon dioxide, carbon monoxide, volatile organic compounds, ozone, and nitrogen dioxide) continuously; data is then recorded to an on-board memory card. Although the sensors used in the U-Pod are less accurate than the more costly instruments used for regulatory purposes, if we leverage both the low-cost and high quality instruments, there is the potential to collect far more detailed information regarding our air quality than currently exists.

New technologies such as this one are extremely valuable for STEM education not only because of their increasing affordability, but also because students can take an inside look at something they could build themselves. These tools are not the traditional "black box" instrument because they utilize a relatively simple design and 'off-the-shelf' sensors. Students can open up the U-Pods and understand how they function, making the technology is ideal for hands-on learning. Using the monitors also provides students with exposure to the various fields of study that went into making it: electrical engineering, computer science, and mechanical engineering in addition to the environmental engineering involved in air quality research. Citizen science is another area where technologies like the U-Pod could have a large impact. Citizen science "refers to the engagement of non-professionals in scientific investigations – asking questions, collecting data, or interpreting results" [9]. Citizen science can range from contributory (where participants collect data as part of a larger, researcher led project) to collaborative and co-created (where scientists and participants work together with both groups engaged in defining the question, collecting the data, and interpreting results) [9]. Our research group sees using the U-Pods for educational applications as a way to move toward

Figure 1: Image of the U-Pod, interior (top left) and exterior

this vision of using low-cost technologies to support collaborative and co-created citizen science.

III. A PROJECT-BASED LEARNING CURRICULUM

A. Project-based Learning

In addition to hands-on learning, we have found that the U-Pods are an ideal way to support project-based learning (PBL) driven by student-generated research questions. Project-based learning is a method of teaching in which students work for an extended period of time on a complex problem, question or challenge, and thereby gain knowledge and skills. [10]. In engineering education, projects better equip students to apply their knowledge in practice, as well as providing a better understanding of the complexities involved in professional practice [11]. Similar outcomes have been observed in K-12 education where research indicates that PBL leads to an increased level of student engagement, higher interest in content, and better problem-solving skills, and an increased depth of learning and ability to transfer skills to new situations [12]. During year one of the project, teachers anecdotally reported similar outcomes including increased engagement and greater depth of learning. For this reason, we chose to build a program and curriculum supporting the PBL teaching method.

PBL challenges students to apply their existing knowledge in new ways and acquire new knowledge to solve novel real-world problems. As students progress with their project, they stumble upon “need-to-knows;” in this case, questions about atmospheric chemistry and pollution that they need to answer in order to progress in their investigation. Additionally, since projects are conducted over a long period of time, students must manage working with a team, adhering to a schedule, and monitoring progress. We currently cover the bulk of the content (discussed in the following section) during the first semester and leaving the second semester for projects. The curriculum introduces students to the U-Pods, and helps them build useful skills with all of the pieces supporting the PBL model [5].

B. Curriculum Development

During the first year, it was interesting to observe the synergism between the continuous data collected through the stationary network and the student-driven projects. For example, we were able to use the baseline data to support student learning about air quality concepts in the classroom. Alternatively, student-led investigations provided our group with information on potential local air quality issues (e.g., agricultural practices like ditch burning). In addition to local knowledge, students use of U-Pods clarified what skills and background knowledge users need. This also led to the idea of developing a curriculum to support U-Pod use.

During year two, the curriculum used in the classroom is being reviewed and polished for public distribution. Five modules are currently under development. These modules provide students with background knowledge and an introduction to the skills necessary for successful projects including data analysis and how to present scientific results. The curriculum will empower students to ask complex and informed questions about local air quality issues. Each module

(summarized in Table 1) includes guidance for teachers, presentations, worksheets, data sets, templates, links to more information, and suggested assessment as necessary. Together the five modules cover skills useful for this project and beyond it (e.g., working with large data sets in Excel, making a poster in PowerPoint, etc...). The series of modules culminates in a ‘Science Symposium’ or poster session, open to other students, teachers, parents, and the community. In line with the goals of PBL, the poster session challenges students to interpret and communicate their research to an authentic audience.

C. Curriculum Implementation

Lack of resources, knowledge, and skills is often as a barrier to technology integration in K-12 settings [13]. To address these barriers, we are creating a U-Pod ‘check-out program’. Given that the U-Pod is a developing technology – a rental program will likely be more successful than selling the U-Pods because this type of program will allow the researchers to maintain the technology. This type of program will provide teachers with access to resources while facilitating technical support and providing our group with a way to maintain and strengthen relationships with districts using the U-Pods. We feel this is a promising model, and plan to make our curriculum publically available in Fall 2015 in the hopes that other groups working with low-cost sensors will replicate this model.

Table 1: Air Quality Curriculum Overview

	Module Description	Skills
1	Introduction to air quality research and the U-Pod (lecture and demo)	Background knowledge and vocabulary for air quality and engineering and concepts
2	Data collection (activity)	Using the U-Pod Critical thinking regarding sources of error and results
3	Data analysis (activity)	Basic statistics and data visualization information Using Excel for calculations and graphing Interpreting results using background knowledge
4	The Project (planning, data collection, data processing and analysis)	Planning and carrying out a research project (scheduling, logistics, designing data collection, etc...) Processing raw instrument data Analyzing data in Excel
5	Interpreting data and presenting results	Data interpretation Communicating results Making a scientific poster or presentation

IV. PROJECT ASSESSMENT

A. Overview

Informal and anecdotal assessment data were collected at the end of year one. Assessment for the second year is more rigorous; formal assessment matrices have been developed for both the NFV Project and the AWG E&O team [5]. The NFV Project goals include developing/finalizing curriculum and conducting formal assessment of both the curriculum and the program. The goals for AWG E&O are broader in scope, for example one of the goals listed in the AWG E&O Assessment matrix is to ‘Integrate AWG SRN Research, Education & Outreach Activities’. We are successfully reaching an underserved rural Colorado community (Delta County

students) by facilitating the use of the U-Pod for E&O in addition to the research it is being used for internally. Year two data will allow us to better determine which goals we are addressing and where we can improve.

Summative assessment data will assist in evaluating the project upon the completion of year two; this data will focus on student skills/attitudes, the project's impact, and opinions regarding the project. Our methods are typical of those used to assess similar K-12 outreach projects [14]. We are also engaging in formative assessment throughout the year, as we work with teachers one-on-one to ensure we are meeting the needs of their class and implementation is running smoothly. Summative assessment activities and our progress are presented in Table 2. Student surveys (4 total) include attitude questions and confidence questions intended to assess whether students are developing the skills intended with each module. Multiple student surveys with repeated questions will allow for pre vs post analysis to provide insight into the impact of the program over the course of the year. Surveys and interviews from teachers will ask whether they would continue participating in this program, what benefits to their students they observe, if they received enough support, and their overall reflections. Input from other stakeholders will allow us to consider whether or not we are meeting the needs of the community. The external review team assessing the curriculum includes an air quality expert and a teaching expert. The criteria this team is using was derived from guidelines developed by Cooperative Institute for Research in Environmental Sciences (CIRES) to assess proposed curriculum for Climate Literacy and Energy Awareness Network (CLEAN) [15]. In all surveys where we have requested that participants rate an opinion or experience, a score of 4.00/5.00 (80%) is our target. Together all of this data will be used to not only evaluate year two, but also inform future implementations of the project, the overall structure of the program, and revisions to the curriculum before it is made publically available.

B. Preliminary Results

Table 3 provides an indication of the scope of the project during years one and two. Following the completion of year one, all three of the teachers were interviewed and a simple student survey was distributed. The teachers shared the following observations regarding their students:

- Increased engagement in science classes
- Student ownership of their projects
- A better understanding of the scientific process (particularly the iterative nature of data collection and analysis that is not typically demonstrated in high school science classes)
- Students strengthened skills likely to help increase their success in higher education (e.g., problem-solving and analysis skills)

Teachers also mentioned that students benefited from working with a graduate student mentor, access to new classroom resources, and hands-on use of technology (both the U-Pod and tools such as Microsoft Excel, and the Google Drive platform to facilitate collaborative work). Finally, all three teachers expressed interest in continued participation in this program.

Table 3: Project Scope

	Year 1	Year 2
Number of Districts	1	2
Number of Teachers/Schools	3	5
Number of Students	40	81

Complete assessment data from year two will help us to evaluate whether or not outcomes and benefits we observed during year one are occurring repeatedly. In the meantime, we can provide a discussion of preliminary results. The Module 1 and 2 Survey results are available in Tables 4 and 5 respectively. The Module 1 Survey was distributed to the high school students following our first classroom visit. This survey sought feedback on students' attitudes regarding engineering and air quality and their reactions to the module. The results suggest that the presentation offered a valuable learning experience as students from District 1 (Delta County) rated their understanding of the impact of air quality research as a 4.60/5.00 and the amount they learned highly as 4.50/5.00, both meeting the goal of a minimum score of 4.00/5.00. District 2 (SVVSD) shared similar results with a rating of 4.31/5.00 for their understanding of the impact of air quality research and 4.60/5.00 for the amount they learned. Mean scores below 4.00 for both school districts are reflected for questions 1, 2, and 5, which indicates that these are areas

Table 2: Assessment Overview

Stakeholder	Type of Assessment	Progress
Students	Surveys (4 total, all students)	1 st & 2 nd complete (results available) 3 rd & 4 th incomplete (mid-may)
Teachers	Survey (1, all teachers) Interview (1, 2 teachers)	Both incomplete (mid-may)
Community (e.g., partner with Public Health Dept.)	Interview (1, 2 stakeholders)	To be given (mid-may)
Curriculum	Survey for external review team (1 per module)	1 st & 2 nd complete 3 rd , 4 th , & 5 th in progress (may)

Table 4: Module 1 Survey Results

Question	Mean		P-value
	District 1 ^a (n = 20)	District 2 ^b (n = 35)	Two Sample T-Test
1. I am interested in learning more about air quality.	3.50	3.69	0.399
2. I want to know more about what an environmental engineer does.	3.35	3.40	0.868
3. I feel that engineers have made major accomplishments and advancements.	4.85	4.60	0.126
4. I would have a difficult time explaining these topics to another person.	3.10	3.09	0.965
5. I know where to go to find out more about these topics.	3.45	3.57	0.732
6. I understand the impact of air quality research on the community.	4.60	4.31	0.190
7. I learned a lot in this presentation.	4.50	4.60	0.570

Table 5: Module 2 Survey Results

Question	Mean		P-value
	District 1 ^a (n = 15)	District 2 ^b (n = 30)	Two Sample T-Test
1. After doing this activity, I feel more confident that I could use this technology to collect air quality data	4.27	4.30	0.887
2. I learned something new about the process of data collection and experimental design in a complex environment.	4.33	4.43	0.743
3. This activity led me to think about scientific investigations I might conduct, either for this air quality project or in another context.	3.67	4.27	0.047

^aDistrict 1 is Delta County School District 50, ^bDistrict 2 is St. Vrain Valley School District

where we may be able to improve students' attitudes over the course of the project. Responses to similar questions in the final student survey will help us understand if the project may have positively impacted students' attitudes toward air quality, attitudes toward environmental engineering, or their knowledge of sources for information on air quality and other STEM

related questions. Lower scores were also observed for question 4, but this question is a reflection of students' comprehension of the material, and a lower score indicates comprehension. Additional open-ended questions in the Module 1 survey revealed that students responded most positively to the hands-on demonstration of the technology

The Module 2 Survey (Table 5) was distributed to students after they participated in an activity to measure car emissions during which they were able to practice using the U-Pods. The data indicates that the desired mean score of 4.00/5.00 or higher mean was met for every question and for both districts (with the exception of one score for question 3 and District 1). The qualitative feedback indicated that students enjoyed the hands-on aspect and the opportunity to do the experiment themselves. One student commented, "I liked how we got involved in the activity" and another noted the change in teaching style was valuable and that "it was nice to get out of the classroom and learn a different way.

C. Discussion

Engineering outreach programs "introduce students to the joys and frustrations of engineering" [16]; this type of

experience can have a multitude of benefits. Some students may be inspired to pursue a degree in engineering or STEM, while others (who may go on to work in entirely different fields) gain an increased understanding of STEM and its role in our society enhancing their multidisciplinary education. We believe that using the U-Pods for E&O has the potential to provide this type of experience. Comparing our preliminary data to results of the evaluation of four outreach projects at the Colorado School of Mines indicates that we are building a promising outreach program [17]. Among the observed benefits to middle school students (the target audience) Mines researchers listed:

- Increased use of technology
- Increased classroom resources
- Availability of college role models
- Increased interest in science mathematics, and computer science
- Increased exposure to and interest in college
- Successful participation in academic competitions, including several awards [17]

Many of the benefits listed above match or are similar to benefits our teachers observed during year one (mentioned in the Preliminary Results section).

Year two is providing more quantitative information regarding our project's impact and thus far the indication is that the modules are serving their intended purpose. Students responses resulted in mean scores of over 4.00/5.00 for

questions 6 and 7 (Table 4), these questions cover the primary purpose of Module 1 – introducing students to air quality research and communicating why it is important. Lower scores (below 4.00/5.00) for interest/opinion questions regarding engineering and air quality are not uncommon and have been found in other studies where high school students were surveyed [18]. It is possible that 80% is an unrealistic expected score for questions such as these, or that a lack of exposure to engineering in traditional curricula results in lower scores. We plan to compare these initial scores to the scores of similar questions in the final survey; however, this may be an area where more research is necessary.

Module 2 is intended to prepare students for data collection. As indicated by the scores, students came away from the activity feeling more comfortable with the technology, and thinking about study design. The one exception is the low score from District 1 for question 3 (Table 5) regarding whether the activity led them to consider project ideas. This may be an indication that the module was implemented differently, and it would be worthwhile to add suggested discussion questions into the curriculum to address this need. Additionally, this mean score is significantly different from District 2. All other mean scores were not significantly different (p -values $> .05$) between districts, which indicates that students in both locations are reacting to the curriculum and project similarly. We will continue to observe the differences and similarities between the school districts throughout the remaining surveys, as it will inform our program design, and specifically designing to meet the needs of a variety of school types.

V. LIMITATIONS AND FUTURE PLANS

The primary limitations of our assessment data are the lack of a control group and small sample size. These are limitations we will address in future iterations of the program. We already have plans for implementation in new districts during year three, which will provide a larger population. We would also like to refine our assessment tools and implement established tools developed by external groups, as well as examining how we can incorporate more established outreach frameworks into the program. Year three of the project will include the above, as well as implementation of the final version of curriculum, continued assessment, and building the U-Pod ‘check-out’ program. In the long-term, we are interested in working with school districts to track the long-term progress of students and their degree choices in college.

In addition to planning for future iterations of the project, we are considering program viability. One key to ensuring our program is sustainable is to refine our ideal role as a university partner. Although the relationships built between high schools students and the graduate student mentors are an integral piece of the project, currently a graduate student mentor leads or co-teaches each module. Ideally, we would like graduate student mentors to support rather than lead, which in turn gives teachers more independence and flexibility in implementation and promotes program sustainability. To facilitate this transition, we will add teacher training sessions providing hands-on experience prior to their using U-Pods in the classroom. This model will result in a more resilient program

and allow our team to take a facilitator/resource role and reach a greater number of students and classes across Colorado.

We are also aware that sustainability beyond the AWG grant period is another challenge to consider. Karp and Gale report in their paper on long-term program sustainability that a means for continuing beyond the initial grant was forming partnerships with established organizations [19]. These partners were then able to assist the program in continuing after it had been built through the initial grant. This may be a model that would work for our project as well, and we will continue to explore our options.

We see this program as having the potential to benefit participants in a lasting way. This program provides students with a window into engineering, academic research, and even public and environmental health. For example, a group of students from one of the high schools in Delta County incorporated a U-Pod into their science fair project. They used the U-Pod to compare by-products from the combustion of homemade biodiesel to the combustion of regular diesel fuel. This group was subsequently invited to the state science fair at Colorado State University (Ft. Collins, CO). At the state level they were awarded an honorable mention and scholarship money for college. Their teacher also reported that visiting CSU increased their interest in higher education. While in Ft Collins, the students were able to participate in a state-wide academic competition, attend classes, and tour the campus. With support from our team and access to resources like the U-Pod, the students were able to go from making biodiesel to assessing the impacts of using biodiesel – moving toward an understanding of the entire lifecycle of the fuel. This provided these students with experiences similar to those of environmental engineers, and also an idea of the supporting disciplines (e.g., mechanical engineering and computer science). Utilizing the program for a science fair project provide an example of a group taking the U-Pod further than the intended PBL curriculum, which is something we hope to see more of and support in the future. We hope that through opportunities such as this, increased access to university resources, or even simply by connecting them with researchers we can inspire students to consider the wide variety of options available post high school.

VI. CONCLUSION

The NFV Project is the beginning of a promising K-12 outreach program. The project has evolved from a grassroots effort to work with rural Colorado students into a systematic project undergoing implementation in multiple school districts, funded by the National Science Foundation, and aiming for sustainability and longevity. We believe our unique model of a U-Pod ‘check-out’ program will ensure teachers are provided with access to resources and the necessary technological support and facilitate building partnerships that may lead to future collaborations and opportunities for our University. This program has the potential to build and sustain a community of learners using the U-Pods and inspire students to consider careers in science, engineering, and public and environmental health.

ACKNOWLEDGMENTS

We would like to acknowledge our funding source the National Science Foundation (NSF AWG-SRN Project, CBET: 1240584); the University of Colorado Boulder's Office of Outreach and Engagement, as well as the other members of the Hannigan Air Quality Lab (Joanna Gordon, Ricardo Piedrahita, Nicholas Masson, and Evan Coffey) and all of our community and educational partners throughout Delta County and St. Vrain Valley School District.

Measuring Undergraduate Students' Self-Efficacy in Engineering Design in a Project-Based Design Course

Deeksha Seth and James Tangorra
Mechanical Engineering and Mechanics
Drexel University
Philadelphia, PA

Ahmed Ibrahim
Department of Psychology
University of California, Riverside
Riverside, CA

Abstract— Engineering design pedagogy coupled with strategic problem-solving activities can foster real-world skills in students, and measuring students' confidence in executing the activities can help understand the effectiveness of the pedagogy better. However there is little understanding of how strongly students' confidence in problem-solving activities is related to students' confidence in conducting engineering design. In this study, the students' self-efficacy in engineering design and problem-solving activities was studied in three rounds (N = 67, 55, and 92 students). Data was analyzed to assess the students' self-efficacy and to study how closely the efficacies in problem-solving and engineering design were related. Results showed an increase in students' self-efficacy in areas related to engineering design. Regression and correlation analysis showed strong relationships between students' self-efficacy in engineering design and other problem-solving activities.

Keywords— design engineering; engineering education; engineering students; problem-solving; product design

I. INTRODUCTION

Engineering design, taught in the form of a structured problem-solving process, can foster real-world problem-solving skills in students [1] - [3]. In addition to providing strong analytical skills, undergraduate engineering education needs to strengthen skills that prepare graduates to work within rapidly diversifying and innovative fields [4]. Future innovators need to be prepared to adapt to changing technology, collaborate with people from outside their discipline, and be able to apply their skills to solve new problems. Anderson *et al.* cite attributes such as problem-solving, team work, clear communication, and effectively working within time and budget constraints as some of the crucial skills that engineers must possess to be successful in the workforce [5]. In recent years, engineering design has gained significant attention as a way to incorporate these skills into engineering education to better prepare graduates to succeed in the workforce [1] - [3]. Project-based engineering design courses, coupled with a real-world application, can help strengthen these skills in students.

Though capstone design courses have been adopted by universities throughout the country [1], [6], many courses continue to use traditional teaching methods instead of project-based courses. Due to the traditional teaching methods

involving textbook questions, written exams and limited hands-on work, students often underestimate the importance of creative-thinking, problem-solving, communication, and team work skills in the engineering education. Students often relate good mathematical and analytical skills to being good engineers; but overlook the problem-solving and creative skills which are also important to succeed post-graduation [5], [7]. They sometimes think about design and manufacturing in a way that is isolated from cross-disciplinary communication, teamwork and problem-solving skills. Though researchers have looked at students' perception of engineering and design [8] - [11]; little is known about the extent to which students relate various creative-thinking and problem-solving skills to conducting engineering design.

One way to tackle this disconnect is to study how students' confidence in engineering design compares to their confidence in various creative-thinking [12], [13] and problem-solving skills [14] - [16]. Self-efficacy is the measurement of a person's confidence in carrying out an activity. Educational research has shown that motivation, self-efficacy, and value-expectancy influence students' academic behavior [17] - [21]. Further, it has been shown that the students consider various aspects of performance to report their efficacies and the self-efficacy varies during a learning period. This variation in self-efficacy during learning influences the students' self-regulated learning processes and outcomes [22]. Therefore a self-efficacy instrument was developed and administered three times during a project-based design course taught in the Mechanical Engineering and Mechanics (MEM) department at Drexel University. The self-efficacy instrument asked students to rate their confidence in carrying out 19 activities related to creativity and problem-solving skills. In addition to the 19 activities, students also rated their confidence in conducting engineering design. This was done so we can make compare efficacies in problem-solving to efficacy in engineering design. The reader is referred to [23] for details on the course.

Several self-efficacy instruments have been created to measure students' confidence in carrying out learning activities. In particular, Carberry *et al.* developed an instrument identifying individuals' self-concepts specific to engineering design [24]. This instrument has been adopted by groups (example: [25]) to monitor self-efficacy in engineering

students during design courses. Though the instrument serves as a great tool for educators to collect data on students' design self-efficacy, it lacks information about activities that are important in creative thinking and problem-solving. Therefore the instrument is not able to map self-efficacy in engineering design to that in creative thinking and problem-solving skills. Problem-based learning and creative thinking skills have proven to foster the necessary skills in students to become successful engineers [1], [3], [5], [7], [26] - [29]. These skills have also been emphasized by the United States Accreditation Board for Engineering and Technology (ABET) [15]. Further it has been shown that students need to have the will and skill to succeed in school [30]. Therefore in addition to seeing how self-efficacy changes over the course, it is also important to study the relationships between students' self-efficacy in engineering design and students' self-efficacy in problem-solving and creative-thinking.

The purpose of this study was to monitor changes in self-efficacy during the design course and to investigate relationships between efficacies in creativity and problem-solving skills and efficacy in engineering design. To that end, the following research questions were addressed:

- (a) Did the students report changes in self-efficacies related to conducting engineering design and various creativity and problem-solving skills?
- (b) What creativity and problem-solving skills had self-efficacies that were strongly related to those in engineering design?
- (c) How did the relationships between efficacies in creativity and problem-solving skills and efficacy in engineering design change over the ten week course?

II. BACKGROUND

Engineering design and its assessment can benefit a great deal from the work conducted by Woods *et al.* [14], the model established by the Partnership for 21st century skills [12], and Sternberg's theory of creativity [13] in conjunction with the skills listed by ABET [15].

By combining the ABET criteria and the work done by Woods *et al.*, problem-solving can be defined as a decision-making process to find solutions to a problem subject to needs and constraints. In addition to being good "problem-solvers" it is desirable that engineering students also possess creative thinking and communication skills [2], [4], [5], [28]. Similarly, inspired by Sternberg's theory of creativity [13], we can define creativity to include the ability of a student to combine and process different kinds of intelligence and personality traits within themselves, their team members and others such as their customers.

In order to do become creative problems-solvers, engineering students must possess the ability to do the following:

- (a) gather information to formulate design and engineering problem statements
- (b) listen effectively to extract the meaning, knowledge, and intentions of their customer
- (c) design solutions to meet desired needs and constraints
- (d) draw on self-knowledge and objectively assess quality and accuracy of work
- (e) evaluate solutions based on accuracy
- (f) use a structured process when identifying solutions and troubleshooting problems
- (g) self-monitor skills and reflect upon self-progress
- (h) be flexible and adaptable to changes and challenges
- (i) communicate effectively and systematically in a team and with a multi-disciplinary audience
- (j) articulate thoughts and ideas effectively using oral, written and nonverbal communication skills
- (k) work effectively and respectfully in teams
- (l) share responsibility for collaborative work, and value the individual contributions made by each team member.

These 12 attributes were extracted by referring to [12] - [15].

III. METHODS

A. Sample

The sample of the study consisted of undergraduate students in the Mechanical Engineering and Mechanics department of Drexel University. The study was conducted with students enrolled in a ten-week design course. A total of 118 students were registered for the course (100 male students, and 18 female students), out of which 37 students were juniors and 81 students were seniors (i.e. in their final year).

B. Course and setting

A ten-week design course is developed and taught to undergraduate mechanical engineering students at Drexel University. The objective of the course is to teach students a formalized product development method [31]. During the course, students develop concepts, and design for an educational device to be used by K-12 Science, Technology, Engineering, and Mathematics (STEM) educators to teach STEM topics. The students also build a prototype to prove the crucial functionality of the proposed device. The course is divided into three phases that were slightly modified from those described in [31]. The course uses a problem-based learning (PBL) approach in which the students work in teams, interact with real-world users of the device and build the device to address the needs of these stakeholders [23], [32].

C. Self-efficacy instrument

The instrument was developed to record students' self-efficacies in design tasks during a design course in which they learned a formal product development methodology [31]. The instrument criteria were developed by observing activities performed by students during past iterations of the course and by incorporating the creativity and problem-solving skills described in the previous section.

The instrument asked the students to rate their confidence in 19 activities related to the engineering design process, creative thinking, problem-solving, and communication skills. In addition to those 19 activities, the students were asked to rate their confidence in conducting engineering design. This was done so the response to the 20th activity could be compared to the response to the other 19 activities.

The students were asked the following: "Rate your current degree of confidence (i.e. belief in your current ability) to perform the following activities by marking a number from 0 to 10, 10 being extreme confidence and 0 being no confidence". Table I lists the activities provided during three rounds of survey during the 10-week course. Some activities were omitted from the survey during different rounds. This was done based on the relevance of the activity in the specific phase of the course. For example, the students were not asked to rate their confidence in their ability to "refine concepts based on feedback" in week 10, because they only had that opportunity during and before week 5. Similarly, the students were only asked to "justify design solutions" in week 10, because they developed designs and got opportunities to defend design solutions between week 6 and 10. Some activities, such as forming problem statement, developing design specification, integrating multiple subjects, communicating designs in different ways were an integral part of problem-solving and creative thinking skills, and therefore were included in all three surveys. This facilitated the monitoring of these crucial skills over the entire course. The column on the far right in Table I notes the problem-solving skills from section II that are related to the activities in the instrument.

D. Data collection

The instrument was administered online three times during the 10-week course; during week 1, week 5 and week 10. The forms were created and shared, and data was collected using Google forms. Out of the 118 students in the course, 67, 55 and 92 students submitted their responses in week 1, 5 and 10 respectively.

E. Data analysis

The self-efficacy of the student population related to each activity was compared with the self-efficacy of the student population in "conducting engineering design". The average efficacy numbers were plotted with standard errors (standard deviation/ $n^{1/2}$) while monitoring changes in the efficacy over the 10-week course.

Linear regression analysis was conducted to investigate the extent to which self-efficacy in each activity was related to the self-efficacy in conducting engineering design. The efficacies in the problem-solving activities were considered to be

TABLE I. 20-POINT SELF-EFFICACY ASSESSMENT CRITERIA INCLUDED IN THE INSTRUMENT

Activity	Included in			Creativity and problem-solving skills (a) – (l) from section II.

6. Revise concept based on feedback		X		(e), (f), (h)
7. Use computer simulation and analysis to analyze a design	X		X	(e)
8. Communicate design details through CAD	X		X	(i), (j)
9. Justify design decisions and solutions			X	(d), (e), (f), (i), (j)
10. Evaluate and test a design	X		X	(d), (e)
11. Re-design based on feedback from customer	X		X	(h)
12. Understand manufacturing constraints and incorporate those in making design decisions			X	(c), (h)
13. Make and justify trade-offs in design (i.e. compromising one design feature for another)			X	(c), (f), (h), (i), (j)
14. Integrate information from a non-engineering field/subject with engineering while developing product solutions	X	X	X	(d), (f)
15. Explain designs to non-engineers	X	X	X	(i), (j)
16. Work effectively in a team	X	X	X	(i), (k), (l)
17. Communicate project details orally	X	X	X	(i), (j)
18. Communicate project details in writing	X		X	(i), (j)
19. Manage my time efficiently to accomplish activities			X	(g)

"predictors" of students' efficacy in engineering design. The objective of the linear regression analysis was the following:

(a) To examine if the relationship between the efficacies in problem-solving activities and engineering design was significant. In other words, did the efficacies in problem-solving activities predict the students' efficacy in engineering design?

(b) To determine the estimates of the linear regression model parameters. These values of the estimates represent the strength and the sign of the estimates represent the proportionality of the relation. For example a high strength for activity 14 would imply that the students' efficacy in activity 14 is strongly related to efficacy in engineering design. Further a positive estimate would imply that a direct relationship between the efficacy in activity 14 and engineering design. In other words, an increase in students' efficacy in activity 14

would be accompanied by an increased in students' efficacy in conducting engineering design.

We used nine out of the nineteen self-efficacy activities (shown in Table II) as the predictor variables for the self-efficacy in conducting engineering design, which was the predicted variable. The nine self-efficacy activity variables were chosen because they were included in each of the three rounds the instrument was administered.

IV. RESULTS

A. Gains in self-efficacy

Students reported an increased self-efficacy in all 20 activities listed in the instrument over the 10 weeks of the course (Fig. 1). The largest increase was seen in students' ability to use computer simulations and analysis to analyze a design. The smallest increase was seen in students' ability to work effectively in a team, i.e. activity 16. Though the increases over the course of 10 weeks in activity 16 were the smallest, students' confidence in the activity had the largest average score among all activities. Similarly, though there were increases in students' efficacies related to integrating multiple subjects to design solutions (activity 14); the average values related to this activity remained within the bottom two spots among all activities. Students' self-efficacy related to communicating project details orally (activity 17) and explaining design to non-engineers (activity 15) showed no significant changes from week 1 to week 5, but showed a significant increase from week 1 to week 10 and week 5 to week 10 (p-test with 95% confidence interval). For all other activities, students showed an increase as the course progressed.

B. Relating self-efficacies in engineering design to other activities

The linear regression analysis showed a significant relationship between the self-efficacy in the nine activities and in conducting engineering design. Table II illustrates the significance of relations, the coefficients of the linear regression, and the coefficients of determination (r^2) values. The significance is denoted by an asterisk in Table II. The coefficients of the linear regression show the strength of the relation between the efficacy in the activity and engineering design. The r^2 values indicate how much variability in the "dependent variable" (self-efficacy in engineering design) is accounted for by each "independent variable" (self-efficacy in the nine activities).

The following can be summarized from the regression analysis:

- Self-efficacies in all the nine activities were significantly related to the overall self-efficacy in conducting engineering design, except for activities 14 (integrating information from a non-engineering field with engineering to develop solutions) and 17 (communicating project details orally) for the first round of administering the instrument (in week 1). This implied that students' efficacy in integrating information and oral communication did not predict

their efficacy in engineering design in the first week of the course.

- All the regression coefficient values were positive, indicating a direct relationship between efficacies in all nine activities and engineering design. In other words, an increase (or decrease) in efficacy in any of the nine activities was likely to be accompanied by an increase (or decrease) in efficacy in engineering design. The highest regression coefficient value was seen for activity 3: developing design solutions (0.978), and the lowest coefficient was seen was activity 17: communicating project details orally (0.066). This implied that efficacy in developing design solutions was the strongest predictor of efficacy in engineering design, and efficacy in oral communication of designs was the weakest predictor of efficacy in engineering design.
- Between the three rounds of administering the instrument, the coefficient values increased for activity 10, 14, and 17, decreased for activity 2 and 15, and were a mixture of increases and decreased for activity 1, 3, 4, and 11 (Table II), (Fig. 2). This implied that the efficacy in evaluating and testing a design (activity 10) became a stronger predictor of efficacy in engineering design as the course progressed. On the other hand, the efficacy in developing measurable specifications (activity 2) weakened in predicting efficacy in engineering design as the course progressed.
- The amount of variability accounted for in the dependent variable (self-efficacy in conducting engineering design) by each of the nine-predictor variables changed throughout the three points of administering the instrument (Fig. 3). The data were inconclusive but will be examined more carefully in the future.

V. DISCUSSION

Students showed gains in self-efficacy related to engineering design and problem-solving activities, indicating a good execution of the course. It can be hypothesized that these gains are a result of: (a) the increase in student knowledge and learning as the course progressed, and (b) the increase in hands-on engagement of the students with their projects and real-world customers. As the course progressed, students developed a greater understanding of the engineering design process and realized the importance of several problem-solving activities in developing good designs. Students also showed appreciation towards working on an application that integrated engineering with non-engineering principles. Readers are referred to [23] and [32] for details on the course, the project, and quotes from students.

The correlations between the self-efficacy in the nine problem-solving activities (listed in Table II) and the self-efficacy in conducting engineering design (activity 0 on the instrument in Table I), showed some interesting trends. It is

0. conduct engineering design
1. Form a problem statement
2. Develop design/product specifications
3. Develop design/product solutions
4. Objectively select best design solution/concept
5. Evaluate a concept
6. Revise concept based on feedback
7. Use computer simulation and analysis to analyze a design
8. Communicate design details through CAD
9. Justify design decisions and solutions
10. Evaluate and test a design
11. Re-design based on feedback from customer
12. Understand manufacturing constraints and incorporate those in making design decisions
13. Make and justify trade-offs in design (i.e. compromising one design feature for another)
14. Integrate information from a non-engineering field/subject with engineering while developing product solutions
15. Explain designs to non-engineers
16. Work effectively in a team
17. Communicate project details orally
18. Communicate project details in writing
19. Manage my time efficiently to accomplish tasks

Fig. 1. Self-efficacy in all 20 activities in the instrument, recorded three times during the 10 week project-based design course. The average values of the class are plotted with standard error bars.

TABLE II. COEFFICIENTS OF THE LINEAR REGRESSION AND DETERMINATION VALUES FOR NINE OUT OF NINETEEN ACTIVITIES IN THE INSTRUMENT

Activity	Round 1 (n=65)	Round 2 (n=55)	Round 3(n=92)
1. Form a problem statement	.716* ($r^2 = .613$)	.773* ($r^2 = .469$)	.347* ($r^2 = .105$)
2. Develop measurable design specifications	.895* ($r^2 = .414$)	.610* ($r^2 = .373$)	.361* ($r^2 = .149$)
3. Develop design solutions	.978* ($r^2 = .465$)	.724* ($r^2 = .528$)	.809* ($r^2 = .524$)
4. Objectively select best design solution/concept	.550* ($r^2 = .479$)	.469* ($r^2 = .202$)	.614* ($r^2 = .319$)
10. Evaluate and test a design	.505* ($r^2 = .251$)	.516* ($r^2 = .268$)	.664* ($r^2 = .392$)
11. Re-design and refine based on feedback from customer outside of engineering	.627* ($r^2 = .211$)	.629* ($r^2 = .381$)	.546* ($r^2 = .252$)
14. Integrate information from a non-engineering field/subject with engineering to develop solutions	.278 ($r^2 = .044$)	.350* ($r^2 = .331$)	.490* ($r^2 = .208$)
15. Explain and communicate designs to non-engineers	.411* ($r^2 = .082$)	.254* ($r^2 = .162$)	.105* ($r^2 = .009$)
17. Communicate project details orally	.066 ($r^2 = .003$)	.318* ($r^2 = .235$)	.379* ($r^2 = .121$)

Fig. 2. Changes in coefficient of linear regression for the nine activities

Fig. 3. Changes in coefficient of determination for the nine activities

important to note that the regression and correlation analyses only indicated how and to what extent the nine problem-solving activities were related to conducting engineering design. The analysis does not decipher any causal relationships. Also, recall that the correlations are between students' self-rated confidence in the activities and in conducting engineering design. Hence, the low coefficients of regression for a certain activity could potentially imply that students' confidence in conducting engineering design did not depend on the students' confidence in that certain activity. We will now discuss some examples.

The largest increase in efficacy, from week 1 to week 10, was seen in the students' ability to use computer simulation and analysis to analyze a design (activity 7). The efficacy in activity 7 increased by 25% from week 1 to week 10. We believe this was primarily because the students were given an assignment that required them to work in teams and use several tools to analyze their designs. The tools included CREO Mechanisms, MATLAB, Ansys, Excel etc. Though these junior and senior engineering students were knowledgeable about the analysis and simulation tools (example: mechanics, controls, dynamics, statics, heat transfer etc.), the course gave them the opportunity to apply the knowledge through a hands-on project.

The students' self-efficacy in integrating information from non-engineering fields with engineering (activity 14) received consistently low scores. The students did not feel very confident in being able to integrate topics from biology, chemistry, business etc. with engineering. The course required the students to develop a product that can teach biology and engineering to K-12 students; therefore it was fundamental for the students to understand biological principles. The instructor and teaching assistants of the course often found students struggling with this integration. The challenge of integrating these subjects was also expressed by students through course evaluations and comments on surveys. Students in college, rarely get the opportunity to work on an assignment that pushes them out of their comfort zone and encourages them to bring in information from fields outside of engineering. In addition to receiving low efficacy scores, activity 14 also had low values for coefficient of regression. In other words, the efficacy of students to integrate information from different fields was not a strong predictor of their efficacy in conducting engineering design. Though the strength of this relationship between the activity and engineering design increased from week 1 to week 10, its value remained low (0.278, 0.350, and 0.490). It can be concluded that students' self-assessed ability to integrate information from multiple fields did not adversely affect their self-assessed ability to conduct engineering design.

Similar to activity 14, the low regression coefficients values for oral communication (activity 17) for all three round of surveys illustrates that students' confidence in oral communication did not have a strong relationship with the students' confidence in conducting engineering design. One way to explain that behavior is that students who do not feel confident in communicating project details orally may still feel confident in conducting engineering design. Further, the low coefficient of determination (r^2) implied that the regression coefficient does not explain the variability in the data well (Fig.

3). A larger sample of data may assist in understanding this correlation better.

Students' confidence in "forming a problem statement" had a strong correlation with their confidence in "conducting engineering design" for the first two rounds. However, that strength decreased in round 3 (Fig. 2). This may be explained by considering that the students worked iteratively in constructing a good problem statement for their products up till week 6 of the course. After week 6, students were more involved in designing their products, manufacturing prototypes, testing prototypes, modifying designs based on customer feedback etc. Hence, we see strong relations between activity 3, 4, 10 and 11 in week 10; activities that were more representative of what the students were actually engaged in before taking the survey.

Students' efficacy in their ability to re-design and refine based on feedback (activity 11) was strongly correlated to their ability to conduct engineering design in the first two rounds, but that correlation got weaker in round 3 (Fig. 2). This was particularly interesting because the self-efficacy of the students related to this activity increased from week 1 to week 10 (Fig. 1). The students gained more confidence in being flexible and adaptable to making changes but the regression analysis did not show a strong correlation of that with conducting engineering design.

Students' efficacy in their ability to explain design to non-engineers (activity 15) did not show a significant increase from week 1 to week 5, but showed a significant increase from week 1 to week 10 and week 5 to week 10. It is important to note here that from week 1 to week 5, the students mainly communicated their ideas with customers through text, flow charts, sketches, and 3D solid models (made through CREO Parametric). In week 10, when the students responded to the third round of survey, they had communicated their ideas through a physical prototype (built by the students), along with analysis of the prototype. We believe that having hands-on experimentation time with their prototype and having a physical device to explain ideas, made the students feel more confident in their ability to carry out the communication.

Based on the trends seen in students' self-efficacy in problem-solving activities and the relations between efficacy in the problem-solving activities and engineering design, we can make some suggestions to improve engineering design education.

- More courses, even during the first two years of college, should be constructed to provide students with added hands-on work with a real application. Applying physics and engineering principles to a real design or product can help improve students' knowledge of analysis and simulation tools, and can increase students' awareness of the importance of simulation and analysis in conducting engineering design.
- More project-based courses should be developed where students get a chance to interact with customers from non-engineering fields (example: non-engineering teachers, nurses, artists, business analysts

etc.). Learning how to gather and interpret information from non-engineers is crucial for engineers. It is equally essential for engineers to learn how to use different modes of communication (written, oral, or non-verbal such as virtual 3D models and drawings) to convey ideas to non-engineers.

- Project-based courses should also enable students to step outside their engineering coursework (which often includes math-heavy course work) and encourage them to spend time researching and gathering information about a non-engineering topic. It is important for engineering students to be comfortable and confident to study a new topic and be able to integrate information from the new field with engineering to design a solution to a problem.
- Project-based design courses should facilitate prototyping activities so that the students can develop physical devices to experiment with, understand its use, and use the physical prototype to communicate their ideas to peers and customers.
- Project-based design courses should facilitate repeated feedback from peers and customers, refinement of problems statement, and objective evaluation of ideas. These were some of the activities that were strong predictors of engineering design when students were actively involved in executing them. (For example, forming problem statements in week 1 and week 6). These activities weaken as predictors of engineering design when the students are not involved in the activities. Therefore, it may be beneficial to develop design courses where students are performing various problem-solving activities in iteration. This will also reinforce the relation between being flexible and adaptable, and engineering design.

These suggestions can help improve the engineering students' abilities and perception of engineering, to address the creativity, teamwork, communication and problem-solving skills discussed in section I and II.

VI. CONCLUSION

Overall, the students reported an increase in their ability to carry out the problem-solving activities on the instruments and ability to conduct engineering design. Self-efficacy is a useful measure to monitor students' self-assessed growth in conducting engineering design. The activities on the instrument proved to be good predictors of efficacy in engineering design. Though, the correlation and regression analysis does not give any causal relationships, the information helps identify strong and weak correlations between problem-solving activities and engineering design. This can further help in developing the pedagogy that can adequately foster essential creative problem-solving skills in engineering students. In other words, can weak correlations between creative problem-solving activities and engineering design be improved by incorporating those activities in engineering pedagogy? If students conducting engineering

design regularly communicated with non-engineers, conducted rigorous analysis of designs, formed problem statements, evaluated and tested designs, and re-designed based on feedback from customers, will these problem-solving activities become stronger predictors of engineering design among students?

VII. FUTURE WORK

Future work involves, further investigating the gains in self-efficacy and correlations between efficacies in the problem-solving activities and engineering design. Data will be collected from a larger student population in various project-based settings. We will also gather a more controlled data set by assigning identities to each response, so that individual growth can be monitored over the 10 week course. The instrument will be used in additional institutions to see how well the existing results hold, and to see the influence of real customer on the self-efficacies of the students.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under the following grants: NSF CAREER-1150681 and NSF EFRI BSBA-0938043. We thank the Academy of Natural Sciences of Drexel University, The Franklin Institute and Center for Aquatic Sciences for their support and cooperation during the execution of course. We also thank Anthony P. Mignano of Laboratory of Biological Systems Analysis of Drexel University for his assistance in editing this manuscript.

There's More Than One Way to Analyze Feedback on Design

Farshid Marbouti, Heidi A. Diefes-Dux, Monica E. Cardella
School of Engineering Education
Purdue University
West Lafayette, IN, USA
farshid@purdue.edu, hdiefes@purdue.edu, cardella@purdue.edu

Abstract — Most studies on feedback and design use thematic analysis. In this paper, we apply three text analysis methods that are not commonly used in feedback and design studies to encourage researchers to think outside of the box and try different methods. We show how word cloud representation, word frequency, and reading ease and grade level tests can be applied to a feedback on design dataset in order to highlight the strengths and limitations of each approach. In general, findings of these three methods are aligned with those from our previous thematic analysis and provide new insights about the feedback. We recommend that these methods be used in addition to thematic analysis in analyzing feedback on design research.

Keywords— *Design Education, Information Visualization, First-Year Engineering, Feedback on Design*

I. INTRODUCTION

Engineering educators are encouraged to provide students with authentic learning experiences that reflect aspects of engineering practice. This can be accomplished through the integration of real world design problems. As design is seen as a central [1] and defining [2, 3] aspect of engineering practice, it is essential that engineering students develop design skills, and become more like experienced engineering practitioners [4]. One way of developing design skills is to provide feedback on students' design work. Feedback is a key catalyst for learning [5] and is positively related to improvements in engineering design skills and professional skills such as communication, teamwork, and critical thinking [6].

One of the most utilized frameworks in studying design and feedback is the expert-novice framework [7]. We used this framework to analyse feedback on design [8]. Based on this framework, design work or feedback of individuals who are identified as experts (typically based on greater experience and higher education) is compared to individuals who are identified as novices. The goal of this comparison is highlighting the differences between experts and novices in order to encourage novices to become more like experts. Methodologies used in most of these studies are thematic analysis and case study. In thematic analysis, common themes are identified and coded based on a coding scheme that characterizes the design work or feedback [9]. In a case study, one or a few individuals are selected and their work is reported in detail to provide insight about their design or feedback [10].

In our previous studies, we developed a coding scheme for written feedback on design including two domains Substance (Communication, Design Concept, Design Idea) and Focus of feedback (Direct Recommendation, Investigation / Brainstorming, Expression of Confusion, Negative Assessment, Positive Assessment, Details/Example) [11]. We coded and analyzed the feedback of students and educators in a first-year engineering course based on this coding scheme [8, 12]. In summary, students provided more feedback related to the communication aspects of design work (e.g., grammar, quality of images) and educators provided more feedback on the design ideas specific to a design problem. Both groups gave feedback on design concepts related to the design process (e.g., identifying users, defining criteria and goals). In addition, students gave mostly negative feedback (i.e., pinpointing the weaknesses of the work) and direct recommendations on how to improve the design work. In contrast, educators provided more detailed comments with examples and asked thought-provoking and brainstorming questions to guide the students to think about their design work more deeply and correct their own mistakes [8].

In addition to thematic analysis and case study, there are a number of different ways to analyze written text that may be useful for analyzing written feedback on design. Visualization techniques, calculating word frequencies, and text readability tests are some of these methods. In summary, the goal of information visualization is to summarize data that can be understood easily by humans [13]. Word frequency techniques calculate the number of time each word has been used in the text to draw attention to the most frequently used words. Text reading ease tests (e.g., Flesch-Kincaid test [14]) indicate how difficult it is to read a text and can assign the grade-level education necessary to read the text.

The aim of this paper is to explore some of the text analysis methods that are not commonly used in analyzing feedback on design in order to show their strengths and limitations for this purpose. Some of these methods can be used in addition to thematic analysis to contextualize students' and engineering educators' written feedback on engineering design work and highlight the differences between the students' and educators' feedback across different stages of design project work. This comparison could enable more effective development of pedagogies for instructing students on how to provide feedback on design work and how to design professional development for educators.

This work was made possible by grants from the National Science Foundation (EEC-1329304).

II. RESEARCH QUESTIONS

In this paper, to understand the strengths and limitations of different methods for analyzing written feedback on design, we investigate the following research question: *What are strengths and limitations of using word cloud representation, word frequency, and a reading ease test for characterizing and comparing students and educators written feedback on design?*

III. METHODS

A. Participants and Settings

Instructors and GTAs of a required first-year engineering course were invited to participate in this study as part of their weekly instructors' meeting during the Fall 2013 semester. Before the instructors began to review their own students' design work, they were asked to give written feedback on a sample piece of student team design work. In total, instructors and GTAs gave feedback on four milestones of a design project over the course of four different meetings. The milestones focused on Problem Scoping (Milestone 1), Concept Generation (Milestone 2), Concept Reduction (Milestone 3), and Concept Detailing (Milestone 4). Each milestone was a 2-4 page long document describing the team's progress on a particular aspect of the design project. Nineteen people (instructors and GTAs) provided feedback on Milestone 1, and 14 provided feedback on Milestones 2-4.

In the first-year engineering course, students work together in teams of four to develop solutions to open-ended mathematical modeling problems during the first half of the semester. During this time, the students begin to develop their feedback skills through in-class activities and homework assignments and then provide feedback on their peers' work. During the second half of the semester, students continue to work in their teams on a design project. Approximately 120 students were asked to provide feedback on the four milestones of the same sample student team's design work on which educators provided feedback. The feedback from 30 students was selected for this study.

B. Design Problem

In the design problem, "aliens" are coming to campus to study! Student teams are asked to prepare the campus for the extraterrestrials' drinking water needs [15]. For example, one possible solution could be re-designing the water fountains according to the extraterrestrials' physical abilities.

C. Analysis

1) Word Cloud Representation

To provide a visual representation of the feedback comments provided by educators and students on each milestone, word cloud images of the comments were created using Wordle [16]. In a word cloud representation, after removing common two letter words (e.g., is) and some other common English words (e.g., the), more frequently used words are demonstrated with bigger size fonts. Size is one of the visual features that can be perceived quickly and without much attention by humans [17]. Word cloud representations of comments can highlight similarities and differences between students' and educators' feedback. It can also reveal if students or educators use similar words among themselves or not.

2) Word Frequencies

Another way to analyze written feedback on design is to count and compare the frequency of words used by students and educators. For each milestone, the most frequent words in students' and educators' comments were calculated to characterize the feedback. First the top 100 most frequent words used by educators were selected; then the word frequency divided by the number of educators reviewing that milestone to calculate the average frequency of the words per educator for each milestone. Following the same process, the average frequency of the words per student for each milestone was calculated for students. Then the words that were used by both educators and students were selected and a frequency ratio was calculated by dividing the average frequency for the educators by the average frequency for the students as in (1).

$$Freq. Ratio (word) = \frac{Educators Avg. Freq. (word)}{Students Avg. Freq. (word)} \quad (1)$$

In addition, the words (out of the top 100 words) that were used by only one of the two groups (i.e., only by students or only by educators) were extracted to further highlight the differences between the students' and the educators' feedback.

3) Reading ease and grade level test

Another way to analyze a written text document is by calculating its readability based on the words and sentences in the text. Flesch-Kincaid reading ease and grade level tests [14] were conducted to quantify the differences in students' and educators' writing level. The reading ease score is between 0 (very difficult) and 100 (very easy) and is based on the number of words in the sentences and the number of syllables in the words in the text; the "plain English" score (with about five words per sentence and 1.6 syllables per word) is between 60-70. The reading ease score can also be converted into a grade level. The lower the score, the higher the level of education needed to read the text. The lowest grade level, 5th grade, is equivalent to a reading ease score of 90-100. Reading ease scores of less than 50 will be assigned a grade level higher than 12, meaning the text is at a collegiate level.

IV. RESULTS AND DISCUSSION

A. Word Clouds

Table I shows the word clouds created based on students' and educators' feedback. In addition to participants' word choice, these images show the level of homogeneity among each group. For Milestone 1, the educators' word cloud shows words with a bigger font size compared to that of the students' word cloud. This is an indication that educators used similar words among themselves, and students used a greater variety of words. Since most of the instructional team have been working at Purdue University together for a number of years, it seems they have adapted a similar language and formed a community that can be seen as a community of practice [18]. Similar training, interactions among educators, exchange of knowledge, and similar experiences may be some of the reasons that educators used similar words in their feedback. For Milestone 1, students used longer words, such as stakeholders and constraints – words they learned in the course. Educators' chose simpler and shorter words.

Educators used words such as water, aliens, problem, ideas, schedule, etc. in their feedback more often than students. This can be an indication of providing feedback on design ideas specific to the design problem, which confirms our previous findings [8]. While word cloud representations provide a visual summary of feedback, the images are not always easy to use to make fine-grained comparisons among groups' feedback characteristics.

B. Word Counts

Table II shows the common words used by educators and students at least twice as many times by one group as compared to the other group. This ratio indicates how many

times educators used a word compared to students. For example, the word "list" in Milestone 1 was used 10 times more by the educators than the students. Words with a ratio of greater than 2 were used at least twice as often by educators than students and words with a ratio of less than 0.5 were used by students at least twice as often as by educators. As can be seen in Table II, most of the common words are used more frequently by educators. Only a few words (shown at the bottom of the table for each milestone), and sometime no words, were used more frequently by the students. This confirms the word cloud representation results - educators used similar words and students used a greater variety of words.

TABLE I. WORD CLOUD REPRESENTATION OF STUDENTS' AND EDUCATORS' FEEDBACK ON DESIGN.

drink	2.37			because	2.14	questions	2.14
define	2.11			does	2.14	plan	2.14
				energy	2.14	criteria	2.14
				rationale	0.48	very	0.39
				matrix	0.41		
				cons	0.37		
				pros	0.34		

In the list of common words used more frequently by educators, design problem specific words such as Purdue, water, aliens, and installation indicate that educators focused more on design ideas specific to the design problem than students. Also some words such as how and does, which are commonly used to start sentences in the form of questions, indicate that educators asked more questions than students. This aligns with our previous finding that educators asked thought-provoking questions [8].

Table III lists words commonly used by both educators and students. Words such as stakeholders, rational, constraints, and goal indicate that both groups emphasized design concepts.

Table IV shows the words (from the top 100 words) that were used by students and not educators and the words that were used by educators but not students as well as the words average frequency per person. Use of words such as bullet, points (typically used together), pictures (in three of the milestones), and sketch by students shows that they focused on the communication aspect of the design.

TABLE III. COMMON WORDS FOUND IN STUDENTS' AND EDUCATORS' FEEDBACK ON DESIGN WITH RATIOS OF BETWEEN 0.5 AND 2. THESE ARE WORDS USED SIMILARLY BY BOTH GROUPS.

Milestone 1		Milestone 2		Milestone 3		Milestone 4
provide	physical	need	know	top	did	problem
effective	just	how	better	provide	team	captions

TABLE IV. FEEDBACK ON DESIGN WORDS USED ONLY BY STUDENTS' OR EDUCATORS' BUT NOT BOTH GROUPS WITH AVERAGE FREQUENCY PER PERSON.

Milestone 1				Milestone 2			
Students (n=30)		Educators (n=19)		Students (n=30)		Educators (n=14)	
Word	Frequency	Word	Frequency	Word	Frequency	Word	Frequency
points	0.40	solution	0.74	pictures	0.77	design	0.64
explain	0.37	design	0.74	team	0.47	sub-functions	0.57
bullet	0.37	clear	0.42	include	0.30	clear	0.50
user	0.33	know	0.42	statement	0.20	morph	0.50
cheeks	0.30	way	0.37	chemicals	0.20	function	0.50
team	0.30	example	0.37	ethical	0.20	strategies	0.43
pictures	0.30	project	0.32	seem	0.17	overall	0.43
very	0.23	might	0.32	hard	0.17	functions	0.36
intake	0.23	seem	0.32	confusing	0.13	example	0.36
without	0.23	alien	0.32	missing	0.13	work	0.29

Milestone 3				Milestone 4			
Students (30)		Educators (14)		Students (30)		Educators (14)	
Word	Frequency	Word	Frequency	Word	Frequency	Word	Frequency
weighted	0.43	data	0.71	pictures	0.40	design	0.71
chart	0.33	pros/cons	0.64	list	0.23	cost	0.64
read	0.27	options	0.50	page	0.23	project	0.57
solutions	0.27	clear	0.43	label	0.23	procedure	0.43
statement	0.20	model	0.36	sketch	0.20	sketch-up	0.36
needs	0.20	benchmarking	0.36	get	0.17	work	0.36
problem	0.17	evidence	0.36	well	0.17	does	0.36
list	0.17	measurable	0.29	statement	0.13	missing	0.36
errors	0.17	scale	0.29	specific	0.13	see	0.29
best	0.17	humans	0.29	blank	0.13	price	0.29

While calculating word frequencies can be an effective way to summarize and get an insight about the context and choice of words, it may be better to use these methods in combination with other methods, as it is not easy to look through a list of words and get a sense of the feedback. One suggestion is to code the most frequent words based on a previously develop coding scheme instead of coding the whole text. If the results are similar, coding only the most frequent words is less time consuming than coding the whole text.

C. Readability and Grade Level Tests

Table V provides results of the Flesch-Kincaid reading ease and grade level tests. Educators' reading ease score is consistent across milestones and is in the 60s, which is consistent with the plain English score. In contrast, students' reading ease varies greatly from the first milestone, 43.7, to the last milestone, 69.6. As can be seen from the word cloud representations, the low reading ease score for Milestone 1 may be based on the choice of long words (with more syllables) that students adapted from the course. In contrast, educators avoided using "jargon" and provided their comments in plain English. As students progressed in the design milestones, it seems they started to use simpler words in their feedback.

TABLE V. FLESCH-KINCAID READING EASE AND GARDE LVEL TEST.

Milestone	Flesch-Kincaid	Students	Educators
M1	Reading Ease	43.7	63.8
	Grade Level	14.5	6.8
M2	Reading Ease	60.4	61.4
	Grade Level	8.7	7.8
M3	Reading Ease	64.6	68.4
	Grade Level	8.1	6.4
M4	Reading Ease	69.6	66.5
	Grade Level	5.6	6.3

Reading ease and grade level tests are a great way to quantify feedback for comparison purposes, but they are better used in combination with other methods that can provide deeper insight about the feedback. In addition, because the test scores are calculated based on the number of words in the sentences, texts that are not properly punctuated (such as feedback in bullet lists) may lead to erroneous results.

V. LIMITATIONS AND FUTURE WORK

In addition to the limitations discussed earlier for each method, one common limitation of the presented work results from combining everyone's feedback for each milestone. If one person overuses a specific word, that word may show up as frequent but only has been used by very few people. To avoid this problem it is possible to count the number of participants that used a specific word instead of word frequency in general.

Another suggestion is to combine each of these methods with thematic analysis. For example, it is possible to create a separate word cloud for different substance of feedback (i.e., Communication, Design Concept, Design Idea) for each milestone. This can make a more detailed visual representation of the choice of words not only for each milestone, but also based on different substances of feedback.

VI. CONCLUSION

In this paper, we briefly reviewed three different and unconventional approaches to analyzing feedback on design. We applied them on a feedback dataset to highlight the strengths and limitations of these methods. In summary, while all three methods provide good insight about written feedback on design, we recommend that these methods be used to complement more conventional methods in analyzing feedback such as thematic analysis. Since the methods discussed in this

paper are efficient in analyzing large text datasets, this can be a first step to analyze a large amount of feedback automatically. For example, it may be possible to use a combination of these methods (e.g., word counts) with a developed coding scheme to monitor changes in feedback over time.

Abstract—Scrum framework disseminates principles that guarantee a dynamic and adaptable Software development process. Supporting the software engineering teaching using agile methodologies and Scrum framework with some proper adaptations is the challenge of Federal University of São Carlos in the Software Engineering specialization course for graduated students. The article presents an evaluation of Scrum adaptations performed to evaluate the capstone project. In this case study, the adoption of Scrum to manage the capstone project represents a direct and objective approach in order to have an environment similar to the real one. Moreover, the inexperience of the teams, the partial dedication in the projects and the distributed teams showed the necessity of self-management of the teams among other lessons learned to teach Software Engineering in this setting. Finally, evaluating a capstone project using Scrum framework in a flexible and collaborative way made it possible to realize the difficulties faced by the teams and the need for technical improvements, thanks to Scrum framework functions.

Keywords — agile methodologies, software engineering, higher education, SCRUM

I. INTRODUCTION

Software Engineering teaching needs to follow the industry demands when the purpose is to improve the skills of graduated students who seek better placements in industry or want to update knowledge to complement the graduation learning.

Developers in Software industry complain about the constant changes in software requirements. In traditional methods, the clear requirements are prerequisites to the next level. Currently, developers need to transform the constant chaos of Software development industry in advantage and find a way of better assisting the client [1]. Due to fast changes in this industry, traditional approaches are not very practical to some professionals [2].

The Software development in the industry is fast and offers our students an unstable environment in relation to the aspect of technology, requirements management and team management. The industry needs a professional who is flexible to manage all the chaos in an unstable environment and able to deliver a functional product in a short period. It is possible to conclude that there is the necessity of an approach closer to the real environment, in which theories and practices can be

applied allowing the student to have a further learning using agile methodologies of Software development [2].

In face of this setting, the Federal University of São Carlos/Brazil offers a Software Engineering specialization course for web development for graduated students based on agile methodology principles. For this to be achieved, Scrum framework was chosen and the course was adapted so that the students were able to learn and, at the same time, apply Scrum principles.

Since the first group in 2003, the traditional methodology was adopted in the capstone project. However, some problems were faced during this period such as partial delivery of the project, because the complete project was developed in a single cycle and the traditional methodology was used [2]. Some studies discuss that this is an ideal methodology for inexperienced students [3]. However, the analysis of the course reality showed that some variables needed to be included such as time dedicated, experience, talent for programming and auto-management. Some of these variables were only realized in the end and reflected on the capstone project.

Agile methodologies and Scrum framework principles, mainly the iterative aspect of the production cycle for a delivery in each Sprint, were adapted in the course. All the subjects were enrolled, allowing the student to learn new programming techniques and to deliver a part of the capstone project following the Backlog, Sprint and stories.

In a general view, Scrum has some important meetings that guide the team so that the members can understand what is necessary to deliver. For example the Sprint Planning, the Daily Scrum, the Sprint Review and the Sprint Retrospective [1,8].

In Scrum, the Product Owner prioritizes and inserts in a list called Product Backlog the functionalities expected for the Software. The functionalities are presented to the team in order to have an assessment and the Sprint Planning establishes what the team will assume. During the period of stories performance, named Sprint, the teams perform the daily meeting for a daily follow-up of tasks and difficulties. In the end of the Sprint, the Sprint Review is performed, considering the delivery of what was performed during the period and after that, the Sprint Retrospective aims at identifying positive and negative points, and what can be improved [1,8,5].

During Software process development using Scrum, some artifacts are generated to give an idea of what the team needs to do. These artifacts are the following: the Sprint Backlog showing the stories contemplating desired functionalities to be implemented in the product; the Burndown charts showing the performance relation versus the stories assumed by the team; and the Backlog release that relates everything that will be delivered, which might comprise one or more Sprints. All these meetings and artifacts are inserted in the Software development process and they will guide the work [1,8].

The entire course syllabus was divided in phases that allow the students to learn gradually and release a compatible part of the capstone project based on subjects studied during the classes [2]. In order to make the academic environment closer to the real world, the students were grouped in teams of 6 to 7 people, a Technical Product Owner was named to help all the teams, and a Product Owner was chosen for each team in order to create a reality and have an impact in the learning setting.

Organizing a course with such a structure has an impact in the student's learning process. This way, the purpose of this paper is to determine, discuss and quantify how Scrum became flexible and collaborative when teaching Software Engineering. Adaptation and other aspects of development were evaluated with a questionnaire applied in about 34 students who were concluding the specialization course in 2013.

The paper is organized as follow: Section II shows how teams were organized during the course so that Scrum methodology could have a real application. Section III shows the outcomes and discussion about the questionnaire applied to students in the end of the last year of the course. Section IV presents the related works; Section V presents the lessons learned for this kind of application according to the student's point-of-view. Finally, Section VI presents the conclusion of the research.

II. ADAPTING SCRUM FOR THE SPECIALIZATION COURSE

In general, there are 30 to 40 students attending the Software Engineering specialization course per year. The course lasts 444 hours distributed over two years [2], the classes are offered twice a week and most people in the teams live in different cities, making it difficult to manage the capstone team.

During this period, since the beginning the students are grouped in small teams. According to the Scrum philosophy, small teams, not exceeding 10 people, are easier to manage [1]. Therefore, in this course, the teams are organized in 6 to 7 students who have to develop a web project based on a real problem presented by the professor responsible for the Software agile development subject.

The course coordinator and the professor look for a Product Owner that will offer a problem for each group. This action creates a solution based on real requirements raised by the teams to an alleged real client. From this moment, the teams effectively start using Scrum.

Scrum framework is transmitted to students in the first day of class and in the course of two years, the topics highlighted in

the course such as Sprint Planning, Daily Scrum, Sprint Review and Sprint Retrospective are reviewed. Often, these topics are reviewed before students start using Scrum to develop the project.

The class that finished the course in the end of 2013 had 34 students grouped in five teams. Each team was responsible for a project that became a software solution for the Product Owner. The systems created during two years of course are briefly described as follow:

- a) SICOM: SICOM offers control and management of properties and residents in the campus of the Federal University of São Carlos, such as identification and location for the people who live there.
- b) University Restaurant System: the university restaurant system automates the stock control process reducing the time of this operation and making it easier to raise administrative and financial information.
- c) Student assistance system: The student assistance system offers computational support for requests and management of scholarships handled by the University social assistance department.
- d) IIS: The institutional identification system is responsible for managing the individual's identity in the Federal University of São Carlos.
- e) Property management system: the property management system aims at managing the life cycle of Federal University of São Carlos properties.

By analyzing Scrum adaptation under a general view, it is possible to report some changes in the quantity of days for a Sprint. According to the official version of Scrum, a Sprint must take 2 to 4 weeks and in the academic setting, a Sprint took about 41-84 days. This modification was an explicit order given by the course coordination because the quantity of days each Sprint must have is defined by the coordination.

Another adaptation is the definition of Scrum Master role turnover. This role turnover has allowed each student to understand the idea behind the daily meeting management, remove obstacles, protect the team from external problems and make things easier. The addition of the Scrum Master role turnover in the course promotes its use in a collaborative way.

Another challenge originated from the application of Scrum in the course is that most students have full-time jobs, and they dedicate time to the project only on weekends and free time during the week. Thus, in this course, teams reported the necessity of appealing to instant communicators such as messengers to deal with distance issues.

In the official version of Scrum, in-person daily meetings are necessary. Later on, in the academic adaption, the daily meetings were replaced by one meeting with all members through online communicators as a solution. Another resource used by students was emailing during the project. Most communication was performed through email among all the members and the Product Owner.

Another adaption was the replacement of Kanban used to present task lists through an electronic worksheet. Therefore, all artifacts necessary to manage the capstone project migrated to an online version. All the documents such as backlog, sprint backlog and burndown charts were shared by the members of the teams to promote interaction and follow-up.

The team starts applying Scrum since the first contact with the Product Owner. After the first meeting with the Product Owner, the groups raise the requirements. So, the members of the team discuss to start the creation of the Backlog. During the capstone project, the professor responsible for the agile development subject and a tutor support the team. Both have technical expertise to guide the teams in technical issues and in the Scrum.

Leite and Lucrédio's work [5] reported the adaptation of the Scrum in the team that developed the University Restaurant System. And we verified that the same adaption was applied in other groups in the same specialization course concluded in 2013. In the article [4], Prado and Ferrari report that the distributed teams appeal to the online communicators and email. But there is a difference realized by the teams mentioned in Prado and Lucrédio works, the need of meeting in person in the end of classes to clarify some doubts concerning the development. Other topics mentioned concern the use of SVN to centralize the code and keep the files updated for all the members in all the teams.

All adaptations made by the teams helped to develop the capstone project during the two years available to define the scope, the interviews with the Product Owner and the implementation. Thus, in the end of each Sprint, the Sprint Review is performed in the presence of the professor responsible for the agile development subject and the tutor. The Product Owner is not present in all Sprint Reviews, being invited only to some of them. In this case, another adaption to the academic setting is characterized. During the Sprint Review, it was possible to control the evolution based on the implementation according to the level of difficulty of the subjects already studied. The idea is that the students deliver parts of the project based on the subjects learned.

In the beginning, as reported by Leite and Lucrédio in [5], the team faced some difficulties. In the first Sprint, the professor helped the students to define the stories to be implemented. After defining each story, students played the Planning Poker in order to determine the points of each story. Each story has a level that defines its complexity. In this phase, students felt the necessity of further knowledge about the technology to be used in order to improve the outcome of the first Sprint.

Leite and Lucrédio [5] reported all the regressions in their work. A summarized version of what is faced during the period can be seen in Table 1 with the implementation of the "Federal University of São Carlos Restaurant Management System" project. The table shows the main obstacles identified by this group, but in general, it can be extended to others.

The Sprint analyses of all teams showed all the challenges faced in this process using Scrum in a flexible and collaborative way. Reviewing the Burndown chart of each

Sprint developed by all the teams, it is possible to realize the evolution during these two years studying new technologies and working on the the capstone project. The idea of using the Burndown chart for follow-up is because the chart shows how many tasks are performed by a team during a period. In this case, the period reported in the chart is the time of each Sprint.

TABLE I. GENERAL VIEW OF SPRINT – TABLE ADAPTED FROM [5]

<i>Sprint</i>	<i>Days</i>	<i>Stories</i>	<i>Obstacles</i>
1	41	4	Project Scope.
2	71	8	Lack of planning in the meetings.
3	56	4	Complications in the self-managing model.
4	84	4	Technical issues.
5	63	5	Outdated documentation.
6	63	10	Lack of dedication from the member of the project.
7	55	12	Overload of programming activities.

It is possible to highlight a team among the followed-up teams, for example, the team reported by Leite and Lucrédio. Figure 1 shows the main point of the team evolution. In the first and fourth Sprint, this team suffered some regressions causing delays in the tasks. In the fourth Sprint, a lack of commitment with Scrum practices was reported due to the amount of overwork. This episode generated a lack of trust in the real situation of the project in the Sprint causing a delay in the activities; and it was reported that some tasks were not accomplished [5].

However, the team showed a significant improvement in Sprint 7 thanks to an experienced Scrum Master that is always vehemently following the framework principles and characteristics according to Leite and Lucrédio[5]. In the last Sprint, the team showed more maturity in the development process and dealt better with the regressions. This was verified in all the other teams too. Thus, the outcome of Sprint 7 in Leite and Lucrédio's team showed that all tasks were performed, except one that was not concluded because there was a disagreement concerning the operation flow.

In general, in the end of the project, the teams realized that if everybody dedicated more and lined up with the goals, the outcome of each Sprint could be much better, as mentioned in work [5].

The flexible and collaborative use of Scrum applied in the capstone project provoked some changes in the learning process of these students. Students worked on the capstone project during the two years and delivered it in parts due to the Sprints. An important aspect using an approach based on Scrum is how much it helped the students in the learning process and what were the lessons learned with this experience from the students' point of view. The experience reported by Leite and Lucrédio can similarly describe other teams' behavior. However, in order to obtain an opinion and evaluate the approach, a questionnaire was applied for each student

based on his or her own experience developing the capstone project.

Fig. 1. Active flow – Adapted [5]

III. EVALUATING THE ADOPTION OF SCRUM

In order to evaluate the impact of the Scrum-based approach in the class of 34 students who concluded the specialization course in 2013, a questionnaire was sent by email to all the students. After the end of the period of collection, all the answers were summarized and analyzed. The questionnaire considered a view of students' profile, how the team used Scrum, the positive and negative aspects when using Scrum and if the student knew the Scrum

The questionnaire was composed of nine questions, with five objective questions and four open-response questions. In all objective questions it was possible to define a percentage and assess the maximum and minimum value. In the open-response questions it was necessary to summarize the main ideas in the answers and group them to have a better analysis. Therefore, it was possible to quantify more precisely the students' opinion about the use of Scrum adaptations in the capstone project.

The questionnaire sent to the students was composed of the following questions:

- Do the members of the team have any knowledge about Scrum?
- Are the members of the team from the same city?
- How often does the Sprint Planning happen?
- How was the Sprint Planning performed?
- How did the team adapt the Scrum for the capstone project?
- What are the positive points of Scrum in the project?
- What are the negative points of Scrum adaptations in the Project during the course?
- Did the previous knowledge contribute for the project?
- Do you use Scrum in other settings besides the Software development one?

The answers from each student were summarized and discussed. In the following summary, the students' profile, the Scrum adaptations by the team, the positive aspects using Scrum and the negative aspects using Scrum adaptations are initially related.

A. Student's Profile

The specialization course is offered twice a week and most students are from cities near São Carlos, which is located in the countryside of São Paulo state in Brazil, or from the capital. Therefore, 100% of the students do not live in the same city where the members of the team live, and the teams were composed of members from different cities characterizing distributed teams without full dedication to the project.

Another point observed with the questionnaire is that not all the students know Scrum framework. In total, only 29% of the members knew it. This contributed to create a setting where the students had no knowledge about agile methodologies, generating new challenges for the course.

As the questionnaire was applied in the end of the specialization course, it was possible to quantify if the previous knowledge in programming or any other technical knowledge helped the user in the project. In general, 94% of the students reported that the previous knowledge contributed to the capstone project. This result might be related to the type of course. With regard to a specialization course, some prerequisites are demanded before the student gets in. Thus, the more the student is prepared, the more it will help him during the activities, even in the capstone project.

Other issues define if the student uses Scrum in other setting besides the Software development one. It can sound conflicting, because only 47% claim that use Scrum in different settings and 71% claim that they do not know Scrum.

It is possible to relate the 47% of students to the setting where they work. In some reports, they mention that they use Scrum in the bank office, in the production process control, in the development of games and even in the Software development setting. Maybe the 71% is related to the further knowledge of Scrum, because living the routine where the

Scrum is applied is different from having a further understanding about the framework.

The profile of students were mapped using questions (a), (b), (h) and (i). All results showed that the 34 students came from different cities, only 29% of the students knew Scrum and 71% of the students did not know Scrum. Most students (94%) mentioned that the previous knowledge in programming language and Scrum contributed to the project and 41% of the students used Scrum in another setting.

B. Scrum adaptations

Adaptations were necessary because the teams need to develop the capstone project in a distributed way and the responsibility for the Project needs to be shared. However, the use of Scrum demands intensive contact among the teams. Thus, it was necessary to adapt mainly the Kanban and the meetings that provide a closer follow-up. In order to apply Scrum in an academic version, students had to take some actions such as replacing the board containing the stories and tasks of a Sprint by digital resources and using the online communication to keep the Sprints in progress.

In general, all the students combined the online communication, email exchange and in-person meetings to perform the Sprint Planning. Therefore, in 65% of times, the use of instant communicators and e-mails were more frequent than the in-person meetings. Only 26% used all the options to perform the Sprint Planning, as presented in Figure 2.

For a better understanding, the Sprint Planning is a meeting in the Scrum that defines what is necessary to do in that Sprint based on what is available on the top of the Product Backlog. In the official version, the Sprint Planning is performed with the Product Owner. In this case, it was not possible to have the Product Owner always available, so the meetings were organized online most of the time, as presented in Figure 2. The outcome of this meeting is that the students need to implement during the Sprint. In general, the Sprint Planning is performed in the beginning of a Sprint to define and understand the tasks.

Sprint Planning frequency varies from team to team. The rule is that the team has a date to initiate a Sprint and a deadline to deliver a functional part in the same Sprint. The Sprint planning time increased twice a month (18% of the team), weekly (41% of the team) or monthly (38% of the team). Only 3% of the students did not know how to answer this question, as presented in Figure 2.

The Sprint Planning do not replace daily meetings, aims at planning the Sprint and must be performed primarily always in the beginning of a Sprint. However, the distance and the lack of time make the students create a strategy that allows a closer follow-up with monthly, weekly or bimonthly meetings. In order to complete the Scrum adaptation in the capstone project, the answer to question (e) was analyzed. Therefore, a brief description of the students' answers is shown as follow.

It was interesting to analyze the students' answers because it was possible to note the Scrum potential. As a framework, Scrum provides an idea of how it can be used. Therefore, the main concern of students was keeping the communication to

guarantee a good project. Some students, almost 32%, reported that used the online communicators to have a daily meeting; and to reduce their distance; they also exchanged emails. In general, the students told that they arranged weekly meetings with online communicators to have information about the Project development.

Almost 18% of the students reported that they inserted the Product Backlog, Sprint Backlog and Burndown in web tools to share the content with some members, allowing the online follow-up. Some students told that the in-person meetings were held mainly in the retrospectives and in planning meetings. Other students commented that in the end of the classes they used to meet to discuss the evolution of the project. Other students reported the creation of long-term Sprints, and other students addressed the tasks according to the technical ability of each member. Eventually, other students told that when they finished the task, they used to help others who had not finished yet.

By analyzing question (e), some students, about 24%, did not give an opinion about Scrum adaptation performed in their teams. Almost 12% of the students told that using Scrum was difficult in the beginning and two students from this group reported that the problem was in the difficulty of communication.

What is the frequency of the sprint planning?

How were the sprint plannings executed?

Fig. 2. Graphics to understand Scrum adaptations

C. Negative aspects of using Scrum adaption.

Students are free to adapt some framework points such as communication and follow-up. All the changes can have a negative impact based on the options defined by each team. To have a better understanding about the impact of adaptations, the answers to question (g) were analyzed. All the answers were analyzed and the main idea was summarized and grouped for a complete understanding of the impact. A brief description is presented as follow.

By analyzing the questionnaire, it was possible to conclude that the flexibility and collaborative use of Scrum represents a challenge of 41% of the student in the agile methodology learning process. Although the flexible use guaranteed the adoption of the framework by the course and by the teams, the mapping shows some negative aspects in Scrum adaptation.

About 6% of the students considered that replacing the in-person meetings by virtual meetings contributed to the negligence on the part of some members in the team; 6% of the students considered that learning with the project management was more demanding; 6% of the students considered the lack of dedication from the members a problem; 12% of the students faced difficulties in following Scrum in a distributed format and 9% of the students considered that the lack of experience with the Scrum caused some regression.

The remaining 18% of the students did not comment on the negative aspect of adaptation and only 3% did not identified problems with the respective teams using Scrum adaptations.

Considering all the percentages, it is possible to infer that the use of Scrum in the capstone project caused a change of attitude from the students. The use of this framework clearly showed the members that really participated and others that did not show interest. Therefore, in the end, a member draws the attention of other uninterested members to be more participative, or in some situations, this members give up.

The capstone project became demanding for only 6%, but the advantages of living in an academic area similar to the professional area is reassuring. On the other hand, the capstone project is made in parts, making it easier to follow the evolution of the project.

D. Positive Aspects of using Scrum.

Besides the negative aspects raised in this questionnaire, the positive aspects of using Scrum were identified. The good news is that the positive aspect of this approach justifies the management of the capstone project development using Scrum. In order to analyze the positive aspects of adopting Scrum, the answers for question (f) were summarized and a brief description is presented as follow.

In the evaluation, all the students who answered the question reported that the use of Scrum stimulates the participation of all the members of the team and helps to release functional products in a faster way, adding more agility to the team. This agility provides a continuous improvement in Software delivery, because at the end of each Sprint it is possible to receive a feedback, make more changes and understand better the product.

The students appreciated this approach because with a minimum view of project it is possible to start the implementation and gradually understand the new requirements. In addition, the flexibility in using the framework provides a different way of working, for example: working remotely. The students say that the use of online spreadsheets makes it easier to understand the status of the Project and defines the user who is performing the task.

A student said that using Scrum in this format provides a more real framework setting, which is truly used in the industry. Another student reported that it is possible to use all the twelve principles of the agile methodology with this approach.

In a general view, the students told that the use of Scrum provides an agile setting, continuous feedback, frequent deliveries, less bugs, more motivated team, improvements in organization, clear delegation of tasks, the possibility of focusing on a product functionality, a better view of the Project development and improvement in the communication. These improvements increase the interaction and participation of the members in the team.

According to the percentage summary, around 18% of the students told that this approach increases the speed in delivery of some functional parts of the project; 18% of the students agree that it increases the participation of the members; 15% of the students told that it is easier to manage the project when they face adversities; 3% of the students told that it is possible to use a framework used in the market in practice; 6% of the students told that the use of Scrum allows a continuous improvement; 29% of the students told that it is easier to manage the project using Scrum; and 3% of the students told that it is possible to use principles of agile methods.

IV. RELATED WORKS

The review of some works related to the evaluation of the impact of Scrum identified this impact on the area of industry development versus academic area [6,10]; Scrum application in capstone projects [7] and Scrum applied in the academic area approaching the Software project to reality [9].

In work [6], Vicentin applied a questionnaire in two parts to evaluate the impact of a possible use of Scrum on a Software House. Based on the answers, Vicentin concluded that the use of Scrum could be a good tool to manage the teams. However, the problem starts with the change, where the laziness of some friends will have an impact on the use of Scrum. The author realized that when he applied the same questionnaire to his own team that was making the capstone project managed by Scrum, the opposite happened. The use of Scrum was well accepted. In addition, this kind of use helps to bring the members closer to develop the work.

In another work [7], Carnevali and Lucrédio reported that when Scrum was applied in a Software House to improve the requirement engineering, it showed improvement in communication and in the roles in the Software House. In general, it is clear that the individuals' commitment is necessary when the Scrum is adopted.

In Wagh's work [9], Scrum application is performed to provide the students with a practical view of the Software development industry, getting closer to the reality in the profession. The Scrum application evaluation in a class project proposed by Wagh was performed through a questionnaire answered anonymously by the students. The aim was to understand how much the students learnt with this approach and its efficacy. As result, most students saw improvements in how the project was managed and in the teamwork with the use of Scrum. The questions that evaluated the use of artifacts and Scrum meetings showed that the daily meeting is the most popular technique among this group, followed by the follow-up chart, sprint planning, user's stories and assessment.

Finally, in work [10], Mahnic and Rozanc discuss the use of Scrum in a capstone project and ask for the students' point-of-view based on the use Scrum. The result is compared to other research carried out with professional developers. In short, two important factors were realized: the first is the teamwork and communication among the members of the team and with the Product Owner. However, other points present different points-of-view such as clarity in the specification of requirements, daily meetings and sprint planning.

In works [6,7,9,10] it is possible to realize that Scrum helps in the organization, teamwork and commitment of the members in the team. These points can be seen in the evaluation performed with the teams that concluded the capstone project in the end of 2013.

V. LESSONS LEARNED

The evaluation showed that the approach is valid when analyzing the positive aspects in relation to the negative aspects. According to the students' point-of-view, the flexible and collaborative use of Scrum increases the communication, feedback, continuous improvement and provide faster deliveries compared to the traditional model. In other words, students see the outcomes from their work in a faster and gradually way when compared to the traditional models to perform the capstone project.

According to Leite and Lucrédio [5], it is understandable that the adoption of a framework like Scrum will provide the self-management of the members. The students need to take responsibility for what they need to deliver. This practice is sometimes different from what the students face in some organizations, when they receive a work and are constantly charged for faster deliveries. In Scrum, the team needs to work together and cooperate to reach a goal. In their work [5], Leite and Lucrédio report this kind of experience, and they add that it is important to define clear purposes, the roles and the tools.

Other lessons learned in Leite and Lucrédio's work [5], and which can be extended to the teams that concluded the capstone project in the end of 2013 are the following: the communication is an essential tool; defining points to be discussed in meetings is a good methodology to improve the efficiency; identifying the limitation and trying a solution for the next iteration are great techniques; sharing knowledge among the members and tutors; omitting the use of Scrum in

some period of the project can cause delays; and the commitment and shared knowledge provide positive outcomes.

VI. CONCLUSION

The article proposes to determine, discuss and quantify how Scrum becomes flexible and collaborative in Software Engineering teaching. It presents a general view of the specialization course offered in São Carlos, in the state of São Paulo/Brazil focused on web development. Next, the way the course allows the flexible and collaborative use of Scrum to teach Software engineering is presented. In order to evaluate the impact of this approach, a questionnaire was sent to the students who finished the course in the end of 2013.

Considering the students' point-of-view, the approach allows to improve the experience in the capstone project development. Adaptations performed by students taking into account the flexibility, communication and releasing of functional parts of the system are important points.

Finally, using Scrum during the capstone project helps the professor to see the difficulty, guide the student as best as they can and provide assistance to the team with big difficulties during the project development. With this approach, it is possible to create points of action to try to reduce problems related to delivery.

A Self-Assessment Instrument to Assess Engineering Students' Self-Directedness in Information Literacy

Kerrie Anna Douglas, Todd Fernandez, Şenay Purzer, Michael Fosmire, & Amy Van Epps

School of Engineering Education
Purdue University
West Lafayette, IN
tfernand@purdue.edu

Abstract—Information literacy, the ability and processes of information gathering and application, is of paramount importance to engineers, engineering design, and engineering decision-making. Building on prior qualitative research, this paper presents the development and initial validation study of a self-directed information literacy assessment for engineering and technology students ($n = 366$). Internal consistency was found to be high, ($\alpha = 0.895$). Exploratory factor analysis results provide evidence of structural aspects of validity and support for scoring structure. In addition, areas were identified for future development of the items and instrument.

Keywords—Instrument Development, Information Literacy, Exploratory Factor Analysis (EFA)

I. INTRODUCTION

Engineers must gather, evaluate, and make use of information as they go about their work. This information provides engineers a basis on which to make decisions, evaluate concepts and ideas, and meet clients' needs. The way that engineers use information derives from a set of personal beliefs, habits, and knowledge. Known generally as information literacy, those components of engineering behavior are vitally important to professional success [1], [2]. The goal of the paper is to present the initial development and psychometric studies of a measure of engineering and technology students' self-directed learning in information literacy. Specifically, we are examining structural aspects of validity.

This study performs initial development work on an assessment instrument designed to measure self-directed learning in information literacy for engineering and technology students. The 69 item instrument, known as the evidence-based self-assessment of problem solving skills (E-SAPSS), was developed from prior qualitative work [3], with data collected from students in the engineering program of a large Midwestern research university. The study identifies items whose removal increases measures of reliability and proposes a modified factor structure that captures the behavior of E-SAPSS items on the population studied. This work serves as an initial step in constructing an argument for the instrument's use on undergraduate populations.

II. RESEARCH QUESTIONS

This study addresses one overarching and two specific research questions. Overall, this study addresses (RQ0) what

items can be scored together as a measure of students' self-directed information literacy in a design problem. More specifically, it answers; (RQ1) Do items conceptually written to explore stages of the information literacy process in undergraduates factor together? (RQ2) do those items show evidence of unidimensionality on theorized factors?

III. THEORETICAL FRAMEWORK

A. Definitions and Components of Information Literacy

The exact definition of information literacy has been parsed and argued at length. In a 2005 study, Owusu-Ansah performed a review and historical description of the development of both the term information literacy and the myriad of closely linked concepts that exist [4]. He identified 15 general concepts at the core of information literacy and also notes the migration of information literacy work from library centric domains to domains more situated in discipline specific work. He concluded that the ALA definition of information literacy, the ability to "recognize when information is needed and have the ability to locate, evaluate, and use effectively the needed information" [5, p. 2] sufficiently documents the core principles of information literacy and suggested a shift in focus from field definition to educational development.

Kuhlthau developed a conceptual framework known as the Information Search Process (ISP) [6]. The framework defines six stages of the information process beginning with task initiation and ending with presentation. The framework was built from interviews of students in various disciplines. The ISP framework has been adjusted for this study to more closely meet the needs of engineering education researchers and the engineering design process. Work by Fosmire and Radcliffe [7] identified overlaps between information literacy, the ISP framework, and engineering design processes. They proposed a use of the overlap with information literacy and develop interventions that increase students' abilities. As part of their work, Fosmire and Radcliffe [7] proposed a revision of the information literacy stages to form and measure the behaviors in engineering design.

Theories and research in information literacy also have significant ties to a broader discussion of self-directed learning in engineering students [8], [9]. These lifelong learning skills are called out in ABET program evaluation and accreditation

as fundamental skills that engineering programs must develop [1]. There is a strong interdependency of information skills and information literacy [9]. Strong information literacy skills give students tools with which to effectively pursue the growth of their own knowledge in the engineering discipline. This correlation is vital to the instrument developed here, and the self-directed learning work is used as the underlying theory.

B. Measurement of Information Literacy Skills

A difficulty present in the field’s prior work is the measurement of information literacy skill and knowledge in students. Different approaches have included test assessment, skill inventories, or self-assessment. Oakleaf [10] reviewed scored assessment approaches for information literacy. She identified three general categories of information literacy assessments: fixed-choice tests, performance assessments, and rubrics. She suggested that the choice between these summative assessment methods largely speak to the abilities of students to either apply the information literacy concepts in their work, identify information literacy skills being applied, or identify knowledge gaps in a scored way. An instrument by Wertz et al. [11] is an alpha version example which takes the form of eight multiple choice questions requiring students to use information literacy concepts when evaluating a technical memo. This approach is representative of the fixed-choice test category from Oakleaf [10].

Denick et al [12] considered student citations in engineering reports as an indicator of information literacy ability and performance. She argued that the structure of educational interventions by libraries in engineering classes, often a single class period, tend to over focus the field on a singular direct assessment. Other assessment approaches include skill inventories, or allow students an opportunity to self-assess their information literacy skills encouraging self-monitoring and self-efficacy. Monoi et al. [13] developed validity evidence for an instrument that assesses students’ self-efficacy using their online searching behaviors. The resulting instrument includes items such as “I can construct a search using Boolean operators” [13, p. 103]. While constructed in a true/false style, the focus of the questions on modern manifestations of information literacy skills in students is important to effective assessment of the construct through modern manifestations and reappears in this study’s instrument.

Collectively, these approaches measure students’ abilities to recognize, identify, and implement information literacy strategies in structured classroom assessment or through student artifacts via a single dimension. However, they do little to drive an understanding of students’ beliefs, habits, or abstracted knowledge in terms of information literacy, especially in the more holistic view of information literacy presented in the ISP framework. The assessment methods largely lack a tie to the stages defined in Kuhlthau [6], and do

not consider students’ beliefs about their information skills to make informed design decisions.

IV. METHODS

A. Instrument Development and Prior Work

The development of E-SAPPS was guided by the recommendations for scale development from Netemeyer and colleagues [14]. Netemeyer and colleagues recommend beginning by identifying what will be measured through construct definition and domain. For this initial step, we consulted existing literature on information literacy, including assessment designed to measure students self-reports. In addition, we built from previous work [3] detailing semi-structured interviews into the actual strategies used by students in design situations using a protocol informed by the Kuhlthau ISP framework [6]. This served as the first stage, reducing the interviews to a set of theorized factors, detailed in Table IVV-1, that represent the stages in information literacy apparent in students’ progression through an engineering design project.

After the completion of the interview analysis, the development process moved to the generation of specific measures in the form of individual items. The individual items were written to fit the factors created through the interview process. When possible, the items were grounded in specific good and bad example behaviors identified in the qualitative interviews. In total, 69 items were written for a 5 point, strongly disagree to strongly agree, Likert-type scale. Both forward and reverse scaled items were written for each theorized factor, as recommended by Spector [15]. Example items for each theorized factor are shown in

Table IV-2.

Table IVV-1 Theorized factors, definitions, and items in instrument

Factor	Definition (Students...)	Items
Recognize	identify what information they have and what information they must gather.	19
Locate	gather information via appropriate search methods, using appropriate search terms, and correctly identifying or employing different types of information.	16
Evaluate	assess the credibility and accuracy of information that they find based on the source, the age, and the purpose	7
Apply	make use of information that they gather to improve designs or make decisions not just confirm their beliefs.	7
Document	appropriately document, keep, acknowledge, and cite sources.	12
Reflect	intentionally engage in a process of evaluating and improving their	8

	information literacy behaviors after completing a design project.	
--	---	--

Table IV-2 Example items for theorized factors

Factor	Example Item
Recognize	"It is my responsibility to identify what I need to learn in order to complete the design problem."
Locate	"I use the general information I find to help focus my search for more information."
Evaluate	"When I gather information, I consider the trustworthiness of the source."
Apply	"While reading an information source, I take notes of all my ideas of potential applications to the design problem."
Document	"As I find information, I keep track of where it came from."
Reflect	"I consider how I could synthesize information more efficiently."

After we wrote the base items, they were tested using a think-aloud activity of 10 undergraduate engineering students. Using a protocol derived from Czaja and Blair [16], students were asked to 'think-aloud' as they answered the questions. This process allowed for the identification of items that students had to reread, paused on, or did not understand. Items that were identified were revised prior to the third stage of work presented in this study which comprises a first quantitative test of the instrument structure.

B. Data Collection

The survey was distributed through two courses at a large Midwestern research institution during the fall semester of 2014 (2014-2015 Academic Year). The first course was a single section of a required first semester first year engineering class 'ENG'. The second course presented with the survey was 'TECH' the equivalent class in the College of Technology. All students in the 16 sections of the TECH course were given the opportunity to complete the survey. The potential sample size was 119 and approximately 600 for the ENG and TECH courses respectively.

In the ENG course, students completed the survey during class time while the TECH population completed the survey outside of class for a small amount of extra credit. Respondents completed the survey electronically. Instructions were presented to respondents once, at the beginning of the instrument. Demographics information was gathered after completion of the E-SAPPS component of instrument. Of the potential respondents, 525 completed the instrument.

1) Participants

The responding participants were generally representative of the overall potential population at the study institution. Of the 410 TECH respondents, 331 (81%) were male while 77 (19%) of respondents were female. Within the ENG population, the respondents were 26% female. Ethnically, the ENG data set

saw 75% of respondents self-identified as White, 18% as Asian, and 5% identified as underrepresented minorities. In the TECH data set, 70% of students self-identified as White, 16% as Asian, and 9% as underrepresented minorities. Finally, 84% of ENG respondents and 89% of TECH respondents reported English as their first language.

2) Data Cleaning

The responses and associated data were cleaned based on a modified versions of the LongString procedure described by Meade and Craig [17] and the time based criteria proposed by Wise and Kong [18]. Individual responses were flagged and removed from later analysis for failing one of two criteria: (1) All answers on a single page being identical (i.e. all of the first page responses are 2's), or (2) a response time of less than 4 minutes (e.g. shorter than feasible for valid individual responses). The cleaning was performed prior to correction of items designed as reverse scored. Overall, 159 responses were removed for the two noted reasons with 108 based on the response time criteria and 51 from the answer variance criteria.

The 366 responses remaining after cleaning are the data used for analysis in the remainder of the study. The responses contain 100 ENG and 266 TECH data points.

C. Methods of Analysis

This paper focuses on the second foundational aspect of assessment instruments, observation, as articulated by Netemeyer [14]. The prior qualitative work to develop theorized factors serves as the basis for the assessments. As noted in Douglas and Purzer [19], the use of the term cognition is not exactly appropriate for the case at hand, but the theorized factors and qualitative factors serve as effective analogues for our understanding of the underlying cognition or behavior that is being assessed. This paper's focus on the observation component makes it an appropriate place to apply methods that gather psychometric evidence on the instrument. Initial data processing and analysis were performed with Microsoft Excel while IBM JMP was used to calculate coefficient alpha, calculate bivariate correlations, and perform exploratory factor analysis (EFA)

Four methods of analysis were used to answer the research questions noted above. The first three methods serve as prerequisite work to prepare the instrument for EFA analysis as suggested by Fabrigar [20]. This preparatory work focused on improving the unidimensionality of the scale through removal of items that perform poorly. This unidimensionality refers to the underlying construct and focuses on ensuring that all items focus on a cohesive measurement of information literacy based on the underlying self-directed learning theory.

Within the focus on overarching unidimensionality of the *complete scale*, we also expect to see a multidimensional measurement of the information search process' *different stages*. The performance of individual items was assessed using three approaches. Descriptive statistics including the mean, standard deviation, minimum, and maximum, were

used to examine the general behavior of individual items including their center and response patterns. We examined descriptive statistics to ensure that items generally fell within an expected pattern of means and standard deviations and that no items established clear correct/incorrect answers. Second, the impact of individual items on the instrument's internal reliability was assessed using coefficient alpha. The E-SAPSS instrument presents an appropriate use of the coefficient alpha as detailed by Douglas and Purzer [19]. The coefficient alpha is a calculation of the degree of consistency between individual items within the instrument [21], [22]. An item whose inclusion lowers the alpha of the overall instrument may potentially be measuring something other than the main construct. Items whose inclusion lowers the overall alpha were removed from further analysis as suggested by [22]. The final technique applied prior to EFA was the assessment of inter-item correlations. A linear bivariate correlation was calculated for all individual item pairs. Using the theorized factors, items were grouped and compared to other items of the same theorized factor and direction. Items that did not correlate above a threshold (>0.30) with at least one other item within the theorized factor were removed [23]. Together, these techniques align with RQ2 and assess evidence of scale unidimensionality.

After the prerequisite work on individual items was performed, EFA techniques were applied to answer RQ1. EFA is a data-driven approach to examine the underlying factors represented in learners' responses. The main goal of factor analysis is to summarize the interrelationship among variables in a concise and accurate manner, for the purpose of aiding in conceptualization [24]. EFA was used to examine whether the data set supports the characterization of the items as members of the theorized factors. EFA provides evidence by which items that do not function *as intended* may be identified.

For this study, EFA was performed using best practices suggested by Fabrigar [23]. An oblique rotation method (Promax) was used to allow factors to be correlated. Oblique factor rotations are generally considered more appropriate for data in the psychological or educational realm [23, p. 281]. Scree plots were generated for all runs. Decisions on the appropriate number of factors were based on a combination of Scree plots for each analysis and the Eigen value greater than 1 (K1) rule. The maximum likelihood item fitting procedures was used for all runs because of its ability to provide significance testing of factor loading. The analysis was rerun after every change in the items included, details of which are documented in the results section

V. RESULTS

The results section presents the analysis of the instrument using the techniques detailed in the previous section. The analysis makes use of the 366 responses that remained after the data cleaning process discussed in section IV.B.2. Throughout, we will refer back to the theorized factors and their respective definitions that were noted in Table IVV-1.

A. Descriptive Statistics

We calculated descriptive statistics after the scoring of reverse written items was inverted to standardize the entire instrument. The mean score of responses to items ranged from 2.68 (item 59) to 4.18 (item 12) with the mean of all responses at 3.62 on the zero to five point Likert-like scale.

The descriptive statistics differed between items written as forward ($M=3.83$, $SD=0.76$) and reversed ($M=2.88$, $SD=0.98$) scored items, even after standardizing item scoring. The difference was highly statistically significant ($t(21.7)=8.86$, $p<.0001$) suggesting that respondents displayed a tendency to agree with items, a phenomenon commonly noted in psychometrics research [25]. The standard deviation of the forward items was also significantly lower ($t(39.3)=9.80$, $p<.0001$) than the standard deviation for reverse scored items. The highest item mean was found on item 12 ($M=4.26$, $SD=0.77$). No items were removed at this stage as all items were behaving within the expected range.

B. Coefficient Alpha

The value of Cronbach's Alpha for the entire instrument was 0.8950. A value for Cronbach's Alpha was then calculated that excluded each item. Alphas between 0.7 and 0.9 are considered good, while value above 0.9 considered excellent [26]. Two items were found to be decreasing the overall instrument reliability. We excluded those items, number 34 (excluded $\alpha=0.8957$) and 41 (excluded $\alpha=0.8954$), from further analysis. With the removal of those items, the data provides evidence that the instrument as a whole is functioning in a sufficiently unidimensional for continued analysis.

C. Bivariate Correlations

The items remaining after the Cronbach's Alpha analysis were used in an inter-item correlation test to gather evidence of unidimensional behavior within each of the theorized factors. The factors used for grouping were the same as those reported in Table IVV-1. Forward and reverse scored items were assessed separately. Four items were removed because they did not significantly correlate with other items in the same theorized factors.

After removing the four items, the remaining correlations between items in the different factors used for item construction was generally high. The average correlation between items of the same theorized factor ranged from 0.44 in the 'locate' factor to 0.59 in both the 'evaluate' and 'reflect' factor. A full cross tabulation of average correlations between items in theorized factors appears in Table V-1.

Table V-1 Avg. of Item Correlations Between Factors

Original Factor	Apply	Document	Evaluate	Locate	Recognize	Reflect
Apply	0.52	0.39	0.39	0.35	0.28	0.37
Document	0.39	0.55	0.39	0.33	0.29	0.36
Evaluate	0.39	0.39	0.59	0.38	0.30	0.37

Locate	0.35	0.33	0.38	0.44	0.31	0.34
Recognize	0.28	0.29	0.30	0.31	0.49	0.28
Reflect	0.37	0.36	0.37	0.34	0.28	0.59

D. Exploratory Factor Analysis

After the preparatory work described above, 63 items remained. This item set was used to perform an EFA analysis addressing RQ1. The EFA runs were performed iteratively with a single change made between runs to isolate individual impacts.

The initial EFA run was performed with the remaining 63 items included. This run identified a strong grouping of the reverse scored items to the same factor. This phenomenon mirrors the separation seen in the descriptive statistics and inter-item correlations between the forward and reverse scored items and has been noted in other psychometric research [27]. Based on this result, the reverse items were removed from subsequent EFA runs for separate treatment.

In the first runs, the nine factors had an Eigenvalue of greater than one (satisfying the K1 rule). However, a clear final drop, using the Scree plot rule, was seen after the fifth factor. Based on that information, a six-factor model was used. The resulting best-fit factor structure had multiple cross-loaded and non-loaded items. Those are items that loaded on more than one factor at a value greater than 0.3 or failed to load on any factor above 0.3 respectively. The EFA analysis was then repeated iteratively removing a single item at a time. The cross loaded items were removed first, followed by the no-loading items. The number of factors suggested by the K1 rule began to converge to that supported by the Scree method as the poorly performing items and single item factors disappeared. Overall, 10 EFA runs were performed.

The results of the final EFA analysis run on forward scored items only appears in

Table VI-1 on the following page. Most of the theorized factors, such as 'recognize' and 'reflect', clearly establish on single, isolated factors. All items from those two scales that were not removed during the EFA runs grouped together on a single factor, and no items from other factors loaded with them. Further, the loading of those items on the factor was quite strong ranging from 0.51-0.69 for the recognize items and 0.49-0.74 for the items on the reflect factor. The final EFA run maintained 38 items in a 6 factor model with no cross loading or unloaded items. This structure explains 77.53% of the overall variance in the data.

The final run items and loading were used to assess the naming and definition of the theorized factors. Generally, the theorized factors were appropriate. Of the 38 remaining items, 2 were realigned from one theorized factor to another final factor. Because EFA does not assert and test a hypothesis (as confirmatory factor analysis does), items are allowed to shift to the best fit factor. In this case, 2 items which were originally written as locate items factored with the application

items. The wording of the items, which suggests the application of prior knowledge to the process of locating information, presents a fine-grained understanding of the application of information to the information process. Based on their wording and EFA results, the 2 items were moved from the theorized to the EFA derived factor.

As a final check, Cronbach's alpha was calculated for the overall and each subscale using the remaining items. The Cronbach's alpha for complete set of remaining items was 0.9250, which is excellent [26]. Further, none of the remaining 38 items decreased the reliability of the scale. The Cronbach's alpha for the factors was 0.88 for Recognize, 0.87 for Reflect, 0.76 for Apply, 0.76 for Document, 0.66 for Seek, and 0.77 for Evaluation. While these are lower than the overall scale, they are sufficient for the subscales given the low number of observations on several of the factors.

VI. CONCLUSIONS AND DISCUSSION

The initial presentation of validity evidence for the E-SAPSS instrument was focused on testing the items and structure developed from qualitative interviews presented in prior work [3]. This study focused on the third step of scale development proposed by Netemeyer [14], conducting studies that aid in developing and refining the scale.

The items that were retained in this study represent a set of items from which future validity evidence can be built. Fabrigar [23] suggests four to five items per factor represent an appropriate number of items. Three of the theorized factors contain at least that many remaining items. In the case of the 'reflect' and 'recognize' scales those numbers are considerably higher (8 and 13 respectively). On other factors, notably 'Evaluate' and 'Locate' the number of items remaining from the original development pool is not sufficient to ensure reliability and representation of the factors and require development of further items to ensure appropriate redundancy.

Where a large number of items do exist, the 'best performing' items from the EFA procedure will be maintained as the representative variables that best measure unidimensional factors or substages of information literacy behavior in respondents as suggested by Fabrigar [20] and Netemeyer [14].

For the factors that did behave well, namely the recognize and reflect stages, evidence exists that these items can begin to be used as a measure of student's self-directed information search process. Other factors require caution and some revision or addition of items to ensure reliability of those components of the instrument. Work will also focus on validation of the reverse scored items that were removed from the EFA analysis. These steps represent the later, stage 4, components of the process for scale development suggested by Netemeyer [14].

The process of information literacy continues to be vitally important to the practice of engineering. The developments presented here continue the process of developing measures of student's self-directed processes. This improved measure is important to allow for educational interventions to effectively increase students' abilities in these areas.

A. Pedagogical Implications

We encourage readers to contact us for access to the improved instrument for use in their own information literacy educational efforts. The construction of instruments with documented evidence of validity and reliability is useful for helping instructors understand their students. This instrument presents a method of understanding students' personal views on their information literacy practices. Combined with other

methods of information literacy assessment (e.g., those presented by Oakleaf [10]) allow faculty to more deeply understand their students abilities to gather and use information, a skill critical lifelong learning and design.

This instrument may be used to explore what modern and classical components of effective information literacy students do or do not perform. Such understanding has the potential to allow more targeted educational interventions that, for example, target the ways in which students gather information in the age of google or document information in the age of Twitter. The stages and specific behaviors represent specific behaviors that manifest in student work, which can be tracked to understand the efficacy of such interventions for the improvement of classrooms and programs.

Table VI-1 Resulting forward item details and structure after EFA

Item #	Item Text	Recognize	Reflect	Apply	Document	Seek	Evaluation
5	I take time to think about what I need to learn in order to address the design problem.	0.50					
9	I seek feedback on my understanding of the design problem's constraints from an instructor or TA.	0.50					
7	I create a list of information I will need in order to address the design problem.	0.52					
14	It is my responsibility to identify what I need to learn in order to complete the design problem.	0.57					
15	I ask for feedback on my list of design criteria and constraints.	0.57					
12	I participate in group discussions to plan out project completion.	0.58					
3	I seek clarification of the design expectations.	0.59					
6	I collect information to become familiar with the concepts needed to carry out the task.	0.59					
4	I create an action plan for completing the design problem.	0.61					
8	I brainstorm information needed to complete the design problem.	0.63					
11	I talk with others to gather a variety of perspectives about the design problem.	0.64					
2	I identify constraints of the design problem.	0.66					
1	I identify what needs to be done to complete the design problem.	0.70					
63	I consider whether I utilized information appropriately.		0.52				
62	After I finished a design, I reflect on whether I found enough information.		0.57				
68	I consider how I could synthesize information more efficiently.		0.60				
69	I reflect on how to more effectively determine an information source's credibility.		0.62				
67	I consider how I could better organize information.		0.67				
64	I reflect on how I could improve my information search strategy.		0.73				
66	I consider what I could do to improve gathering information.		0.73				
65	I reflect on whether I understood what information was needed.		0.74				
43	I am open to changing my idea based on information found.			0.36			
47	When I read information related to my design project, I generate ideas.			0.45			
23	I use the general information I find to help focus my search for more information.			0.51			
48	I make design decisions based on the information I find.			0.52			
21	I relate information I find to my pre-existing knowledge.			0.55			
49	When I find new information, I incorporate it into my design.			0.62			
60	I am comfortable determining what information needs a citation from information that is common knowledge				0.32		
33	When presented with conflicting information, I critically review the evidence for each stance.				0.33		
50	When I give an oral presentation of the information, I acknowledge the source either verbally or in my slides				0.55		
54	I have a method of organizing my references.				0.56		
52	As I find information, I keep track of where it came from.				0.58		
51	When presenting information from a source, I use correct and complete citations.				0.75		
25	Once I find a reputable article that is relevant to my design, I look at the					0.41	

	reference list for more potential sources						
27	I compare information from different sources in an organized way.					0.44	
24	I know when to use different kinds of information (e.g. patents, standards, handbooks).					0.69	
36	When gathering information, I assess the accuracy of the information I find.						0.40
37	When I gather information, I consider the trustworthiness of the source.						0.96

Abstract—The role of anonymous assessment in ensuring fair and equitable outcomes for students has been one of the major tenets of educational reform over the last few decades [1]. One of the major goals of these efforts is to reduce the impact of subconscious discriminatory behaviour in assigning grades based on perceptions of ability of gender or minority groups by the examiner. Recently however research has been emerging which challenges the widespread assumptions about the benefits of anonymity drawn from Newstead's work. Contrary results include the work of Dorsey and Colliver, 1995, in medical education, and Batten et al. 2013, who explore the impact of student reputation on assessment. These and many other studies conclude that anonymous assessment resulted in no apparent changes in assessment outcomes. In this paper we explore the implications of anonymity taking examples from educational settings where student anonymity is already an adopted practice. We discuss the positive and negative implications of student anonymity, and identify areas for future research.

I. BACKGROUND

In many countries quality assurance processes place emphasis on the role of anonymous assessment in ensuring fair and equitable outcomes for students. The goal is to eliminate discrimination and other types of bias from the process of assessing or evaluating student knowledge and ability. Student anonymity has been identified in some contexts as an important mechanism for reducing systematic discrimination in assessment. The most influential study, resulting in widespread adoption of anonymous grading, is that of Dennis and Newstead, 1990 [1].

Following the introduction of anonymous written examinations, another body of research emerges which challenges the widespread assumptions about the benefits of anonymity resulting from Newstead's work. Results which challenge the impact of anonymity include the work of Dorsey and Colliver, 1995, in medical education, and Batten et al. 2013, who explore the impact of student reputation on assessment. These and many other studies [2] conclude that anonymous assessment resulted in no apparent changes in assessment outcomes.

The anonymous assessment movement is also in apparent conflict with simultaneous movements in pedagogy and didactics resulting from the trend towards student-centric learning, and continuous assessment. This trend emphasises (see for instance the work of Gibbs) the importance of seeing the

individual student, and providing multiple contexts for student-teacher interaction and dialogue. This appears to be in direct conflict with providing increased anonymity in assessment situations.

Anonymous assessment also results in a concomitantly increased administrative overhead, as has been observed in our own context (a Swedish Research 1 University), and has also been discussed by Gledhill in Higher Education Management (David Warner and David Palfreyman editors) as early as 1996. These overheads need to be weighed in terms of the cost/benefit proposition that introducing anonymous assessment represents.

In this paper we explore the implications of anonymity taking examples from an educational setting where nearly absolute student and teacher anonymity is already required as a result of cultural norms, for a significant proportion of students. Even though the degree of anonymity in this environment surpasses that which is usually discussed in relation to fair and equitable assessment in a Western context, we believe that these examples expose other implications of anonymity that should be considered in the current debate.

Drawing on interviews with teachers, and observational data gathered in anonymous teaching and learning situations by the authors, we build up a "thick description" through which to explore the range of positive and negative impacts that anonymity can have for both educational quality and student learning.

II. THE STUDY

This study explores some of the implications of student anonymity in higher education using qualitative data collected in an environment where student anonymity is nearly absolute. The environment has not been designed to achieve anonymity, but to fulfill other cultural and legal requirements. However, the resulting educational environment does provide almost complete student anonymity. The paper draws on the authors' personal observations and experiences, in the form of field notes, as well as interview data from two academic colleagues who spent approximately three weeks teaching in an environment where more than half the student cohort were completely anonymous.

The study uses the "thick description" technique to build up a nuanced picture of the anonymised character of the teaching

and learning situation. Using this as a background we draw on data collected in our discussions with teaching staff and students who are working in this environment to explore the impact of anonymity on the learning process and the attitudes of the participants.

“Thick description” is discussed by Ponterotto, 2006 [3] as a means to provide a rich context for the interpretation of actions and events.

“As emphasized by all the authors heretofore referenced in this Brief Note, a central component of “thick description” is the interpretation of what is being observed or witnessed. Denzin (1989) has made a major contribution to qualitative research by carefully showing the sequential link of “thick description” to “thick interpretation.” It is the qualitative researcher’s task to thickly describe social action, so that thick interpretations of the actions can be made, presented in written form, and made available to a wide audience of readers. Without “thick description,” “thick interpretation” is not possible. Without “thick interpretation,” written reports of research will lack credibility and resonance with the research community, the research participants themselves, and with the wider audience of readers for whom the report is intended (Ponterotto and Grieger, in press). It is the thick interpretive work of researchers that brings readers to an understanding of the social actions being reported upon.”

To provide the necessary context we first describe the teaching and learning situation in detail in the next section. In the subsequent discussion we use quotes from discussions and personal observations in a “thick interpretation” of the implications that anonymity can have for teachers and students.

III. TEACHING IN A GENDER SEPARATED ENVIRONMENT

The authors are teachers at a Swedish research university who have had the opportunity to visit a university in a Middle Eastern country frequently over a period of several years. The country is Islamic, and, in comparison to Sweden, religion plays an important role in the local culture and in peoples’ everyday lives. In the education, as well as in many other situations, the genders are separated. On the few occasions where men and women are at the same place, women wear black clothing that cover their entire body, including the face, so called abaya and niqab. When only women are present, however, they wear whatever they like. Since one of the authors is female, she has had the unique opportunity of being able to visit both male and female campuses and take part in activities both among men and women.

In the following discussion we present our observations and information gathered by talking to teachers and students working in the environment. We stress the fact that these observations are subject to our interpretation and therefore, necessarily, coloured by our own cultural background and experiences.

What might be the implications of teaching and learning in an environment where anonymity is enforced in the educational setting? In much of the Islamic world gender separation throughout higher education is the norm. In addition, due

to shortages of qualified female staff, a consequence of the gender separation is that female students are anonymous to male teachers in the regular classroom situation.

Male and female students are taught separately, in different campuses. The students that we have met have only encountered male lecturers. There are teaching assistants (TAs) of both genders, male students meet only male TAs and female students meet only female TAs. No men are allowed to enter the female campus, which is surrounded by a wall and the entrance is guarded to make sure that only women enter.

Male teachers teaching female classes lecture from a studio in a building outside the campus. Computers in the studio are connected to screens in the classroom and there are cameras in the studio, one directed toward the desk, used to display anything the teacher writes during the lecture, and one directed towards the teacher. The teachers that we have met choose not to use the second camera. One teacher explains this by saying that he perceives that he will be at a disadvantage if the students can recognize him if they should meet outside the teaching situation while he cannot recognize them.

Oral communication is possible, the teacher has a microphone on his desk and there is a microphone for the students in the classroom. Teachers tell us that it is hard to hear the students and that they have no idea about which student they are talking to. Most of the time, they either hear nothing from the class and wonder if there are any students present, or they hear a mumbling and wonder whether the students are paying attention to the lecture or discussing something else. Our observations inside the classroom reveal that classroom microphone is attached to the wall on one side of the room. This means that most of the students are sitting too far from the microphone to be heard clearly by the teacher.

A female member of staff accompanies the female students in the classroom. Her main responsibility is to make sure that the students are in the right room and that audio and video works. If teaching is not done in the students’ native language, the staff member sometimes translates words that the students struggle with or the students sometimes help each other with translations. This is one explanation for the mumbling that the teachers can hear. Another explanation is that keeping the students’ full attention for an entire lecture is a challenge even when you are in the room with them. When voice and slides are the teachers only tools, it is likely that the students do lose focus and talk about other things every once in a while.

In rare cases, when courses are given to a small class consisting of both male and female students, both genders are taught simultaneously with the male students in the studio with the male teacher. With that setting, it is easy for the men to get caught up in discussions where the invisible female students are forgotten.

IV. INTERVIEW

Two lecturers from our own university spent three weeks teaching in the environment. After their return we performed a semi-structured interview with them to find out how they had perceived teaching in the environment and in particular

how they perceived teaching anonymous and invisible students. They had taught a group of Master-level students in mathematics. The group consisted of 4 male and 8 female students. Teaching was in English, which is not the most common for the students, but passing a TOEFL-test was a requirement for admission. For the first course meeting, they were able to meet the students outside the campus, in the same room with only a screen separating the genders. That gave the teachers an opportunity to see the female students once, which is not common in the environment. The rest of the course was given at the female campus with the male students present in the studio. To communicate with the female students they used voice communication and a camera directed at the teachers desk, showing his hand, writing on paper. The notes were then made available to the students. The teachers describe that it felt bizarre to not see the students, but only know that they were there from the constant mumbling that he could hear. They told us that the female students differed from the male students in that they did not ask any questions.

V. DISCUSSION

Why is anonymity prized? Anonymity has been seen as a way to ameliorate the subjective nature of assessment. In essence, however, all assessment is through its very nature a judgement of how well a person performs in relation to defined criteria. The nature of these criteria vary significantly as a function of the complexity of the outcome under consideration.

Ways of viewing and valuing learning outcomes has been in reference to taxonomies. A number of taxonomies have been proposed as a means to reason about learning and learner development. Perhaps the best known of these is the Bloom taxonomy [4], which hypothesises an hierarchical structure of learner sophistication in relation to ability and learning outcomes. Another approach can be found in the SOLO taxonomy [5], which emphasises the interconnected nature of knowing, and relates learner processes and reasoning to the ability to contextualise and interrelate items in the conceptual ecology of the individual. Entwistle takes a third approach in his work on learning objects and conceptual change [6], where he distinguishes between learner's conceptions of knowledge, and approaches to knowledge acquisition. Figure 1 summarises Entwistle's model. Drawing on a large body of prior work, Entwistle theorises that conceptions of knowledge and strategies for learning are related, and form two dimensions of learner development. Learners progress from an initial understanding of knowledge as ability to recall facts, to a perception of knowledge as a philosophical position, that must be supported by argument and logic. Congruently, learning strategies develop from pure memorisation to encompass ability to reason about alternative solutions, and the realisation that the definition of an optimal solution depends on the context of the problem posed.

Regardless of the model chosen, it is clear that the complexity of making a judgement in relation to a type of learning increases as the learner develops, and as learning outcomes include higher order cognitive processes such as evaluation,

and synthesis. What observable phenomena provide assessors with evidence that a learner is performing high cognitive order activities? Inevitably questions of subjective judgement and interpretation arise in the dialogue between teachers, and also between teachers and students in the context of associating grades with learning processes and outcomes.

This type of argument leads often to a discussion of the subjective nature of assessment. A particularly sensitive topic is subjective judgement, which we define to mean judgements made on grounds other than those which can be associated with aspects of academic performance, and which can therefore be judged to be inappropriate and inequitable.

In many legal systems discrimination on the basis of ethnic background, race, religion, gender, and a range of other grounds has been specifically identified as unacceptable. This protection from discriminatory behaviour naturally also extends to professional judgement in the workplace, employment situations, and education, as well as a range of other areas, such as health care, legal systems. In Sweden this has become a part of the higher education dialogue, in particular a question for student associations.

What goals are identified by student groups? The major areas identified in recent publications aim to avoid bias based on the individual knowledge of the student, as well as eliminating systematic discrimination and protect examiners from accusations of favouritism and bullying. This approach allows students to challenge lecturers' opinions and give critical feedback without risking a negative impact on their final grade.

One reason for making assessment anonymous from the student union perspective is based on assumptions regarding the areas we identified above, in particular student groups identify a need to

allow students to challenge lecturers' opinions without risking effects on marking ¹. In this reasoning, there is an implicit assumption that the lecturer might be expected to disapprove of being challenged, or be threatened in their professional role, rather than appreciate the fact that a student might challenge the lecturer, giving strong arguments in doing so, thus providing evidence of high order cognitive order skills. In a setting where the lecturer is trusted to make a professional judgement, and continuous assessment is used, this evidence could be included as a positive element in the student's final grade.

In our example setting, however, the anonymous students rarely, if ever, participate in classroom discussions, and if they do, the lecturer is highly unlikely to know which student is making an argument, or if it is one student or many that are taking part in a discussion. The student's achievement is most likely lost in such a situation.

In our example setting, discrimination on the basis of gender is not avoided. In fact, all teachers we have talked to tell us that the (anonymous) female students are better than the male students, despite having never interacted with them in person.

¹One website that is relevant in this context is <http://services.su.nu/galway.ie/site/view/2545/>

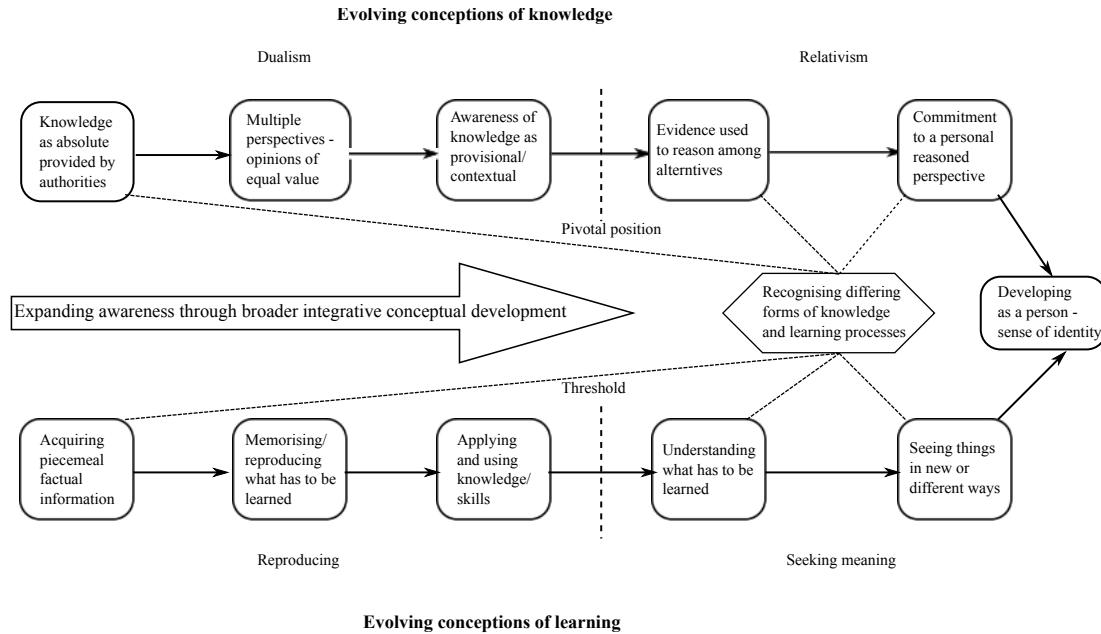

Fig. 1. Entwistle's integrative model of learner development

This suggests that in the anonymous setting, there may still be gender, or some other type of observational bias in the assessment process.

A difference between the male and female students that is reported by (especially among Swedish) teachers, is that female students don't ask as many questions and do not interact with the teacher as much as male students. An important part of engineering education is to achieve competencies necessary for professional engineers such as the ability to apply content knowledge in projects working with others, and presenting and discussing the topic of study [7], [8]. These competencies need to be practiced in the educational setting, but in our example setting, the anonymous students are separated both from discussions with teachers and with other student groups.

In conversations with the female students, they reveal that they do know what their male teachers look like on Facebook, but despite this, that they have a strong wish to see them in real life. They also express a desire to have female teachers, or to be able to interact with the teacher directly. In our interpretation, these students lack contact with a role model. Separation of student groups also entails that the students lack insight into what other students do and learn. We were able to let some female students see male students present course work and they expressed that they were surprised to see that the male students learned the same content as they did, even though the students were studying in the same year in the same study program.

One can argue that some of the problems we have high-

lighted above stem from other characteristics of the study context, and are not associated directly with anonymity. For example, that gender bias exists only because of the gender separation, even though the students are anonymous, the teacher knows their gender. However, it is easy for a teacher to get an idea (correct or not) regarding a student's gender by e.g., looking at their handwriting. Some of the problems related to isolation of the student group can be avoided in other cultural settings but achieving student anonymity in a teaching situation without separating the students from the teacher is not easily accomplished. Consequently, we believe that it is worthwhile considering these implications in any cultural setting.

VI. SUMMARY

The negative impact of large scale classes, and impersonal learning environments on the student learning experience has been well documented [9]. What is less broadly discussed is the tension between tailoring the learning experience to the individual, and constructively aligned student-centric learning and assessment, and an increasing pressure on universities to offer anonymous assessment, especially in relation to written examinations, but even in the context of essay marking in the humanities.

The experiences of learners and teachers in a nearly completely anonymous educational environment has been explored in the thick description which forms the core of this paper. Even though the degree of anonymity in the environment

surpasses that which is usually discussed in relation to fair and equitable assessment, the implications of anonymity revealed by these experiences are important to consider in the current debate. It is clear in the experience of teachers and learners as related there, that anonymity also presents many challenges. Interaction is reduced, ability to communicate is curtailed by the paucity of the facilitating technologies, and the considerable negative impact on the social dimensions of learning reduce student motivation and engagement.

We conclude that anonymity in assessment is difficult to reconcile with other student-centric, and continuous examination strategies. Naive approaches to achieving anonymity, such as separating teachers from students, clearly do not result in a system desirable to either teachers or students.

Trust and transparency lie at the core of the issue. The university teaching profession must reclaim its professionalism and reputation of impartiality. To do so we must strive to elucidate our learning goals, and assessment criteria in a manner that rebuilds student trust in the manner in which we judge and assess learning. Through such a strategy universities can circumvent the shortsighted attraction of anonymous assessment.

Abstract— This paper examines the use of reflections in engineering education. The paper provides a review of practices in engineering education, especially during the last century. It starts by reviewing the research and pedagogical approaches in utilization of reflections and various reflective activities in engineering education. Then the authors provide various perspectives regarding reflective activities. The first part of the paper establishes the case for featuring reflective activity in engineering education. The writers were a pairing of a committed reflective practitioner and a staunch disciple of Dewey. An alternative commentary is given by the third author.

Keywords—Reflections, Engineering Education, self-assessment, intramental

I. INTRODUCTION

Recently engineering researchers and educators have expressed renewed interest regarding the affordances of reflective activities and the role of reflections in engineering education. Since reflections have for some time been an established and practiced methodology for on-going professional development in many discipline areas, the current interest regarding engineering education is worthy of careful consideration. As engineering educators, it thus behoves us to carefully review current reflective practices in engineering and elsewhere in both higher education and continuing professional development.

Our paper opens by the first two authors' review of basic pedagogical writings about the role and potential of reflections and various reflective activities in tertiary education in general, and engineering education in particular. It points briefly to some of the noteworthy developments in various professional areas that, in our judgement, have been successfully using reflections as learning/evaluation/development tools in continuing professional development. The third author then provides an alternative perspective regarding reflective activities in general, with an examination of reflections and reflective activities and their validity in assessment/evaluation of student growth, education, critical thinking, and becoming lifelong learners.

II. REFLECTION AS THE ESSENCE OF HUMAN THINKING

The term and concept of "thinking" has a wide embrace. In the cognitive domain alone, thinking covers such mental

activities as analysis, problem-solving, the formulation of judgements, what is commonly called critical thinking, but might more helpfully be renamed reasoned thinking - and reflection. All of these, and more, are sub-sets of the overall sphere of "thinking" or cognition - as is metacognition, which is thinking about our thinking. [Cowan, 2006) [1]

Before discussing the role of reflections in engineering education, we should briefly define and describe cognitive reflection and what it entails, according to current usage. This meaning of the concept is of course far removed from the Internet dictionary definition of reflection, which can centre upon something that is bounced back at us, as is an image from a mirror. In contrast, Moon writes helpfully of reflection as "a common idea that has a variety of connotations"[2]. Drawing on the work of Dewey and of King and Kitchener (Dewey; King & Kitchener)[3-5], she proposes that cognitive reflection is:

"A form of mental processing with a purpose and/or an anticipated outcome that is applied to a relatively complicated or unstructured idea for which there is not an obvious solution."(Moon, 1999: p4) [2]

Moon echoes the words of John Dewey (almost a century earlier),

"one reflects in order to know whatever one wants to know, wherever a state of perplexity arises. The method of reflection is a three step process including problem definition, means-ends analysis, and generalization that are carried out with attitudes of open mindedness, responsibility and whole heartedness"

Cowan (2006)[1] has expressed this to his students in simplified terms by telling them that they will be reflecting when they pose a question whose answer, as yet unknown to them, should be useful to them - and when they immediately seek that answer. It is this sub-set of thinking with which our paper is concerned. This echoes the seminal writings of Dewey (1910, 1933) [3-4] who stressed a century ago that exemplary reflective thought distinctively originates in doubt, hesitation, perplexity or mental difficulty. It will then lead into searching, hunting, inquiring, and above all self-questioning to resolve doubt and dispose of perplexity. This will then be accompanied by motivation to apply the consequent learning to the enhancement of that practice (Hughes, 2009)[6]. Reflection

should thus first entail a searching interrogation of one's own experiences, to identify and resolving issues worthy of attention (Bourner, 2003)[7].

III. RECENT DEVELOPMENTS IN THE USE OF REFLECTION IN LEARNING

Reflection is nowadays well established as valued component of education and lifelong learning (Atman, and Turns, 2003[8], 2015[9], Jay and Johnson, 2002[10]; Davis[11], 2003; Cowan and Westwood, 2006[12]; Findlay et al.,[13] 2010; Moon, 2004[14]). Recently, University of Washington established the Consortium to Promote Reflection in Engineering Education (CPREE) that is led by Atman and Turns. The center is focusing on studying reflective practices in engineering education with the premise that reflection accelerates the learning that happens through experience, and so it is critical for preparing the next generation of engineers (Atman 2011)[9].

Thus the widely acclaimed suggestions in the keynote texts on reflection for learning (Schön, 1983[15]; Kolb, 1984[16]; Boud et al.,1985[17]) have been taken up for some time in educational programmes and schemes for professional development (Bourner, 2003[7]); Williams and Grudnoff, 2011[18]). Generally learners are encouraged to consider both past and impending actions, with a view to effecting future enhancement (Hatton and Smith, 1995[19]). The reflective process can commonly take place within a written, keyed or narrated reflective journal or blog within which writers engage with their learning experiences, and unearth their tacit knowing (Bickford and van Vleck, 1997 [20]) thus leading them to new insights, understandings and appreciation (Boud et al., 1985 [17]).

Many justifications for such practices have been advanced (McGarr and Moody, 2010[21]). Anecdotal claims of the benefits, issues and challenges associated with this aspect of self-directed learning have proliferated (O'Connell and Dymont, 2011[22]). Journal writing is said to increase the sense of ownership of learning, to acknowledge the role of emotion in learning and above all to encourage metacognition (Moon, 2004[14]; Samuels and Betts, 2007[23]; O'Connell and Dymont, 2011[22]). Journaling has been described as a bridge across which learners can move from the specific to the general, through developing a habit of reflection (Griffin, 2003)[24].

However it must be acknowledged that presentation of data-based evaluations of reflecting is sparse. Recent criticism of critical reflection has been helpfully summarized by Hickson (2011)[25]. Such critics have cautioned against the wave of euphoria, commending reflecting on experiences as a valuable component of constructivist learning through which learners construct understanding. Many publications virtually presume the effectiveness of reflective practice in developing meta-cognition (thinking about thinking), in promoting self-directed development, and in nurturing valuable abilities used in professional life (Moon,1999)[26]. Yet there are few rigorous evaluations of the effectiveness of reflective writing in achieving valued learning outcomes (White et al., 2006)[27], which omission does not of course necessarily imply that the

enthusiasts are deluded in what they believe reflection is achieving for their learners.

IV. THE POTENTIAL OF REFLECTIVE PRACTICE FOR ENGINEERING EDUCATION

Half a century ago, the principal demands that the world of employment made of engineering graduates were a knowledge and understanding of the properties and use of materials in an engineering context, together with ability to use certain fairly common methods of calculation to support the processes of analysis and design. The situation has changed. The on-going explosion of knowledge is such that the half-life of a curriculum in electronic engineering education has been put at two years. Additionally, the Internet, through effective use of search engines, can readily provide more information and advice than any single graduate mind could hope to store and recall. Sophisticated programs and apps carry out calculations whose basis would be beyond the grasp of the graduates who comfortably employ them. Hence the principal demands on the graduates of today and tomorrow are to develop and exercise higher-level abilities - in conceiving designs and solutions to problems, in exercising oversight over computerised data and productions, in relating to customers, clients and colleagues in hectic workaday situations, and above all in exercising informed self-evaluation leading into further professional development.

We therefore make an important distinction here between learning and development. We take learning to describe the grasp and mastery of concepts and subject matter, such that, in respect of the certain "learning", when an acceptable cognitive outcome that is provided in assessment by one individual, it will be similar to that from another. For example, explaining the meaning and relevance of "entropy" will cover common ground for most competent learners. In contrast we take development to describe improvement in an ability, which may be cognitive, interpersonal or affective. The ability can be applied in situations where assessors may agree on the nature of the demand and the outcomes of a successful performance; but how that performance is successfully achieved through exercise of the ability in question is likely to be highly personalised. An example is problem-solving, where assessors may agree that a problem has been adequately solved by someone, but will generally only have a vague notion of the intermental and intramental thought processes that led to that outcome - a distinction which it may now help to clarify.

V. INTERMENTAL AND INTRAMENTAL THINKING IN DEVELOPMENT

Vygotsky[28] saw learning as a social process in which communication between people is essential. He maintained that productive thinking has its beginnings in the social plane (*between* people engaged together in activity), and is later internalised *within* the learner, on their individual plane. Hence it progresses through an 'intermental' activity to 'intramental' consolidation. The ultimate internalisation depends upon reflection in personal terms. For intramental thinking, by definition and in practice, occurs within an individual's mind. While interaction with others contributes to our mental processes, our eventual generation of an innovative solution to a problem, our noticing of a weakness in a reasoned argument,

our empathy for the declared difficulties of another, our discernment of the attitude behind a particular comment and way of speaking, and above all our development of an ability, all entail much which is essentially intramental in nature. This is prompted by reflective and formative self-evaluation and forward planning, embodying Dewey's frequently neglected principle of the active experimentation that further refines our generalised and still speculative thinking (Cowan 2012)[29].

VI. FACILITATING REFLECTIVE DEVELOPMENT

At times, the vagueness and strangeness of what reflection is creates problems for engineering educators. Typically engineering faculty are used to making judgements of learning based on tests, quizzes, laboratory reports, different forms of examination and formal report writings. These call for a range of responses, from direct return of learnt knowledge and understanding, to the open-ended use of understanding in response to creative challenges. Nurturing and judging learners' competence becomes more and more difficult. As the hoped-for learning outcomes progress to higher taxonomic levels, featuring demanding mental abilities, then nurturing and judging learners' competence becomes more and more difficult. This is understandable. For reflection in particular, it is no easy task to develop or assess the vital (self-) questioning ability.

Postman and Weingartner (1971)[30], echoed Dewey (1910)[4] in maintaining that the most important intellectual ability for humans to develop is the art and science of asking questions. They valued those who perceived and posed searching questions, much more than they venerated those with a rich store of book knowledge. For

'Here is the point; once you have learnt how to ask questions – relevant and appropriate and substantial questions – you have learned how to learn and no one can keep you from learning what you want and need to know' (Postman and Weingartner, 1971: p34)[30].

Furthermore, reflection in particular can come in many ways, and can feature as parts of tests, quizzes and all student activities. Historically, however, reflective practices have been popular in many circles of thoughts, educations (learning and teaching) and even faith based practices. [31]

Reflections probe the ways we think, imagine, verbalize, and depict "what is going in our thoughts!" They are connected to our cognitive process, value systems, thinking circles, imagination, experience, verbal abilities, memory management, and all cognitive connectivity that defines us. When a scientist conducts an experiment or when an engineer tests something, they take "notes" on the data, their thoughts, their observations, and even at times on "what and how they felt". Those are true observations. However, even the best scientific notebooks and observations can be considered biased by our knowledge and belief structure. These notes can feed our reflections, which should be (are) a part of organized process of our engaging and visualizing our critical thinking capabilities. They are the cyclic process of inquiries that develop our "holistic self". However, even the best scientific notebooks and observations can be considered biased by our knowledge and belief structure. At times they can also

be tainted with our feelings and emotional context. They reveal how we develop ideas, how we interact, think, and perceive the world. Reflections, consequently, can be valid avenues into the status and level of maturity of our critical thinking capabilities.

From our pragmatic approaches and experience, we have seen how the utilization of reflection can help engineering students focus more critically on probing what they know, what they think, what they feel and what they can do. Consequently, reflecting can help them explore their holistic approach to the subject at hand. Experience and research shows that when students practice personal as well as group reflections, they critically examine their thoughts, their beliefs, and disbeliefs and they re-examine their approach to problems.

VII. REFLECTION AS A VEHICLE OF SELF-EXPLORATION AND EXPRESSION

There are two interesting practices that have appeared in engineering and sciences. In these fields many concepts are represented in equations. Good examples include Maxwell's equation for Electromagnetism, Bernoulli's equation, the continuity equation that appears with slightly different forms in different engineering fields. These equations are pictorial symbols of many connected and complicated concepts. One of the interesting reflective practices (that frequently features in PhD oral examinations) is to ask a person to describe, in their own words: "What does this equation mean?" Answering such questions helps the student to examine his or her understanding of major concepts and connections, as well as his or her technical and active vocabulary and communication capabilities. The words, the verbalization, expression, and description bring about a more in-depth critical connections in their mind.

A second useful practice is the process that every educator has experienced for themselves when the process of teaching, explaining and presenting make them question more, think deeper into something, and examine the subject and all connections more critically. That is why we all believe "the best way to know something in depth is to teach it." We always encourage students to create their own lecture summaries of the main concepts of each section and each class. That process helps them carefully examine their knowledge, related to the meaning and connections of the equations and subject interconnections of the field.

VIII. REFLECTION LEADING THROUGH SELF-ASSESSMENT TO IMPROVEMENT

When reflecting, and examining our knowledge, our inner belief systems and the interconnections of our thoughts, basics, applications and facts, we have an opportunity to reflectively seek answers to such questions as:

1. How fluent are we with the basic terminology and assumptions?
2. How well do we know the subject as a whole?
3. How well do we know the connections of the subject to other fields?

4. How well do we know the ways to apply ideas based on the subject?
5. How capable are we to synthesise our knowledge, and created designs and focus on the practical aspects of the knowledge?

The process of inquiry (into our own knowledge), and verbalization (constituting the ease and fluency in a subject) help us know what we need to work on, what we need to connect, and what we need to change. When such self-evaluative reflection is done honestly, openly, realistically, bravely and clearly, it can accelerate one's self-assessment and help one design ways for improvement, growth, and meaningful change.

IX. INTEGRATING REFLECTIVE ACTIVITY INTO AN ENGINEERING CURRICULUM

Over 35 years have elapsed since student centred learning with a concentration on individual ability development was first established on a significant scale in engineering - in Canada by Woods [32] and in Scotland by Cowan. Since it is our view that the development of reflection and metacognition are facilitated and not taught, the distinction between directive teaching and facilitative tutoring is thought important for the subject matter of this paper. Cowan's innovations, even or especially at first year level, emphasised metacognition - thinking about thinking - as well as self-assessment and the facilitation of reflective practice centred on the development of abilities of professional relevance. He promoted a regular discipline of facilitated weekly reflection-on-action in relation to the development of abilities, as the means of nurturing the intramental heart of the exercise of constructive self-assessment and insightful metacognition. At the close of each academic term, learners critically reviewed the evidence of their journaling, and formulated a self-assessed claim of their professional development. At the end of the first academic year, one student (of average ability) wrote when introducing his claim for substantial development through reflection:

"Now, when I'm working at home at my desk, it's maybe fanciful, but I often feel as if a ghost has come out of me, and is looking over my shoulder at what I'm doing, offering useful comments and suggestions."

He was describing how he thought usefully about his thinking - even if he did not know he was engaging in metacognition. He went on:

"And, even more weird, sometimes it's as if another ghost has come out of the first ghost, and is offering comments and suggestions to the first ghost about how to advise me."

This first year student had discovered and practiced meta-meta-cognition - in his own words! He had never heard of the concept, nor had he encountered Pask's thinking on this topic [33]. His claim for development epitomised the potential of reflection for development of abilities, and its relationship to intramental metacognition.

We were heartened recently to encounter an independent initiative in engineering education in an Irish university, where reflection-on-learning informs the preparation and presentation

of evidence-based reflective self-assessment claims in regard to development and use of what learners had identified as key abilities. In the same setting, students are to be encouraged to engage in reflection-for-action as they prepare to engage in the next problem solving to be featured in their undergraduate project work. It is these innovators' hope that their increasingly metacognitive students may constructively contribute to the action researching and formative evaluation of these developments. This example indicates for us one way ahead that is currently being purposefully explored in engineering education west of the Atlantic.

We consequently see development of key professional abilities as even more important today and for the future than fifty years ago. In the interim, however, reflective practice has progressed in many professional areas. Hence any question asking what an engineering educator should be doing now in regard to promoting and using reflection should have a revised and enhanced focus, appropriate to this decade of this century.

X. IS REFLECTION EFFECTIVE AS A COMPONENT OF AN ENGINEERING PROGRAM?

While this paper was being finalised, Cowan found himself drawn into communication with a pair of Irish academics who were teaching undergraduate engineers and architects, and trying to put into practice some of the notions in *On Becoming an Innovative University Teacher* (Cowan, 2006). At that point in their program, the students had been asked to draw together their reflective reviews on the various elements in the program. Cowan volunteered himself into position as a supportive online tutor, to assist students (if they so wished) to refine their draft claims for the learning and development which featured for them in their program experience.

In the exchanges which ensued, Cowan noted:

- The commendable and almost universal concentration on generic and transferable abilities, rather than the (common in other engineering programs) focus on very specific learning;
- The tendency to simply state claims for learning and development, rather than to set out data or reasoning in support of such claims;
- The responses, when this weakness was pointed out, in the form of amplification in which the key role of metacognitive and hence transferable thinking and analysis had often prevailed in the students' reflections and in their self-directed pursuit of enhancement;
- The interest of a few of these students, during communication which overlapped with preparation for examinations, to engage in reflective pursuit of issues arising for them from the messaging.

Cowan formed a strong and somewhat informed impression of a cohort of engineers and architects on whom a program

featuring reflective review had had a strong impact in terms of effectiveness in developing generic abilities.

XI. PERSPECTIVES ON REFLECTION: A COMMENT BY JOHN HEYWOOD

Reflection is a term that is a terminological inexactitude. While the development of skill in reflection is advocated as a goal of higher education, it is not always clear what teachers understand by the concept. It takes its meaning from the person using it and is, therefore, context dependent. For some it is used in the sense of “review” that is a formal or informal review of the past in some context or another. In engineering it is sometimes caused by a review of something that has failed, particularly when numbers of individuals have been killed. At other times it is used by designers evaluatively of machines when they ask- “what could I have done to improve its performance?” Or, “Given the same opportunity would I approach the design differently?” Those who write about reflection often fail to mention the context of the “self” yet we spend much time thinking about ourselves and what we would have done differently about large and small things. Reflection, or *thinking* as I would prefer to call it, contributes to our feeling of being and it can range from dealing with mechanical issues at one end of the spectrum, and at the other end to matters relating to the spirit. It is something that we cannot help doing: it easily tips over into neurotic introversion for by its very nature it is an introverted activity. A balanced person balances it with some extraverted activity. Clearly it is an activity in which we learn and for this reason many educators believe that our reflective skills can be improved: therefore, we can be trained to reflect. If that is correct then such training will be for a particular context.

Professional education provides two quite different contexts for reflection one of which is totally neglected. It relates to the questions that drive our continuous state of reflection namely – Who am I? What is (are) my purpose(s)? Who is it I want to be? And so on. It is answers to such questions that drive our being, or give us the will to live or as we are becoming more aware not to live. It is evident that some reflection can be harmful. It is equally evident that an education system that does not help “normal” students to answer such questions is failing in its duties. Thus it is that questions about the aims of education become important, and we can only understand the role of reflection when we have a grasp of what it is we believe education should aim to do. Many of the current problems of higher education stem from a complete failure since the end of the second world-war to discuss the aims of education or to assume that no discussion was necessary since they were economic and utilitarian. Yet it is clear that this does not resolve the issue relating to the fundamental questions posed a few sentences above. A liberal education is the only approach that has any conceivable chance of answering such questions, but in current views of the engineering curriculum there is no room for such study. How can a person be expected to develop in the educational context without an education that is liberal? It is only through

a liberal education that a person has a hope of learning about him/herself and the others with whom he lives. It may be argued, and is argued, that such learning is simply obtained from living and that education has little to add to a person’s understanding of living.

The second use of reflection relates to method – in this case the method of engineering.

“A method is a normative pattern of recurrent and related operations yielding cumulative and progressive results. There is a method, then, where there distinct operations, where each question is related to the others, where the set of relations forms a pattern, where the pattern is described as the right way of doing the job, where the operations in accord with the pattern may be repeated indefinitely, where the fruits of such repetition are not repetitious, but cumulative and progressive” (Lonergan, 1971)[34].

Such a pattern is the design process which is a holistic process that relies on particular *operations*, as for example “formulating”, “conceiving”, “deciding” (between alternatives), “marshalling and weighing evidence”, “judging”, “reflecting” and “evaluating”. Some authorities base their assessment schemes on linear models, and the analysis of data of some of these schemes shows that students have particular difficulty formulating problems, in establishing realistic as opposed to nonsensical judgments, and in evaluating their products. There is pretty clear evidence that they can be trained in the short run to perform better in each of these areas, in particular through the use of examples. Evaluating a product that one has designed is also called self-assessment, and some consider it to be a reflective activity. If that is the case some training can be given in reflection, but we will have little idea of what is learnt in relation to the use of the skill in a situation where transfer at a distance (a problem of an entirely different kind) is required.

It seems pretty evident that if a person is to learn these skills for use in design that they need to undertake individual projects in order to develop these skills. It is evident that team projects cannot guarantee learning of these particular skills and that the neglect of individual projects in curricular seriously limits the development of reflective skill in engineering. Just as the development of the other operations is supportive of the skill of evaluation (reflection) so is that skill supportive of the development of the other operations. It is concluded that different learning approaches contribute to the development of different operations of which reflection is one.

XII. FINAL REMARKS

This paper started by reviewing the research and pedagogical approaches in utilization of reflections and various reflective activities in engineering education. Two of the authors provided a critical approach of utilization of

reflections in engineering education from the perspectives of John Dewey and some of the recent engineering educators with more pragmatic inclination in engineering pedagogy. To provide an alternative critical approach, one of the authors provided other perspectives into reflections and their use and meaning in engineering education, and provides practical and important questions and thoughts.

Abstract— The current stage of study covers past 5 years of IL education research focusing on undergraduate engineering students. The first observations have risen a question: Could effective IL education improve students' skills to formulate their research problems? This paper is part of a study which aims to find ways to improve students' research skills based on the development in their information retrieval mindset. Tentative analyses have been made of 111 questionnaires and 36 seminar papers. At the current stage, observations deal with two different types of student groups. One group consists mostly of freshmen and the other group is close to their graduation.

Keywords—*information literacy; research skills ;undergraduate students*

I. INTRODUCTION

Information literacy (IL) means the ability to find, use, and evaluate source material used in various assignments. The concept was first presented in the ACRL international IL competency standards [1]. Internet has changed the role and availability of open information sources. Banks [2] argues, that instead of being cautious about using information found in the open web, information users need to learn to analyze critically the retrieved information. Tingting Liu and Haibin Sun [3] conclude that IL also helps users apply information to solve problems creatively.

Johnston and Webber discuss how American and Australian views of IL differ [4]. American standards focus on outcomes and IL is seen as a "cluster of abilities", while the Australian framework focuses on generic skills, information skills and values and beliefs. Moreover, cultural differences in understanding IL exist even within the same institution. Wilkinson and Bruch present how barriers like the academic culture need to be crossed to build an effective and sustainable IL education program [5].

In universities, IL education has been given to students using four different approaches. According to Wang [6], IL education can be offered as a course outside of academic curriculum, as a session add-in to an academic course, integrated into a course, or as an independent course within academic curricula. While some authors consider IL as an integral and indispensable part of faculty courses, others prefer to see it as an independent discipline [4]. In this paper,

integrating IL education into substance teaching means close cooperation of the faculty teacher and the information specialist so that both have at least basic knowledge of each other's discipline.

Libraries struggle with resource problems. According to Borrelli, Johnson and Cummings, IL instruction in most academic libraries suffers from lack of librarians who would be able to provide meaningful instruction to large student populations [7]. However, even with limited resources carefully planned IL education can give good results [8]. Locknar [9] introduces the Discovering Scientific Information Program (DSIP) which successfully aimed at saving both the faculty teacher's and the librarian's time.

Research on the learning results of IL education in higher education units has mainly studied improved searching skills and changes in students' searching behavior. Kari and Savolainen [10] have, however, studied the connections between information use and the learning process. Students' research skills are hardly covered in literature. If they are, the concept means how to find information and how to understand the process of using information and evaluating the content of it [11, 12].

Modern technological problems have a multidisciplinary nature. This requires advanced skills to find appropriate literature to formulate and solve these problems. This paper presents two cases in which students study production processes and their environmental impacts in connection with certain products. Similar interdisciplinary outreaches have been presented in literature. Vanasupa [13] presents a pattern in which they utilize a modified team based learning structure combining disciplines like nanotechnology, biology, and ethics. Moreover, Locknar and her colleagues [9] have succeeded in their DSIP program for first-year students. In this program, teaching and learning laboratory staff cooperate with a librarian. The aim of the program, in addition to saving teaching resources, is to explore the nature of scholarly literature and the processes and skills needed to search information successfully.

II. BACKGROUND

At Lappeenranta University of Technology (LUT), IL education is integrated into faculty courses. IL instruction is

given by professional information specialists. As in many institutions, teaching resources are limited both in the library and in faculties. Therefore, it is necessary to make the most of the teaching sessions.

IL education at LUT is based on the ACRL international IL standards and national recommendations given by the Information Literacy Network of Finnish University Libraries in 2004 [14] and revised in 2013 [15]. The emphasis is on the education given as part of the Bachelor's seminars. In addition to these, teachers sometimes ask academic librarians to teach their students how to retrieve information for their assignment on courses which require individual information searching.

During the past years, the effects and performance of IL education have been studied at LUT. The results have shown that students struggled with huge numbers of retrieved references and have big problems in finding search words [16]. Recently, the question of the benefits of IL education to students has become a wider issue in LUT research. The main interest has been on the development of students' research skills, meaning, in our case, how they interpret their research problem and turn into a search query, what the quality of referred sources is, and how they utilize the found information. A pilot study was conducted in 2013 [17]. The results showed that IL education has a positive effect on students' information searching behavior and on their ability to do scientific research. One of the key findings was, that after the information literacy instruction (ILI), search queries and the quality of found and used sources improved. Students also handled the subjects more deeply and understood better how to turn their research problem into the process of information retrieval and use [8]. The results of the pilot study had to be verified by a full-scale research. This paper presents findings of the full-scale research project carried out during the academic year 2014-2015.

III. RESEARCH SETTING

This research involved undergraduate engineering students, two information specialists, and two faculty teachers. ILI was given by information specialists and faculty teachers were responsible of their courses into which ILI was integrated.

A. Student groups and their research tasks

Two groups of students were studied. Group of 'Course A' was Master's level students studying 'Selection criteria of construction materials' and 'Course B' mainly (64 per cent) first-year students taking 'The basic course in environmental technology'. Students were divided randomly into the research group that attended ILI and the comparison group that did not attend it.

Student teams wrote seminar papers on given topics. Course A aimed at finding solutions to material selection problems of certain mechanical engineering products focusing in green manufacturing and environment protection. Teams were also supposed to determine their research problem and use literature review as their research method. Course B students' assignments dealt with common consumer products. Using literature, they were to identify environmental aspects in different product life cycle stages, evaluate the significance of various factors and environmental impacts, and suggest

methods for managing them. The research objectives were thus given to the Course B students.

B. IL instruction

To the research groups, ILI was given before students started information searching. The content of ILI followed a set pattern to cover the learning goals of the national recommendations [14] [15]. The topics included characteristics of different information sources, selecting information sources and search words, combining search words, using the e-material portal (Nelli), demos of searching in ProQuest, Science Direct, and Scopus, using the analyzing tool of Scopus, and the meaning of impact factors in Journal Citation Reports (JCR).

Instead of instructing how to use individual databases, emphasis was on teaching information retrieval principles in scientific work and on understanding the information retrieval problem as part of the research problem. The ILI content followed different scientific aspects such as objectivity, critical evaluation, openness of sources, repeatability, and self-repairing.

Using an online survey tool (Webropol), all students were asked about their searching plans before dividing them into research and comparison groups. Another questionnaire was given to Course A students after the lecture to find out possible changes in their information searching mindset. Both Course A and B research group students answered the last questionnaire after the hands-on training session (Course A) / joint lecture and hands-on training (Course B).

C. Faculty teaching

On Course A, emphasis was on solving cross-technological material selection tasks using systematical and analytical approaches. The faculty teacher had concentrated on six main material groups, namely metallic materials, polymers, ceramics, composites, adaptive and nanomaterials, and 54 sub-groups.

Course B top issues were the most significant challenges related to environmental protection from industrial activities and communities, typical management tools of environmental problems, and terminology of environmental engineering. They also learned to understand how other fields of engineering are connected with environmental engineering.

IV. RESEARCH RESULTS

Students' search word use was studied before and after ILI. The results were compared with the appearance of keywords related to the main topics of faculty teaching. The research problems expressed before ILI and those in the seminar papers were also studied and results of IL educated and non-IL educated teams were compared.

A. Search words

Search words that students planned to use and what they eventually used in their searches developed greatly after ILI. At first they mainly planned to use single words. On Course A the use of single words decreased to 1/6 (from 62.5 to 10 per cent) and combining words with Boolean operators (AND, OR,

NOT) increased over four times (from 18.75 to 80 per cent) compared with the initial situation. Course B students' results were parallel to Course A results. Both groups had also learned the idea of truncating words to include possible plurals and endings of words in their searches.

In Course A papers, the appearance of eight keywords (e.g. material selection based on "wear" or "corrosion") describing the main content of the course was calculated. It was found that students concentrated mostly on classical construction materials (metallic materials, polymers, ceramics, composites). Adaptive and nanomaterials were mentioned less. The same grouping could be seen in the way they used search words. In Course B papers 16 keywords (e.g. life cycle assessment based on "sustainability" or "environmental impact") were studied.

The numbers of words representing the observed topics was higher in the research group's papers compared to those of the comparison group's papers. In case of Course A, the differences were statistically significant while in the Course B papers the differences were not equally notable. The class level may explain the variation. Observations of the appearance of the same keywords in the reference lists gave parallel results. The results are shown in Table 1.

TABLE I. APPEARANCE OF TOPICS IN SEMINAR PAPERS

Average number of observed words representing substance topics		
	Research group	Comparison group
Course A, text	189.8	119.8
Course B, text	66.1	58.5
Course A, references	11.4	2.8
Course B, references	9.1	6.9

B. Development of research problem description

Before ILI all Course A students were asked to formulate their research problem. At first, most of the students either had no idea of what a research problem was or they presented the title of the paper or the given task as a research problem. The answers can be seen in Table 2.

TABLE II. ABILITY TO DETERMINE RESEARCH PROBLEM, COURSE A

Ability to determine research problem, before IL instruction	
Classification of research problem	Percentage of students
No idea what 'research problem' means	16
Title of the paper	42
Presented as a task	29
Fuzzy idea of the research problem	3
Clear research problem	10

Seminar papers of Course A were observed to study students' research understanding. Both groups recognized nearly equally that they are making research and differences in their research problem formulations hardly existed. However, the fact that in both groups there were teams that did not understand literature review as a tool to solve their problem was surprising. Final grades of teams that have not understood

literature review as a research method were lower than those of teams that recognize literature review as a research method.

Descriptions of research problems were also observed in the seminar papers. As shown in Table 3, the research group was able to present their research problem more clearly and more reasonably (80 per cent of teams) than the comparison group (25 per cent).

However, one very unclear description of the research problem was discovered in the paper of a team that attended ILI. Therefore we can assume, that variations in these results can be explained also partly by team dynamics and different background knowledge of team members. Team dynamics was visible in two ways: firstly the substance teacher was able to observe the teams' working practices and interaction between team members during ten weekly meetings and secondly some remarks about insufficient team dynamics could be found in the feedback report of the course. Differences in background knowledge were evaluated by the substance teacher based on students' study reports. Moreover, cultural and previous IL knowledge differences as well as diverse educational backgrounds possibly affect the results. According to these findings, faculty teaching seems to have more influence on research problem formulation than IL education does. Grade-wise the overall quality of the IL educated teams' papers was higher than that of the comparison group. The grade average of the research group is one unit higher than that of the comparison group. Results are presented in Table 3.

Parallel results can be seen in Course B papers although the academic level of the work is more elementary. The faculty teacher evaluated the way students used references and the value of referred sources. The score from the use of references accounted for a maximum of 17 per cent of the maximum total score of the team assignment. The score given for the use of references strongly correlated (99.6 per cent) with the overall grade which was given for the assignment. Participation in the IL education and the students' score for the use of references showed a weak positive correlation (7.3 per cent). Results are collected in Table 4.

TABLE III. RESEARCH PROBLEM AND OTHER INDICATIONS OF UNDERSTANDING THE TASK

Seminar paper, Course A, faculty teacher's evaluation			
Teacher's comments		Research group, 5 teams Percentage	Comparison group, 4 teams Percentage
Team has recognized that they are making a research.		60	75
Literature review recognized as a tool to solve the problem	commented and clearly recognized as a tool to solve the research problem	40	50
	mentioned but not as the research method	20	25
	not commented at all	40	25
Research problem and goal description	described clearly	40	25
	described reasonably	40	0
	not clear	20	75
Grade average, max 5		4.1	3.2

The assignments were graded without considering which students had attended IL education. Table 5 shows marginal differences in the total score of the assignment and the final grade of the course between all students together, those student who had not attended the IL education and those students who had attended the IL education. However, both the total score of the assignment and the final grade were better for the IL education students. The biggest difference was in the score of references in the assignment.

TABLE IV. COMPARISON OF GRADES OF COURSE B

Course B scores of seminar papers	Average, all 106 students	Average, 84 students not participating IL	Average, 22 students participating IL
Total score, max. 30 points	25.87	25.64	26.77
Score of the use of references, max. 5 points	3.65	3.49	4.23
Final grade, max 5	3.04	3.01	3.14

In Course B there were students from all class levels of LUT although the major part was first-year students. In each research group team there were 1 to 4 students that attended IL education. There were also students from different faculties attending this course. The class level did not show any significant correlation with the scores given for the use of references in the written report. Respectively, the proportion of those students who had attended the IL education in a team did not show a significant correlation with the scores given to the team. Neither could the field of study reliably explain any variation in the scores of students.

C. Classification of references

Course A teams who attended IL education used nearly twice as much academic references than teams that did not participate in it. On the contrary, research group teams used open web sources much less than the comparison group teams. The average number of references in the research group teams' reports was 23 while the comparison group listed an average of 26.5 references. This is presented in Table 5.

TABLE V. CLASSIFICATION OF REFERENCES

Classification of references, per cent of all referred sources				
	Course A		Course B	
	Research group	Comparison group	Research group	Comparison group
Academic sources	38	20	22	4
Open web sources	23	44	53	65
Average number of references	23	26.5	20.3	15.6

In case of Course B, research group used significantly more academic sources than comparison group. All teams used a lot of open web sources but the research group, however, used them less than the comparison group.

The average number of references in case of Course B research group teams was greater compared with the

comparison group as shown in Table 5. However, teams that had (one or more) students attending ILI had less references in their reference list in 56 per cent of cases compared with the teams which studied the life cycle of the same product and did not have any students attending the ILI. IL education may have affected the quality of the references and more information was gained from fewer references.

V. CONCLUSION

According to this interdisciplinary research, there are signs that IL education has, in addition to improved searching skills, some positive effects on undergraduate engineering students' research behavior and ability to write research papers.

Connection between the formulation of the research problem and the selected search words cannot be explained with a simple correlation of a relationship. Apparently, IL education does not solve the problem of limited knowledge of research methods and methodologies. However, IL educated students expressed more clear research problems than the comparison group students.

There are many factors other than IL education that have an impact on students' ability to formulate their research problem and research questions. Faculty teaching plays a key role in educating students to work in a scientific way. In this paper collaborating student teams' work was studied. It became obvious that e.g. team dynamics and different discipline knowledge backgrounds or former IL skills of individual team members have a considerable influence on the final result. Moreover, especially when students use other languages than their own mother tongue, their language and academic writing skills have a great influence on the final result.

A big challenge is to separate the students' own thoughts and ideas from the guidelines of seminar assignments given by the teacher and from IL education aspects.

Students tend to work as little as possible for a grade that satisfies them. Therefore, the time and effort students put to the assignments may sometimes be inadequate to gain a deep insight into the topic. IL education, at its best, can give students wider perspectives to their topic while it, at the same time, helps them find information more efficiently and thus save their time.

In its initial form, IL education gives students tools to find high quality information. However, the IL teachers face a challenge that they put too much emphasis on the scientific value of retrieved sources. According to the faculty teachers, the application in question determines the relevance of sources which can be high regardless of their scientific level. Even commercial documents can be highly relevant as well as interviews, emails etc. Both IL and faculty education should have a common goal: students need to learn to discuss the topic via referred sources.

Both of the faculty teachers involved in this research seemed to appreciate the work of those students who attended IL education. This can be seen in the distribution of final grades although not all the discovered figures showed better success in completing the tasks, some even vice versa. This phenomenon would be worth further studying.

Drafting a Code of Ethics for Engineering Education

R. Alan Cheville

Lewisburg, Pennsylvania, USA

John Heywood
Trinity College, Dublin
The University of Dublin
Dublin, Ireland

Abstract—Some within the engineering education community have asserted that engineering education should be considered a profession. While the formal meaning and identifying characteristics of a profession are debated, in general an individual that is considered professional meets at least three criteria: recognized expertise drawn from a widely accepted body of knowledge, accepted norms of professional behavior, and adherence to codified ethical standards. This paper addresses the third of these issues by exploring canons that could and should be contained within an engineering education code of ethics. To develop the framework for a code of conduct, published ethical codes from four professions—engineering, education, law, and medicine—were analyzed for both content and structure. Both areas of overlap and divergence within the codes were identified. From the areas of overlap between these professional canons a draft code of ethics for engineering education was developed and is compared with the recent American Society for Engineering Education code of ethics. The development process and resulting draft are presented to stimulate larger discussion within the engineering education community around purposes for engineering education.

Keywords—ethics, ethical code, profession, professional

I. INTRODUCTION

Editorials on engineering education have made the claim that it is becoming or should be a discipline [1], or at least a field of scientific inquiry [2]. For the purposes of argument, this paper will posit that engineering education is: 1) a discipline, 2) a professional activity, and 3) distinct from other disciplines an engineering educator may also belong to such as mechanical or civil engineering.

The origin of the word “profession” comes from the Latin for public declaration and was first used in the Middle Ages in a religious context, but over time its meaning evolved to encompass the occupation one professes to be skilled in, an implicit acknowledgement of expertise, and those who are skilled in that occupation. The word “professional” is also used in a vernacular sense to distinguish experts from amateurs, e.g. in sports. Thus a professional has a high level of technique that distinguishes her or him from amateurs. Furthermore a professional is expected to behave as a professional both on and off the field. Technique and behavior set the perceptions of a profession. For example mental images of a physician may suggest dress and work environment. Professional codes often address image and identity either implicitly or explicitly [3]. Many fields seek the designation as a profession for the status and independent governance it brings.

Beyond competence and behavior, a profession is also defined by ethical standards that are freely accepted by those who choose to be members of the profession. Davis states that “ethical standards, not standards of competence or organizations, seem to distinguish professions from other skilled occupations” [4]. Part of being a member of a profession is to agree to abide by that profession’s ethical code. Kallenberg [3] has outlined five ways that a code of ethics supports professional identity.

For engineering educators to distinguish themselves as a profession they must meet the three criteria of: the existence of a common body of knowledge that defines expertise, expectations of behavior that distinguish one from others in society broadly, and ethical standards. While a body of knowledge does exist [5], not all engineering educators subscribe to it in a way that affects their practice. Society does expect certain behaviors of university faculty. Similarly a code of ethics was recently approved and published by ASEE.

This paper investigates the adequacy of ASEE’s engineering education code of ethics by broadly exploring published professional codes in engineering, education, law, and medicine; categorizing canons common to these professions into nine topics; and comparing these to the code of ethics produced by ASEE. Areas of overlap and divergence between canons led to a synthesis that was used to draft a code of ethics for engineering education that addresses canons of professionalism the ASEE code fails to capture. The draft code is explored from a pragmatic standpoint using Kallenberg’s five lenses [3] and from a standpoint of practice using Hoyle’s definitions of extended and restricted professionalism [6].

The act of drafting a code of ethics both frames a moral ideal and acknowledges that engineering education has specific knowledge requirements from which a consensus for how that knowledge should be used needs to emerge [4]. Clearly the authors cannot speak for all engineering educators on what the ideals of our discipline should be. Therefore the intent of this paper is not to present a code for immediate adoption, rather it offers tenets that provide centers of dialog, stimulating discussion within the engineering education community around issues of professional identity. A code of ethics may also be useful for illuminating tensions inherent to the multiple roles assumed by engineering faculty.

II. EXPLORING PROFESSIONAL ETHICAL CODES

While there are many career paths that claim to be a profession [7] in this study we analyzed ethical codes from engineering, education, medicine, and law. The inclusion of

engineering and education are obvious. Medicine is included due to the emphasis on the physician-patient relationship which may provide insights into ethics of student-teacher relations. Similarly law was included since the law is a living body of knowledge that is continually reinterpreted by the legal profession much in the way the engineering state of the art is constantly evolving and needs to be reinterpreted by educators. Codes of ethics from representative professional organizations including engineering (NSPE, IEEE, ASME), education (NEA, English Government, ASEE), law (ABA), and medicine (AMA) were analyzed and the canons grouped into similar broad categories.

The structure of codes varies between professions. While engineering and education codes typically consist of an extensive list of statements that serve as canons, law and medicine define a smaller number of overarching canons which are expanded upon by lengthier, contemporary written opinions. Here we focus only on canons, ignoring opinions. These canons were sorted into nine broad, inclusive topics that are common between most codes, and listed in Table 1. Table 1 also compares similarities and differences between canons of the four professions within these topics.

The overlap of canons with the nine topics is imperfect. Multiple canons may address aspects of one topic or one canon may overlap with multiple topics. Furthermore each profession's canons emphasizes some topics more than others. In addition, most codes have a preamble stating the larger ideals of the profession that the code of ethics serves to support. In the case of engineering the ideal is public welfare or quality of life, in education human dignity and truth, in medicine patient care, and in law justice.

The ASEE board of directors has recently published a code of ethics [8]. The preamble states those members who perform professional work in a technical discipline serve the ideal of public welfare. The code lists fourteen canons that closely align with canons of other engineering codes. Ten of the fourteen canons of ASEE's code align directly with the topics listed in Table 1. The four exceptions are the first three canons of the ASEE code that define obligations members have for students to: understand ethical responsibility, work towards human welfare, and be aware of impact. The thirteenth element of ASEE's code partially aligns with topic (5), professional relationships, but also addresses the stipulation for fair assessment. ASEE's code does not address topic (9), while (1) is addressed through codes of another engineering discipline if the ASEE member does technical work in that discipline. It is not clear what ideals ASEE members follow if they do not perform technical work. Furthermore, since nearly all canons of ASEE's code have correspondences in other engineering codes there is significant redundancy for those ASEE members who are affiliated with a technical engineering discipline. Finally, the close alignment with engineering codes results in ASEE's code failing to capture some canons of other professional codes relevant to education broadly

III. A DRAFT CODE OF ETHICS FOR ENGINEERING EDUCATION

The nine broad topics of Table 1 were used to draft an engineering education code of ethics. For each of the nine topics relevant canons were drawn from ethical codes from the four professions. The synthesized code is given below with canons listed in the same order as Table 1. A preamble outlines the ideals for the profession of engineering education.

Table 1: Topics common between professional ethical codes

Topic	Comparative Notes
1) Obligation for the greater good or public welfare	All explicitly address the greater good, but vary in definitions. Engineering codes put the public welfare above other concerns but do not define it. Medicine is focused more on individuals than the public at large with an emphasis on care, dignity, and rights. Education emphasizes the greater good least with a general statement of belief in the value of education. Law frames good through the lens of justice and places the profession at the nexus of upholding trust in a system of laws.
2) Relation to those outside the profession	Engineering and education treat individuals equally regardless of race, gender, or other factors. In addition the legal and medical professions are charged with providing access to professional services for all individuals.
3) Professional roles and conflicts of interest	Most professions give stipulations about avoiding conflicts of interest but otherwise implicitly assume the professional plays a single role. Law explicitly identifies multiple roles played by lawyers and addresses when these roles are harmonious and how conflicts between multiple roles are to be resolved.
4) Relations with those whom the profession serves	Engineering defines service to employers and clients while educators predominately serve students and to a lesser extent schools. Medicine allows the physician choice of whom to serve with the provision patients are cared for. Law serves clients, but lawyers also act as agents of the court and as private citizens have an obligation to serve justice.
5) Professional reputation, relationships, and responsibilities	All codes of ethics have an obligation to maintain the reputation and standards of the profession and report those whose acts or character are unprofessional. Engineering places the most emphasis on these and medicine the least. Engineering and education put some stipulations on behaviour towards others within the profession. Law additionally requires respect for the legal system and judicial process, as well as independent self-governance.
6) Professional competence	All discuss competence, but engineering places more explicit emphasis on boundaries of competence than other professions and how qualifications are represented. Some educational codes are highly specific.
7) Need for confidentiality	All codes address the need for confidentiality within the limits of law for those they serve. Both law and medicine go into detail in specific opinions that are ancillary to the main canons.
8) Need for continuing education	Some (but not all) engineering and education codes make explicit mention of the need for continuing education and the obligation to contribute to others' professional development. This is not a primary precept for lawyers, but physicians have an explicit commitment to continue their own education, medical and patient education more generally, as well as advance the state of the art.
9) Commitment to advocacy	Engineering and education codes discuss upholding societal values. Law and medicine have canons of advocacy in which medicine advocates for patient interests and law advocates for access to and fairness of justice, particularly for vulnerable members of society.

The Engineering Educator's Code of Ethics

Preamble: Engineering education has a large impact on the world, serving the ideal of human development through education and the ideal of truth through scholarship. Engineering educators respect the impacts culture and individuality have on these ideals. To serve these ideals engineering educators:

- 1) Recognize that engineers and engineering works may impact the world for good or for ill. Engineering educators strive to develop their own and students' capacity for moral purpose, serve as an example of human life lived well, and recognize the rights of others to define their own welfare and quality of life.
 - 2) Treat others fairly, support others' learning at all times, and honor differences between learners that arise through opportunity and culture.
 - 3) Balance responsibilities of the multiple roles they assume within the education system.
 - a. In the role of a teacher or mentor the engineering educator seeks to support learning, professional development, and enabling human thriving through education.
 - b. In the role of a scholar the engineering educator dedicates himself or herself to seeking truth and awareness of his/her own ideology.
 - c. In the role of an administrator, the engineering educator is guided by principles of fairness, justice, and compromise.
 - d. In the role of a patron, constituent, or client the engineering educator provides actionable feedback to improve education and helps support others' professional development.
- While most times these roles are harmonious, in some cases the engineering educator will face ethical dilemmas that arise from overlaps of these roles. Resolving such conflict requires both adherence to law and moral judgment, tempered with respect for colleagues and students, and the recognition that vulnerable populations may often lack a voice. The engineering educator acknowledges the tensions inherent in supporting individual learners and an educational system with limited resources while undertaking unbiased evaluation of learning.
- 4) Serve educational needs through:
 - a. supporting the needs of learners and upholding the rights of all individuals to an education with particular care for the vulnerable and disadvantaged;
 - b. recognizing the impact of credentials and the limitations inherent to measuring learning, and striving to improve how learning is assessed;
 - c. recognizing that learning occurs within a community and valuing the diverse expertise and contributions of their colleagues and the supports offered by the wider educational institution in which they function; and
 - d. building professional liaisons with others across the education system and those who employ engineering graduates.
 - 5) Uphold standards of professionalism in any role they play within the education system.

- 6) Balance their role as an educator with their role as an engineer by accurately interpreting state-of-the-art engineering theory and practice for learners and drawing upon the science of learning to effectively promote and support student development.
- 7) Act in ways that develop and hold the trust and confidence of others so as to support their role as teacher and mentor.
- 8) Seek to advance, apply, and integrate the state of the art in both education and engineering theory and practice and dedicate themselves to life-long professional development.
- 9) Recognize a responsibility to participate in activities that contribute to access to education, and seek changes to situations that are contrary to the best interests of learners.

In creating this code professional ideals were outlined in the preamble since Davis [4] points out that a code of ethics serves "...as a way a profession defines relations between those who want to serve a common ideal..." Adopting other ideals would necessitate changes to the code. To be useful codes need to be written for a given audience; the code above was written for engineering educators to acknowledge the ethical dilemmas potentially introduced by the multiple roles they inhabit. Kallenberg acknowledges that while any code of ethics must be imperfect, imperfect codes may be useful to trained professionals [3]. Such imperfections may be offset by extended written opinions such as those in law and medicine.

Kallenberg [3] points out that ethical code may be interpreted through five different lenses:

1. As an emblem that distinguishes the profession from others in society.
2. As guidelines to action written for those with sufficient expertise in the profession to understand their application.
3. As a covenant of behavior one must agree to in order to retain membership in the profession.
4. As centers of conversation that allow dialog around inevitable ethical tensions.
5. As a framework for what is ethically allowed in a profession rather than what is forbidden.

The code above is designed to the extent possible to serve these purposes. By adopting canons of care and advocacy from law and medicine the code serves as an emblem to distinguish the profession of engineering education from education and engineering more generally. As guidelines to action, the code frames responsibilities around assessment, social justice, and advocacy. As a covenant the code seeks to identify moral purposes which engineering educators can freely commit to. As a center of conversation the code acknowledges ethical dilemmas that may arise from role conflicts in order to stimulate dialog. The code is furthermore written to define and promote behaviors rather than proscribe them.

IV. RESTRICTED VS. EXTENDED PROFESSIONALISM

The draft code of ethics presented previous was drafted to stimulate dialog on one element that engineering education requires to be considered a profession. In a larger sense what does it mean to be a professional? Since a code of ethics is designed to guide behaviors, in crafting the code we consider whether engineering educators are or should be "restricted" or "extended" professionals, borrowing from Hoyle's definition [6]. A restricted professional is one who relies primarily on

their own insights and intuition developed through their day-to-day experiences. An extended professional is guided by the theory underlying their experiences and approaches problems using a more rational and scholarly approach. For example from a historical perspective the 1955 Grinter report [9] defined the ways engineering should be taught to align better with expectations of an extended profession.

Table 2: Restricted vs. Extended Professionalism in Engineering Education

Restricted professionalism in engineering education	(#)	Extended professionalism in engineering education
Instructional skills derived from experience	8	Instructional skills derived from mediation between experience and theory
Perspective limited to immediate time and place	1,3,4	Perspective embracing broader social context of education.
Lecture room and laboratory events perceived in isolation.	4c,7	Lecture room and laboratory events perceived in relation to institution policies and goals.
Introspective with regard to methods of instruction	8	Instructional methods compared with those of colleagues and with reports of practice.
Value placed on autonomy in research and teaching.	4d	Value placed on professional collaboration in research and teaching.
Limited involvement in non-teaching professional and collegial activities	3	High involvement in non-teaching professional and collegial activities.
Infrequent reading of professional literature in educational theory and practice.	8	Regular reading of professional literature in educational theory and practice.
Involvement in continuing professional development limited and confined to practical courses mainly of a short duration.	8	Involvement in continuing professional development work that includes substantial courses of a theoretical nature.
Instruction (teaching) seen as an intuitive activity.		Instruction (teaching) seen as a rational activity.
Instruction (teaching) considered less important than research.	3	Instruction (teaching) considered as important as research.
Assessment is a routine matter. The responsibility for achievement lies with the student	4b,c	Assessment is designed for learning. Achievement is the co-responsibility of the institution, instructor (teacher) and student.

An interpretation of Hoyle's definition [6] for engineering education is provided in Table 2. The alignment with canons of the draft code are shown in the middle column of Table 2 with the numbers corresponding to the numbered points in the code of ethics on the previous page. This distinction between restricted and extended professionalism may help complement the ethical code in several ways. First, while a code of ethics defines what it means to be considered a member of a profession, Table 2 indicates the extent of professionalism and thus may serve as a basis for extended, written opinions like law and medicine have adopted. Second, such a table provides practical guidelines for action and further centers of conversation [3]. Third, Table 2 can serve as an emblem to better distinguish engineering education professionals from engineers or educators more generally.

V. CONCLUSIONS

The code of ethics drafted from common canons of four professions was created for several purposes; to stimulate dialog around engineering education as a profession and to serve as a foil for the ASEE code have already been mentioned. Other questions arise in the application of an ethical code. For example what implications does an ethical code have for technique (pedagogy), and how might engineering education sanction those who are somehow deemed to behave unprofessionally?

There are additionally questions of professional identity [10] that the code raises explicitly. These are highlighted as tensions within the code to highlight that they need to be navigated consciously and explicitly, a question the current ASEE code does not address. These questions of the identity of faculty members are in some ways microcosms of the identity crisis of universities at the present time. As the role of the university in society and the economy has changed over the past decade, these questions of identity loom large. Regardless of economic function and any utilitarian role of a university, a code of ethics stipulates that there is also a moral imperative in claiming to be an educator that transcends this context. This code's canons of advocacy, social justice, and the defining ideals of truth and human development make these explicit. A code of ethics that is well designed should help individuals navigate such dilemmas.

ACKNOWLEDGMENT

Abstract—The rapid development in the IT area brings a series of shifts, in underlying theories, technology and work practices. In the normal course of events, most changes are evolutionary, with small, incremental improvements being made to theoretical understanding or practical application. Occasionally, however, changes occur of such magnitude that they do not just alter current operational practice but require a thorough reappraisal of the underlying assumptions on which that practice is based. In short, they require a review of the dominant way of thinking, or paradigm. Ability to adapt to evolving circumstances is critical, not only for industrial and commercial organisations, but also for individual employees, to survive and remain successful during paradigm shifts.

How can we prepare our students so they can survive in a working life characterized by frequent paradigm shifts? It is important that CS and IT education prepares students for coping with shifts induced by technological development in their future careers, that students develop the competencies needed. To understand what competencies are needed, it is important to investigate characteristics among employees that have flourished in earlier paradigm shifts and not least to build knowledge on how to develop learning environments where such competencies and personal characteristics can be achieved. This paper is about setting the stage for an action research project aimed at enhancing education with regard to being able to survive paradigm shifts in the IT industry.

Keywords—*paradigm shift; action research; competencies; capabilities; learning environments; adaptability*

I. INTRODUCTION

Adaptation to evolving circumstances and continual management of change are critical features for success in industrial and commercial organisations. In the normal course of events, most changes are evolutionary, with small, incremental improvements being made to theoretical understanding or practical application. Occasionally, however, changes occur of such magnitude that they do not just alter current operational practice but require a thorough reappraisal of the underlying assumptions on which that practice is based. In short, they require a review of the dominant way of thinking, or paradigm. These are “paradigm shifts” in the Kuhnian sense [1] - changes in the “constellation of concepts, values, perceptions and practices shared by a community, which forms a particular vision of reality that is the basis of the way a community organises itself” [2] - and their arrival signifies a period both of creative opportunity and cultural tension and disruption.

We will use the concept of “paradigm shift” in this sense, i.e. one that signals a need for changing fundamental

assumptions about working practices, where previous knowledge and skill sets lose significant amounts of value or, in extreme cases, are made completely irrelevant. It might be argued that this term is being applied too loosely when used to describe the case where IT development puts severe strains on industry and education. However, we argue that the concept of a paradigm shift is appropriate to capture a situation where some of the more technology specific knowledge and techniques that students learn at universities are often already outdated when they obtain their first job, and where employees might find their current skill set to no longer be a valuable asset when new technology is introduced.

Examples of what we see as paradigm shifts in the IT Industry brought on by technological advances are the advent of the Internet and the World Wide Web [3], the introduction of the PC [4], open source [3, 5], and the emergence of new programming paradigms such as object-oriented programming [6] and concurrent programming [7]. Other recent technological advances that have this potential are the development of cloud computing infrastructure and smart devices like mobile telephones and app technologies. That the IT industry has been through a number of these dramatic changes in a short period of time should not be seen as a reason to view this as something less than paradigm shift, or to not take the consequences seriously. The fact that IT companies need to pursue new trends or be quickly overtaken by rivals can be illustrated by examples such as Facit [8] and Nokia.

One potential strategy for coping with such change within a commercial environment is to replace experts in the old paradigm with those who more fully grasp the implications of the new one. However, this would lead to other problems such as critical loss of domain knowledge. Even though new employees may have expert knowledge concerning the new technology, they may lack an understanding of the application domain and tacit knowledge of how the company works. This is due to an increased need to understand the environment in which the IT-system is to be used in addition to knowledge of the latest technology. We will consider this deeper integration into a company as a non-technologically driven paradigm shift. An example of a non-technologically driven paradigm shift is radically increased demand to be able to interact in a wider context, e.g. internationally, across disciplines, and with society at large. From a business perspective, therefore, when paradigm shifts occur, it is of vital importance to maintain some degree of continuity in the core area and have individual employees who can quickly learn and adjust to new situations with new technology or due to changes in work practices.

'Learning to learn' is a competence likely to be important in coping with paradigm shifts. This is also supported by research indicating that competence development will largely be met through employees' own efforts. This is illustrated in a study that indicates that only 10-20% of learning in companies takes place in an organized manner [9]. Other research studies of learning in workplaces have been carried out by e.g. Mittendorf et al. [10], Xiao et al. [11] and James-Gordon and Bal [12]. Much of this research has focused on how companies and organisations can create the conditions for learning [13], which is relevant for the individual's ability to cope with paradigm shifts. We have however not found any work specialising on which competencies for such adaptability are required of the individual or what competencies are required for paradigm shift survival.

The purpose of this paper is to set the stage for an action research project aimed at enhancing education with regard to being able to deal with paradigm shifts in the IT industry. The research questions underlying the work presented in this paper are:

How should a study be designed to investigate what competencies and characteristics an individual IT professional needs in order to cope with paradigm shifts?

and

How can educational settings be constructed to better prepare individuals for a working life with frequently occurring paradigm shifts?

The paper starts by discussing the relevance of the research questions from different perspectives. The impact paradigm shifts have on society is discussed after which research areas of special importance in performing the action research project we propose is presented. There are three such areas, 1) Competencies, 2) Personality, and 3) Learning environments. The paper is concluded with a suggested study design and some conclusions.

II. IMPACT ON SOCIETY

The IT sector represents a significant part of any modern society. For instance, a country such as Sweden has historically built much of its welfare on high technology industry where IT has emerged as a major actor in the last few decades. On the Swedish IT & Telecom Day 2013, organised by the trade and employers' organisation, IT & Telecom Industries, competence (expert) provision was voted to be the industry's key question [14]. There are, therefore, good reasons for studying paradigm shifts in the IT industry, since successful strategies for surviving and taking advantage of these changes are vital. Previous research has pointed to the fact that paradigm shifts might be problematic even for experienced professionals [15, 16].

An unspoken requirement is that individual employees in the IT industry manage to keep abreast of technological developments and, when necessary, learn new technologies [16]. This is visible in different codes of ethics for professional engineers, e.g., IEEE's [17], saying that members agree to maintain and improve their technical competence. This applies

to all employees, including recent graduates. Employees who do not manage to cope with knowledge paradigm shifts will find themselves outpaced by younger or more flexible colleagues. From the company's perspective, rapid turnover in the workforce will mean a loss of general competences and knowledge of the company. It is thus vital for IT companies that their employees can cope with knowledge paradigm shifts.

Due to rapid technological developments, certain technical aspects of a university education might be already outdated at graduation and, consequently, it is necessary for individual professionals to be able to learn new technologies and cope with constant changes in their working lives. Indirectly this means that universities must provide IT students with the competencies needed to cope with such knowledge paradigm shifts. Given this, we suggest that there is an urgent need to investigate the nature of these individual competencies and how educational settings, at universities, in the industry, and individually composed, can provide individuals with appropriate learning experiences in order to develop them. Indirectly this is for the good of a society where IT companies can continue to develop and successfully compete internationally, and adaptable individuals continue to thrive in the face of technology changes.

III. THE COMPETENCIES ASPECT

There is an increased attention to competencies other than purely technical, e.g. as seen in [18, 19, 20]. There is still confusion about what constitutes a competence and the Definition and Selection of Competencies (DeSeCo) project [18] is an effort to aid in understanding competencies in general and place them in the European context. A competence in the DeSeCo project is viewed as knowledge and the ability to deal with complex situations in particular contexts. They further state that what they define as a key competence must:

- Contribute to valued outcomes for societies and individuals;
- Help individuals meet important demands in a wide variety of contexts;
- Be important not just for specialists but for all individuals.

The key competencies belong to three broad categories: being able to use tools for interacting with the environment, being able to engage with others in heterogeneous groups, and being able to take responsibility for one's own life in a broad social context and act autonomously. Important in all categories is the ability to think and act reflectively.

We have in earlier research addressed the competencies aspect in the learning environment area [21, 22], where for instance we have pointed out that there is a gap between what degree programs are supposed to develop in terms of competencies and what is actually covered in the course units comprising the program. There are several reasons for why this is the case, e.g. competencies are seen as being assimilated during education and they are not considered as measurable, and this paper addresses the issue of faculty not realizing what

competencies are, why they are important, nor how to help students develop these competencies.

In the proposed study, we will use a model of competence based on work by Graham et. al [23] and developed by us [24] in which we view a competence as being composed by knowledge, attitude, and skill. This is a model that has been useful in understanding different aspects of what is seen as a competence. There is also an aspect of this model that a person should show all three aspects in order to be seen as having the particular competence. This model also fits well with the idea of communities of practice [25], where each of these aspects can be used to explain why someone moves towards the center of a community whereas others remain on the outer as peripheral members.

The research study we propose is intended to provide understanding and evidence regarding competencies considered crucial to flourish in a fast changing environment. This critical importance provides a motivation to truly reform course units to have learning objectives that includes development of competencies. Such a study would also provide a base for understanding the nature of these competencies, which is a precursor for creating a learning environment in which to develop them.

IV. THE PERSONALITY ASPECT

We have earlier addressed the personality aspect in the learning environment area [26], where we point out research stating that perseverance is a strong predictor for academic success [19], e.g. a study showed that conscientiousness and intelligence were equally strong indicators for academic success in higher education and that they were independent of each other [20]. A study by the Department of Education in the US points out that grit, tenacity, and perseverance are critical factors for succeeding in the workplace in the future [32]. Another study states that conscientiousness is central to the intra-personal competency, which is identified as being highly important for life in general as well as in the work place [33].

There is no doubt that an individual's personality also is a factor when it comes to survival in paradigm shifts. There are strong reasons therefore to take personality into account when studying how individuals cope, partly to get a more holistic view and partly as an indicator of what to address in creating learning environments aiming for preparing students better for coping with paradigm shifts.

There are many issues to consider if personality aspects should be studied. One is which instrument to use when finding out more about the personality of persons. The Five-Factor model [27] is the basis of some of the most commonly used instruments. The name derives from capturing the behaviour as belonging to five more or less independent general personality characteristics; Extraversion, Neuroticism, Openness to experience, Agreeableness, and Conscientiousness. These are defined as subsuming more low-level characteristics, e.g. being strong in conscientiousness is associated with self-efficacy, organisation, cautiousness, self-discipline, and persistence. There is also work that suggests that it would be more interesting to look at personality types and characteristics at a

finer granularity [29], e.g. academic tenacity [30] and grit [31] in the academic success case.

Another aspect to consider is how to capture the personality shown in the work situation in question and also that personality also changes over time, e.g. as a person gets older it is common to mature and in that process score higher in emotional stability (lower in neuroticism), agreeableness, and conscientiousness [28]. That personalities can change is a reason to consider how that could be integrated into education, how educational institutions can foster paradigm shift survivors.

V. THE LEARNING ENVIRONMENT ASPECT

An essential outcome of an action research project such as the one we outline below is that identification of competencies and characteristics will provide important insights for creating educational settings that better prepare individuals for coping with paradigm shifts (as well as ordinary development). A better understanding of which competences and characteristics are important for individual success in a paradigm shift, will form a basis from which recommendations can be drawn for setting up and improving learning environments that help individuals develop in that direction.

There is a gap between what the industry needs short term and what we are supposed to prepare our students for long term and there is also a gap between what is stated as general learning outcomes from degree programs and the learning outcomes of individual course units. We argue that these gaps are partly due to faculty and education developers not having a vocabulary to express competencies and personal characteristics in terms of education, which also leads to students not being familiar with these concepts nor motivated to take them seriously if addressed in a course unit. Breaking up a degree program into a set of rather small course units also undermines development of perseverance as such.

In [34] we reason about development of competencies in terms of a model based on Stahl's model of collaborative knowledge-building. We will here give a short summary. Stahl's theory draws on organizational learning [35] and communities of practice [24] and is attempting to:

"... understand learning as a social process incorporating multiple distinguishable phases that constitute a cycle of personal and social knowledge-building. The cyclical character of this process allows increasingly complex questions to be posed on the basis of more and more sophisticated understanding". [36]

We intended the model to be used to help build a foundation to describe how development of competence is related to a social context. A key element in Stahl's model is social knowledge construction where discussion and analysis leads to formation of a shared communal perspective. This crucially depends on individuals being capable of clearly

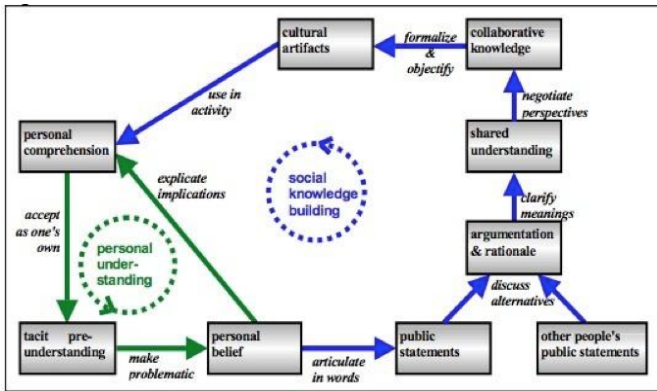

Fig. 1. Stahl's Model of Collaborative Knowledge-Building (from [36], p. 3).

articulating views and insights. Lack of clarity or completeness as well as issues with not valuing what each other contributes will lead to limited analysis and rigour of the subject matter. Such deficiencies hinder creation of shared understandings of the subject and thus leads to difficulties for collaborative knowledge-building. Artefacts created under poor conditions will have limited usefulness and will thus be hard to use to build group identity. The cycle described in figure 1 relies on a high quality of reflection and perceptions of value.

The basic idea in Stahl's model, see figure 1, is that tacit pre-understanding is the foundation of personal knowledge [37] and that this leads to individual and collective understanding which shape how we perceive the world. Sometimes elements of these understandings conflict with experience [38]. Dealing with this conflict is part of the process in this model that eventually leads to new tacit understanding, from where new understanding and learning can start [36]. For us, an interesting aspect of this model, apart from describing a learning process, is that it captures interaction between an individual and others, including use of artefacts.

Of particular interest is the key role a shared language plays. This fits well with our ambition to identify and describe competencies and personal characteristics useful in paradigm shifts in order to integrate them in a learning environment. This is also consistent with the model of competence where it is seen as consisting of knowledge, attitude, and skill. Competencies are mostly applied in interaction with others, which makes this model particularly useful as a base to develop learning environments suitable for development of these competencies.

We see this model as a means to create a common understanding of how to design learning environments which include development of competencies and personality traits among the students that will better equip them to manage in an environment with continual paradigm shifts.

VI. PROPOSED ACTION RESEARCH PROJECT

We will now outline a design for a study that aims at enhancing university educations when it comes to fostering future employees that are equipped to survive and maintain their productivity in paradigm shifts. The study is based on the idea of studying employees that are regarded as having coped well with at least one paradigm shift to identify important competencies and personality traits. The discoveries can then be used to design learning environments that promote development of these.

The authors of this paper have positive experiences from Action research [39, 40] and suggest that a study should be based on this methodology. This is especially true for the aspect of setting up suitable learning environments. We propose to precede the first action research cycle with a gathering of information phase. The intention of this first phase would be to conduct a fuller literature study, including establishing a definition of what we mean by paradigm shift, competence, and personality in this context.

The first action research cycle is mainly focused around an industry study where information is gathered from selected employees. The preceeding literature study should influence how the investigations are carried out. Potentially useful methods to gather information are semi-structured interviews and questionnaires/instruments based on these interviews. The topics to cover in the interviews, and later in the questionnaires/instruments, will be decided based on an initial study of potentially interesting areas regarding a person's ability to cope with a paradigm shift.

Employees selected for the study should be those that are regarded as having coped well with at least one paradigm shift. Care should also be taken with regard to selection of companies and organisations to study and we suggest that this could be influenced by first identifying which paradigm shifts to look for. Choosing a set of paradigm shifts to look for will help identifying relevant workplaces to study and also provide a basis for comparison. We believe that large companies will, at least in the initial stages, be the ones most relevant to study, but still suggest that also smaller companies should be approached in order to capture a potentially different set of needs. We further propose that large companies and organisations should be approached through their human resource division as these will be helpful in identifying relevant employees to interview and also, subsequently, to distribute questionnaires/instruments. They are also the ones most likely to understand the concepts of competence and personality. We also advise to collaborate with relevant employer's organisations, e.g. Almega [14], in order to both identify companies and find appropriate contact persons within relevant companies.

The stage of conducting semi-structured interviews and sending out questionnaires would be among the early stages in the first action research cycle along with identifying the focus to use. The middle stages of the first cycle should be to evaluate the interviews and questionnaire responses followed

by identifying the general findings. We further suggest that each research cycle should be concluded with a workshop where researchers, and other potentially relevant parties, discuss the findings and plan for the upcoming cycle. Then, in subsequent cycles, the research question can be refined based on the findings in the previous action research cycle and investigations in the industry can be repeated with the refined questions.

This could be seen as an action research study of its own, but we propose that this industry study will be extended, starting from the second cycle, by identifying actions leading to the development of learning environments. The reason to wait until the second cycle would be that information about competencies and personality gathered from the workplace will be available at that time. We propose that this new “thread” should be based on the Stahl model and a model of what a competence is that is based on our previous work on competencies [24]. This is a model where a competence is seen as being composed of three interrelated parts, i.e. knowledge, attitude, and skill. This will allow the capturing of different aspects of what a competence is and to form a clearer understanding of how a competence can be developed in an educational setting. Issues to study in this “thread” should include studies on how the identified competencies can be addressed in education. The intention of the full action research cycle would be to both identify relevant competencies and develop recommendations on how they can be developed in different educational settings, e.g. at universities, companies, and for individuals, and in different formats, e.g. traditional courses, training events, and distance courses (including Massive Open Online Courses - MOOCs). This setting can continue with several new cycles, where we believe that the identifying part will diminish over the cycles and the educational aspects take over.

The intended goal with this proposal is to raise awareness of the value of the competencies and personality traits that are identified as important in coping with a paradigm shift and especially to promote an understanding that these competencies and personality traits can be developed.

VII. CONCLUSIONS

We have identified the individuals coping, or survival in paradigm shifts as an area where further research would be highly valuable and outlined a study design aimed at addressing this area. This paper and other earlier work by the authors provides a first base for engaging in such research. It is also our firm opinion that conducting a study of the type we outline would be beneficial for education developers and teaching staff for achieving broader learning objectives.

Another benefit should be to gain a better understanding regarding paradigm shifts in the workplace, which could be costly if not fully disastrous for a company or organisation. The outlined study involves both academics and industry representatives thus creating an environment where results

from this study can reach the workplace faster than the traditional route of educating new students how to survive paradigm shifts.

Abstract— Unlike technical graduates such as engineering and science, liberal arts graduates usually encounter difficulty finding jobs in their majors. A good percentage of them becomes under- or unemployed. This paper investigates and discusses an innovative approach to address this problem. We provide these students with an accelerated 12-month certificate in advanced manufacturing to help them apply for manufacturing positions. The paper discusses the design and content of the certificate.

Keywords—*Mal-employment; liberal arts graduates; advanced manufacturing; mfg. technology; mfg. innovation*

I. INTRODUCTION

The mal-employment, occurring in the first job, of liberal arts majors is well known and documented [1, 2]. Liberal arts graduates are either under- or unemployed. This hinders their full contribution to society; prevent them from reaching their full potential, and making it hard for them to pay back their students loans. There are many current efforts to encourage students to pursue STEM pathways, but very few programs focus on pathways for cross-disciplinary workforce integration.

This paper presents a model to transform liberal arts graduates to seek jobs in advanced manufacturing, a current field with plenty of jobs that go unfilled each year as manufacturing makes a comeback in the US. The model targets the intellectual and creative talents of recent BA (Bachelor of Art) graduates coupled with internships and skill development.

This work is supported by the National Science Foundation under grant numbers DUE - 1407160. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

The model is centered on offering a fast-track 12 month certificate in advanced manufacturing coupled with internships to prepare BA graduates for career in advanced manufacturing and empower them to compete successfully for manufacturing jobs. BA graduates are viewed as well-rounded individuals with many desired skills. They lack only technical skills. By offering a certificate in manufacturing, they should be ready to join the manufacturing workforce.

II. CURRICULUM DESIGN

The curriculum is a 12-month stackable curriculum in advanced manufacturing. The curriculum has two tracks: manufacturing technology and manufacturing innovation. The manufacturing technology track is for those BA graduates who are interested in day-to-day manufacturing activities and operations. The manufacturing innovation track is for those BA graduates who have the entrepreneurial spirit and would be interested in creating a startup.

The certificate is designed to be 25 semester hours, so students are eligible for financial aid if needed. Students will take a full load (12 semester hours) during summer and fall semesters and complete their co-op internship during the spring semester before graduation.

Each track has required core and elective courses to provide students (BA graduates) with flexibility to customize the curriculum to their personal background, needs and goals. The curriculum details for the two tracks are shown in Tables 1 and 2.

Table 1 Manufacturing track curriculum

	Core courses	Elective courses
Summer Semester	Total of three courses (9 SH): 1. MN121 Mechanical Detailing 2. MN130 Engineering with CAD I 3. NC Programming (<i>new</i>)	Total of one course (3 SH): 1. MN135 Engineering Design with CAD II 2. Applied Computer Science CS 101 class (<i>new, modular course</i>) 3. Career-Readiness and e-Portfolio(<i>new</i>)
Fall Semester	Total of three courses (9 SH): 1. MN261 Animation Materials, 3D Modeling 2. MN140 Project Management 3. IE4530 Manufacturing Systems (@NU and @MBCC)	Total of one course (3 SH): 1. IE5620 Mass Customization (@NU and @MBCC) 2. SCHM2301 Supply Chain and Operations Management 3. SCHM3301 Global Supply Chain Management 4. MN272 Designing Plastic Parts 5. MN 251 Electromechanical Design 6. MN 125 Engineering Computation with Application Software
Spring Semester (Co-op)	1. Co-op dialogue (<i>new</i>)	

	Management 2. Manufacturing Systems (@NU and @MBCC) 3. Sustainability and Innovation (<i>new</i>)	(@NU and @MBCC) 2. MN 261 Animation, Materials and 3D Modeling 3. Career Readiness and e-Portfolio(<i>new</i>)
Spring Semester (Co-op)	1. Co-op dialogue (<i>new</i>)	

The tables for both tracks use this sequence: Classes → Classes → Internship instead of Classes → Internship → Classes. The selected sequence enables BA graduates to do internships during the spring semester instead of the highly competitive summer semester where many college students look for work.

III. COURSE CONTENT

The curriculum is designed to build on the valuable skills and knowledge that BA graduates acquire from their BA degrees. The curriculum is part of a collaborative program between Northeastern University (NU) and Mass Bay Community College (MBCC) in Boston, Massachusetts. A team from both institutions oversees the curriculum design and delivery. Some courses are new. All courses are offered at Mass Bay. Following is list of the courses and their focus for each track.

Manufacturing technology track:

Existing courses at MBCC

MN121 Mechanical Detailing – Uses SolidWorks CAD software and focuses on engineering drawings.

MN130 Engineering with CAD I – Uses SolidWorks and focuses on CAD part design and modeling.

MN135 Engineering Design with CAD II – Uses SolidWorks and focuses on assembly modeling.

MN261 Animation Materials, 3D Modeling – Create assembly animation and realistic rendering models.

MN140 Project Management – focuses on project management theory and use of MS Project software.

MN272 Designing Plastic Parts – focuses on designing Plastic Parts and mold design.

MN 251 Electromechanical Design – Uses SolidWorks to design electrical-mechanical components.

MN 125 Engineering Computation – Introduces students to engineering analysis using MatLab.

New courses at MBCC

CS 101 Applied Computer Science – project-based course teaching computational thinking.

Career-Readiness and e-Portfolio – In this course, students will have a chance to practice interviewing skills, create

Fall Semester	Total of three courses (9 SH): 1. MN140 Project	Total of one course (4 SH): 1. Mass Customization

resumes and electronic portfolios, and listen to industry speakers.

Co-op dialogue – This is a 1-credit hour course held in conjunction with the Co-op job experience. This course is an online course with well-organized discussions and topic based presentations. The course is augmented by face-to-face meetings once every month. As part of the course, Students are required to submit a report and create a portfolio.

Existing courses at NU

IE4530 Manufacturing Systems and Techniques – focuses on manufacturing and design.

IE5620 Mass Customization – focuses on manufacturing customized products at mass production prices.

SCHM3301 Global Supply Chain Management – Analyzes supply chain management operations.

SCHM2301 Supply Chain and Operations Management – focuses on management of business activities.

New Courses at NU

NC Programming: focuses on NC concepts for milling and drilling, and G- and M-code.

Manufacturing innovation track:

Existing courses at MBCC

MN130 Engineering with CAD I – see Manufacturing Technology track

MN 121 Mechanical Detailing – see Manufacturing Technology track

MN 261 Animation, Materials and 3D Modeling - see Manufacturing Technology track

MN140 Project Management - see Manufacturing Technology track

New courses at MBCC

CS 101 Applied Computer Science - see Manufacturing Technology track

Digital Communications – focuses on strategies for marketing/branding manufacturing products

Career Readiness and e-Portfolio - see Manufacturing Technology track

Co-op dialogue - see Manufacturing Technology track

Existing courses at NU

ENTR2301 Innovation – focuses on transforming innovation into commercial entities and start-ups.

ENTR 2305 Business Modeling for Entrepreneurs – focuses on business modeling for new ventures.

New Courses at NU

NC Programming - see Manufacturing Technology track

IV. CURRICULUM DELIVERY

The curriculum uses an innovative approach to deliver the above courses to keep liberal arts students interested and motivated. We develop course modules within each course and then cluster different modules to serve the students' needs and interests. For example, in the NC programming course we develop a foundation module (call it NC basics). Then, we offer modules that apply the knowledge gained in the foundation module to different contexts, e.g. machining metals, machining plastics, and prototyping artifacts. This helps liberal arts students stay attracted to the new discipline of manufacturing and preserve their love by mixing art and technology.

We also offer the program courses in dual modes: online and in class. Online courses will have weekly in class face to face meetings. Both NU and MBCC has the infrastructure to offer and support online courses. Both offer full degrees online. We work with the Manufacturing Institute (MI) [3] to recognize (accredit) the new proposed certificates into a badge, we call it M-badge. The MI has embraced the badging concept [4] and is leading the way in creating National Manufacturing Badges. Thus TRANSFORM participants can earn an M-badge representing their M-certificate, thus making their certificate recognizable at the national level by manufacturers.

V. ASSESSMENT PLAN

An evaluation plan of the program success will be conducted by an impartial external evaluator. Evaluation instruments include surveys and interviews with both the BA graduates participating in the program and the industry partners who provide internships for these graduates. Focus groups will also be conducted with BA graduates to seek their feedback on the program. Another metric to measure success is the placement of the program graduates and finding jobs after completing the certificate program.

VI. INTERNSHIP PROGRAM

The internship (co-op) program is modeled and developed after the flagship NU co-op experiential learning program, founded over a century ago. Now, it is one of the largest and most innovative programs in the world. Students alternate semesters of academic study with semesters of full-time employment in positions related to their academic/career interests. Co-op is closely integrated with course curriculum, scheduling, and an advising system. Co-op coordinators in each college provide support for students in preparing them for successful co-op opportunities.

NU leads the development of the internship and infrastructure program and helps implement it at MBCC [5, 6]. The program works with companies interested in partnerships, identify internship positions, formulate them into job descriptions, add them into an internship bank, and coordinate the administrative logistics for student placements.

VII. STUDENT SUPPORT AND ADVISING

In addition to creating a unique BA co-op program, we provide a unique advising and support system for the BA graduates for the two different tracks. The advising system addresses the following issues: (1) Smooth transition from liberal arts to manufacturing; (2) Advise on the two track options, and select the best pathway option; (3) Advise on course selection and schedule; (4) Advise on financial aid resources; (5) Develop technical and social programs to help student retention and motivation; (6) Develop an advanced manufacturing club; (7) Provide support and guidance for students who face personal problems or hardships; and (8) Use existing advising tools and software to keep track of student progress.

VIII. STUDENT RECRUITMENT

The recruitment efforts focus on contacting recent graduates in Massachusetts. Massachusetts enjoys a large presence of many public and private major universities and colleges that offer a variety of liberal arts degrees. We reach out to these universities and colleges in addition to reaching out to NU BA graduates and students from MBCC Liberal Arts Associates degree programs. This BA graduate population is of special interest to us because they have done co-ops already during their BA degrees. This offers us the added benefit of comparing the performance of other BA graduates who come from non-co-op programs against that of NU grads to shed some light on the success of the program.

We utilize social networking and career fairs to raise awareness of our program with our target audience. Also, we share program information with manufacturing firms already committed to new strategies that might address their employment needs.

Our activities to reach out and recruit BA graduates are as follows:

- Identify the targeted population by utilizing current institutional resources in addition to our regional employment boards

- Develop a flyer to be distributed to the target population in collaboration with career service departments at universities across the state
- Develop an online version of our recruitment activities
- Hold information sessions at NU and Mass Bay each spring for the following year program that starts in the summer semester
- Attend career and advanced degree fairs at Massachusetts colleges to share program information directly with potential applicants

We recruit 20 BA graduates per year each for three years from the New England area to test our model. Each of the three cohorts forms a class. We keep the class size small to be able to serve the students well and observe their transformation. We provide each student with a co-op job through the newly proposed co-op program.

IX. CONCLUSION

The paper presents an innovative new model to address the mal-employment of BA graduates. The model hypothesizes BA graduates have strong education and skills that help them make the transition smoothly to manufacturing careers.

Implied Identity: A Conceptual Framework for Exploring Engineering Professional Identity Practices in Higher Education

Maryam Khosronejad, Peter Reimann, Lina Markauskaite
Faculty of Education and Social Work, The University of Sydney
Sydney, Australia

maryam.khosronejad@sydney.edu.au, peter.reimann@sydney.edu.au, lina.markauskaite@sydney.edu.au

Abstract—Developing a professional identity, as an engineer, has been the focus of engineering educators. However, previous research illustrates a lack of an integrated framework that conceptualizes the process to explain how individuals practice professional identities and what are the relations between educational design and such practices. We respond to this by proposing a conceptual framework that applies two main concepts: 1) a new concept of *implied identity* to refer to different aspects of professional identity perceived by individuals during their experiences and 2) Archer's reflexivity, as an internal dialogue, that mediates between individuals and their social context. We discuss implications of the framework for empirical studies and its contributions to engineering learning and assessment. To illustrate, we draw on empirical data from engineering students' collaborative work and apply the framework to compare different aspects of engineering identity as practiced by two groups.

Keywords — *Engineering education, Implied identity, Professional development, Professional identity, Reflexivity*

I. INTRODUCTION

Universities are expected to prepare students for professional settings. Therefore educational designers are expected to develop learning environments, learning materials and learning activities that promote graduate attributes for work after graduation. Professional identity development is the focus of engineering education scholars to look at engineering learning within the broader frame of becoming an engineer [1-2]. Professional Identity is defined as an important outcome of engineering education and a mediator for other outcomes such as persistence in engineering [1].

II. REVIEW OF THE LITERATURE

Professional identity has mostly been studied based on psychosocial theories of identity to consider both one's own perception and social views of oneself. However, there are different approaches among scholars about how it could be conceptualized. In an attempt to understand professional identity practices in higher education, a line of research focuses on influencing factors that contribute to the process [2-3]. In a study by Meyer and colleagues engineering identity development is modeled using a stage theory from a developmental psychology view [2]. This study suggests three

factors for students' self-identification as engineers. These include making competent design decisions, working with others to share ideas and accepting responsibility.

Walther, Kellam, Schacka, and Radcliffe define engineering education as a complex system with a range of influences some of which are in practice outside the realm of explicit and formal instruction [4]. *Accidental competency formation* is applied in this study to investigate professional formation within engineering programs. The study invites scholars' attention to the conceptions of unintended learning and the notion of hidden curriculum as the things students learn during their informal experiences at university rather than through explicit teaching and learning events. We further note that learning also happens within the broader social context and outside institutional scope as well as through the things that are not included in explicit teaching.

To address how engineering professional identity is practiced, and unpack further how influencing factors are played out, studies have investigated micro level practices as in talk in interaction. Discourse analysis [5-6] and positioning theory [7] are among the approaches used to this purpose.

Among other approaches used in studies of engineering professional identity development is Lave and Wenger's notion of communities of practice [8]. Shaffer's idea frames engineering identity practices by drawing on this looking at professional identity practices as participation in a community of practice that involves developing community's way of doing, and being. According to Shaffer's argument, this practice is seen as an epistemic frame of the engineering profession composed of knowledge, skills, values, identity and epistemologies linked with the engineering profession [9].

In addition, Eliot and Turns describe engineering identity formation as an interaction between the engineering social expectations and characteristics of engineering students [1]. The results of the study show students engage in two processes of sense making, one related to external expectations and one regarding their internal abilities and values as engineers.

Existing research on professional identity practices in engineering education contributes to unfolding different aspects of the processes involved. However, it does not offer a holistic approach to the complex multi layered process of

identity practices to cover and explain both micro level practices of talk in interaction and macro level organizational processes. A broader review of professional identity development in higher education also suggests that further study is required to unpack the term of professional identity and to discuss its possible implications for higher education learning, teaching and assessment [10]. The following questions are still unanswered, as to how professional identity practices happen both within the realm of formal education and through educational design, as well as outside institutional practices and within a larger social context. And what are the mechanisms involved, for specific aspects of professional identity to be practiced by a specific person at the certain point in time.

In the next section we address these questions by proposing a holistic approach based on the social realism view to explain the process of professional identity practices.

III. IMPLIED IDENTITY: A CONCEPTUAL FRAMEWORK FOR PROFESSIONAL IDENTITY PRACTICES IN HIGHER EDUCATION

Scholars in the field often distinguish engineering professional identity practices as separate, external or overlapping processes to learning experiences. We look at engineering education through the lens of engineering identity development. Our definition of professional identity draws on Harre's concept of positioning [11]. Episodes of learning are defined as opportunities to develop a sense of belonging to a community of engineers. Students' learning and assessment experiences are therefore processes of professional identity formation practices through which students position themselves or get positioned by others as engineers.

To understand how such identity practices happen and how educational design could facilitate or hinder these practices, one should address the question of what educational design works invites one to be or to do or to think. Educational design includes anticipated learning events, learning spaces, and learning materials. We suggest the answer to this question lies in the concept of *implied identity*. It originates in the concept of implied reader, first introduced by Iser [12], which refers to a reader as presupposed by a literary text.

The new concept of *implied identity* refers to suggestions of professional identity to individuals through their experiences of identity resources, including educational designs. From a social realism approach, *implied identity* is an emergent property arising from the configuration of identity resources and students' interpretations of them. It may remain unexercised if a relevant identity resource is not experienced by an individual (i.e., an agent). Otherwise, it may hinder or facilitate specific aspects of professional identity in individual's practices.

Professional learning and identity development is a lifelong process shaping and re-shaping through individuals' experiences of identity resources both within and outside the realm of formal education. Professional identity practices emerge at the intersection of identity resources and agency including both individuals and collective. In the proposed view, individuals are seen as active receivers of socially offered *implied identities*. To explain how individuals respond to the perceived *implied identities*, we draw on the Archer's notion of

reflexive deliberation [13] and the emergentist theory of action [14]. Reflexive deliberation, which is at the core of Archer's definition of human agency, is an individual's internal conversation with oneself that mediates between individual and a social context. Reflexivity is firstly seen in contrast to Pierre Bourdieu's concept of *habitus* or socialized norms and tendencies that guide behaviors and thinking. However, Elder-Vass [14] proposes an emergentist theory of action that "explores how human dispositions and reflexive decisions are related to the determination of human action" (p. 1).

As illustrated in Fig. 1, individuals encounter identity resources with dispositions in forms of beliefs about who they think they are, identity concept, and who they want to become as their ideal identity. These dispositions are the result of individual's previous experiences. We argue that a person's professional identity practices are caused non-consciously by his/ her *habitus* if implied identity is compatible with individual's sense of self and his/ her ideal self. However, individual's responses to incompatible *implied identities* happen through reflexive deliberations, which in turn are mediated by their *ideal identity*, and *identity concept*.

In addition, we apply the term *intended identity*, to distinguish between identity as intended by educational designers for students and students' perception of suggested identities (*implied identities*). An example of educational *intended identity* is identity embedded within the list of graduate attributes assumed for engineering students.

The proposed framework extends on previous works (such as [1] and [4]). It proposes a more holistic approach that explains relations between educational designer, educational design works, and learners' professional identity experiences.

IV. STUDY AIMS AND METHOD

An empirical study was designed with the aim of investigating implications of the proposed framework and exploring if it provides a possibility to get an insight into the process of professional engineering identity practices during collaborative work. Here we draw on part of the study to take an in-depth look at two participant groups to address the following research questions: 1) What are different aspects of

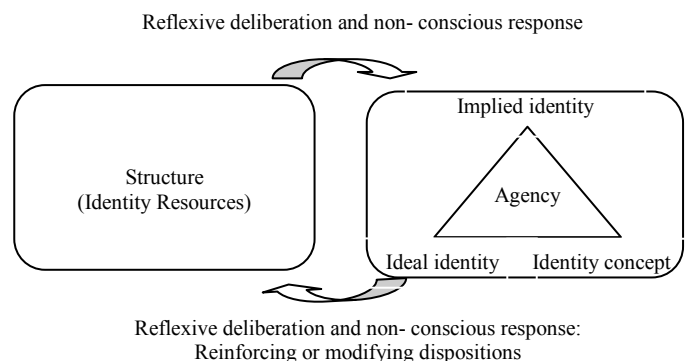

Fig. 1. Implied Identity, A Social Realism Approach to Professional Identity Practices

engineering identity practiced by the two groups of engineering students while working collaboratively on a sustainability task? 2) Is the proposed framework of implied identity explaining the differences between the two groups in terms of groups' decisions for practices of professional identity?

A. Data collection and research setting

Two groups of four undergraduate students of Chemical Engineering worked collaboratively on a sustainability task. A task was designed to address a problem of air pollution in mega cities and participants were asked to provide solutions and prioritize their solutions based on their proposed criteria list. Participants were asked to give a report at the end of their collaborative session. Group 1, consisted of international exchange students who voluntarily participated in the study. Group 2 experienced their participation as part of the course which is an elective subject in their degree. For this group, the collaborative task was one of the assignments, worth 20% of the students' total grade for that unit of study. The collaborative sessions were conducted at a special studio designed for group work, and were video and audio recorded.

B. Preliminary analysis

According to the proposed framework, assessment experiences are themselves resources for learning and identity practices [15]. Hence we look at students' participation as a learning experience and their collaborative work as a learning episode, which can be investigated using the implied identity framework. We identify two main identity resources for the analysis of *intended identities*: 1) the task description and 2) speech acts at the time of conversation. We further investigate students' responses to the task and its *intended identities*, and explore similarities and differences between practices of the two groups.

Audio transcriptions were qualitatively analyzed in NVivo to find practices of engineering identities. To explore aspects of engineering identities, we applied Figueiredo's model where engineering is seen to consist of four dimensions connected within a transdisciplinary relation [16]. These include: 1) engineer as scientist, 2) engineer as designer, 3) engineer as doer, and 4) engineer as sociologist. Sub categories were added according to the description of each category. As an example, using mathematical language and contextual thinking were added to the categories of engineer as scientist and engineer as designer, respectively. A new category was added for engineer as environmentalist to highlight concerns about the environment and sustainability.

V. RESULTS AND DISCUSSION

As the summary of preliminary results illustrate in Table 1, there are similarities between the two groups' professional identity practices in the four categories of engineers as designers, engineer as doers, engineer as environmentalist and engineer as scientist. However, the two groups differ in relation to their practices in the category of engineering as sociologist. In addition, frequency of identity practices differs between the two groups. As an example, Group 2 practice engineering as basic sciences more frequently and these practices cover about

24.34% of group's conversation as opposed with Group 1 with the coverage of 7.51% of their collaboration.

In this paper we focus on the difference between the two groups in the category of engineering as a social science and the subcategory of *education* and *engineering as educator* as one of the emerging differences. Group 1 rejects to see themselves, as engineers, responsible for promoting social awareness, while Group 2 two puts "educating people" in their report as one of their suggested solutions to tackle the problem of air pollution.

Applying the *implied identity* framework for further analysis and explaining the emerging difference, provides an opportunity to look at the *intended identities* and investigate how the two groups interpret the task, and *intended identities*. An identity intended by the researchers through the design of the task was to reflect upon social, ethical and cultural sides of the proposed solutions and to foster inclusion of these aspects in group's discussion and report. We argue that differences in groups' identity practices are the result of how the two groups perceive *intended identities* in the form of *implied identities* through their experience of the task and how they position themselves accordingly.

Members of Group 1 are pre-positioned as "participants in the study" by the start of the collaboration due to their voluntary participation. Once the collaboration starts and they read the task, members of the group re-position themselves as "engineers working in a company" by referring to the task statement "You are invited to join a consulting engineering team". They further continue reading the task and make group decisions based on their new positioning as engineers and their beliefs about who they think engineers in a company are.

However, members of Group 2 are pre-positioned as students in the course. They continue their collaboration in the same position of "students doing an assignment". This influences group's decision to follow steps of the task description more precisely presumably to have a better performance. The pre-positioning of being a student, results in paying no attention to the scenario explained in the task statement "you are engineers working in a company". Group 2 values elements of the task statement including suggested steps to follow in providing a report, such as "make sure you comment on the social and economical aspects" and "address ethical considerations as well as technological ones as part of your discussion".

In terms of the implied identity framework, the same identity resource, the task in this case, is read and interpreted differently by the two groups and proposes different *implied identities*, "being an engineer", to participants. The *implied identity* that Group 1 offers to themselves, which is assumed to be the ideal identity they imagine for "an engineer working in the company", is not engineers as educators. This in turn directs group's decision making in refusing practices such as "educating people and promoting social awareness". This illustrates how group's positioning practices and beliefs in relation to the taken position influences group's decision making. Previous research has also shown how positioning practices influence group's decision making [17].

TABLE I. IDENTITY PRACTICES

Dimension of Engineering	Group 1		Group 2	
	Number of utterances (Coverage)	With references such as	Number of utterances (Coverage)	With references such as
Engineer as Scientist	54 (7.51%)	Using mathematical language; Research and discovery; Analysis and experiment	70 (24.34%)	Using mathematical language; Research and discovery; Analysis and experiment
Engineer as Designer	25 (3.20%)	Contextual/ holistic vision; Intuition; Personal experience	15 (3.75%)	Contextual/ holistic vision; Intuition; Personal experience
Engineer as Doer	66 (7.82%)	Engineering artefacts; Changing the world	11 (3.14%)	Engineering artefacts; Changing the world
Engineer as Sociologist	78 (11.17%)	Management; Social nature of the world; Economic value; Ethics; Art	60 (17%)	Management; Social nature of the world; Economic value; Ethics; Education
Engineer as Environmentalist	10 (1.13%)	Sustainability	1 (0.10%)	Sustainability

^a Preliminary Results

As shown, applying the *implied identity* framework provides a possibility to gain an insight into the process of professional identity practices. It enables us to understand further layers of such complex process by uncovering relations between educational designs and learner's experiences of them. Furthermore, it enables us to look at multiple identity resources simultaneously including micro level resources such as talk in interaction and higher level organizational practices such as being a student or volunteer in the research and how these impact learner's experiences of the task.

We are interested to further investigate how the use of online resources in the two groups provide students with suggestions of engineering identity and how suggested identities are taken up and practiced by them. In addition, we are interested to explore how individuals' reading of the task is communicated between members of the group to gain a mutual understanding of the offered *implied identities* and how this helps a group to make decisions and establish agreement.

ACKNOWLEDGMENT

We wish to thank Professor Peter Goodyear, CoCo Co-director, and two other CoCo colleagues, David Ashe and Martin Parisio for their assistance with data collection. Additionally we gratefully acknowledge Dr. Morteza Khosronejad, Director of SUCCLS at Shiraz University, whose

insights contributed significantly to developing idea for this project.

Campus to Career, Understanding How Engineering Student Skill Perceptions link to Future Career Pathways

Glenda Young and David B. Knight
Virginia Tech
glenda87@vt.edu, dbknight@vt.edu

Abstract— The National Academy of Engineering's *Engineer of 2020* (E2020) report identifies skills and attributes that engineering undergraduates will need to possess to find success in the engineering workforce. Our study seeks to extend prior research that developed typologies of engineering seniors based on a set of E2020 outcomes to investigate variation in career pathways across outcomes-based groupings of students. Student clusters range from those who self-report highest on each outcome and are the most well rounded (i.e., those who most closely resemble "the Engineers of 2020") to clusters characterized by 50% of the reported abilities of students in the E2020 cluster on different outcomes. In this paper, we examine how six clusters of mechanical engineering students perceive their future career pathways, evaluating the likelihood of students in each outcomes-based grouping to enter an engineering or non-engineering related career path. Findings shed insight on how students' perceived relative competencies on a variety of skills related to their career decision-making and/or views of possible careers. This work serves as preliminary analysis that we will extend across multiple engineering disciplines in our next steps.

Keywords— Pathways; Career; Engineer of 2020; Workforce

I. INTRODUCTION

Members of industry consistently claim that graduates of engineering programs are not prepared when they enter the workforce. Collaborations between members from academia and industry have offered insight into the skills that are needed to support the future engineering workforce. The Engineer of 2020 skills, identified by the National Academy of Engineering in 2004, offer one example of a set of outcomes that engineering graduates should possess to be prepared for industry positions in the future. As educators and employers respond to the President's call to dramatically increase the number of STEM graduates and workers [1], it is important to understand how student-perceived abilities of such outcomes impact their career pathways. By looking at students' perceptions of their skills and abilities versus their anticipated career pathways, we can begin to understand how skills translate to feelings of preparedness for different careers.

Efforts to minimize the skill gap (i.e. the notion that students do not graduate with the skills necessary for day one in the workplace [2]) have highlighted the need for higher education institutions to be more accountable in ensuring student outcomes are met, producing students with the skills necessary to be successful. For this study, we consider that the skill gap might exist because of mismatch

between student skill perceptions and anticipated skills for a particular career pathway. Students may be entering careers in which their skill set is not best fitted, so in response to a poor fit between the job and employee, employers cite the skill gap.

Prior research has taken a similar outcome approach to understanding student career pathways. The Academic Pathways Study and the Engineering Pathways Study has examined student perceptions versus anticipated and actual career pathways in a series of cross sectional and longitudinal studies [3-6]. These findings reinforce the need to further understand the extent to which students' perceptions of their skills impact career pathways.

We hope to contribute to the skill gap literature by shedding light on the fact that a student's self perceived set of skills relates to their career decisions. With this information, we will be better able to determine how we may need to change conversations about what careers entail or how we structure education to change sets of outcomes to better inform students of how their skills map to various career paths. In this study, we identify career pathways as engineering, management/sales, and non-engineering roles post bachelor degree. Also, graduate school with plans to enter faculty, industry, or professional schools are considered potential pathways. This study extends prior research that developed a typology of engineering undergraduates based on a set of E2020 outcomes and investigates variation in career pathways across those groupings of students. This research is a work in progress, and our ultimate goal is to investigate patterns across engineering disciplines.

II. METHODS

A. Data

Drawing on data from the Prototype to Production: Processes and Conditions for Preparing the Engineer of 2020 (EEC-0550608) project sponsored by the National Science Foundation, this study utilizes undergraduate survey data from a nationally representative sample of engineering programs in the United States. Students provided information on their precollege academic preparation and socio-demographic characteristics, curricular and co-curricular experiences, and self-ratings of their engineering-related competencies.

B. Data Collection, Preparation, and Sample

Students were enrolled in a thirty-one institution sample, which were selected to be representative in terms of engineering discipline, highest degree offered, and institutional level control. Because the study seeks to understand the preparation of mechanical engineering students at the point at which they would be ready to enter the workforce, our analyses include only mechanical engineering students in their 4th or 5th years ($n = 771$; the senior response rate was 16%). To account for response bias in an effort to enhance external validity, weights were developed and applied (e.g., [7]) so that the proportional representation of students by gender, race/ethnicity, and discipline within each institution was equal to the population of students at each institution (e.g., a different gender weight was applied for each institution). Weights were also applied to account for differences in institutional response rates.

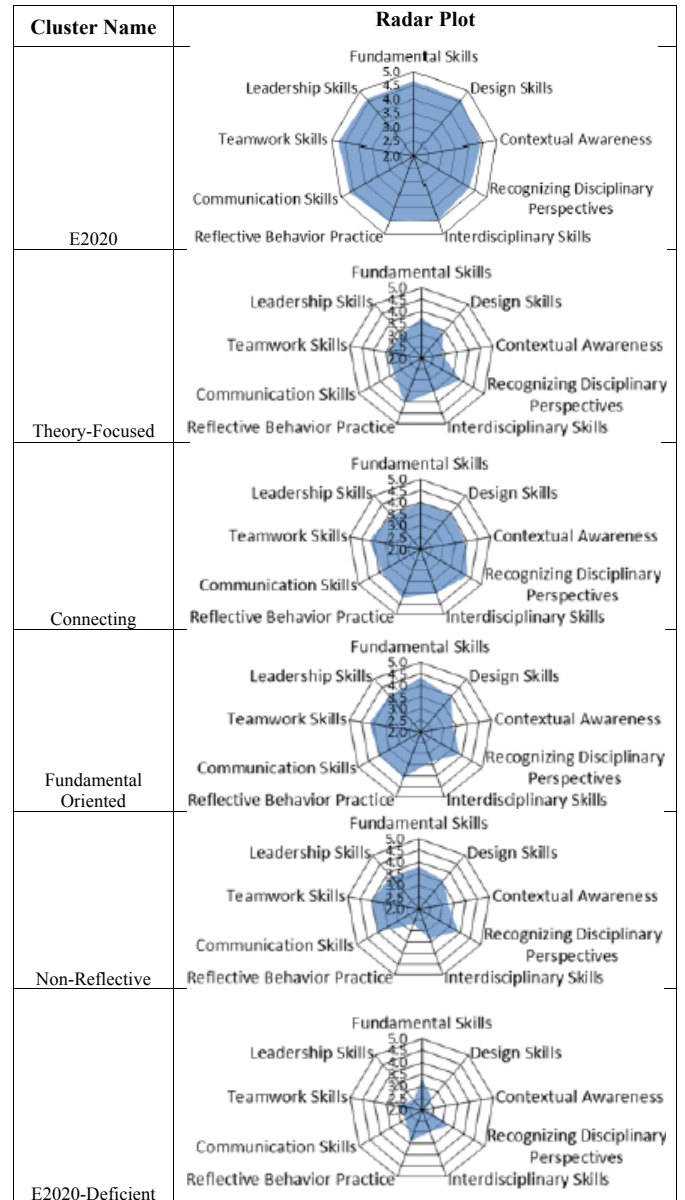

C. Cluster Grouping

Cluster analysis identifies homogeneous groupings in multidimensional space within a sample. Students were clustered into groups using the nine E2020 learning outcome scales. Although all nine E2020 outcomes were used to assign students into clusters, describing a cluster on nine different dimensions was complex, and we describe categories along four categories: Fundamentals, Design, Interdisciplinary, and Professional skills. Radar plots illustrate the reported levels of proficiency and well-roundedness of students in each cluster, see Table 1. The “fundamental skills” scale describes applying foundational knowledge to solving engineering problems and is described on its own (top of plots). Leadership, teamwork, and communication skills are described as a “professional skills” dimension (left side of plot), following the norm set by engineering education researchers and practitioners (e.g., [8]). Design skills and contextual awareness are described together as “design skills” since these are closely related competencies (e.g., [9] [10]) (right of plot). Recognizing disciplinary perspectives, interdisciplinary skills, and reflective behavior practice are described as an “interdisciplinary skills” dimension because items originally were developed to measure this construct (bottom of plot).

D. Variables

Independent variables were six categorical variables, student clusters. Cluster names were chosen to characterize the shape of the shaded area relative to the shaded area of the “E2020” cluster (i.e., the cluster with highest average outcomes and well-roundedness). Each concentric circle represents the grid scale for an outcome, where the center is 2.0 out of 5.0 (no average values were less than 2.0), and the outer ring is the maximum 5.0.

TABLE I. INDEPENDENT VARIABLES, STUDENT CLUSTERS

Dependent variables were the average student ratings for each cluster on the likelihood of entering each of the seven career pathways.

TABLE II. DEPENDENT VARIABLES, CAREER PATHWAYS

Career Pathways
Stem: Three years after you graduate, how likely is it that you will:
Be self-employed in engineering
Be a practicing engineer in industry, government, or non-profit organization
Work in engineering management or sales
Work outside engineering
Be in graduate school preparing to become an engineering faculty member
Be in graduate school in engineering preparing to work in industry, government, or non-profit organization
Be in graduate school in a field other than engineering (business, medicine, law, etc.)

1. Likert Scale Values: 1=Definitely won't, 2=Probably won't, 3=Not Sure, 4=Probably will, 5=Definitely will

E. Analysis

Comparisons across clusters for likelihood of a career pathway three years post graduation used a Kruskal–Wallis test (“K-W test”— the nonparametric equivalent of analysis of variance [ANOVA]). This analysis revealed that clusters did differ across likelihood of career pathways.

To identify specific cluster differences on each career pathway, or each dependent variable, we examined all pairwise comparisons. We conducted pairwise comparisons for all clusters using Mann–Whitney U post hoc analyses, applying a Bonferroni correction when determining significance levels to account for multiple comparison errors.

III. PRELIMINARY RESULTS

In examining the mean rating for each career pathway we conclude that 4th and 5th year mechanical engineering seniors are not certain of what their career pathway will look like three years post graduation. The only career pathway with a mean score above 3 is ‘Be a practicing engineer in industry, government, or non-profit organization,’ which fell above ‘Not Sure’ and approached ‘Probably will.’ Students mean ratings were ‘Probably not’ or approaching “Not Sure” for the remaining pathways.

TABLE III. CAREER PATHWAY PERCEPTION MEANS

Career Pathway	Mean
Be self-employed in engineering	2.14
Be a practicing engineer in industry, government, or non-profit organization	3.82
Work in engineering management or sales	2.77
Work outside engineering	2.44
Be in graduate school preparing to become an engineering faculty member	2.07
Be in graduate school in engineering preparing to work in industry, government, or non-profit organization	2.83
Be in graduate school in a field other than engineering (business, medicine, law, etc.)	2.31

A. Kruskal-Wallis Test (K-W Test)

The K-W test identified statistically significant differences between the cluster groupings for five of the seven career pathways based on an alpha of 0.05. We saw no differences for being self-employed in engineering or for becoming a practicing engineer in industry, government, or non-profit organizations.

TABLE IV. CAREER PATHWAYS

Career Pathway	Sig.
Work in engineering management or sales	0.002
Work outside engineering	0.001
Be in graduate school preparing to become an engineering faculty member	0.025
Be in graduate school in engineering preparing to work in industry, government, or non-profit organization	0.016
Be in graduate school in a field other than engineering (business, medicine, law, etc.)	0.012

B. Pairwise Comparisons

Mann–Whitney U pairwise comparisons revealed which clusters were statistically significantly different when considering the likelihood of entering each career pathway three years post graduation.

Work in engineering management or sales

Students in the E2020 Deficient cluster differed from students in the Non-Reflective ($p=0.038$) and Connecting ($p=0.014$) clusters. E2020 Deficient students were less likely to perceive themselves as working in engineering management roles three years after graduation. This difference is likely due to the fact that these students perceive themselves to lack overall skills (especially design and professional skills) that are most common in a managerial or sales role.

Work outside engineering

Students in the Fundamental Oriented cluster were more likely to perceive themselves as working outside of engineering than students in the E2020 Deficient ($p=0.015$) and Non-Reflective cluster ($p=0.011$). Perhaps students who have higher abilities in engineering have higher self-confidences and think that they can also perform well in a different focus area. Students in the E2020 Deficient and Non-Reflective cluster alternately may perceive their lack of fundamentals as a barrier to working in another discipline or field.

Be in graduate school preparing to become an engineering faculty member

E2020 outcome students were more likely to consider a graduate school to faculty career path than students in the Non-Reflective cluster ($p=0.030$). E2020 outcome students are those who perceive themselves as highly skilled across all outcomes. In contrast, students in the Non Reflective cluster might perceive their lesser developed design and interdisciplinary skills as barriers to being faculty.

Be in graduate school in engineering preparing to work in industry, government, or non-profit organization

Theory-Focused students ($p=0.038$) are more likely to perceive themselves as attending graduate school to prepare to work in industry, government, or a non-profit organization than Non-Reflective students. Students who tend to be strongest in fundamentals relative to the other skills tend to be more likely to choose this pathway than the ones who are weaker on reflective skills. It is not clear why this difference exists, future work will need to investigate this relationship further.

Be in graduate school in a field other than engineering (business, medicine, law)

Students in the Fundamental Oriented cluster were more likely than the Theory-Focused group ($p=0.035$) to be in graduate school in a field other than engineering. The Theory-Focused group had lower perceptions of their interdisciplinary skills in addition to professional skills and excelled on core engineering skills. Theory-Focused students might feel more comfortable remaining in the engineering field based on their comfort and/or expertise with engineering theory. Students in the Fundamental Oriented cluster, rather, similarly perceive themselves as having strong core engineering skills, but they also perceive themselves to be more well-rounded; they might be more

likely to consider how engineering thinking may apply to other fields.

We still have more work to complete to understand these relationships, but our preliminary results suggest that senior engineering students differ in their likelihood of entering different career pathways based on their self-assessment of a variety of outcomes.

IV. NEXT STEPS

Future work includes examining other engineering disciplines and identifying similarities and differences to understand how students perceive career pathways across majors. Additionally, we plan to compare these findings to similar analyses using alumni three years out from school.

Academia could use this information to inform programming and curriculum to support competency development that offers students a broader set of career options. Additionally, academia could offer more tailored recommendations for specific experiences (e.g. internships, co-ops) based on a student's career interests and skill perceptions. Industry can benefit by planning recruitment efforts to highlight how student skills map to different engineering roles. Additionally, industry can benefit by understanding how students perceive their skills to fit the field and support training for new hires to assist in the school to workplace transition.

Abstract—In this work, we describe a range of prototyping boards such as Arduino, Raspberry Pi, and BeagleBone Black, and we show how these devices are being used in our ECE curriculum in a range of courses for projects. We describe the continuing challenges we have with adopting such technology from an educational standpoint, and some best practices/techniques we have learned and adopted to include these devices in our courses. We believe integrating these devices into our course flow is of a huge benefit to both our curriculum and our students.

I. INTRODUCTION

In 2011, we wrote a paper called “Arduino for Teaching Embedded Systems. Are Computer Scientists and Engineering Educators Missing the Boat?” that asked the question if electrical and computer engineering (ECE) was ignoring the growth of Arduino (arduino.cc) prototyping boards as a platform to teach aspects of ECE, and in particular, to teach embedded systems [1]. At that time, the Arduino world was showing large growth because the artist created community was allowing people from all walks of life to use a micro-controllers and electronics to implement all sorts of projects in a strong sharing community. This community differed significantly from the heavy front-end learning expected by engineers who used and supported traditional microprocessor boards. We felt that these devices had some place in traditional ECE education and we described how a course on embedded systems used Arduinos and the pros and cons of such devices.

The Arduino has continued to have success in the “Maker” world, and our curriculum has expanded the use of the Arduino to more than the embedded system course. Additionally, we have opened our embedded system design course to more than just Arduino boards and have seen students use Raspberry Pi (raspberrypi.org) and BeagleBone Black Boards (beagle-board.org). These new boards still have much of the open source and maker communities, but the devices themselves are more powerful allowing even more design possibilities.

In this paper, we describe what these devices are, and then, we describe how these devices are being used in our ECE curriculum in a range of courses. With our experiences, we describe the continuing challenges we have with adopting such technology from an educational standpoint and some best practices/techniques we have learned and adopted to use these

devices in our courses. In particular, with the large wealth of open source projects available online, how do we assess projects to determine what students are building and learning. Additionally, we make claims as to why we believe integrating of these devices into our course flow is of a huge benefit to both our curriculum and the student.

The remainder of this paper is organized as follows: section II provides a background these prototyping devices and open source and how people have assessed projects. Section III takes a more detailed look at the prototyping devices, and section IV describes student projects that used them. Section V provides a description of best practices we have adopted for using these devices in courses. Section VI includes a short discussion and conclusion of this work.

II. BACKGROUND

The three main areas we address in this paper are Project Based Learning (PBL), open source projects assessment, and prototyping boards used in ECE curriculum.

A. Project Based Learning

Project Based Learning (PBL) curricula (which is a version of Problem Based Learning and has a wide literature base [2]) is normal in many fields with examples in engineering, business, and medicine [3], [4], [5]. PBL pedagogy centers learning around the activity of the student. The approach focuses on building projects and allowing the student to learn on the fly as they face problems. Projects are spaced throughout the degree, hence the name PBL curriculum. The accreditation agency, ABET, among other entities, influenced engineering programs into including a major capstone around 1995 to 1997 [5]. For computer engineering curriculum, lab only courses [6], [7] slowly evolved to include both labs and final projects. The senior capstone has been studied to help understand how to prepare students for this culminating experience [8], [9].

Among the vast range of research on the impact of PBL on engineering curriculum (among other areas) there has been some focus on both the usefulness [10] and the assessment of projects (though assessment is still lacking). Much of the

research on assessment of PBL is lacking and most contributions are focused on describing the PBL course [11]. There are some academic reviews by Dym *et. al.* [3] and Graham [12].

B. Open Source Projects

Within the domain of PBL, two questions tend to arise: First, should projects be allowed to use the available plethora of projects on the web released as open source software (OSS) and projects (OSP)? Second, if OSS and OSP are allowed to be used, then how do we assess students contributions and learning?

The majority of literature that, partially, address these issues is from the OSS and computer science and software engineering education. In particular, many of the early documented attempts are in teaching software engineering use OSS [13], [14]. This includes using the most popular OSS project, Linux, to help teach operating systems [15], and includes senior capstone student work [16].

Assessment of these projects is not not deeply examined, but there are a few documents that talk to the issue. Nascimento *et. al.* go into the most depth with their study on the research issues of using OSS in courses [17]. In addition, Pedroni *et. al.* take a look at assessment techniques, but focus more on student perception of the value of the experience [18]. Unrelated to academic class assessment, Rigby *et. al.* [19] take a look at peer-review assessment of software, which is a common practice in software design, and has some ideas that could be used in a classroom setting.

C. Prototyping Boards

In electrical and computer engineering (among other majors) the prototyping board is a prefabricated board that includes a microchip or set of chips that allows various types of systems to be experimented with, designed, and tested without having to build the PCB (Printed circuit board) and test that part of the system. The word *prototyping* implies that the system, once, completed, could be designed more efficiently, but during prototyping most of the systems features can be used on these boards. These boards are used both in industry and education.

We do not provide a comprehensive list of such boards, but some common examples include: Altera's [20] FPGA prototyping boards such as Terasic's DE2 board that allow full systems to be implemented. Similarly, an open source FPGA related board called, NetFPGA [21], is being used to kickstart a prototyping board - ONetSwitch www.kickstarter.com/projects/onetswitch/onetswitch-open-source-hardware-for-networking. DSP boards, such as Texas Instrument's TMS320C6713 DSP Starter Kit (DSK) www.ti.com/tool/tmdsdsk6713, can implement DSP applications. Microprocessor boards, including the ones we will discuss in this paper (Arduino www.arduino.cc/, Raspberry Pi www.raspberrypi.org/, and BeagleBoard beagleboard.org, allow embedded systems to be prototyped. Ettus Research's USRP devices used in implementing Software Defined Radio systems, might also be considered as a form of prototyping board that has had an impact on education by allowing students to work in the radio domain [22].

Though these boards are used in undergraduate education, there is little discussion or evaluation on how to use them in courses. Pritchard and Mina do take a look at similar types of prototyping boards and classify them from three perspectives: hardware intensive, software intensive, and ease of implementation. Other work has focused on remote lab implementation, which includes a large body of scholarly work (we suggest a review paper [23]). Additionally, since microprocessors were available they have been included in labs and continue to be a major part of computer engineering [24]. PBL and prototyping boards make a good mix and multiple efforts have focused on this including robots embedded throughout the curriculum [25] [26], and FPGA boards for projects and learning digital logic [27], [28], [29].

The major question we have is with the availability of open source designs, cheap prototyping boards, and access to hobbyists and professional, how do we include these powerful tools in the modern ECE curriculum?

III. ARDUINO, RASPBERRY PI, AND BEAGLEBONE BLACK ... OH MY

A. Arduino

"Arduino is an open-source electronics prototyping platform based on flexible, easy-to-use hardware and software. It's intended for artists, designers, hobbyists, and anyone interested in creating interactive objects or environments" [30].

The UNO (the base system) consists of a microcontroller (an ATmega328 [31] microprocessor), a USB to serial chip, and an AC to DC power converter. The UNO can either be built by hand or can be bought premade from a seller such as sparkfun.com costing approximately 25 USD. The Arduino software platform is written in Java and is based, mainly, on Processing [32] (a language developed for artists). The IDE is installed on a machine and then can program the UNO over the USB. The base IDE includes a number of examples for blinking LEDs, making noises, etc. The UNO is only one type of Arduino board and many others exist in varying form factors.

We would classify the Arduino UNO as a simple microprocessor board that is easy to use for bit-banging based projects. Bit-banging is the fine grain manipulation and control of single bits or pins. The device is easy to learn to the point that the student can learn how to use the device with web resources alone without any formal instruction. This is because of the community that supports Arduino started with artists and these people provide significant help to beginners (as they are) as opposed to engineering forums for other microprocessors, which include responses such as, "go do your own homework/assignment". The ease of use and friendliness of the community does, however, bring a challenge to educators when assessing projects developed on these devices (which we will discuss later).

B. Raspberry Pi

"The Raspberry Pi is a low cost, credit-card sized computer that plugs into a computer monitor or TV, and uses a standard keyboard and mouse. It is a capable little device that enables people of all ages to explore computing, and to learn how to

program in languages like Scratch and Python” raspberrypi.org.

The Raspberry Pi (we will call it just Pi) is a full-fledged computing system with a 900 MHz ARM based processor (www.arm.com/). The board can be loaded with the Linux and GNU tools, a monitor can be connected to it via the HDMI port, and input devices, such as a mouse or keyboard, can be connected to the USB ports. In other words, the Pi is a full computer that can be used for embedded system projects, but is also useful in the domain of implementing servers and other computer system applications. The additional processing power makes the Pi a much more powerful device, but accessing and using the general purpose input/output (GPIO) ports is more difficult and makes the Pi less useful as a starter device when controlling (bit-banging) simple electronic circuits. The Pi costs approximately 40 USD.

The Raspberry Pi community is also very active and helpful. However, a student needs to learn command line usage in Linux, programming tools in Linux, and other computing concepts/skills, which makes it harder to use for beginners to programming. Since the device is newer than the Arduino there are not as many open source resources, but there is more projects than one person can track meaning that assessment is equally challenging.

C. BeagleBone Black

“Makers, educators, explorers, professional engineers and corporations seeking to build upon a rich ecosystem are all encouraged to participate in BeagleBoard.org. With so much openness and thousands upon thousands of examples of people doing fun, interesting and profitable things with Beagles, you’re missing out if you don’t count yourself in for whom Beagle is intended. beagleboard.org”

The BeagleBone Black (which we will call BBlack) provides functionality of both Arduino and Pi. The BBlack has a powerful processor (ARM processor at 1GHz) that can run Linux similar to the Pi, but the BBlack also has I/O capabilities to do simple bit-banging with circuits to the point that the BBlack can run the Arduino IDE (with a little bit of configuration www.logicsupply.com/blog/2014/09/24/tutorial-running-arduino-ide-beaglebone-black/).

The BBlack is also low cost and costs approximately 45 USD. The community is open and helpful, but is smaller than other two groups, but has the benefit of leveraging various projects that are designed for the other prototyping boards.

IV. STUDENT PROJECTS AND COURSES USING THESE BOARDS

A. Courses using these boards

At Miami, the Arduino UNO has been used in a number of courses. In particular, the UNO is used in our introductory electrical and computer engineering course (ECE 102), our second course on circuits (ECE 303), our embedded systems design course (ECE 387), and optionally, in our computer organization course (ECE 289) and our senior capstone. In the introductory course and the circuit course, the department provides kits for the students, but for the other courses,

students are expected to purchase the device in lieu of a textbook.

For projects in both our Senior Capstone and embedded system design, both the Pi and BBlack are common choices depending on the needs of the project. Again, these devices are purchased by the students both because of their low cost and student preference to have the device to play with and use outside their course work.

The amount of instruction provided on how to use these devices is very little. In the introductory course (ECE 102), the Arduino is introduced over two 55 minute lectures where the instructor shows how to connect an LED and pull-up switch. A basic program that shows how a light can be dimmed using pulse width modulation is shown to the students. From there, a student is expected to complete six labs using arduino and basic circuits to complete 3 assigned tasks:

- Knight Rider display which is a timed lighting of a series of LEDs
- Control a servo with a switch
- Build a simple ball catching system

and 3 student/TA created challenges that create a problem that needs to be solved using the device, some components, and some creativity.

In the circuit course (ECE 303), additional instruction is provided on the Arduino since some of the students come from outside the electrical and computer engineering department (for example, mechanical engineers), and they require a basic introduction to the board. Other than this, students are expected to learn how to program and interface their circuits with the Arduino by accessing tutorials and projects on the web.

For the Pi and BBlack, no formal instruction is provided, and students are expected to learn how to use these devices on their own. Computer engineering students will have learned command line Linux instructions and the compilation process in their computer organization course (ECE 289), but electrical engineers, who do not have this training, are expected to learn this as needed for their projects.

B. Student Projects

With these devices, students have created some impressive projects. The majority of these impressive projects are built in the ECE387 course and senior capstone design projects. For example, in ECE387 students created auto-tracking paintball guns, built a segway like device, built a bug-tracking system, and hypno-cubes. Videos and source code for many of these projects can be found at www.users.miamioh.edu/jamiespa/teaching.html, but as Google Code hosting service will be terminated in 2015, the availability of these design files will be for a limited time.

There are also a number of senior design projects that use these devices as the microprocessors in the student’s designs. For example, in 2015 a group of students is building a microphone array that can distinguish people location in a room based on conversation. In 2014, a group of students used vibration sensors and a Raspberry Pi to triangulate the location of people based on their foot steps. These are just

a few examples of complex systems that students can create with these devices.

Lastly, the IEEE student group commonly uses these devices for their projects which includes a 60 inch spectrum analyzer (built with CPU fans, foam chips, and led lighting) and a coin operated arcade game emulator. The availability of these boards has vastly expanded the projects that the student run group can do.

V. CHALLENGES WITH ADOPTING PROTOTYPING BOARDS

As great as these microprocessor prototyping boards are based on functionality and low cost, including them in courses has a number of challenges. In particular, the most difficult challenge is with how to deal with the availability of open-source projects and shields and libraries, and then assessing what a student has done. We will describe what our current best practices are, but by no means have we solved the problem of assessment and project creation completely.

A. Assessing Projects with the Availability of Open-Source

We have been using Arduino UNO in classes since 2010 and were one of the earlier adopters in this community. In 2010, there was a significantly large community of users and open source projects, but since then there has been a continuous increase of projects and people. The number of Arduino shields and supported libraries, where a shield is an easily connectable separate device that can be attached to an Arduino and allows interfacing with another chip (for example a motor drive shield), has also increased significantly making it possible to use complex chips without students having to understand much on interfacing. Additionally, libraries that support both shields and interfacing with sensors, actuators, and other chips are continuously being improved. All of this means that there is a massive amount of information, code, and designs that students can leverage in creating their own designs. The question remains, how can we assess the idea of “their project” and verify that students are learning.

One simple solution is to move towards first principles and push students to do low-level interfacing without libraries. Arguably, this approach should be done at least once since it helps student’s understand some of the details in interfacing. However, forcing students to reinvent the wheel for every device they will use is less useful since, arguably, in their industrial jobs the goal will be to leverage existing designs and code bases to create larger systems.

Another solution is to allow students to use any code base and assess the system based on the final product. In this approach, the instructor assumes that to create a complex system that a student will spend significant time understanding existing libraries, how those libraries can be used, and mixing more than one library/api together to achieve a complex task. We used this approach for a number of years, but we have begun to notice that some students are building projects that are similar to complete kits that can be purchased. For example, the hypno-cubes student’s created in 2010 and 2012 can now be built with the purchase of a kit. For this reason, these types of projects are no longer considered an appropriate project.

The third approach we have used is to have the students deliberately prepare a document that shows what code they

used and what they have added/designed. In this approach, we allow students to use any code, but they are required to show how their code is differentiated from the existing code. In this way, a student is required to describe how they created their system and used existing modules within their system. This process is similar to a diffing a code-base from the open-source base, but we require the student to illustrate this in a single organized document that allows instructors to easily see what the students have done and what was already available. The downside of this approach is that it requires the students to spend additional time organizing their design in the final deliverable. Also, this approach can make the students design appear simple, when in reality, to even get each device to interface requires significant time and learning even with an existing code base.

Of each of these approaches, the main question is what are the learning objectives. In the courses where we use these devices, the main learning objectives in the third year is a “create” (metacognitive and create) and in the introductory courses is a “use” (metacognitive and apply) in the Revised Bloom Taxonomy [33]. At these levels in the taxonomy, the question of what the student is learning is mainly related to the product, and all three approaches are sufficient for assessment. However, to promote creativity and reflection, we are moving towards our last approach in which students need to show their contributions differentiated from existing code-base and examples.

B. Project progress and success

Another significant challenge with projects, which is true independent of working with the above described prototyping boards, is scale of projects and ensuring student progress towards completing a successful project. In particular, students that transition into college think that a project can be completed in a single (long) evening, have a difficult time creating a project, and have very little skill at project organization. Additionally, students face many challenges in terms of working in group projects such as finding common meeting times, and dealing with non-contributing team members [34], [35], [36].

For project creation, we use one of two approaches; first, student’s propose (orally and written) what they would like to do, which the instructor can modify, make suggestions, and provide fallback options, and two, a custom project is created that all students will do in the class. In both situations, the projects are successful based on the experience of the instructor and their understanding of what is doable in the time allotted.

To ensure progress we have tried to implement progress meetings, and these are successful for senior design projects, but they seem to have very little impact on early courses. We believe reality is that until a student experiences how difficult a project is to complete in a very short period of time, they do not learn to work continuously through a semester. As much as we provide direction, the learner has to experience how hard it is to get things built and working.

We also provide instruction on the use of design methodologies such as agile design [37], but this is not necessarily the focus of the courses the projects are in, and are ideas that tend to be taught later in the curriculum. Even with knowledge of these methodologies and best practices, students still have a

difficult time applying the techniques to improve the progress of their projects.

VI. CONCLUSION

In this paper, our goal was to expose educators to the benefits and challenges of using modern prototyping micro-processor boards - Arduino, Raspberry Pi, and BeagleBone Black. Each of these devices has been used in a number of our courses for student projects of many different levels. The main challenge with using these boards is identifying and assessing student projects based on the availability of open source designs and the community that supports these projects. We describe how we approach these problems, but we still do not believe we have perfected the use of these devices.

Overall, the students like the low cost of these devices and the ease of use that allows them to create significant projects. As instructors, the projects that are being delivered show that students are improving on system design and are delving into real engineering systems motivated by their own creativity. This we believe justifies adopting these boards in a curriculum with the risks described earlier.

Design and Implementation of a Microcontroller Based Workstation with Educational Purposes for the Control Systems Area

Juan Felipe Patarroyo, Gerson Beauchamp, Aidsa Santiago

Electrical and Computer Engineering Department

University of Puerto Rico at Mayaguez

Mayagüez, PR 00681-9000

juan.patarroyo@upr.edu, gerson@ece.uprm.edu, aidsa.santiago@upr.edu

Abstract—This paper presents the design and implementation of a microcontroller based workstation for improving the learning process of undergraduate students in the Digital Control Systems Area. High level tools such as Simulink® and Labview® have provided excellent results in the development of laboratory experiments due to their ease of use and friendly user interface. Students that develop their control projects using these tools do not commonly learn important concepts such as motor driver implementation, digital to analog converter and analog to digital converter. The implementation of this work is based on a pedagogical experiment that includes a set of workshops and a course project development. Workshops were designed following a backward design approach in which the content, assessment, and pedagogy used to implement the proposed system are aligned. Assessment tools revealed that the learning objectives were accomplished and students showed an acceptance toward this tool.

Keywords—ball-and-beam system, digital control systems, education, laboratory experiences, microcontroller applications.

I. INTRODUCTION

The use of microcontrollers is playing an increasingly important role in a wide range of engineering applications [1]. Specifically, the area of control systems depends significantly on the use of microcontrollers for control systems implementation.

Most of the course projects in the Control Systems Area are implemented using high level simulation tools and data acquisition boards. These methods have yielded excellent results because they offer a block based environment which makes all the internal details transparent for the user. However, they have the disadvantage of not exposing students to implementing digital controllers directly with microprocessors. Furthermore, programming skills are becoming more important nowadays and a drag-and-drop block based environment does not provide enough understanding on how a digital controller is implemented in real world using computer programs. Multiple approaches teach students how to develop digital controllers directly with microcontrollers [2, 3, 4, 5, 6]. However, there is no formal course design to implement these tools. Additionally, is not common to find formal assessment methods to measure the effectiveness of their approaches. Our

approach is to align assessment methods with course content and delivery.

Beauchamp-Jimenez, et al, analyzed performance of two implementation methods for the controller of a Ball-and-Beam (B&B) system: Using a Microcontroller Unit and using Simulink [7]. They used the bilinear transformation and the z-domain direct design process to implement the controllers. The author showed that the implemented controller yielded similar but not identical results in both implementations (Simulink, MCU). This work followed a hybrid problem-based methodology which was implemented with a group of students of the University of Puerto Rico at Mayaguez (UPRM). A limitation of this work was that there were no formal methods to validate assessment and the effectiveness of this approach in an educational environment.

In this paper we document the development process of a microcontroller based control system (MCS) with pedagogical purposes. This MCS is intended to be focused in the improvement of the Digital Control Systems (DCS) course project. The MCS uses the Texas Instruments C2000 TMS320F28069 microcontroller and the DRV8412 motor driver.

The implementation of this work is based on a pedagogical experiment that includes a set of workshops and a course project development. These activities are part of the Digital Control Systems course of the Electrical Engineering program in our department. Workshops were designed following a backward design approach in which the content, assessment, and pedagogy used to implement the proposed system are aligned [8]. The professor evaluated student's performance through oral presentations using a rubric that has been designed to measure student outcomes as established by ABET criteria. These evaluations were compared against those students who did not receive the workshops in previous years.

II. EDUCATIONAL SETTING

A. Program Structure

The Digital Control Systems (DCS) course is currently offered as an undergraduate technical elective in the UPRM Electrical and Computer Engineering Department (ECE). The

Introduction to Control Systems and the Signals and Systems courses are prerequisite for the DCS course.

The undergraduate Electrical Engineering Program in the Electrical and Computer Engineering (ECE) Department consists of 165 credits that should be completed in a period of 5 years. The curriculum provides students with a general education background in mathematics, science, and humanities. The program has four areas of emphasis: Applied Electromagnetics, Communications and Signal Processing, Control Systems, Electronics, and Power. Most students in the DCS course are in their fourth or fifth year of their course plan and are specializing in the area of Control Systems.

Some of the students in this course have already taken the microprocessors course, which is one of the core courses in the curriculum. At this point, students have basic knowledge on the use of microcontrollers but they do not have the required skills to create an embedded controller.

B. Course Structure

The DCS course has as an objective making students proficient in analyzing, designing and implementing digital control systems for single-input single-output physical systems [9]. To achieve this objective, students should take classroom lectures, homework assignments, and a term project.

1) *Classroom Lectures:* As part of the classroom lectures, students learn the theoretical background of digital control systems. The topics covered in the DCS course include modeling of discrete-time control systems, using the z-transform to analyze discrete-time systems, stability criteria, and root locus design in the z-domain. These topics appear commonly in digital control systems textbooks [10,11,12,13].

2) *Homework Assignments:* Students receive a set of exercises that should be delivered before each exam. Thus, students reinforce the theoretical knowledge learned in class.

3) *Term Project:* Students are organized in teams of two or three students and the instructor specifies an assignment to carry out one or more tasks that lead to the design and implementation of a digital controller for the Quanser's Ball & Beam experiment [14] (see Fig. 1) available in the Process Instrumentation and Control Laboratory (PICL) [15]. The controllers should be implemented using microcontrollers as well as with Simulink through Quanser's Quarc® tool. Finally, students should make a comparison between both implementations.

Fig. 1. Ball & Beam Experiment.

To document the project, students should prepare a time schedule, two progress reports, and one final report. The time schedule is used by the students to organize the time needed for each task. Progress reports allow instructor to assess the current state of the work for each team. Teams must present a demonstration and an oral exam to validate these reports. In the final report, students are expected to explain the development process of the B&B controller by applying the theory acquired in lectures and assignments.

III. MICROCONTROLLER BASED CONTROL SYSTEM

The microcontroller based control system (MCS) integrate the Texas Instruments (TI) C2000 TMS320F28069 Microcontroller [16], the DRV8833 motor driver [17], and a custom made Analog Signal Conditioning Board. A general system overview of the MCS is shown in Fig. 2. One of the most important components of the system is the Analog Signal Conditioner Board. This board converts the voltage levels from the Quanser analog sensors to a range that could be read from the microcontroller (0-3.3V). Also, a DC motor driver (DRV8833) was configured and used. The motor driver receives PWM signals generated by the microcontroller to change the average output voltage applied to the motor. The Optical Encoders send two square wave signals to the microcontroller according to the shaft angular position and rotating direction. Finally, a Timer Interrupt Unit sends a signal to the CPU indicating when the control action should be performed.

The MCS uses a C2000 TMS320F28069 microcontroller. It operates at 80MHz and is equipped with 16 Analog-to-Digital Conversion (ADC) channels with a resolution of 12 bits, 2 Quadrature Encoder read-modules (eQEP), 16 independent 32 bits PWM channels, Floating Point Unit (FPU), JTAG emulation tool, and other characteristics that make this microcontroller ideal for high capacity digital control purposes.

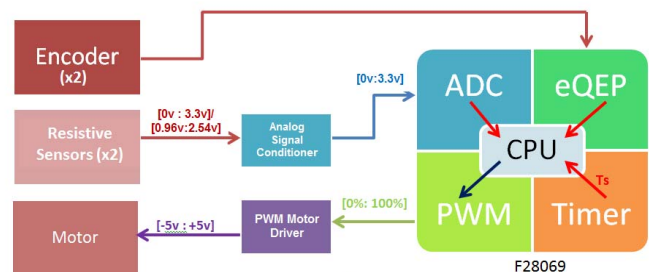

Fig. 2. MCS System General Overview

A. Analog Signal Conditioning Board

The MCS was designed to work with two Quanser® analog sensors, these resistive sensors were designed to have a dual power supply of -12V to +12V. Using a couple of 7kΩ bias resistors, they convert this voltage level to -5V to +5V. For this reason, a Signal Conditioner Circuit is used to convert these voltage levels to a range of 0V to 3.3V which is the operative range of the microcontroller ADC unit.

The use of negative polarization voltages represents a disadvantage because the system should use a dual voltage power supply, making it less portable and incrementing costs

of production and flexibility. The proposed solution was to use a single power supply of 3.3V on the resistive sensor; this yielded an output voltage range between 0.96V and 2.33V. See Fig. 3.

Fig. 3. Quanser® Resistive Sensors Voltage Levels. Left: Quanser® Power Supply Voltage Levels. Right: Proposed Power Supply Voltage Levels.

Thus, it is necessary to amplify and add an offset this signal to read it adequately with the microprocessor. The AD623AN instrumentation amplifier was used for this task. It allows a single power supply and its gain is set using only one resistor R_G defined as: $R_G = R_{AG} + 49.9k\Omega$. Fig. 4 shows the proposed analog signal conditioning circuit design. The output voltage is given by

$$V_{out} = \left(1 + \frac{100k}{R_G}\right) \left(V_{in} - \frac{3.3R_{OFF}}{R_{OFF} + 4.87k}\right) \quad (1)$$

Fig. 4. Analog Signal Conditioning Circuit

The desired amplifier gain and DC-offset is obtained by adjusting R_G and R_{OFF} . Values of $R_G = 71.42k\Omega$ and $R_{OFF} = 2.005k\Omega$ are obtained. The output equation that converts the input signal range of 0.96 to 2.33V to an output signal range of 0 to 3.3V is given by

$$V_{out} = 2.4(V_{in} - 0.9625) \quad (2)$$

A voltage divider was used in the analog signal conditioning circuit to provide an offset voltage of 0.96V on pin 2 of the AD623N. The variable resistor R_{OFF} is used for calibration to minimize tolerance errors. The two capacitors C1 and C2 are used to isolate noise from the microcontroller and other digital circuits. A 3 pin jumper JP1 was used at the output to bypass the amplifier in the case when the sensors already work at the same voltage range of the microcontroller ADC and their signals do not need to be conditioned. This circuit was simulated using ORCAD Capture™ and it showed adequate performance. Fig. 5 shows that the input signal (purple line) is amplified to be in a range of 0-3.3V (red line).

Fig. 5. Signal Conditioner Simulated Results

The S_{out} pin is connected to the ADC pin of the microcontroller development board. This board has all the protection circuitry required to prevent from input over-voltage or input inverse-voltage. This is accomplished using diode voltage clippers at the input of the ADC pins of the microcontroller.

A PCB layout was developed using Eagle®. Several factors had to be taken into account for the PCB design, for example, conditioned signals should have a testing point for troubleshooting and path widths should be wide enough to prevent ground loop noise. A photo of the PCB prototype is shown in Fig. 6.

Fig. 6. Photo of the Analog Signal Conditioning Board

B. System Assembly

Each of the twelve MCS stations was packed in an enclosure with a power supply port, sensor ports for the connections with the Quanser® Experiments, and test different situations that may appear in practice such as overvoltage and bad connections among others. Fig. 7 shows photos of the final box assembly. The MCS is organized so that the student may visually identify its main modules and use them with little risk of damage.

Fig. 7. Photo of the final box assembly of the MCS stations. Left: External view. Right: Internal View.

C. Peripheral Configuration Libraries

The implementation of the digital controller using the MCS differs significantly from the Virtual Instrument in Simulink because the controller should be coded in C language and all the I/O functions of the microcontroller must be configured separately. Students received a set of C code configuration libraries for the most used peripherals in the development of digital controllers. Students were trained about how to modify these libraries to meet the signal requirements of each experiment actuator and sensor. The configuration libraries are based on the TI Control Suite™ package. It contains some sample projects for configuring the main peripherals of C2000 microcontrollers [18].

1) *Analog-to-Digital Converter (ADC)*: ADC unit is used to read from analog sensors. The MCS uses 2 ADC channels (A6, A7) triggered in continuous mode. This means that every time the ADC produces a conversion, an End of Conversion (EOC) flag is set; this flag initiates the next conversion and so on. The window size is set to 7 clock cycles, this is the minimum amount of time that the ADC needs to produce a reliable conversion.

2) *Enhanced Quadrature Encoder Unit (eQEP)*: Most of the Quanser® rotational sensors use quadrature optical encoders for angle measuring. An optical encoder is a sensor that generates 2 square wave signals indicating angle and rotating direction. Fig. 8 shows both signals and their meaning.

Each signal has a 90 degrees phase shift from the other depending on the rotating direction. TMS320F28069 microcontroller has 2 eQEP units capable of decoding these signals and counting the rotating steps in the sensor. Encoder input pins are located for Channel A in GPIO pins 20 and 21, and for Channel B in GPIO pins 24 and 25.

Fig. 8. Quadrature Encoder Signals

3) *Enhanced Pulse Width Modulation Unit (ePWM)*: The DRV8433 [17] motor driver was used to generate the voltage needed to move the SRV-02 motor. Changing duty cycle affects the output voltage of the motor driver, see Fig. 9. Two independent PWM Channels were used for this task. To move the motor clockwise (CW), pulse width in PWMA channel must be fixed to 100% and the pulse width in PWMB channel determines the CW angular velocity. To move the motor counterclockwise (CCW), pulse width in PWMB channel must be fixed to 100% and the pulse width in PWMA channel determines the CCW angular velocity.

Fig. 9. Effect of changing duty cycles difference on the motor speed.

4) *CPU Timer Interrupt Unit*. This Unit is used to generate interrupts at a fixed time interval; this allows using the microcontroller in between control actions, taking advantage of all the features that it offers. When these interrupts occur, the processor will execute the difference equations that realize the control action.

IV. BALL & BEAM CONTROLLER

A. Controller Design

A Lead-Lag Controller for the B&B system was implemented using the MCS. Fig. 10 shows a block diagram of the B&B digital controller. The blocks inside the dotted rectangle represent the difference equations performed by the digital controller, while the blocks outside the dotted rectangle represent the dynamical system of the B&B system.

System Transfer Functions are derived in *Quanser's Student Handout* [14]. A sampling period of 30ms was selected according to Shannon's sampling theorem [13]. Controller requirements were established according to experience in previous courses. The ball position controller was specified to have an overshoot under 30% and a settling

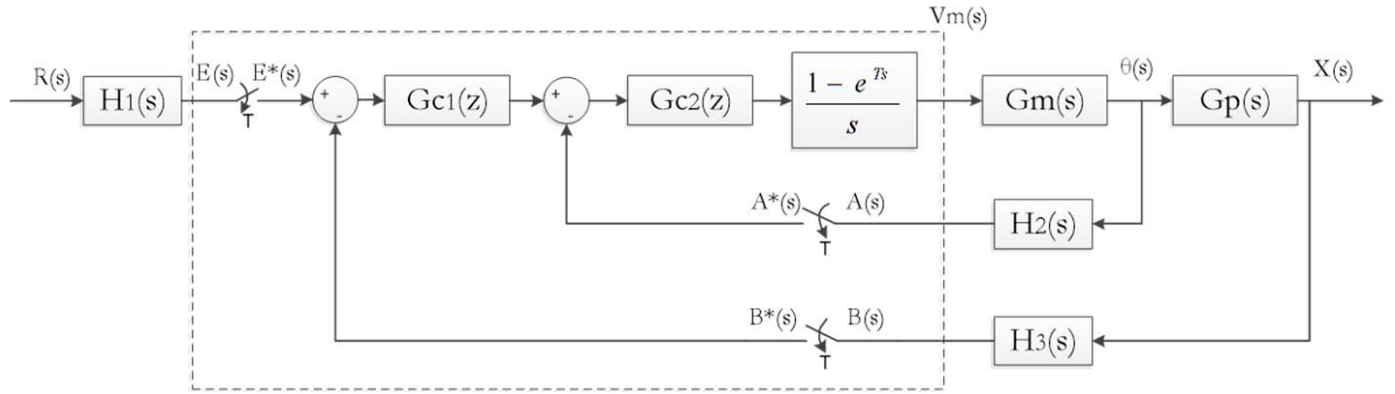

Fig. 10. Ball & Beam Controller Block Diagram

time under 5 seconds. According to these specifications, a Lead-Lag compensator was designed using z-plane root-locus methods. The Lead-Lag controller has two poles and two zeros. A pole-zero pair corresponds to the Lead compensator and the other pole-zero pair corresponds to the Lag compensator. The Lead compensator has its zero to the right of its pole in the z-plane while the Lag compensator has its pole to the right of its zero; but very close to each other. The designed Lead-Lag Controller resulted in

$$G_{cl}(z) = \frac{\theta_{ref}(z)}{X_{error}(z)} = 82.86 \frac{(z - 0.986)(z - 0.995)}{(z - 0.6287)(z - 0.999)} \quad (3)$$

where $\theta_{ref}(z)$ is the Z-transform of the output of the controller and $X_{error}(z)$ is the Z-transform of the error between the reference position and the actual position of the ball. To obtain the difference equations, it is necessary to apply a Z-transform property

$$Z^{-1}\{z^{-k}\theta_{ref}(z)\} = \theta_{ref}(z)[k - n] \quad (4)$$

This property is called *Time-Shift* and states that whenever a z^{-k} factor multiplies a discrete time function, it generates an n -times translation in time that is interpreted as a register in the microcontroller program. The difference equation performed by the lead-lag controller (3) is given by

$$\begin{aligned} \theta_{ref}[k] &= 82.86x_{error}[k] - 164.145x_{error}[k-1] + \dots \\ &81.291x_{error}[k-2] + 1.627\theta_{ref}[k-1] - 0.628\theta_{ref}[k-2] \end{aligned} \quad (5)$$

The motor Angular Position Controller was chosen to be a proportional controller with $K=4.7$. The output voltage applied to the motor is given by

$$V_m[k] = 4.7(\theta_{ref}[k] - \theta[k]) \quad (6)$$

Once (5) and (6) were obtained and all the peripherals were configured, a control action should be performed each time the CPU generates a timer interrupt. The values of all the registers in the controller are updated every time (5) and (6) are executed.

V. WORKSHOP DEVELOPMENT

The implementation of this work includes a set of workshops to train students in the use of the MCS. The workshop content was designed to assist participants in accomplishing ABET student Outcome E of the DCS course [19, 9] which is expressed as: *Implement a digital controller using a digital computer and software*. Workshops were designed according to Streveler's Outcome Based Education (OBE) framework [8] which follows a *Backward Design* approach as presented by Wiggins and McTighe's book [20] [21] and the *How People Learn* framework presented by Bransford, et.al [22]. Refer to [23] for more details about the pedagogical design of this approach.

Workshops were given in the PICL and were two hours long each. Students were organized in pairs and were assigned a computer workstation and an MCS workstation. The instructor gave a tutorial where a step-by-step guidance was given according to the learning objectives of the session.

Workshops were dictated alongside the development of the course project. According to this, students were evaluated in their progress reports on how they integrated the use of the MCS in their projects. Three different workshops were designed to achieve the learning objectives:

- The first workshop focuses on the fundamental elements of embedded control systems. Students recognized the main differences between implementing a digital controller using an MCS and using high level tools. Also, in this workshop, students learned basic operations in a C-code programming through the use of the Code Composer Studio Development Software. Finally, students implemented a basic C-code blinking-led program which allowed them to familiarize with the Code Composer Studio Environment.
- The second workshop trains on the configurations and a hands-on experience with the microcontroller stations. Students learned how to use the microcontroller peripherals to read signals from sensors and to control the motor driver. They were expected to learn about the working principle of each sensor of a Ball & Beam system and to read them using the microcontroller. Then, students learned to

translate the signals coming from the peripherals to the international system units (meters, radians, Volts). Finally, students created a GUI to view the variables measured by the sensors.

- The third workshop was about implementing a real controller using difference equations and the Texas Instruments GUI Composer. This workshop synthesized the concepts learned in the two previous workshops by implementing a digital controller using C-code. Specifically, students were expected to learn how to transform a z-domain transfer function to a difference equation and how to convert this difference equation into a C-code program to control a servomotor.

VI. RESULTS

A. GUI Implementation

One of the most important features of the Texas Instruments® C2000 microcontrollers and Code Composer Studio™ is the debugging tool. GUI Composer™ is an extension of this software. This tool allows developers to create Graphical User Interfaces (GUI) to access directly to the microcontroller registers in real time. Once the student develops the software, he or she can create a Graphic Panel where the defined variables can be watched in real time and parameters may be modified on-the-fly. The student is able to change zeroes, poles, and all the controller parameters. Three sample GUI's were created to be used as templates for other projects: SRV-02 Proportional Controller, SRV-02 Lead-Lag Controller, B&B Lead-Lag Controller. Additionally, further implementations in the discrete-time state-space were developed with aims to be implemented in the Linear Systems Analysis Course.

The B&B Lead-Lag controller performance acquired from the GUI Composer Interface is shown in Fig.11. The blue line is the reference signal, the orange line is the actual ball position in response to the reference signal. Fig. 12 shows the controller performance of the same controller using Simulink. Both controllers have similar performance.

Fig. 11. Ball & Beam Controller Performance using the MCS

Fig. 12. Ball & Beam Controller Performance using Simulink

B. Workshop Assessment

To assess the contribution of this work, we evaluated students' performance in their term project compared to those students who did not receive the workshops in previous years. For this, we developed a set of rubrics written according to the cognitive domain of Bloom's Taxonomy and ABET criteria [24, 19, 23]. Final project reports provided enough information about students' fulfillment of the project outcomes for those students that took the course in previous years. Specifically, we assessed the ability of students to implement and validate a digital controller using Simulink and Microcontrollers. A total of 18 reports were assessed divided in three categories:

- (1) 6 reports from Students from 2013 Fall semester who implemented and validated digital controllers using only Simulink.
- (2) 4 reports from Students from 2013 Fall semester who implemented and validated digital controllers using Simulink and additionally implemented their controller on a microcontroller voluntarily. These students were not trained in the use of microcontrollers for digital control implementation.
- (3) 8 reports from Students from the 2014 Fall semester who were required to implement and validate digital controllers using both Simulink and MCS. These students were trained with the workshops developed in this work.

Reports were assessed in a scale of three levels: Good (80-100), Acceptable (70-79), and Insufficient (0-69). Average results of the assessment analysis are presented in Fig. 13. Each team was evaluated according to five main course outcomes:

- Punctuality (Outcome 7).
- Design of Controllers (Outcome 3).
- Simulations (Outcome 8).
- Controller Implementation (Outcome 4):
 - Using Simulink.
 - Using Microcontrollers.
- Controller Performance (Outcome 5):
 - Using Simulink.
 - Using Microcontrollers.

Fig. 13. Outcome Assessment Compared to Previous Years

Fig. 13 shows that students who only used Simulink had excellent scores on punctuality, design, and simulations. However, they had lower scores on controller implementation and performance. This is because they did not accomplish the microcontroller component.

Those students who used Simulink and used the microcontroller voluntarily had lower scores in all outcomes. These students did not receive any training on the use of microcontrollers for digital control implementation.

A deeper analysis of the project reports revealed that students could not focus on the project because they spent too much time dealing with the microcontroller configuration and hardware connections. In fact, some students could not finish their project and thus, did not pass the course. These students repeated the course in 2014, attended the workshops, and had an average score over 90% on the project using the MCS.

Finally, those teams who used Simulink and microcontrollers yielded the best performance. These were students who received the workshops developed in this work and learned about the use of microcontrollers for digital control implementation.

Results revealed that those students who were trained on the use of microcontrollers for digital control implementation had better scores than those who were not. This indicates that the DCS course was improved by enhancing the performance of students in the project. In the past, students were not able to fulfill project outcomes related to the microcontroller implementation.

To guarantee inter-rater reliability, a second evaluator assessed a representative sample of 9 groups: 3 for the first category, 2 for the second category, and 4 for the third category [25, 26]. The results of this evaluation were compared against the results obtained by us. A mean correlating factor [27] of 0.93 was obtained. According to Cohen this indicates that no arbitrary considerations were made in the evaluation of project reports [28].

VII. CONCLUDING REMARKS

To the best of our knowledge, only a small number of the reviewed works teach students how to develop digital controllers directly with microcontrollers using C language. However, there is no formal course design to implement these

tools. Finally, in the works reviewed, it was not common to find formal assessment methods to measure the effectiveness of their approaches.

A set of workshops were developed following an outcome-based education and a backward design approach. The DCS course was improved by enhancing student outcomes fulfillment in the implementation of the project.

A microcontroller based system was developed for the project implementation. Experimental results indicate that the controllers implemented with the MCS have the same performance to those controllers implemented using Simulink or LabVIEW. Also, the MCS demonstrated to be well designed since it was an effective tool for implementing the digital controllers of the student projects.

The workshops provided students with a good understanding of embedded control systems. The process of programming the controller provided students a deeper understanding of how digital control systems are implemented in real world through embedded systems. Also, using Texas Instruments® Code Composer helped in the debugging process. In the past, digital controllers were implemented using microcontrollers, but there were no formal debugging methods for troubleshooting.

The methodology presented in this work could be used in the future to introduce new tools in other courses in the engineering discipline. Also, the MCS represents a multi-purpose platform that can become a commercial product of pedagogical interest that may be used to improve the learning process in a higher education setting.

ACKNOWLEDGMENTS

The authors would like to thank Texas Instruments for the donation of the C2000 microcontrollers and motor drivers. Also, thanks to Dr. Gerson Beauchamp for his excellent mentoring and to Dr. Rogelio Palomera for supporting this project.

Autonomous Robot: An Intellectual Way of Infusing Microcontroller Fundamentals into Sophomore Students

Chirag Parikh

School of Engineering
Grand Valley State University
Grand Rapids, MI, 49504
Email: parikhc@gvsu.edu

Abstract — Use of microcontrollers has become inevitable in almost every field of engineering. Thus in our program, we have adhered to the idea that knowledge in microcontroller fundamentals is necessary for all types of engineering majors. However, the difficulty arises when a traditional classroom teaching with examples and non-creative projects instill boredom amongst students. Students fail to make the connection of how important this understanding will be in their future studies, be it mechanical, electrical or other majors.

We feel there is a missed opportunity to engage engineering students early in their program with a highly relevant and easily tangible experience working with intellectual microcontroller-based projects. In order to improve the experience, we introduce our students to the basics using laboratory exercises on the Arduino platform and then transition to a full-featured in-house autonomous robot platform for the final project.

The paper first talks about our current approach in teaching microcontroller topics to the students followed by the need to develop the autonomous robot platform. The robot platform was developed in-house by the undergraduate students using the available in-house resources. The autonomous robot utilizes a commercial chassis, wheels and tracks along with geared DC motors that include embedded quadrature position encoders. In addition to the chassis, the undergraduate students have also used off-the-shelf hardware for robot control and Arduino interface for student developed code. The paper then talks about the various kinds of laboratory exercises and projects that can be implemented on this platform by the students in their introductory digital systems course that they take as sophomores.

We further include student assessment data that supports our approach and shows that the students appreciated this intellectual way of learning microcontroller fundamentals so that they can apply the concepts they have learned in a logical and sequential manner to solve practical engineering problems. Finally, we conclude the paper with lessons learned and ideas for an improved learning experience.

Keywords — microcontroller, autonomous robot, Arduino

I. INTRODUCTION

With the technological advances in semiconductor electronics, manufacturing and process; control problems are now being solved more effectively and reliably using microcontroller rather than mechanical and electrical switching systems. Microcontroller-based sensing and control has become imminent in almost every field. This increased use of microcontroller in the industry has led to a new era of teaching microcontrollers in the academia. An area that has traditionally been reserved for electrical or mechanical engineers is now multidisciplinary, integrating digital electronics, communications and computing with a variety of systems ranging from medical to biological to environmental. Thus in our program, we have adhered to the idea that knowledge in microcontroller fundamentals is necessary for all types of engineering majors [1][2]. The new trend is to take this area beyond the traditional engineering setting and to make it accessible to students from various disciplines in a way that would foster their practical understanding and use of it.

Initially, the microcontroller fundamentals were taught in a traditional classroom setting where the instructor used to lecture and the students used to learn through listening and observation. Throughout the course, the students used to learn about the microcontroller theory and interacted with the microcontroller only through a simulator. This approach did not benefit the students since they had difficulties working with a real microcontroller in an embedded setting. With microcontrollers becoming inexpensive, a new approach called *Hands-on Learning* [3][4], started becoming popular. This approach allowed students to have a greater control on what and how they learn by allowing them to try things that are beyond the scope of traditional classroom setting. This approach emphasized on group-activities and learning exercises that required students to work with the microcontroller hardware in the classroom.

Faculty in School of Engineering at Grand Valley has taken this approach a step ahead by incorporating an in-house autonomous robot designed by two undergraduate students to infuse microcontroller fundamentals to the sophomore students in their course *EGR 226: Introduction to Digital Systems*. The primary objective of this approach is to present

microcontroller theory in a way that is appealing and applicable to all engineering disciplines.

This paper describes our approach of using autonomous robot to teach the microcontroller fundamentals to the sophomore students in our introductory digital systems' course. The paper is organized as follows: the next section describes the robotic platform that we introduce to the students in our Digital System course. The paper then describes the development of our laboratory exercises and how they build towards the final project assigned to students. We further include student assessment data that supports our approach and shows that the students appreciated this intellectual way of learning microcontrollers. We finally end the paper with our concluding remarks.

II. ROBOT PLATFORM

In order to integrate hands-on learning with the microcontroller, the students were required to purchase the Arduino Uno board for the course. The Arduino board [5] and programming language is an inexpensive way for faculty to teach microcontroller fundamentals in introductory courses. The students were assigned learning exercises in class and laboratory exercises where they had to use the Arduino board to complete them. With this being said, we still felt that the spark was missing that would instill excitement in the students and provide them with an educational learning experience with the microcontrollers.

Brainstorming session with two undergraduate students working in the electronics laboratory support led to the idea of designing autonomous robot [6][7] that would be utilized in the laboratory by other students taking the course. Since the two students had already taken the Digital systems and Circuit analysis courses, it made sense to assign them the task of designing the robots. The next task was to identify the wireless communication scheme to autonomously control the robot. After extensive research, the students were able to find a low-cost and reliable radio frequency (RF) chip (Nordic NRF24L01)[8] that had an improved range and greater programmer flexibility. It was also decided that it would be beneficial to design an RF transmitter to be able to communicate with the robot.

After several iterations of prototypes, final product specifications were finalized and the two students began working on the final product. Students used *Solidworks* for prototype modeling, 3D-printer (*Makerbot*) for printing enclosure, *Eagle* for circuit layout and soldered components on the printed circuit board and took them about 4 months to get the final product (RF-LCD controller and RF-robot) as shown in Fig. 1. After the final product was created, it went through severe testing to make sure everything worked as expected. Since we had a tight budget constraint, the robot platform was developed in-house by the using the available in-house resources.

Fig. 1. RF-LCD Transmitter and RF-robot

The RF-LCD controller housed following components:

- Nordic NRF24L01 RF chip
- Arduino compatible LCD shield
- Breakout board for connecting Arduino board
- Connectors for accessing Analog pins of Arduino

The RF-robot housed following components:

- Nordic NRF24L01 RF chip
- Commercial chassis, wheels, tracks and geared DC motors with embedded quadrature position encoders
- Motor shield
- Gadget shield (with peripherals like buttons, LEDs, potentiometers, speaker, microphone, accelerometer and many more)
- Breakout board for connecting Arduino board

This design and build process was a very good learning experience for the two undergraduate students who were assigned the task of building the robots.

III. SAMPLE LABORATORY ASSIGNMENTS AND PROJECT

The course laboratory exercises are meant to help students design and understand the use of microcontroller in an electro-mechanical system. The course laboratories are structured as four assignments and one project. They cover the following topics: introduction to the microcontroller platform; general purpose input output; timer peripherals; interrupt mechanism and analog-to-digital conversion. These laboratories expose the students to become familiar with the microcontroller platform and learn to program a microcontroller to perform the desired functions. Each laboratory has a set of deliverables; typically including the successful demonstration of a working design, source code with comments, and a brief report.

The following is an outline of the four laboratory assignments that we offer in the course:

- **Laboratory #1:** The purpose of the laboratory was to introduce students to the microcontroller platform that

they use in the course. The laboratory teaches students to write and upload C programs for the microcontroller platform. The laboratory also provides an insight into some of the built-in functions that is available through the open source database and then makes them write their own custom functions that provides the same functionality.

- **Laboratory #2:** The purpose of the laboratory was to teach students to work with general purpose input and output (GPIO) of microcontroller and communicate with Arduino over serial interface. To be able to do this we provide students with an add-on shield (Gadget shield as shown in Fig. 2) that has several peripherals and sensors that students can take advantage of. In this laboratory, students are required to display the least significant 4-bit representation of the character user enters on the terminal window on the Gadget shield LED's.

Fig. 2. Sensors and actuators on the Gadget Shield

- **Laboratory #3:** The purpose of the laboratory was to teach students to interface Arduino with the liquid crystal display (LCD). For this laboratory, we provide students with the RF-LCD controller that has the LCD module embedded in it and students insert their own Arduino board into the controller. In this laboratory, students are required to design Rock-Paper-Scissors game that the user plays with the microcontroller. For this laboratory, we allow students to use some of the pre-built functions for random number generation. Sample output of the game is shown in Fig. 3 below.

Fig. 3. Sample output for Rock-Paper-Scissors game

- **Laboratory #4:** The purpose of the laboratory was to teach students the principle of pulse-width modulation (PWM). In this laboratory, students were required to design a menu-driven LED dimmer application that varies the intensity of the LED on the Gadget shield based on user input.
- **Final Project:** The final project is spread over two weeks where students learn about interrupt mechanism and analog-to-digital (A/D) conversion and apply those concepts during the first week of the project. In the second week, students integrate everything together (knowledge about GPIO's, timers, PWM, interrupts, A/D conversion) to create a working application. The students are given two weeks to design and implement the project by using pre-designed components from the laboratory assignments and/or creating new components from scratch.

With the introduction of RF-LCD controller and the autonomous robot, students are required to accomplish RF communication between two RF-LCD controllers during their first week of the project. In the second week, students put the RF-receive code on the robot along with interrupts, A/D conversion and PWM functionality of the microcontroller to move the robot in the maze based on the commands send by the RF-LCD controller (that has the RF-transmit code).

IV. ASSESSMENT

The course "Introduction to Digital Systems" introduced the autonomous robots for the first time in Winter 2015 with an enrollment of 54 students. In order to obtain finer-grained feedback from the students, at the end of the semester we encouraged the students to complete a customized anonymous questionnaire to learn the benefits of using the autonomous robots and help improve the efficiency of the robot usage for future semesters. All of the students filled out the questionnaire to identify their actual impressions of using autonomous robots in this course.

A. Questions

The students were asked four questions as well as they were given the opportunity to include written comments. The questions were rated on a five point scale, where '1' indicates "not at all" and '5' indicates "very much". The questions were:

1. Was there a benefit to learn writing custom functions rather than using Arduino built-in functions?
2. Did the laboratory exercises allow you to apply theoretical concepts in a practical manner?
3. Was the Final Project "Autonomous Robot Navigation" appropriate for the course?
4. Did you enjoy your experience with the RF-LCD controller and the Autonomous Robot?

5. Please provide comments/suggestions as to how the experience can be made more beneficial in future offerings.

B. Questionnaire Results

Fig. 4 shows the graphical representation of the feedback received from the students. Each bar in the graph represents the question number in the questionnaire and the bar shows the average ratings by the students for each question asked.

Fig. 4. Student Questionnaire Results

C. Written Comments

As previously noted, this was students' first introduction to the autonomous robot device and majority of the students appreciated the opportunity. However, the students indicated that it would be best if the autonomous robot was used very early in the course in the subsequent laboratory exercises. Students also feel that they would benefit by learning about the RF communication in the lecture so they could write the entire code by themselves rather than relying on the template that was provided to them. These views are reflected in the sample student comments below:

"Give more time to work on the robot. So you can refine the specific speeds and make it more of a racing competition"

"I would like to know more about how the RF works because we were given the template and asked to structure the code accordingly"

"Difficult subject matter made fun. The physical hands-on learning is always easier for me to understand"

"I really enjoyed learning new custom functions and RF communication"

"Incorporate more robot labs since they can be fun compared to other labs. Possibly using RF chips to perform other unique applications"

These written comments support the findings that we have already mentioned.

V. CONCLUSION

Autonomous robot is an excellent platform for infusing microcontroller fundamentals into sophomore students. Teaching microcontrollers this way presents an integrated approach to target student's knowledge of microcontroller to a practical application of maneuvering the robot through a custom built maze. The laboratory activities introduce students to the various concepts and systems discussed in lecture. The projects are used as a mechanism for the students to apply the concepts they have learned in a logical and sequential manner to solve practical engineering problems. While sometimes challenging for students, using this robot provides them the opportunity to grow significantly early on in their academic career and with generous help, most students can succeed.

In the assessment, student reaction to using autonomous robot in the course was positive apart from little inefficiency such as less exposure to RF communication theory and some hardware inconsistencies. The approach seems to have the right blend of incorporating the theoretical fundamentals into a real-life experience for the projects. We conclude by stating that in our experience, giving students this opportunity with some modifications to remove inconsistencies is an intellectual way of imparting the required knowledge to the students.

Development of a Novel Modular Integrated Stackable Layer - Analog System Environment (MISL - ASE) Platform for Embedded Systems Education

Gang Sun, Joseph Morgan, Jay Porter, Hester Yim

Department of Engineering Technology and Industrial Distribution

Texas A & M University

College Station, Texas, USA

Abstract— With the support of Texas Instruments and NASA, a novel Modular Integrated Stackable Layer - Analog System Environment (MISL - ASE) platform has been developed to provide a comprehensive educational hardware environment for three embedded system design courses and two capstone design courses in the Electronic Systems Engineering Technology (ESET) program at Texas A&M University. The MISL-ASE platform uses the TI-MSP430 intelligence layer of the MISL architecture as the main core and control system that can be directly interfaced to the ASE board. Moreover, the MISL-ASE platform encompasses various analog and digital peripherals, such as GPIO outputs/inputs, LEDs, 7-segment displays, audio system, switches, keypad, and TFT LCD with touch screen, typical signal conditioning circuits such as A/D and D/A conversion for analog voltage simulation, battery life and light density measurement, 3-axis accelerometer, high-resolution external ADC converter, multiple analog signal generators, and motor control, etc. Several communication interfaces and protocols are also available such as UART (USB, RS-232/485, Bluetooth, and Zigbee), SPI (Ethernet, Wi-Fi, Micro SD card, and flash memory), I²C (DAC and EEPROM), and 1-wire communication devices. Additionally, the robust design of the ASE board facilitates it being interfaced to a number of other embedded intelligence boards such as the Launchpad development system. This paper will discuss the overall design and capabilities of the MISL-ASE platform and the development of a series of laboratory assignments that can be accomplished using this novel MISL-ASE environment in the area of analog electronics, digital interfacing, and communications.

Keywords— *Modular Integrated Stackable Layer (MISL); Analog System Environment (ASE); Embedded Systems*

I. INTRODUCTION

Over the last decade, the rapid advancement of computer, sensor, communication, data storage, and IC technologies has had a tremendous impact on embedded system design in many different types of industries [1]. For example, Bluetooth has emerged as a standard inter-device communication protocol in embedded systems. Traditional data measurement methods are being steadily replaced by

one-wire communication technology for numerous embedded systems. Thus, there is an acute need to integrate new and relevant devices and technologies into current embedded system teaching and learning processes. Moreover, design and implementation of embedded systems requires a broad knowledge in the areas of analog electronics, digital interfacing, communications, real-time operating systems, and software development, which are not traditionally covered in any one discipline. As faculty members, we often observe limitations in student performance when integrating multiple engineering concepts into an embedded system. Thus, it is very important to establish an integration platform that can incorporate recent advances in development tools and design methodologies, as well as the knowledge gained from different disciplines to develop practical new design techniques, so students may easily apply those new techniques to the design of state-of-art and real-time embedded systems.

Unfortunately, none of the existing development platforms/boards [2,3,4] are able to meet typical academic needs. With the support of Texas Instruments and NASA, a novel Modular Integrated Stackable Layer - Analog System Environment (MISL - ASE) platform has been developed for three embedded system design courses and two capstone design courses in the Electronic Systems Engineering Technology (ESET) program at Texas A&M University. The MISL-ASE platform: 1) provides a comprehensive educational hardware environment to support embedded hardware and software design, development, and test; 2) supports laboratory-based experiential learning in digital/analog interfacing and wired & wireless communications; 3) gives students the opportunity to design embedded systems using TI advanced microcontroller technology and a wide range of new analog and communication devices; and 4) helps students learn and use the NASA-designed, space qualified MISL architecture and assemble their own MISL stacks, e.g., power layer, intelligence layer, sensor layer, communications layer, and actuator layer, etc.

II. CONCEPTUAL DESIGN

The MISL-ASE platform mainly consists of two parts: the MISL intelligent layer and the analog system environment (ASE) board. Fig.1 illustrates the conceptual block diagram of the platform with many of the implemented features.

Fig.1. Conceptual block diagram of the MISL-ASE platform.

The MISL intelligent layer, typically the TI-MSP430 [5,6], can be directly interfaced to the ASE board. To integrate new and relevant devices and technologies into current embedded system education, the ASE board encompasses various analog and digital peripherals. Included in this suite of capabilities are GPIO outputs/inputs, LEDs, 7-segment displays, audio system, buzzer, switches, matrix keypad, and TFT LCD with touch screen, typical signal conditioning circuits such as A/D and D/A conversion for analog voltage simulation, battery life density measurement, 3-axis accelerometer, high-resolution external ADC converter, multiple analog signal generators, and motor control, etc. Several communication interfaces and protocols are also available such as UART (USB, RS-232/485, Bluetooth, and Zigbee), SPI (Ethernet, 2.4 G Wi-Fi, Micro SD card, and flash memory), I²C (DAC and EEPROM), and 1-wire communication devices. Furthermore, the robust design of the ASE board supports interfacing to a number of other embedded intelligence boards such as the TI Launchpad development system. Students can program on-board features with other microcontrollers through header pins and jumpers. A fully populated ASE board with the MSP 430 layer installed is shown in Fig.2. The two-board system is a complete development environment suitable for a wide range of embedded systems courses from entry level to advanced.

Fig.2. MISL-ASE platform with MSP-430 microcontroller.

III. DEVELOPMENT OF THE MISL-ASE PLATFORM

A. Overall Functional Diagram

The MISL-ASE platform incorporates many features that directly interface to the MSIL-MSP430 layer. Fig.3 shows the overall functional block diagram for the platform, which has four major parts: 1) MISL architecture – TI-MSP430 intelligent board; 2) GPIOs; 3) Signal conversion (A/D and D/A); and 4) Wired & wireless communications.

Objects shown in red are parts that were provided by Texas Instruments. The features outlined in red represent off-board connections. These are modules that plug-into the ASE board.

The unique features of the MISL-ASE platform are discussed in more details in this paper.

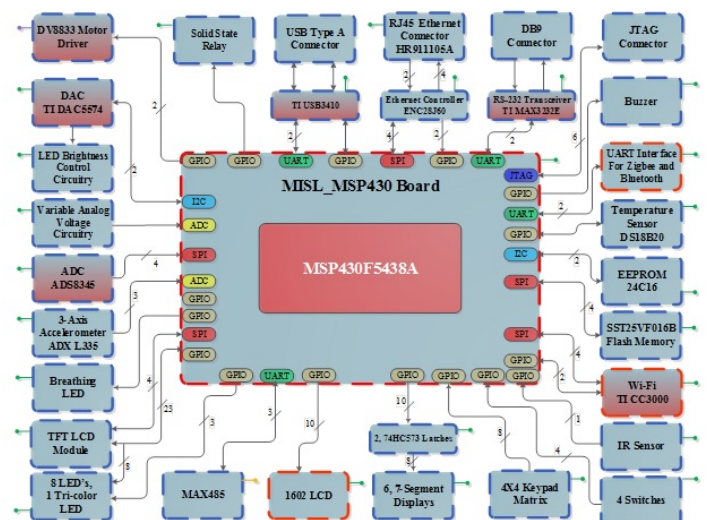

Fig.3. Overall Functional Design of the MISL-ASE platform.

B. MISL Architecture

The Control and Data Handling (C&DH) Branch (located at the NASA Johnson Space Center south of

Houston, Texas) designed and developed the MISL architecture. The C&DH Branch subsequently invited the ESET program to collaborate on the NASA development. ESET accepted three primary responsibilities of the partnership: 1) Co-development of new MISL layers, 2) Integration of the MISL architecture into undergraduate/graduate education curricula, and 3) Establishment of an open environment to make the technology available to all embedded system designers.

The C&DH Branch has developed and maintains control of the MISL form factor, Power Buss and Data Buss definitions. These specifications are available on the web [7] and can be used to support system developers using currently available layers as well as those wishing to develop new layers with expanded capabilities. Additionally, the C&DH Branch will perform space qualification testing on new layers that have value to its mission and development goals. Fig. 4 depicts the layout of a MISL layer and the location of the 40 pin Power Bus and 100 pin Data Bus.

Fig. 4. MISL Layout showing Power and Data Busses.

C. GPIO inputs and outputs

GPIOs are one of the most valuable resources in embedded systems providing the ability to communicate with the external world through digital lines that configured to operate as either inputs or outputs.

1) *GPIO- outputs*: when configured as outputs, GPIOs can control the binary status of external devices by setting an external voltage level to either a logic high or logical low. The typical external devices are LEDs, buzzers, LCDs, and relays. GPIOs have been implemented on most development boards (e.g., TI launchpads). The MISL-ASE platform not only includes those devices, but includes three unique features.

a) *Breathing LED (PWM)*: The Breathing LED is a feature that simulates a breathing response by fading the LED intensity in and out. It is controlled by using the PWM duty cycle function of timers and GPIOs.

b) *Mutiple 7-segment displays*: The MISL-ASE platform incorporates 6 common cathode 7-segment displays that are controlled by 2 octal D-type latches (74HC573). One latch is used to select which display to use and the other latch is used to select what to display. The latches are controlled through the latch enable (LE) pins to prevent the latches from overriding each other. This noval display design only uses one I/O port (8-bit I/O

pins) to control multiple displays instead of using multiple GPIO ports.

c) *TFT LCDs with touch screen*: TFT (Thin-film transistor) LCDs with touch screen are widely used in mobile phones, handheld video game systems, personal digital assistants, navigation systems projectors, etc. On the MISL-ASE platform, a 3.2" TFT LCD Display module is employed, which includes the display controller (ILI9341), the touch IC (XPT2046), and a SD card. The MISL- MSP430 layer uses 20 GPIO pins and a SPI interface to communicate with this TFT LCD display.

2) *GPIO -inputs*: Mechanical contact switches are one of the components most commonly interfaced to microcontrollers as a typical GPIO input example. There are two GPIO input features on the MISL-ASE platform: the 4x4 matrix keypad and the 4 switches. The keypad uses one of the GPIO ports (8 pins) of the microcontroller, where 4 pins are for the columns and 4 pins for the rows. The column pins are shared with the 4 switches. A 4PDT switch is used to switch between the two features.

D. Signal Conversion

One common task for embedded systems is to measure analog signals from the outside world, e.g., pressure, temperature, humidity, flow rate, etc. On the ASE board, the analog-to-digital conversion part includes several typical analog devices interfaced to the MSP430 microcontroller: 1) Potentiometer: it is used to simulate a varying analog input voltage; 2) 3-axis accelerometer (ADXL335): The X, Y, and Z channel outputs of the ADXL335 are connected to three of the 12-bit internal A/D converter inputs of the microcontroller to detect the static acceleration of gravity in tilt-sensing applications, and dynamic acceleration resulting from vibration, shock and motion; and 3) 16-bit, 8-channel SAR external ADC (ADS8345): it is also available so students can gain experience with a high-resolution ADCs instead of the 12-bit internal ADCs.

E. Wired and wireless communications

Most popular wired & wireless communication interfaces and protocols are available on the MISL-ASE platform. These include: 1) four-wire communication networks: SPI (Ethernet, 2.4 G Wi-Fi, Micro SD card, and flash memory); 2) two-wire communication networks: UART (USB, RS-232/485, Bluetooth, and ZigBee); 3) two-wire communication networks: I²C (DAC and EEPROM); and 4) 1-wire communication networks: DS18B20.

1) *SPI*: the Serial Peripheral Interface (SPI) is a synchronous serial bus standard with full-duplex capability to support communications between a master (e.g., microcontroller) and one or multiple slave peripheral devices. On the ASE board, the Ethernet, 2.4G Wi-Fi modules (TI-CC3000 and nRF24L01), the Micro SD card, and the flash memory (SST25VF016B) are able to communicate with the MISL-MSP430 stack via SPI

interfaces. For example, the interface between the MSP430 microcontroller and the Ethernet controller chip (ENC28J60) is based on the SPI bus protocol. The SI, SO, SLCK, and CS pins of the Ethernet chip are connected to SPI pins (MOSI, MISO, SCLK, and CS) of the microcontroller. With this Ethernet feature, many different devices and equipment can be remotely accessed, monitored, and controlled through internet, such as web-based home automation, remote environmental monitoring, Voice Over IP, etc.

2) *UART*: The Universal Asynchronous Receiver / Transmitter (UART), is a very useful feature of microcontrollers for communicating serial data (text, numbers, etc.) to computers or devices. The MISL-ASE platform not only contains typical UART standards (RS232, RS485, and USB), but provides new wireless communication standards (ZigBee and Bluetooth) via UARTs. ZigBee is a reliable, low-cost and low-power, wireless networks based upon the 2.4 GHz IEEE 802.15.4 radio protocol. The ZigBee module (XBee2) is used on the platform and allows students to create wireless distributed sensor networks to remotely monitor and control electromechanical systems in their home, office, or other areas. The RN-42 is a Class 2 certified Bluetooth module, which can be connected to the ASE board to communicate with personal electronic devices, e.g., cell phones, wearable devices, etc.

3) *I²C*: The Inter-Integrated Circuit bus (I²C) is a synchronous serial communication protocol to support on-board interconnection of integrated circuit devices. On the platform, the I²C uses two lines (SDA and SCL) to establish a half-duplex communication bus between the master (MSP430) and slave devices: 16K EEPROM (24C16) and Digital-to-Analog converter (DAC5574).

4) *One-wire communication*: The digital thermometer (DS18B20) is employed on the platform to teach students how to develop distributed temperature monitoring systems through one-wire communication bus in lieu of the traditional measuring method using temperature sensors, signal conditioning circuits, and A/D converters.

IV. MISL-ASE PLATFORM EVALUATION

Final debug and testing of the MISL-ASE Board was completed during the Spring 2015 semester. Based on these results, an initial order of 50 boards were procured and populated. To reduce the overall cost of the boards, ESET students will become part of the development team by hand soldering all through-hole components on the boards they use in lab.

To assess the value and acceptance of the new systems, two students from the entry-level C Programming course were asked to use the new environment for one of their laboratory projects. All students are familiar with the MSP430 microcontroller architecture and software

development environment based on previous labs performed on a MISL stack composed of a 1) Battery Power Layer, 2) MSP430 Intelligence Layer, and 3) Signal Breakout Layer.

The assessment was anecdotal in nature and sought to evaluate the value of the new embedded software environment to support the experiential education aspects of the ESET program. This informal assessment resulted in the following information:

1. Both students liked the idea of having all hardware interfacing requirements available on the MISL-ASE system. Other students using the three-board MISL stack were required to spend time wiring and debugging circuitry rather than focusing on designing, development, testing, and documenting their programs.
2. The students enjoyed the engineering experience of using block diagrams and detailed schematics in determining the ports that would be used and the configuration options of the ASE system.
3. The interest level of the students concerning other MISL-ASE capabilities increased through the use of this environment. Realizing the wide range of technologies available on the ASE platform stimulated the students' interest in doing future labs using the platform.
4. With the feedback from the informal evaluation of the MISL-ASE system, other ESET faculty members have become interested in leveraging the technology. The capabilities of the environment and working knowledge that the students will have after the three-course (sophomore/junior) sequence may allow for more extensive course projects to be considered. The course director for the two-semester, senior-level capstone design experience sees significant value in having the MISL-ASE resource. Being able to use the features of the MISL-ASE environment augmented by other MISL layers, will provide a marked increase in the rapid prototyping of the embedded system necessary to transition a customer's problem/opportunity to fully functional prototype.

V. CONCLUSIONS AND FUTURE WORK

This paper presents the overall design and capabilities of the MISL-ASE platform and the development of a series of laboratory assignments that can be accomplished using this unique MISL-ASE environment in the area of analog electronics, digital interfacing, and communications.

For our future work, we will focus on finalizing the MISL-ASE platform. Students from three embedded systems courses and two capstone design courses will be using and evaluating the platform starting Fall, 2015. The outcomes from using this platform will be quantitatively and qualitatively assessed through the observation of students' performance in the lab/class, their feedback, and surveys. Also, the RTOS (Real-time Operating Systems) education systems will be developed based on the MISL-ASE platform.

ACKNOWLEDGMENT

The authors wish to acknowledge the financial support of Texas Instruments, the MISL design work of the C&DH Branch-NASA/JSC, and the Look College of Engineering at Texas A&M University. The authors would also like to thank undergraduate research assistants Anson Nunley and Jose Sotelo. Their help is very much appreciated.

carmerb@eecs.oregonstate.edu

Mike Rosulek
Oregon State University
rosulekm@eecs.oregonstate.edu

Abstract—We present Vamonos: a new framework for algorithm visualization, designed from the beginning to support embedding, interaction, and unlimited scope. Visualizations are executed entirely client-side on any device that supports a modern web browser; they can be embedded into any website or online textbook. Users can specify breakpoints, watched variables, provide inputs to the algorithm (e.g., by drawing a graph using a mouse), and be prompted for interaction by the visualization. The core framework supports any algorithms and data structures that can be implemented in Javascript. We have implemented a wide range of visualizations of advanced algorithms topics, including dynamic programming and graph algorithms (e.g., spanning tree, max-flow, bipartite matching algorithms).

I. INTRODUCTION

Algorithm visualizations (AVs) have long been appealing to both educators and students alike. Yet, they have not been as widely adopted as one would expect. There has been a great deal of research into effectiveness of AVs in general (e.g., [11], [7]) as well as usability aspects of AV systems which hamper or facilitate their adoption (e.g., [9]).

At the same time, web-based educational resources have become more sophisticated, due to overall advances in web/browser technology and facilitated by the increased popularity of massively open online courses. Specifically, AVs have evolved from static animations (famously [1]) to interactive Java/Flash applets (e.g., [16]), and recently, full-featured web applications (e.g., [6]) that take advantage of standard modern browser features.

Now, with increased effort being placed into high-quality online, *interactive* textbooks (e.g., [14], [17]), interactive visualizations are becoming replacements for the static figures of paper textbooks. Indeed, online textbooks/lessons seem to be the ideal venue for AVs, as [20] found that AVs should be paired with motivational goals and instruction, and [11] found that AVs are most effective in a homework/self-study (rather than exam) setting.

II. RELATED WORK

There are a number of ongoing AV projects that share our goal of leveraging recent developments in webrowsers.

The Javascript Algorithm Visualization Library (JAVL) [10] provides a framework for educators to create browser-based visualizations, with the stated goal of supporting online textbooks. In particular JAVL was created to support the OpenDSA project [19] [5] which seeks to provide a free interactive online data structures and algorithms textbook. JAVL visualizations are highly interactive, with built-in mechanisms (“proficiency exercises”) for quizzing the user. JAVL can follow along as the user simulates the algorithm, providing feedback when mistakes are made. JAVL is very high-level in the sense that it favors visualizing more conceptual rather than procedural aspects of algorithms.

The recent PythonTutor framework [6] is a popular and very successful example of an AV tool that can be embedded into online textbooks. In contrast to JAVL, PythonTutor’s focus is on visualizing low-level, introductory programming concepts (Python syntax, flow control, arrays, references, calling conventions) to novices. Indeed, the AV landscape skews heavily towards introductory material (e.g., sorting algorithms). Shaffer et al. [18] surveyed a wide range of AVs and found that coverage of advanced topics (e.g., dynamic programming, network flow) is lacking, by comparison.

III. OUR WORK

Inspired by the success of PythonTutor, we set out to make a web-based AV framework that supports more advanced algorithmic topics, which are typically expressed in very high-level pseudocode and involve more sophisticated data structures. Since web browsers already have the capability to execute arbitrary Javascript, we also wanted to forego PythonTutor’s reliance on a server-side component. In the context of embedded visualizations in textbooks, client-side visualizations allow the material to be learned away from an active internet connection (or after the server-side maintainer has let the service lapse).

In addition, like PythonTutor, we wished to provide a close coupling of a visualization to the code itself - in our case pseudocode. This provides the end-user with more flexibility and transparency than offered with a visualization in JAVL. With Vamonos, users can see exactly how a line of pseudocode changes the underlying data structure. In contrast, JAVL visualizations provide an English description of what occurs in each frame out of context of the rest of the program. Furthermore, JAVL does not support the visualization of loops, recursion, and other control structures as they work inside an algorithm.

Ihantola et al. [8] give a taxonomy of AV “*effortlessness*” — features of a system that reduce barriers for educators to adopt and maintain visualizations. Among our goals was to achieve a high degree of effortlessness. We highlight some important features of Vamonos, using this taxonomy:

Integrability denotes qualities that make the system attractive to use and easy to set up, encompassing installation, customization, platform independence, internationalization, documentation, interactive prediction support, course management support, and integration of hypertext.

Being web-based, Vamonos has very high integrability. Visualizations require no installation barrier beyond a modern web browser (for either AV producers or consumers) so are inherently cross-platform. At the extreme, all of the page data (HTML, Javascript, CSS) of a visualization can be inlined into a single HTML file. We also inherit all of the power of modern HTML for layout, CSS for stylization, as well as accessibility features (i.e., visualizations are natively scalable). And, of course, the visualizations can be easily embedded.

Scope denotes how widely one can apply the system, encompassing difficulty in installing and running the system, and educational context (how many topics can the system be used for?). We created Vamonos to have essentially unlimited scope within the domain of algorithms, supporting both low-level concepts (arrays, calling conventions, basic flow control) and very high-level ones (e.g., graphs and geometric algorithms). The core framework can, at least in principle, support any algorithm & data structure that can be implemented in Javascript.

Interaction denotes how deeply the consumer can modify a visualization. Lawrence et al. [12] showed that students’ ability to design their own inputs to algorithms is a key factor in AV effectiveness. In Vamonos, the consumer can specify her own inputs to an algorithm: even graphs. Further, the consumer can set breakpoints and watched variables, and step forward and back through the algorithm’s execution. Meta-aspects of the execution are also displayed (e.g., active line of execution, complete

call stack). We also support several kinds of interactive quiz capabilities. (See Section IV)

IV. USE CASES / VIGNETTES

We introduce Vamonos by presenting use cases that take advantage of its highly interactive nature and broad scope.

A. Ford-Fulkerson Algorithm & Eliciting Interesting Inputs

Consider the Ford-Fulkerson algorithm for computing maximum flow. The input to such an algorithm is a flow network — a complicated data structure consisting of a directed graph, with integer edge labels / capacities, and two distinguished vertices (designated source and sink).

Using a Vamonos visualization of Ford-Fulkerson, a student can draw any such flow network using the mouse (see Figure 1). S/he can then execute the algorithm on the graph of her/his choice and see how the max flow is iteratively obtained and how the residual graph is updated.

One particularly challenging concept about the Ford-Fulkerson algorithm is that during the course of the algorithm, flow does not monotonically increase along every edge. Consider the following application for a Vamonos visualization embedded in a web-based textbook. After discussing why it might be necessary to reverse the flow along some edge, the textbook can present an embedded visualization and prompt the reader to draw an example input on which such flow-reversal is necessary. Vamonos supports this kind of input-based quizzing, where the user is asked to provide an input that triggers a certain internal condition to happen; for example:

- An edge case in an algorithm is triggered (e.g., there is a tie among shortest paths).
- Dijkstra’s algorithm proceeds by maintaining upper bounds on each vertex’s distance from the source. These distance estimates are reduced until they converge on the true distance. The user can be prompted to input a graph for which some vertex has its distance estimate modified at least 5 times.

B. Depth-First Search & Topological Sort

In Vamonos, graphs can be manipulated with the mouse not only to draw the input to an algorithm, but to rearrange the graph during the AV’s display mode (this is an optional setting, as it would not be advisable to rearrange vertices while running an algorithm that uses the graph’s planar *embedding*).

We provide a ready-made visualization of depth-first search (DFS), and, following the textbook of Cormen et al. [4] (CLRS), we label each vertex with its “start” and “finish” time (i.e., the time at which it entered and left the stack). For acyclic graphs, CLRS prove that sorting

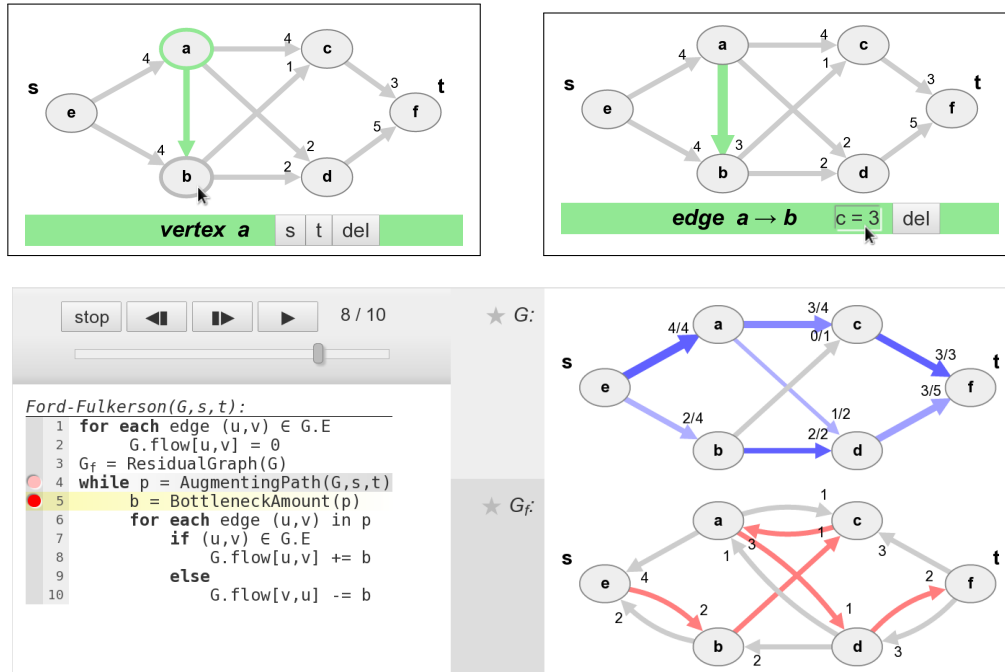

Fig. 1. Vamonos is a web-based algorithm visualization framework that supports high-level data structures like graphs. This series of screenshots shows a Vamonos visualization of the Ford-Fulkerson max-flow algorithm. The two upper screenshots show the modal interface by which a user can input a graph using the mouse. In the upper-left screenshot, the vertex a is modally selected, and a green potential edge ab is shown when the user hovers over b . Buttons below can delete vertex a or set it to be source/sink. In the upper-right screenshot, an edge ab is modally selected, and it can be either deleted or its label/capacity changed. In the bottom screenshot, a user has finished drawing the input graph G (labeled G), set two breakpoints, and stepped through 8 of 10 frames of the algorithm's execution. The red path in the residual graph G_f shows the augmenting path p . In the flow network G , the color denotes saturation: edges with zero flow are gray; saturated edges are completely blue; other edges are an appropriate mixture.

Fig. 2. A visual demonstration of a topological sort based on DFS. Vertex labels represent “start / finish” times. In the final image, it can be visually verified that all edges point upward, hence the ordering corresponds to a topological sorting of the vertices.

the vertices by decreasing finish time yields a topological ordering.

As an in-class demonstration or a guided self-study lesson, a user can execute DFS on a graph so that each vertex is labeled with its finish time. S/he can then drag vertices around to place them in order according to finish time. It can then be verified *visually* that the resulting embedding has all edges pointing in the direction of decreasing finish time. (See Figure 2).

C. Breadth-First Search & Bipartiteness

Other properties of graphs are illustrated well using a similar approach. For instance, consider executing

breadth-first search (BFS) on a graph to label each vertex with a distance value. Then arrange the vertices into columns, one column for each possible distance value, in increasing order. In the resulting graph, it can be visually verified that for every edge uv , we have $|u.d - v.d| \leq 1$. That is, no edge can skip a “height/level” in the BFS tree.

Along the same lines, we have included a visualization for a variant of BFS that colors vertices red and blue, where the colors are chosen to disagree along an edge as it is traversed by BFS. If an edge is encountered with monochromatic endpoints, the algorithm stops highlighting the problematic edge.

When an edge has monochromatic endpoints, an

Fig. 3. A visual demonstration of a bipartiteness algorithm based on BFS. After manually rearranging, it can be visually verified that all edges have one red and one blue endpoint.

odd-length cycle can be easily found visually (hence, the graph is not bipartite). If the algorithm terminates without a monochromatic edge, then the graph can be rearranged with red vertices to the left and blue vertices to the right. Students can then verify visually that all edges cross from left to right; hence, the graph is indeed bipartite. (See Figure 3.)

V. DESIGN & IMPLEMENTATION

The Vamonos framework consists of CSS and Javascript libraries (compiled from Coffescript), along with popular Javascript library jQuery and graphical library D3 [2]. Visualizations (of which we provide a collection of examples) are HTML files that load these libraries.

A. Visualization Engine & Lifecycle

Vamonos visualizations are managed by an instance of a **Visualizer** object. A **Visualizer** object is instantiated with a **callback** that implements the algorithm to be visualized (more details of this are discussed in Section V-C) and a collection of **widget** objects which implement the user-facing elements of the visualization (described immediately below).

Vamonos visualizations are modal, with two modes. By default, a visualization begins life in **edit mode**. (It is possible to make a visualization that exists only in display mode. This may be useful for visualizations with fixed inputs.) In this mode, widgets are collecting input from the user: inputs to the algorithm, and other parameters of the algorithm execution like breakpoints and watched variables.

When the user is satisfied, she uses the controls to finish edit mode. At this point, the **Visualizer** object will execute the algorithm and periodically collect snapshots of the algorithm's state, called **frames**. Each frame contains the contents of all variables, call stack, active pseudocode line, etc. Indeed, the main responsibility of the **Visualizer** object is to constantly maintain a representation of the call stack, manage the various

procedure-local name spaces for variables, and determine the appropriate times to take a snapshot of the current state.

Then the visualization enters **display mode**, in which the widgets display the contents of these frames. Using on-screen controls, the user can navigate through this collection of frames to see the execution of the algorithm. While the user has a sense of being able to pause/rewind the execution of an algorithm, it is important to note that the collection of snapshots is generated all at once and then fixed (until the next edit/display lifecycle). The user cannot change variables, breakpoints, watched variables on the fly. This is primarily because our method for implementing the actual visualized algorithm is not re-entrant, so does not support stepping backwards; again, see Section V-C.

B. Widgets

Generally, a **widget** is any part of the visualization that interacts with the user. The **Visualizer** object provides a standardized API for widgets. In edit mode, widgets may set variables and other execution parameters (like breakpoints and watched variables). In display mode, widgets receive the current frame to display. Widgets are also the mechanism by which the **Visualizer** changes modes and navigates through the collection of frames.

We give a summary of the various widgets implemented so far:

Pseudocode displays the pseudocode of the algorithm. In edit mode, allows users to specify breakpoints by clicking in the gutter (mimicking the interface of a standard IDE). In display mode, highlights the pseudocode line that just finished executing, and the line about to execute.

We point out that the lines of code in the pseudocode widget are purely cosmetic, and have no bearing on what code is actually *executed* to generate the visualization (see Section V-C for more details). Hence, the pseudocode widget can be used to show a very high-level or a very low-level algorithm.

In the example below, lines 4 & 5 are set as breakpoints. In this frame, line 4 is about to execute, and line 3 has just finished.

```
SelectionSort(A):
1 for i = 0 to A.length-2
  # find smallest item in A[i..]
2   m = i
3   for j = i+1 to A.length-1
4     if A[j] < A[m]
5       m = j
6   swap A[i] and A[m]
```

CallStack, in display mode, shows a dynamically updating representation of the call stack. The procedure name, arguments, and return values are all displayed. Vamonos supports algorithms with multiple procedures, and also supports tail calls. Below are two call-stack visualizations for different factorial functions (both showing the final result).

Array displays an array data structure. In edit mode, allows WYSIWYG editing of an input array. In display mode, shows the contents of an array in the given frame. The widget also supports various styling features: the array can be annotated with array index variables from the algorithm, and CSS rules can be applied to cells based on index variables. Array cell zero can also be hidden, to mimic 1-indexed arrays common in many texts.

Below is an example from a dynamic programming visualization that uses the recurrence

$$opt[k] = \max_i \{ price[i] + opt[k - i] \}.$$

Hence, we show variables k and i indexing into $price$, we shade the not-yet-used portion of $price$ (beyond index k), and we show *expression* $k-i$ indexing into opt .

```
new Widget.Array({
  varName: "price",
  showIndices: ["k", "i"],
  cssRules: [[">", "k", "shaded"]],
  ...
})
new Widget.Array({
  varName: "opt",
  showIndices: ["k", "k-i"],
  ...
})
```

price:	1	2	3	4	5	6
	1	5	8	9	10	14
				i	k	
opt:	0	1	2	3	4	
	0	1	5	8	10	
		$k-i$		k		

Graph displays a graph data structure. Edges can be directed/undirected, and optionally weighted. In edit mode, the widget area is a canvas on which the user can draw a graph using mouse/touch actions. **Graph** widgets support a wide variety of informative styling in display mode: vertex labels, edge labels, and CSS styles can be determined according to arbitrary vertex/label attributes set by the algorithm. Variables that take on *vertices* as values can be displayed as annotations similar to how array indices annotate the appropriate cell in an **Array** widget.

In the depth-first-search example below, a directed graph is shown. The `v.color` attribute determines the CSS class of the vertex; the contents of the vertex are computed as "`v.start / v.finish`". Vertex variables u and v are displayed as annotations *à la* array indices. The edge u to v is highlighted red.

```
new Widget.Graph({
  vertexLabels: {
    inner: function(v) {
      return v.start + "/" + v.finish;
    },
    sw: function(v) { return v.name },
    ne: ["u", "v"],
  },
  vertexCssAttributes: {
    color: ["white", "gray", "black"],
  },
  edgeCssAttributes: { red: "u->v" },
  ...
})
```

UserQuiz creates a modal user dialog in display mode that cannot be dismissed until the correct answer is given. The quiz is parameterized by a *condition* (on which frames will the dialog be displayed), a *question* to be asked, and a correct *answer*. Each of these parameters can be computed as a function of the current frame. In the following example, a dialog will be displayed whenever algorithm variable $i > 5$ and the frame was taken just before pseudocode line 4 was to be executed.

```

new Widget.UserQuiz({
  condition: function(frame) {
    return frame.i > 5
      && frame._nextLine == 4;
  },
  question: function(frame) {
    return "What will algorithm put "
      + "in A[" + frame.i + "]?";
  },
  answer: function(frame) {
    ...
  }
});

```

ResultProperty provides an easy way to display a message on the page conditioned on some event happening in the execution of the algorithm. This can be used to make visualizations with self-tests of the form “find an input that causes behavior X from the algorithm.” (See Section IV.)

C. Internals & Creating Visualizations

An Vamonos visualization is concretely an HTML document that imports the Vamonos library. This HTML file contains Javascript invocations of the **Visualizer** and other widgets, as well as HTML layout information and accompanying page content.

1) *Laying out the widgets*: Most widgets are user-facing, and draw elements to the page. The relative layout of these widgets is completely unconstrained (though we provide default HTML/CSS templates), so that a visualization’s collection of widgets can be placed anywhere within a document.

When generating a visualization, the producer typically specifies the visual location of a widget by inserting an empty `<div>` HTML tag into the page source, e.g.:

```
<div id="some-widget"></div>
```

Then the associated widget object instance is attached to this tag in its constructor arguments:

```

new Widget.Array({
  container: "some-widget"
  ...
});

```

2) *Algorithm callbacks*: An AV producer must specify an implementation of the algorithm which is to be run. Naturally, this can be done by passing a callback to the **Visualizer** object. However, there are two major challenges: (1) Stopping the callback mid-execution to take snapshots of its internal state. (2) Providing the **Visualizer** object with access to the internal variables of the algorithm.

We solve these challenges in the following way. For concreteness, consider the following Javascript implementation of Horner’s polynomial evaluation method:

```

function Horner(P,x) {
  var res = 0;
  var i = P.length - 1;
  while (i >= 0) {
    res = res * x + P[i];
    i = i-1;
  }
  return res;
}

```

We solve the first challenge by having the the **Visualizer** pass a callback to the algorithm. By convention we name this argument “_”. The algorithm should invoke this callback with a number *n* to indicate that it is about to execute *pseudocode* line number *n*. This provides a hook to return control flow to the **Visualizer** object so it can generate a new frame if desired. Again we stress that the correspondence between the actual algorithm implementation and lines of pseudocode is arbitrary. Conveniently, the **Visualizer** can also raise an exception if it suspects an infinite loop in the algorithm.

Addressing the second challenge, when the **Visualizer** executes the algorithm callback, it first sets Javascript special global `this` to be a “scope object” in which local variables are stored. As long as the algorithm refers to `this.varName` rather than a local variable `varName`, both the algorithm and the **Visualizer** will have common access to these variables. To further cut down on the extra syntax imposed, we use Javascript’s somewhat obscure `with` statement. Assuming that `this.i` exists in the scope object, all references to variable `i` inside the scope of `with(this){...}` will really refer to `this.i`.

In the end, our example from before becomes:

```

function (_) {
  with (this) {
    _(1); res = 0;
        var i = P.length - 1;
    _(2); while (i >= 0) {
    _(3);   res = res * x + P[i];
          i = i - 1;
        }
    _(4); return res;
  }
}

```

This callback can then be passed as a parameter to the **Visualizer** object via:

```

var viz = new Visualizer({
  widgets: [ ... ],
  algorithm: function (_) { ... }
});

```

3) *Multiple procedures*: An AV producer can specify an algorithm with several named procedures. Instead

of passing in a single callback, an associative array of name→callback values should be given.

The **Visualizer** engine adds a wrapper around each callback which facilitates the calling conventions in several ways. This wrapper is where the engine can maintain its representation of the call stack. The wrapper also handles argument passing, which is not positional but done by name. Finally, the wrapper populates the `this` “scope object” with the (wrapped) procedures, so that the procedure-calling syntax is natural when writing the visualization. A special argument to these wrapped procedures is used to specify tail-call optimization of the call stack.

4) *Watched variables via serialization*: Vamonos supports generating snapshot frames whenever a variable is changed. We achieve this functionality for completely arbitrary data types by using the browser-standard JSON (Javascript object notation) serialization features. Each watched variable is serialized to a JSON string, and these strings can be compared to detect when a variable is changed. Hence, one can set a graph variable to be watched, and a frame will be captured whenever any of the constituent vertices has an attribute changed.

Serialization also allows an easy way to save and share user-provided inputs. When a user enters an input to an algorithm, an encoding of that input is placed in the URL. Students can use this mechanism to submit answers to homework questions (of the form “find an input that causes behavior X”) or share with peers.

5) *Inlining visualization*: One of the benefits of basing our framework on native, client-side web technologies is that visualizations can be contained in a single page. We have avoided use of images in our default styles, and as such, the visualizations require only HTML, CSS, and Javascript resources. These can be inlined into the main HTML page, and we provide a simple script to do so. Without taking any effort to minimize the size of our source files, a complete stand-alone Vamonos visualization (including all prerequisite libraries) is less than 1 megabyte.

VI. ONGOING WORK

So far, our focus has been implementing a fully-featured core system. Our next step is to add levels of abstraction facilitating AV production by non-experts. Ultimately, we envision a workflow in which a user compiles a high-level pseudocode-like language into a Vamonos visualizations, similar to PythonTutor [6] and PCIL [13]. Students themselves could then create fully functional Vamonos visualizations without needing to interact with HTML and Javascript boilerplate.

A particularly interesting direction is to explore the extent to which “visualizable aspects” of high-level code can be automatically deduced from the source code, as

demonstrated in [15]. It seems likely that a compiler would be able to infer which variables/expressions are used as array indices. However, other more sophisticated run-time properties could be automatically inferred and inform the visual presentation. For example: if an array index i monotonically traverses the array, and only indices at most i are ever accessed, then the portion of the array beyond i can be shaded (we hard-code such visual rules already).

A formal evaluation of the current system’s efficacy is also needed, particularly when used in an embedded form in an electronic textbook. User study results would help guide our ongoing development and addition of features.

ACKNOWLEDGEMENTS

The authors are supported by NSF Award 1149647.

International iCampus Forum (IC15)

on

“Smart Education in Smart Cities”

Jason W.P. Ng

Etisalat British Telecom (BT) Innovation Center
P.O. Box 127788, Abu Dhabi, United Arab Emirates
jason_wp_ng@ieee.org

Abstract— The IC'15 iCampus Forum is part of the International iCampus Initiative led by Etisalat BT Innovation Center (EBTIC) – a joint British Telecom (BT) research centre located in the middle-east region. More information about the initiative can be found in <http://www.intelligentcampus.org>.

I. AIM OF THE EVENT

The educational landscape is changing; some have termed it as the “climate change” in education. The students of today engage with the learning environment differently from the students of yesterday. The traditional landscape is often perceived as “formal”, “passive”, “direct”, and “push” learning environment designed largely for the knowledge consumers; and the modern landscape is often perceived as “informal”, “active”, “collaborative”, “social”, and “pull” learning environment designed not only for the knowledge consumers but also for the knowledge creators. This has since brought about the recent launch of several “Smart Learning” initiatives across the various continents, including the “Education” vertical pertaining to the societal “Smart Society” or the wider “Smart City” initiatives as well as several others. Such advances have never been at a greater pace than those experienced today, and have the promise of revolutionizing educational practices and changing the world of education in the modern knowledge-based economies internationally. This paradigm shift in education is imminent and has gathered a lot of interests, among the academia and the industry, in an attempt to bridge the technological gap in the educational sector.

To meet the overall needs and prevailing demands towards the global “smartization” movement within the education sector, the central theme of this year iCampus Forum (IC'15) is set on “Smart Education in Smart Cities”, in particular the smart “technological” and/or “pedagogical” aspects of education. The aim of this forum is to complement the FIE event, by gathering like-minded and cross-disciplinary research communities together, in conjunction with the iCampus consortium, to network, share and discuss as well as be informed of the current frontiers of research in this domain (number of attendees is expected to be about fifty or so). This would also aid to encourage new research ideas and foster cross-collaborations among the researchers internationally.

II. TOPICS OF THE EVENT

To keep up with the changing landscape, this forum will address the various pertinent topics of interest that are aligned with the international “Smart Learning”/“Smart Society”/“Smart City” initiatives in the roadmap towards the smartization as well as the advancement of educational research and innovation within the education sector. To do this, a new paradigm of thinking pertaining to a holistic intelligent campus (iCampus) environment will be investigated which encompasses several domains of intelligence. Some of the topics of interest include (but is not limited to): Cloud Education, Big Data for Education, Social/Collaborative Learning, Blended/Hybrid Learning, Personalised E-Learning, Mobile Learning, Edutainment & Game-Based Learning, Pedagogy for the Internet Age, Smart Classroom, Virtual Classroom/Laboratory, Educational Technology Innovations, Remote Education, Ubiquitous Learning Systems, Digital Library or E-Education, Peer-to-Peer Learning, & Other research issues for iCampus.

III. DETAILS OF THE EVENT

The forum is comprised of two main sessions, namely (1) a research paper session to set the scene and background of the panel, followed by (2) a roundtable/panel session to discuss in-depth into the issues.

To aid in the panel discussion, a total of 5 papers have been submitted by a subset of the key iCampus collaborators/supporters. The papers are categorised into two categories so as to introduce some aspects of the scene and background: (a) pedagogical-oriented; and (b) technological-oriented. As a summary, the former would cover the following papers (1) iCampus: An Exploration into the Attitudes of Young Girls Toward the Field of Computer Science (to bring out the gender aspects and considerations in engineering education), and (2) iCampus: Interaction Driven Composition of Student Groups for Optimal Groupwork Learning Performance (to look into the students dynamics in collaborative learning so as to maximize the full potential of learning and teaching); the latter would cover the following papers (3) iCampus: Development and Implementation of Game-, and Computer-Based Learning in a General Chemistry for Engineering (to explore and report on the results in the use of game-based learning in the engineering

education course), (4) iCampus: Grouping Tool Portal for Collaborative Learning (to propose and assess smart student grouping portal for education), and (5) iCampus: Smart Text-Classification of User-Generated Data in Educational Social Networks (to put forward the use of social networking tools for learning purposes).

All these papers are specially selected to put forward a few snapshot perspectives in the ‘smart-ization’ of the education domain so as to give an introductory overview for wider panel discussion in the technological and pedagogical aspects in smarter education. To ensure the quality of the panel, all these papers have gone through the same FIE review process and only the best papers that have been accepted would be incorporated in the session.

IV. PREVIOUSLY ORGANIZED EVENTS

Please kindly visit “2013 International iCampus Symposium on Smart Learning (IC’13)” in <http://IC13.intelligentcampus.org> or “2014 International iCampus Forum on Smart Education for the 21st century (IC’14)” in <http://ic14.intelligentcampus.org>; or, alternatively, our international iCampus conference series in <http://intelligentcampus.org/events>

V. ORGANIZERS/PANEL CHAIRS OF THE EVENT

The organizers/panel chairs of the International iCampus Forum (IC’15) are:

Jason W.P. Ng
Chief Scientist and Head of iCampus Initiative
Chair of IEEE UAE Education Chapter
Etisalat BT Innovation Centre
BT Innovate and Design
Contact of main organizer: jason_wp_ng@ieee.org

Abstract—This paper addresses the continuing problem in the United States of a lack of female professionals in Computer Science. The research team conducted surveys of middle school students and working adults to examine their attitudes, motivations, and experience with Computer Science. Based on the survey findings, the researchers are able to evaluate the effects of early, positive exposure to computer programming and give recommendations on how to improve the attitudes and confidence of young girls toward a possible career in Computer Science.

Keywords—education, computer science, programming, middle school girls, STEM.

I. INTRODUCTION

THIS research is conducted for a Middle School in Southern California, under the supervision of one master teacher. The Computer Science career field is severely under-represented by females. Many factors contribute to the lack of females interested in Computer Science. Based upon this teacher's experiences and research, many young middle school girls are not afforded the opportunity to learn computer programming, therefore, lack the knowledge and motivation to strive for a Computer Science degree.

Computer Science is one of the most in-demand and fastest growing career fields, with a projected growth of 22% in the next 8 years [1]. Computer Science encompasses everything from network design and engineering to software development. This career field requires extensive knowledge/skills of math and coding. However, designing computer applications can be fun, and it requires a creative mind.

This study took on the challenge of discovering answers to the aforementioned problem, by studying an exemplary computer science classroom in this middle school. This master teacher was awarded the Lowe's Champion Grant to transform her technology class to a computer science class. The goal of this grant is to steer girls towards a Computer Science career by giving them the opportunity to program through inventing 2-D animation and coding. The research team implemented a pre- and post- survey in a class of 7th and 8th grade students in this School District comparing their attitudes towards Computer Science. The target audience was the female students in this teacher's computer technology class, but data were collected from all of the students, male and female. The students are taught by this teacher to create their own computer applications using the MIT App Inventor 2 program. The results can be used to encourage other school districts to adopt a similar class in middle school. This research will be valuable to educators and curriculum planners to empower young girls to pursue a high-paying, in-demand, and rewarding career. Our goal, as a team, is to find a change in the girls' attitudes and thoughts toward Computer Science after completing the class and gaining positive exposure to computer programming.

II. LITERATURE REVIEW

The team wrote two separate literature reviews, both with the purpose of exploring the factors which contribute to young women's attitudes and perceptions of attaining a Computer Science degree and profession. The first review focused on female professionals in computer science to include the topics of: the history of women in computing, women in computer science majors, women in the computer science workplace, and obstacles women face. Based on the literature reviewed, the conclusions are stated below.

1. Women can excel in computer science. History has shown that women were pioneers in the early development of computers and that they can continue to contribute to advancing new computer technologies. Also, while women are

represented in computer science by a small percentage in the United States, the majority of programmers in Malaysia are women [2].

2. More women are needed in computer science. Research shows that programming teams with gender diversity are more effective at meeting users' needs. Women are also highly valuable as mentors to other women in the career field and as professors of computer science.

3. Girls need positive, confidence building exposure to computer science in high school or earlier. Even females who choose to major in computer science during college feel less prepared and confident than males. Hewlett, Sylvia Ann comment in their research: "women are actually excelling in science, engineering and technology, despite the fact that the schools are not very good at encouraging them" [3]

4. Women face many obstacles and negative stereotypes that need to be changed in order for there to be significant progress in recruiting and retaining a larger number of females in computer science. 52% of females leave their computer science job between the age of 35 and 40 [3], due to various reason such as improper treatment, stress of a 70 hour workweek, or starting a family.

The second set of reviews examines academic articles pertaining to the gender gap in the field of Computer Science. The reviews explore STEM strategies and pedagogical practices that motivate and engage young female students. The literature review also serves to explain the severe shortage of women and their lack of interest in computer science. Many factors have contributed to the negative attitudes women and girls hold toward a career in Computer Science. Despite the many efforts to add programs and initiate interest in computer science, the shortage of young girls in STEM classes has declined in the recent years. Further research must be done to explore different ways to ignite young girls' interest and to find solutions for the lack of participation in these programs.

Teachers need to be aware of the factors that contribute to gender bias in the classroom with regard to girls and computer use. Young girls often are discouraged from pursuing their interests in computer science due to several sources of gender bias including common stereotypes, media bias, biased societal role models, resources, software, and the attitudes of parents and teachers [4]. Young girls tend to enjoy software that is free form, exploratory, has free choice, and allows for communication. There are several strategies suggested by McNair, Kirova-Petrova, and Bhargava [4] that can minimize gender bias in the classroom including, but not limited to:

1. Providing equal access for all students to computers and programs, providing software that appeals to girls as well as boys
2. Creating non-competitive or threatening computer tasks and projects that are engaging and include social interactions
3. Providing examples of female role models such as professionals in the CSE (Computer Science Engineering) fields
4. Allowing students to work in supportive pairs

5. Giving students adequate amounts of time to complete computer tasks and scaffolding to build confidence.

With these strategies in place McNair, Kirova-Petrova, and Bhargava [4] believe that teachers can create a safe classroom environment that will promote secure computer learning for all students.

There are several factors that are related to the under-representation of women in the CSE (Computer Science Engineering) and STEM (Science Technology Engineering and Mathematics) career fields. According to Denner and Werner, the factors that deter young girls and women from pursuing a career in CSE include a competitive, masculine and socially isolating culture, low self-confidence in problem solving, a deficiency in early interventions and an inadequate understanding of the underlying causes [5]. Denner and Werner believe that, "working together with a partner in a collaborative way is appealing to girls, because it is aligned with their social interests" [5]. Young girls and women with social interests often view CSE careers as isolating, competitive, and masculine. Denner and Werner's study of pair programming brings awareness to the need for a culture of collaboration in CSE careers to entice young women to enter the male dominated field of study.

Many elementary and middle schools are implementing technology as a tool to teach their classes and improve motivation and engagement. The use of technology in the classrooms is one way to peak student interest especially young girls. At this point further studies are still needed to see the effects of the handheld computing pedagogy's and the needs of future generations. The research will continue to try and find different ways to ignite young girls' interest and find solutions to the lack of participation in these programs. This research will provide insights into how to better encourage and prepare females for careers in technology and computer science.

These reviews helped formulate our research survey questionnaires and interviews as we studied the students' attitudes throughout their Computer Science class.

A. Contextual Features

This study is being conducted at a school in a Southern California school District in a low socio-economic community. The project began in March and continued throughout the rest of the school year. The students who are involved in the project are 7th and 8th graders in middle school. The team conducted a quantitative online Qualtrics survey of the students before they began the class, as well as at the end of the trimester to discover changes in attitudes regarding Computer Science. The team also conducted on site interviews of the students who were involved in the project. The research should help us to determine the limitations and delimitation of this study. Some possible factors that could limit the outcomes of this study include:

1. The main constraint is timing. The whole research time period might not be long enough to have distinguishable differences in the learning process.
2. It is difficult to have close contact with those female students to see their reaction in every class. Interviews and on-

line surveys would assist the researcher in obtaining more survey data, but making an effective survey may be challenging.

3. Not all the female students in this class completed the pre- and post-survey.

By having the students focus their full attention on the project in an elective class that will be part of their school time, the limitations that a public school has during regular school time are avoided. Other limitations that could be a factor are the lack of participation from young ladies in these classes. Some young ladies may feel that this specific area is not for them or more of a male dominated field. Nevertheless these same obstacles and limitations can be overcome by giving young ladies the time to understand and evaluate what the class and program is all about. By addressing these limitations, it is possible that teachers and administrators would be more willing to implement Computer Science programs within the curriculum, since it is the fastest growing career.

III. RESEARCH

A. Methodology

This study tracked the responses of 42 middle school girls in the same computer science class at the beginning of the trimester and at the end of the trimester in order to determine a shift in aptitude and attitude via a pre- and post- survey. Several students were also interviewed concerning their experiences, attitudes, and opinions about computer science.

B. Sample Population

To study whether a computer technology class in middle school impacts students' interest in the computer science field, especially female students, the team found participants through a computer programming class at a Southern California Middle School. Since the study is focused on the attitude change of female students after finishing this class, the team did a survey and interview on both male and female students, while focusing on the female students. Both surveys and interviews are provided in this study. Around 42 female students enrolled in this class and also participated in the online survey. The ratio of male and female of this online survey is approximately 1:1. The team interviewed around 30 7th and 8th grade students in one of the computer technology classes. The ratio of students interviewed, male and female, is about 2:1. Apart from the study of middle school students, an online survey was sent by email to professional women who work in the computer science field to attain more information about female attitudes in the professional computer science field.

C. Instruments

Survey: The team developed surveys for middle school students and professional women who are working in the computer science field. For the survey of middle school students in the computer technology class at this Middle School, the group conducted a pre- and post- survey. The

outcome of the pre- and post- surveys provided the group with more data to compare the change of attitude and interest of female students in the first quarter of the class and after taking the class. The middle school students' survey is more focus on the attitude, interest, and knowledge about the computer science field and also the attitude and expectation of the computer technology class. The survey of professional women in the computer science field has more emphasis on the background, experience, attitude toward this job, obstacles faced in the job, etc.

Middle School Survey:

https://sdsueducation.qualtrics.com/SE/?SID=SV_07ETaP0vMANk66V

Computer Science Professionals Survey:

https://sdsueducation.qualtrics.com/SE/?SID=SV_8Bb2X1seVhOqTEV

Interview: To attain more information about the thoughts and attitudes of middle school students in the computer science field, the pre- and post- interviews were conducted. About 30 students participated in the interview (with representation from both male and female students). Apart from the survey questions, the interview questions are more focused on students' understanding and their perception of this field. For instance, what they think the computer scientists do for their job and why they think there are more males joining this field than females. Through the face-to-face interviews, the group has collected first-hand information from the participants. More importantly, the post- interviews showed the change of attitude, knowledge, and interest of those participants after finishing the computer technology class, which help the group to see if the class enhanced students' understanding of the computer science field and increased their interest in this field.

IV. ANALYTICAL RESULTS

A. Girls Aptitude and Experience with Using Technology

The pre and post surveys show a minimal shift in the girl's aptitude and experience with using technology. Most of the girls are significantly more comfortable using social media, gaming, and the Internet than using academic programs like PowerPoint or Excel. This data suggests that the use of social media programs is high while the use of academic programs is low. The survey data also indicates that the girls have more experience using programs like Photo shop, than in fixing the internal components of a computer, or creating a web page. The most significant shift is seen in the area of defining key terms relating to computer science. Students became more confident in their ability to define key terms by the end of the trimester as seen in Fig. 1.

Fig. 1a Pre Survey: How confident are you that you can define the following key terms?

Fig. 1b Post Survey: How confident are you that you can define the following key terms?

B. Girls' Attitudes and Interest Levels Toward Technology and the Computer Sciences

During this trimester the girls' interest in Computer Science became stagnant and in some cases their interest decreased. The girls' excitement and motivation to learn more about the field of Computer Science decreased by the end of the trimester. In the beginning of the trimester, 62% of the girls were excited to take this class and learn more about Computer Science. By the end of the trimester, 40% of the girls still held this attitude as seen in Fig. 2. As shown in Fig. 3, the pre-survey indicates that 38% of the girls either agreed or strongly agreed that they would consider a Computer Science degree. In the post-survey, 26% agreed or strongly agreed that they would pursue a degree in Computer Science. Likewise, the desire to learn more about Computer Science decreased over the trimester from 70% agreeing or strongly agreeing to 53%. Also, the desire to create something unique decreased by 6%. Similarly the girls desire to use technology to help people decreased over the trimester as well going from 93% agreeing or strongly agreeing to 64%. The girls' confidence in their own ability to do anything as long as someone assisted them also decreased from 81% agreeing or strongly agreeing to 76%. Over the trimester the girls' individual attitudes and personal interest level in computer science subsided.

The most likely explanation for this decreased interest level is the timing of the post-survey. At the time of the survey, the students were just beginning to start their final projects where

they their own computer application. They may still be lacking confidence in their ability to program because they have not seen their own finished product. Completing the application should increase their confidence and positively change their attitudes in a way that the basic instruction they received to this point cannot.

Fig. 2a Pre Survey Results

Fig. 2b Post Survey Results

Conversely, the girls' positive attitudes increased in the areas of women's abilities to do jobs that men typically hold, their belief that they are smart enough to become a computer programmer, and their belief in women achieving in the math and sciences. The girls' confidence in their ability to enter the field of Computer Science increased. At the beginning of the trimester 51% of the girls agreed or strongly agreed that they were smart enough to be a computer programmer. At the end of the trimester 56% of the girls agreed or strongly agreed that they were smart enough to be a computer programmer. When asked if their attitudes have positively changed toward computer science after taking this class 71% of the girls agreed. However, when asked if they would continue down a computer science career path in the future 70% of the girls replied 'no'. It appears as though the girls are gaining confidence in the capabilities of women entering Computer Science fields as well as in their own abilities; however they appear to lack the desire and interest to pursue such a career.

To test the statistical significance of the results, the research team compared data from the two questions that best represent girls' attitudes about computer science. They were both from the Likert scale, asking their level of agreement with a series of statements.

1. I want to learn more about computer science.

2. I am smart enough to be a computer programmer.

The students could choose 1 through 5, strongly disagree to strongly agree. The following figures show the results of comparing the before and after answers to these 2 questions.

	N	Mean	Mean SE	SD
3 Before	41	3.8	0.15	1.0
3 After	41	3.4	0.18	1.2
Differences	41	0.4	0.24	1.6

Fig. 3a. I want to learn more about computer science

	N	Mean	Mean SE	SD
6 Before	41	3.4	0.18	1.2
6 After	41	3.7	0.17	1.1
Differences	41	-0.3	0.23	1.5

Fig. 3b. I am smart enough to be a computer programmer

The girls' desire to learn more about Computer Science appears to decrease slightly; with the average response dropping from a 3.8 to 3.4, where 3 represents "neither agree nor disagree" and 4 represents "agree". Conversely, their belief that they are smart enough to be a computer programmer appears to increase slightly, with the average response moving up from a 3.4 to a 3.7.

To determine if these results are statistically significant, the team used a Student's t test to compare the pre and post survey data. The following figures show the results of this test.

Student t test	
Hypothesized difference	0
t statistic	-1.70
DF	40
p-value	0.0975

Fig. 3c. I want to learn more about computer science

Student t test	
Hypothesized difference	0
t statistic	1.17
DF	40
p-value	0.2484

Fig. 3d. I am smart enough to be a computer programmer

Assuming a confidence interval of 95%, a p-value greater than $p=.05$ indicates that there is no statistically significant difference between the pre and post survey answers to either of these 2 questions. This means that no conclusions can be drawn about the change in the girls' desire to learn more about Computer Science or their belief that they are smart enough to be computer programmers.

A common theme appeared within the final interviews. When asked to define Computer Science, 36% of the students were able to define some aspect of the field. 42% of the students interviewed had extremely positive opinions about the class, stating that it was "fun" and "I like it a lot". The students were also asked to comment on why they believe that women are not going into the field of Computer Science. Several of the girls made thought provoking comments that

should be considered when looking at this study. One of the girls hypothesized that "Girls are just not interested in computers. They are more interested in things like beauty." Another student hypothesized that older women didn't have the proper background knowledge. Insinuating a possible generational gap that may in time correct itself if more classes are offered for girls in schools at a younger age.

A. Professional Women in the Computer Sciences

The professional survey asked the participants to describe the moment, time period, or circumstances that first motivated them to pursue a career in computer science. Several participants mentioned that they became interested in the computer sciences in their college years. For example one participant mentioned, "during the time I was doing my under grad, computer was the buzzword. I started exploring more in the computer world and was amazed by the fact that so much can be done using computers. That was the time I got interested in computers." A second participant recalled, "I took a computer science class freshmen year after a friend recommended it." These responses coincide with the responses given by the middle school students in their post interviews hypothesizing that girls are not exposed to the computer sciences at an early enough age to motivate and inspire them to choose that career path. This gap is shown in Fig. 4.

Fig. 4 When did you become interested in computer science?

V. CONCLUSION

Although there seems to be a general decrease in the attitudes of the girls toward Computer Science over the trimester, there are underlying factors that may be contributing to the girls' lack of excitement and motivation to pursue this field of study. Possible factors may include gender bias, rigorous curriculum leading to frustration, school year burnout, assignment relevance to individuals, or learning environment. It is evident that further research in a variety of areas needs to be considered to determine the source of this decline in interest.

In conclusion, there was a change in the attitudes of the girls in the class by the end of the trimester. While the data show that the girls are less inclined toward a career in computer science, they believe that women are capable of being competitive in this field. Early positive exposure to the

computer sciences appears to be the first step in mending the gender gap and encouraging more young girls and women to explore careers in computer sciences.

By having this program it allows young girls to experience learning in a new way with a focus on integrating technology while maintaining the school's focus on the core curriculum. However, the data gathered in this research might be inconclusive. Results would likely be different if the post-course survey was actually conducted at the end of the class. This class culminates in the students creating their own computer application. The satisfaction of using computer programming to create something will likely increase their confidence and provide the positive exposure to change their attitudes about computer science as a possible career.

ACKNOWLEDGMENT

Special thanks to this master teacher and the School she was teaching.

Abstract—Collaborative Learning (CL) has been considered as an effective way to improve the learning outcomes of students in contrast to individual learning. However, assigning a groupwork task to a team of students does not guarantee a successful performance, and in fact could hinder the benefits of group learning if the members do not interact as expected. Indeed, group learning performance is largely dependent on group composition. In this work we address the challenge of identifying the characteristics of the individual group members that have the significant impact on the performance of the groupwork. Specifically we investigate the impact that a combination of individual student performances and gender have on the group performance and intend to find generic segmentation guidelines that would map smoothly onto the groupwork performance. A novel grouping method is proposed, which splits the set of students into groups that maximize one of the two desired criteria: the expected average groupwork performance or the average improvement achieved by a student as a result of synergic group learning and interaction effects. The model uses global optimization approach to identify optimal students allocation into the groups that best satisfy the optimization criteria. We illustrate our findings on the data obtained from the trial of the Collaborative Learning Environment (CLE) software. The CLE was developed at Etisalat British Telecom Innovation Centre (EBTIC) and tested over one semester with a sample of 122 students working in different groups in the Engineering and Molecular Biology courses at Khalifa University. The results of our method can not only help to understand the significant factors impacting group performance in group-based learning, but can also provide practical strategies on optimal group composition for collaborative learning activities.

Keywords—Collaborative Learning, learning performance evaluation, group composition, global optimization, Genetic Algorithm

I. INTRODUCTION

Collaborative Learning (CL) is defined by Johnson, et al. as the instructional use of small groups so that students work together to maximize their own and each others learning [1]. In CL, learners engage in common tasks and each individual capitalizes on resources and skills from one another [2], [3], [4]. It is based on the model that knowledge can be created within a population where members actively interact by sharing experiences and take on asymmetrical roles [5], [6]. In recent decades, it has been considered as an effective way to improve the learning outcome of students in contrast to individual learning [7], [8], especially with the rapid growth in cheap and powerful knowledge access technologies connecting and enabling students to carry out ever more learning, coursework and assessment tasks together [3], [9], [10], [11], [12], [13].

However, assigning a groupwork task to a team of students does not guarantee a successful performance, and in fact this could hinder the benefits of group learning if the members do not interact as expected. In the typical scenario of a joint group assessment, practiced in educational institution worldwide, the weaker group members might contribute less or even nothing at all, given the lack of pressure, while better student will be left overloaded and hence stripped from the opportunities for creativity, sharing and further development. All

the participants of such unfortunate group will lose out as a result. This indicates that proper student grouping is rather important in collaborative learning and can largely influence learning outcome.

A group is usually characterized by its size, gender and learning ability levels of its individual members. It has been studied in the literature that the composition of groups with different abilities and genders of students is closely related to the ways students engage, collaborate and learn [14], [15], [16], [17], which consequently influences learning performance. In this work we intend to address the challenge of identifying the characteristics of the individual group members that have the significant impact on the performance of the groupwork. Specifically we investigate the impact that a combination of individual student performances and their gender have on the group performance, and try to find generic segmentation guidelines that would map smoothly onto the groupwork performance. We propose a novel grouping method that splits the set of students into groups to maximize one of the two desired criteria: the expected average groupwork performance or the average improvement achieved by a student as a result of synergic group learning and interaction effects. In our method, student grouping to identify optimal student allocation into the groups is modelled as an integer optimization problem solved by using the global optimization technique.

A collaborative learning environment (CLE) platform has been developed under the iCampus initiative [?] at Etisalat British Telecom Innovation Centre (EBTIC) [9], [10] to capture the complete process of collaborative learning in sufficient detail. It was trialed over one semester with 122 students working in different groups in the Engineering and Molecular Biology courses at Khalifa University. During the trial, collaborative learning styles and their dynamics and outcomes were evaluated using three, group-based, formally assessed assignments. We illustrate our findings on the trial data. The results of our method can not only help to understand the significant factors impacting group performance in group-based learning, but can also provide practical strategies on ideal group composition in collaborative learning activities.

The remainder of the paper is organised as follows. Section II introduces the CLE developed at EBTIC, discusses its features and briefly describes the trial setup. The proposed grouping method based on global optimization is presented in Section III. The characteristics of the individual group members significantly impacting on the performance of the groupwork are discussed in IV. Finally, the concluding remarks are given in Section V.

II. COLLABORATIVE LEARNING ENVIRONMENT TRIAL

The Collaborative Learning Environment (CLE) is a system developed at EBTIC [9], [10] that brings together a collection of

tools and functionalities enabling communication, information sharing and collaborative document creation within the same environment. As opposed to individual communication and sharing tools like Skype, Facebook, or Google Drive which focus on a specific interaction or activity, the CLE is designed to integrate these different functionalities together into one cohesive formal learning environment.

The CLE is implemented as a set of modules for Moodle, an open source learning management system (LMS), and as such is able to capitalise on existing Moodle functionalities like group creation, file sharing and forums. By leveraging the flexibility of open-source technologies, the CLE integrates seamlessly into the LMS, providing a workspace that is familiar to both students and faculty, thereby reducing cognitive load and enabling more focus to be placed on the collaborative process.

The aim of the CLE is to stimulate the collaborative learning process and enable instructors to facilitate collaborative assignments more easily. Moreover, the whole interaction history is logged, thereby enabling dynamic analysis of contributions, usage and participation as well as enabling more advanced future functions such as knowledge elicitation. A screenshot of the CLE is shown in Fig. 1.

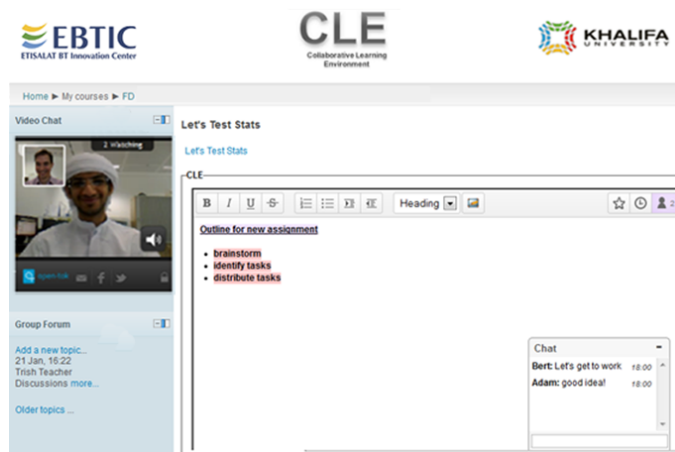

Fig. 1. Collaborative Learning Environment (CLE) in action.

Communication features of the CLE include synchronous text chat and audio/video communication, which allow participants to exchange ideas and communicate directly with each other regardless of their geographic location. Additionally, a collaboration area is provided to allow students to either synchronously or a-synchronously create an assignment. This area, called the collaborative editing pad, provides a canvas on which students can contribute and revise their ideas. Each contributor to the pad is assigned a unique color, so individual contributions are evident, and each keystroke, whether it is an "add", "edit" or "delete" is recorded by the pad. All individual students' assignment progress time series are merged into a single colour-coded progress timeline. Students' collaborative work on the same assignment followed many different patterns, from sequential to concurrent contributions, from one person dominated to evenly distributed workloads, from continuous progression of contributions to sudden bursts of activity and/or paste-ins. Figure 2 illustrates several examples of progress timelines, signifying different patterns of group interactions while working on a single assignment. The vertical axis measures the cumulative volume of the assignment content changes recorded by the CLE, and the horizontal axis represents the

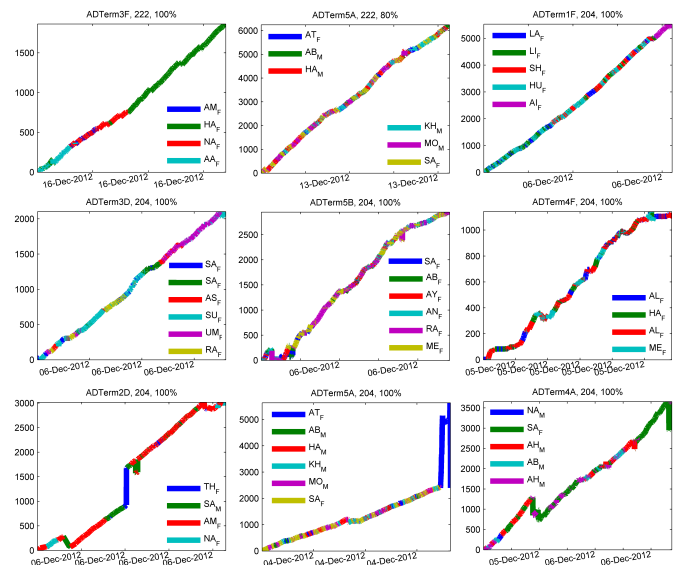

Fig. 2. Sample patterns of student interactions while working on group assignments: progress timelines.

Fig. 3. CLE statistics module, sample group contributions graphs.

time stamps of these changes up to 1s resolution. These progress timelines provide a summarised view of how the contributions from each group member evolved over time.

Another way to illustrate the students' interaction data is by depicting the volume of edit activity at a higher time resolution level. An example of such an edit activity plot for another group of students is depicted in Fig. 3. These two illustrations are just some examples of the interesting insights into how the group collaborated together. There are many other aspects of collaboration within CLE that can be analysed, for example monitoring the exact locations of different contribution edits to assess whether the members work independently on the same or different parts of the assignment or actually trying to understand and assess the value of individual contributions.

All the above approaches to analyse collaborative learning data harvested by the CLE are supported by a statistics module that can output detailed usage statistics at different aggregate levels. Such insights are invaluable for the instructors as they allow them to obtain, in an instant, a detailed analysis of how the group assignment was completed and what were individual members' effort and actual contributions. Beyond statistics, the CLE also provides a playback feature, that allows both the students and instructors to watch the entire creation of the assignment, from start to finish, much like watching a video.

Both the statistics and playback features of the CLE were used by the instructors of the Freshman Design Engineering Course at Khalifa University to assist in analysing student group adherence to a prescribed engineering design cycle throughout the Autumn 2012 semester. Overall 122 students participated in the trial, and their interactions within groups over a sequence of 3 assignments were recorded at up to 1s time resolution. Each group's assignment is assessed by the teachers and a single grade is allocated for the whole group. In the next section, we attempt to identify optimal grouping of students with an aim to maximize the collaborative learning performance. Due to the biased grade distribution of the 1st assignment in the trial where most groups achieved full marks, only the last 2 assignments are covered in our study.

III. GROUPING VIA GLOBAL OPTIMIZATION

In our work, student grouping is modelled as an optimization problem and solved by using global optimization technique, which will be elaborated below.

Let S and G be the set of indices of students and groups, i.e.:

$$S = \{1, 2, \dots, NS\}, \quad G = \{1, 2, \dots, NG\}, \quad (1)$$

where NS and NG are the number of students and groups, respectively. Our objective is to identify optimal student allocation into the groups that maximize the predicted group performance or the difference between the group performance and the average of individual members' performances. These two objective functions with respect to student allocation represented by x used in optimization can then be defined respectively as

$$obj(x) = \frac{\sum_{g=1}^{NG} grade_g}{NG}, \quad (2)$$

and

$$obj(x) = \frac{\sum_{g=1}^{NG} (grade_g - \frac{\sum_{s=1}^{NS_g} grade_s}{NS_g})}{NG}. \quad (3)$$

In (2), $grade_g$ is the predicted group performance of the g^{th} group and can be calculated as

$$grade_g = \sum_{s=1}^{NS_g} |C_s| * grade_s. \quad (4)$$

The second objective function in (3) is to maximize the performance improvement, where NS_g is the number of students in the g^{th} group. In the objective functions, $grade_s$ is learning performance of the s^{th} student, which is estimated here by using the comparative model [18]. In practice, one can also use the grade of a related course taken in the previous semester, or grade point average (GPA) achieved so far, to represent student performance. $|C_s|$ in (4) is the potential contributions of the s^{th} student in corresponding groupwork he/she will participate, which can be estimated from previous groupwork or simply considered all students within a group having the same contribution. We use the actual contributions captured in the trial of CLE software, which is represented by the absolute number of changes (positive: adding / negative: deleting) carried out by the student. Note that the contributions of all students within a group should be normalized to have a summary of 1.

The optimization problem is then defined as

$$\arg \max_{x \in S} obj(x). \quad (5)$$

TABLE I. DESCRIPTION OF CLE TRIAL DATA USED IN EXPERIMENTS.

Number of assignments	2
Number of groups	26, 20
Sizes of groups	[1 – 6]

Fig. 4. Distributions of group sizes and group assignment grades.

Student allocation, x , is represented using an integer vector with a dimension of $1 \times NS$, where each of element, x_s , represents the group id of the s^{th} student, i.e. $x_s \in G$.

In our method, the Genetic Algorithm (GA) is applied to find the optimal grouping scheme that splits students into groups and maximizes the objective function. The GA is an artificial genetic system based on the principle of natural selection where stronger individuals are likely the winners in a competing environment [19]. The intrinsic ability to cope with nonlinear problem makes the GA a suitable solution to solve assignment problems. In the GA, the chromosomes are represented using integer numbers, which represent potential grouping arrangements, i.e. x . An objective value according to (2) or (3) is then calculated for each chromosome. A population is formed with a certain number of chromosomes. Fitter chromosomes in a population are selected based on Roulette Wheel Selection strategy [19], so that the fittest chromosomes have better chances to be chosen and allowed to reproduce. The selected chromosomes are treated as parents to produce new chromosomes called children by genetic operations. Crossover is a basic operation to create a generation of new chromosomes - the offsprings, which then undergo a process of mutation that randomly changes one or more genes to maintain the population diversity. After the crossover and mutation process, the population of new offsprings is chosen to replace the same number of chromosomes in the old population to form a complete new generation. The replacement strategy used is the Generation-Replacement method plus the Elitist Strategy [19] to retain the best chromosomes at every generation. The whole process from encoding and selection to crossover, mutation and replacement follows an iterative cycle that evolves the population towards fitter solutions until it converges or the termination conditions are met.

To illustrate the effectiveness of the proposed grouping method, we compare the group performance of the optimal solutions generated by the GA and that in the CLE trial. Among 122 students participates in the trail, 100 and 47 students were partitioned into 26 and 20 groups, for the 2 considered assignments, respectively. The group sizes varied typically between 3 to 6 students, however there were instances when only 1 or 2 students contributed. Table I summarizes data used from CLE trial. For each assignment, the teacher assessment grade is allocated to the whole group. The distribution of group sizes and grades for both assignments are shown in Fig. 4.

If the group composition is optimized by using the GA based method with an objective function of (2), the group performance is

Fig. 5. Comparison of average group performance between optimal grouping and that in the trial.

Fig. 6. Comparison of the average grade improvement between optimal grouping and the traditional ad-hoc grouping in the trial.

estimated based on the generative mixture model proposed in [18]. When the objective function (2) is employed during optimization, the average of group performance is maximized. Fig. 5 illustrates the average group grades estimated based on the optimal grouping scheme generated by the GA, which are compared with those captured in the CLE trial. It can be seen from the figure that in both assignments the average performance of the associated with the optimal grouping is higher than that achieved by the traditional grouping in the trial.

Let us now consider the objective function (3) in the optimization. Fig. 6 illustrates the average performance improvement between the predicted group grades generated by the optimal grouping solutions consisting of 26 and 14 groups in the 2 assignments, respectively, and the individual student performance. For comparison purpose, the improvement achieved in the CLE trial is also depicted in Fig. 6. As shown in the figure, the expected group performance can be higher than individual student performances in both assignments with the optimal grouping solutions, and the grade improvement is also higher than that actually achieved in the trial by 2.9 and 4.2 marks in the 2 assignments, respectively. The negative improvement in the second assignment achieved in the trial further indicates that student grouping is extremely important to improve learning outcomes. It can be seen from Figs. 5 and 6 that the optimal grouping of students can significantly improve learning in collaborative learning activities.

The statistics of individual student grades and predicted group

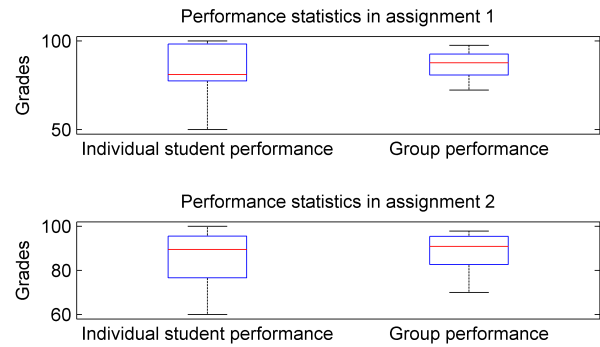

Fig. 7. Statistics of individual student grades and the predicted group grades.

grades with optimal grouping in the 2 assignment are compared in Fig. 7. As shown in the figure, lower performance of individual students has been significantly improved in collaborative learning activities. This is coincide with the findings reported in [16] that low-ability students having high-ability peers as teammates are more likely to significantly improve their performance and thus lower-ability students tend to benefit much more via collaborative learning than higher-ability students [20].

IV. FACTORS OF GROUPING INFLUENCING LEARNING OUTCOME

It is believed that the composition of groups of diverse students, i.e. with different learning abilities, genders and other features can largely influence learning performance. These differences affect the ways students engage, collaborate and learn [14], [15], [16], [17], and thus influence learning performance. In this section, we investigate the impact that a combination of individual student performances and genders have on the group performance.

It has been shown in [17] that both interaction patterns and collaboration effects are varied across various compositions of individual student performances in the group.

Fig. 8 illustrates the performance statistics of individual student members within each group allocated either according to optimal grouping solutions (Fig. 8(a)) or the group allocation used in the trial (Fig. 8(b)). The horizontal axis shows the grade of each group ordered by the group *id*. It can be seen from the figures that the groups in Fig. 8(a) have wider distribution of student learning abilities than those in Fig. 8(b). The fact that the average group performance in the former is higher than that in the latter in both assignments provides us with a strong support for encouraging groups' heterogeneity of members' skills and learning abilities in collaborative learning.

Significant research has been dedicated to study and compare the effectiveness of single-gender and mixed-gender education with various gender compositions in classrooms. These studies suggest that gender composition can largely influence learning outcome in collaborative learning. Fig. 9 illustrates the gender composition of each group obtained for GA-optimized grouping and the traditional ad-hoc grouping applied in the trial. The label of each bar indicated the grade of each group. As shown in Fig. 9, most of groups, i.e. only 10 out of 40 groups allocated according to optimal grouping have single-gender, while 39 out of 46 are single-gender groups in the trial. This can partially explain the source of higher improvement

(a) Optimal grouping

(b) Grouping in the trial

Fig. 8. Statistics of individual student performance in each group for optimal grouping and that in the trial.

of performance expected from optimal grouping, as shown from the performance statistics in Fig. 7.

V. CONCLUSION

This paper introduces a novel grouping method that splits the set of students into groups so as to maximize one of the two desired criteria: the expected average groupwork performance or the average improvement achieved by a student as a result of synergic group learning and interaction effects. The impact that a combination of individual student performances and their genders have on the group performance is investigated following generic segmentation guidelines that map smoothly onto the groupwork performance. Our findings are supported by the series of experiments carried out on the data obtained from the trial of the Collaborative Learning Environment software, developed at Etisalat British Telecom Innovation Centre (EBTIC). The trial was tested over one semester with a sample of 122 students working in different groups in the Engineering and Molecular Biology

(a) Optimal grouping

(b) Actual grouping

Fig. 9. Gender composition of each groups for GA-optimized and ad-hoc trial grouping.

courses at Khalifa University. The results indicate that our grouping method that utilizes the genetic algorithm provides a practical and well performing strategy for achieving optimal group compositions in collaborative learning activities. Our method also helps to identify the factors that play a significant role in successful groupwork and enable the measures of their impact. In a subsequent research we will attempt to investigate further the role of the amount and the quality of the individual student contributions on the groupwork performance.

Abstract— Interactive learning through computer quiz games has been introduced to improve teaching and learning in a freshman engineering chemistry course. This is accomplished through a series of JAVA-based, weekly general chemistry quiz games, developed and implemented as a supplemental and augmentative tool in delivering freshmen chemistry for engineering majors. The introduction of quiz game is anticipated to increase the engagement of students in chemistry classes by improving their attitudes towards chemistry and their overall chemistry achievements. Kolb's four-stage learning cycle is introduced as a possible model for a role the computer quiz games could have in the overall learning process, where the games are anticipated to serve as alternate mode of learning and as an additional motivational tool. In addition to introducing weekly computer quiz games, we report on the effort made to assess their effectiveness. For this purpose, we propose a novel chemistry achievement test developed in this study, Freshman Engineering Chemistry Aptitude Test (FECAT), which aims to comprehensively cover the freshmen engineering chemistry course. Additionally, we implemented an attitude questionnaire. The findings of this pilot study help to advance our understanding of the practical contribution of game-based learning to students' achievement in chemistry and also their attitudes towards learning chemistry at university. At the time of the pilot implementation, we hypothesized that the major benefit of the interactive game would be an increase in students' overall interest in chemistry, with an associated improvement in achievements in the course.

I. INTRODUCTION

Two major novel trends have affected improvements in teaching and learning over the past two decades. One is increased research, development and implementation of teaching techniques based on the interactive engagement approaches [1], and the other is an increased use of sophisticated, personalized, easy-to-use computing devices [1]. This report relies on efforts related to and depending on both trends, and represents a pilot study in which we developed computer quiz games (CQGs), which are short (10 min per week), full engagement, single player activities

for students. The current aim and reach of the CQGs activity is that they serve as a complementary and augmentative activity to the traditionally delivered freshmen engineering chemistry course. We see considerable potential for future upgrades and expansion. As a result of a recent curriculum reform, all undergraduate engineering students at Khalifa University College of Engineering (KUSTAR, Abu Dhabi, UAE), now take *General Chemistry for Engineering Students* as their first science course. The population of students majoring in engineering disciplines at Khalifa University is unique in several ways. More than 97% of students are ESL (English-as-Second-Language) speakers, they come from very diverse socio-economic backgrounds, and they belong either to a large group (~ 80%) of UAE nationals or to a small (~ 20%), but diverse group of predominantly MENA (Middle East and North Africa) region expatriates. Nearly all of the KU freshmen students graduated from local (UAE) high schools, so some features of this study also represent an indirect assessment of the effectiveness of general chemistry instruction in UAE-based secondary education.

Game-based learning has become a topic of increased interest in educational technology [2]. From the literature review, many studies present the view that games have potential as an educational tool [3-9]. It is said that games can enhance students' learning and complement traditional lectures [10-12]. For instance, Moore & Dettlaff [13] suggest that game-based learning could be used as a supplement to traditional methods, because games can add flexibility to the classroom, allowing students to adjust to the way in which they learn best.

For the purpose of increasing students' level of engagement and achievement in a basic science course, such as the *General Chemistry for Engineering Students* course, we implemented a set of weekly computer quiz games (CQGs) consisting of a finite number of questions (total of nine for one weekly CQG) via game-based and computer-implemented interactive engagement classroom activities. This effort echoes other current trends worldwide and in the MENA region, where, according to Nicks-McCaleb [14], there has been some shift in focus from more traditional

education methods, to contemporary approaches following the dramatic growth of the Arabian Gulf region over the past three decades. For example, the UAE Ministry of Education has developed *Education 2020* framework a series of ambitious five-year plans, that are designed to bring a significant qualitative improvement in the education system, both in course delivery and in students' learning [15].

In this study, we explore the effectiveness of our computer-based, interactive learning methods for chemistry learning, and compare these results with those for a more conventional, paper-based quiz activity.

II. EXPERIENTIAL LEARNING PROCESS

Kolb's experiential learning cycle is a known construct from traditional learning theories [12, 16]. We have adopted it in this study, as we hypothesize that it represents a useful framework for understanding the role of game-based learning, as shown in Fig. 1.

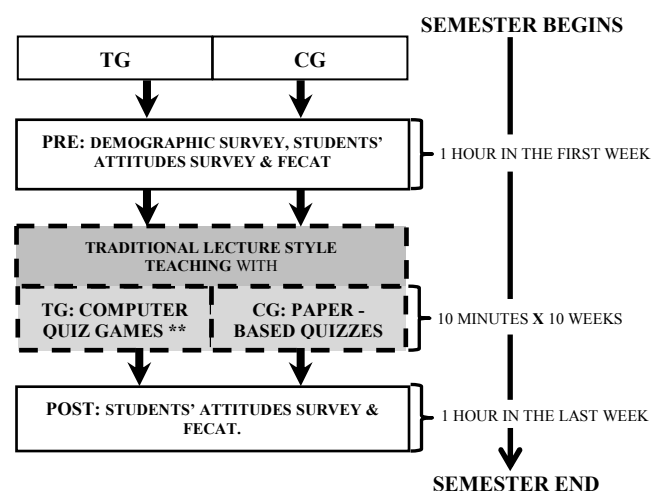

Fig. 1. Experiential learning process

The experiential learning process with Kolb's cycle is used to highlight the anticipated science game-based learning process and its effect on students' chemistry achievement and students' attitudes towards learning chemistry. Here, we briefly explain the implementation mechanism. Students attend the traditional lecture sessions three times a week, and are actively involved in the chemistry learning process while playing the computer quiz games (CQG) during one of these lectures (typically, but not exclusively, the last lecture meeting of the week). They reflect on the topic related from the lecture while answering the CQG questions. During this game, they are allowed to choose to answer questions of different difficulty levels, with the caveat that they don't know the actual content of the question (only the estimated difficulty, where the estimation is performed by the research team beforehand). Throughout the game playing process, students conceptualize, understand and familiarize themselves with chemistry concepts. They actively engage in the game session and other class activities to enhance their knowledge, before moving to the next learning session to continue the chemistry learning process. The CQGs serve as a supplement to the teaching and learning process and are conducted as a part of a classroom-based lecture, but were

not used as an assessment method. They can thus be considered as a motivation enhancer.

A. Methodology development

Fig. 2 illustrates the methodology of this pilot study.

**link to Fig. 1: Experiential learning process

Fig. 2. Research methodology; TG refers to treatment group and CG refers to control group.

Students enrolled the *General Chemistry for Engineering Course* were invited to volunteer to participate in the pilot study. Volunteers were divided into paper-based quiz game (control group – CG, for short) and computer quiz game (treatment group – TG, for short) groups. Separation into two groups was motivated by the need to monitor the effect of quiz taking from the effect of using computer. A set of short surveys was administered for all the volunteers; specifically, a demographic survey and a students' attitudes survey, are administered both at the beginning of the semester and at the end of the semester. Also, in order to assess the students' possible progress in acquiring general and conceptual knowledge a test of such knowledge was created with the working title "Freshman Engineering Chemistry Aptitude Test" (suggested abbreviation: FECAT). This test is utilized according to a standard education research paradigm "posttest vs pretest", allowing for the collection of students' answers to the same test twice in the semester, at the start and at the end of the semester. The FECAT answer data are then analyzed following the Hake's gain expression [17], as well as Dellwo's gain paradigm [18]. The pilot study was carried out during 12 weeks of the Fall 2012 semester, and some highlights of the initial data are presented here. A more thorough study will be forthcoming [19].

A series of JAVA®-based, general chemistry CQGs are games explicitly designed for educational purposes. They are somewhat similar to exercise-based computer games proposed by Kablan [7] and exercise games proposed by

Allessi & Trollip [3] that are intended to be used to increase the learning performance. The games are designed to allow maximum flexibility for any interested future instructors to include their own material in preparing the quiz, because the quiz files are relatively easy to edit for content and each individual question (and its corresponding answer) could come in the form of text, graphics or a combination of both. The CQGs are administered once a week for approximately 10 minutes, typically near the end of the last lecture of the week.

We emphasize that there are no overlaps between the questions asked in computer (or paper) game quizzes and the questions asked on the FECAT test, and that effort was made by the teaching team to avoid assigning homework questions of the same content.

B. JAVA™-based, general chemistry quizzes

An example of two consecutive screenshots displaying the CQG “front end” and an example question are shown in Fig. 3.

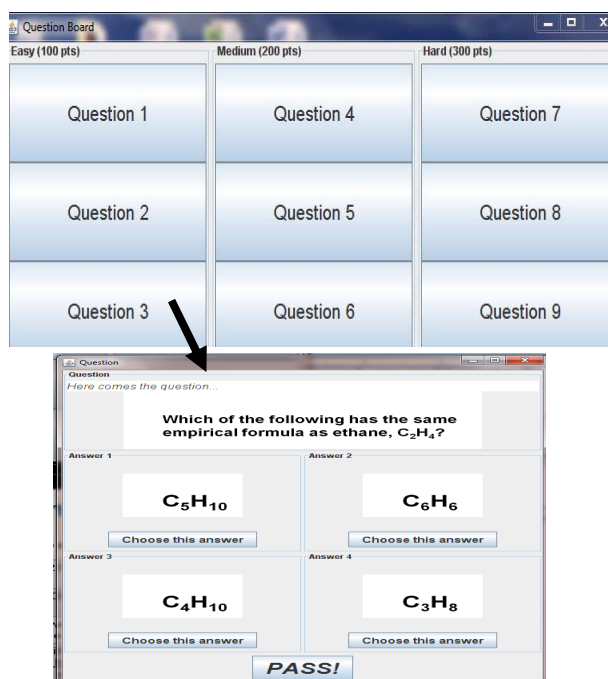

Fig. 3. A snapshot of the computer monitor while a student is playing the game. (upper) the interactive panel which allows students to choose a question of the desired difficulty level; (lower) example of a question and four offered “answers” (only one choice is correct in all questions).

In the course of playing the game, a student is asked to choose any 5 questions (one question at a time) out of a total of 9 from three categories of difficulty (“easy” worth 100 points, “medium” worth 200 points, or “hard” worth 300 points). After choosing the question from the category a student is comfortable with, she/he is then presented with a specific question, where “click-on” provides student’s answer input together with a timer (the

timer is an integral part of the developed application, and is always visible to students, but is not shown here for the sake of brevity). If the answer is wrong, the right answer “pops up” and the player loses points; if the answer is right, the player earns points. Student can choose not to answer the question by clicking the “Pass” button. In this case, no points are earned or lost. The “Help” button (also not shown) is also provided to help the student answer the question more easily by eliminating two of the (wrong) answers. In order to avoid abuse of the “Help” button, student can only use it twice in any game-session.

C. Freshmen Engineering Chemistry Aptitude Test

Due to the lack of a general chemistry assessment test that encompasses both fundamental concepts and elementary knowledge for ESL (English as Second Language) engineering students, we developed the Freshmen Engineering Chemistry Aptitude Test (suggested abbreviation: FECAT). The test follows the US style freshmen chemistry curriculum, but the style of questions differs markedly from examination questions and from questions on weekly computer and paper based quiz games, to ensure no overlap. FECAT has been developed partly as an assessment instrument to be independent of instructors’ individual teaching styles and the content and format of the semester final exams, and partly for application with the standard post-test vs. pretest education research methodology, such as the pilot study we report on here. It can be used for other purposes, including: (a) assessment of students’ readiness to take a one-semester engineering chemistry curriculum, such as the one commonly implemented in US style engineering curriculum, (b) to help instructors in tailoring the focus of lectures during the semester, if used as a diagnostic test in the first week of the semester, and (c) for other purposes, as instructors see fit.

The pilot version of the FECAT contains 36 questions, divided into five topical groups: (1) basic properties of matter and laws of nature; (2) chemical properties of elements and compounds; (3) chemical reactions; (4) energy and heat; and (5) atomic structure and chemical bonds. The KR20 statistical test shows the value of 0.848 (pretest) as well as 0.787 (posttest) and Cronbach’s alpha coefficient is 0.845 (pretest) and 0.766 (posttest), indicating the FECAT can be accepted and has a good reliability. According to Fraenkel *et al.* [20] and Johnson and Christensen [21], coefficient reliability value must be equal to or higher than 0.70 in order to be accepted. A common accepted rule for describing internal consistency in the case of the Cronbach’s alpha test is a value between 0.7 and 0.9, which leads to the test being described as “good”, as also reported in [22, 23].

As mentioned earlier, the FECAT is also administered at the end of the semester, so it serves as an education research instrument in the assessment of learning gain via Hake’s definition [17] (i.e. $GAIN = [POSTTEST\ SCORE - PRETEST\ SCORE]$).

SCORE]/[100 – PRETEST SCORE], where “SCORE” value is between 0 and 100).

D. Students' Attitudes Survey

In this study, students' attitudes survey consists of: motivation components adapted from Science Motivation Questionnaire (SMQ) by Glynn & Koballa [24] and motivation survey developed by Kebritchi *et al.* [12]. A Likert-type scale with Strongly Agree (SA), Agree (A), Not Sure (N), Disagree (D) and Strongly Disagree (SD) was used as the response format of the survey.

III. RESULTS AND DISCUSSION

A pilot study involving 70 students (34 playing CQG, and 36 playing a control paper quiz) was conducted during the Fall 2012 semester. Below are the results for our pilot study. Out of 36 questions on the FECAT, students had negative learning gain on 3 questions only, on 4 questions they had a gain between 0% and 9%, on 9 questions the gain was between 10% and 19%, on 6 questions the gain was between 20% and 29%, on 6 questions the gain was between 30% and 39%, on 2 questions the gain was between 40% and 49%, and on 6 questions the gain was higher than 50% (see Table 1).

Table 1. Summary of the Hake's gain in FECAT

Gain	No. of Questions
negative	3
0 - 9%	4
10 - 19%	9
20 - 29%	6
30 - 39%	6
40 - 49%	2
50% and above	6
Total	36

To offer readers a more concrete, deeper insight into the technical details of the FECAT, we selected four questions and listed them in the Fig. 4. A more thorough report will contain a detailed look of various FECAT features [19].

Q11. Pure substances:

- A. Rarely exist around us
- B. Are homogeneous and have unchanging chemical compositions
- C. Are heterogeneous and have unchanging chemical compositions
- D. Only exist in cubic shape
- E. Mostly exist in regular shapes, like spherical

Q16. Which of the statements below about electrolyte is INCORRECT?

- A. Electrolytes are compounds whose aqueous solutions conduct electricity
- B. Non-electrolytes are compounds that cannot conduct electricity either in solid or aqueous solution
- C. Strong electrolytes are solutions that are a good conductors of electricity
- D. Weak acids or bases are considered weak electrolytes as all the molecules react with water to form ions

- E. A non-electrolyte does not conduct electricity because no ions are present in solution.

Q19. Potassium chloride solution is added to silver (I) nitrate solution in the beaker, and kept for some time, while a precipitation reaction occurs. The new precipitate formed in the beaker is:

- A. Silver (I) chloride
- B. Silver (I) nitrate
- C. Silver (II) chloride
- D. Potassium nitrate
- E. Potassium (II) nitrate

Q22. Which is TRUE during a phase change, such as water boiling or steel melting?

- A. Both temperature and heat energy change
- B. Heat energy remains constant but temperature increase or decrease
- C. Temperature remains constant but heat is absorbed or released
- D. Both temperature and heat energy remain constant
- E. Temperature and heat of the energy either both increase or both decrease

Fig. 4 The content of selected questions on FECAT discussed on this report.

The Fig. 5 shows the comparative gain for these four questions for both students' groups.

Fig. 5 The gain for selected four questions from Fig. 4 above.

We wish to emphasize that there is no specific reason why we selected these particular questions, other than to illustrate that the individual question's learning gains range as indicated in Table I above, and that learning gains can be higher for treatment group in some questions and for the control group in others.

As implied early in this manuscript, this effort is a part of a broader goal of evaluating effectiveness of the novel, partially computer-based interactive course delivery methods. In this regard, the use of Hake's gain has been suggested to be an insufficiently precise measure, in part because it neglects the nuances of the possible processes whereby students improve their post-test score over the pre-test one [18]. For example, Dellwo [18] points out that there can be four options how the answer to a given question on a **pre-test** (FECAT in the case of this report) could change at the time a student takes the same test in the **post-test** mode. In no particular order, the pretest correct answer (T) can remain the same (T) at the posttest level indicating the process we will label as (TT), or it can change to a wrong

answer (F), the process here to be labelled as (TF), potentially (but not exclusively) indicating that a student may have been making a “lucky guess” at the time of taking the pretest. Similarly, the incorrect answer (F) on the pretest could remain incorrect on the posttest, (FF) process, or can lead to the correct answer on the posttest, here labelled as (FT) process. We are interested in these four possible answer “switches” because in interactive engagement course delivery, one wishes to understand which concepts are more easily learned (FT process), compared to those that persist as wrong (FF), whether on the skill and knowledge level or on the level of the concept. For this reason, we plot the percentage of students for each four possibilities (“switching states”) (TT, FT, TF, FF), for both, the treatment group (CQG playing) and control group (paper quiz). The results are shown in Fig. 6, where percentage of students in each “state” is shown for both student groups.

We also employed inferential statistics to analyze students’ performance. The independent pre–post differences in each group were explored using the paired-sample t-test. The pre-post differences in each group (CQG for treatment group and paper quiz for control group) were explored using the paired sample t-test. The results showed that there is a small difference between the two groups, (TG, $t = 6.983$, $p < 0.05$), (CG, $t = 7.200$, $p < 0.05$). This is also in agreement with the comparable Hake’s gain for both groups (29% and 32%, respectively). At first sight, the Hake’s gain result would be discouraging as to the effectiveness of the application of computer based games, except that we found that our group design introduced significant, yet unintended bias. Here, by group design, we mean the assignment of students to a particular group – treatment (CQG for the whole semester) or control (paper based activity for the whole semester). The performance of the control group was enhanced due to overall pre-existing skill and knowledge; namely, the overall English and elementary math skills were appreciably higher in this group), which is something we could not have fully controlled for at the time of the start of the pilot study (due to the lack of access to registration data). We have further established this by analyzing final exam performance, which is common in content and paper-based for the entire class (both groups of students in this study), and, when final exam differences are accounted for, we establish both a small statistical significance and Hake’s gain in favor of the treatment group.

Specifically, corrected (normalized for the final exam average) Hake’s gain is 32% for the treatment group and 28% for the control group).

Fig. 6. Analysis of the error pattern in answering FECAT

Next, we proceed to discuss a characteristic outcome of qualitative survey, and we selected the question “*I find learning chemistry interesting*”, where students entered their preference on the five point Likert scale, as shown in Fig. 7 below. The comparison is shown below for CQG and paper group for a survey data taken at the end of the semester (post-test)

Fig. 7 Difference between students' attitude towards learning chemistry, where “SA” stands for “strongly agree”, and “SD” for “strongly disagree”.

We find similar differences on some other questions on the attitudes' survey, such as question “*I like chemistry lectures*”. The preceding statement and data in Fig. 6 and the preceding are very encouraging information regarding the relatively positive effect of the CQGs on student motivation and enjoyment.

Generally, our results indicated that there is an improvement in students' chemistry achievement and students' attitudes toward chemistry in the group taking CQG compared with those participating in the more traditional paper quiz of the same content. These results suggest that CQGs can have a positive effect on the student performance, lending some quantitative credence to the hypothesis that CQGs provide either a support to the traditional lecture delivery or an alternative method of learning in a freshmen engineering chemistry course.

IV. CONTRIBUTION AND NOVELTY

Before we discuss the overall relevance of this contribution, we would like to remind readers that several other gaming-for-learning attempts have been publicized in recent 15 years or so. Some of the developments in recent years include “Concentration” game [25], based on matching question and answers, “Go Chemistry” game [26], played as the card game focused on a specific goal, for example, the comparison between ionic and covalent compounds, and “Chemistry Taboo”, [27] which separates all clues into allowed and forbidden ones, thus motivating deeper, more discerning engagement with the course material. Introducing a combination of computer- and game-based learning as a supplement to traditional teaching learning in chemistry is challenging, especially at university level in UAE, given the diverse pre-college educational background of students. The approach described here

provides an alternative way to improve pedagogical practices in science and develop novel curriculum elements to augment chemistry learning. The research findings offer an understanding of the strengths and weaknesses of the implementation of game-based learning approaches from the view of instructors and students alike.

For policy makers, the results of this research can provide a source of information regarding contemporary science education issues and trends. Furthermore, the results help the education authorities gain insight towards improvement of the quality of science education. Another contribution of this study is to help in advancement of our understanding of the practical contribution of game-based learning.

Our next contribution and claim to novelty has to do with the context of our study. Introducing a culturally diverse Middle-Eastern audience, for whom the quiz is written in a second language, to game-based learning provides some of the strongest evidence yet of the method's efficiency and widespread applicability. Furthermore, the approach that is introduced in this study is very practical to use, and instructors do not have to change their general delivery method, as the team designed the game engine specifically for this purpose.

V. SUMMARY AND CONCLUSIONS

This is a pilot report on the development and implementation of computer quiz games in introductory freshmen engineering chemistry class, where we show how playing one computer quiz game per week, while following the traditional US-style curriculum enables instructor and students to alter the expectations and attitudes in terms of possible improvement of learning gains. In addition to development and implementation of computer quiz games, we developed and implemented novel chemistry aptitude test, FECAT, which is designed to serve as both, research instrument for pre- and post-test applications and as assessment tool.

ACKNOWLEDGMENTS

This study was approved by the KU Institutional Review Board. We acknowledge the support from the KU Office of Research Support, Ms. M. Hassan and Prof. T. D. Burton (both from KU), and we thank the CHEM-115 teaching team for the assistance in data collection. We acknowledge stimulating exchanges with G. W. Hitt of KU.

Abstract—Learning theory in education has progressed dramatically with the rapid development of modern technologies. Modern learning theory has found that learning performance can be improved effectively through cooperative/collaborative learning. How to group students in one class based on their different learning capabilities is a key to success in education. Two grouping types of homogeneous and heterogeneous have been applied into class grouping. Research proves that homogeneous groups are good at specific goal and heterogeneous groups are better in expanded tasks. Learning efficiency is affected in both group level and individual level by different grouping method. However grouping students in an optimal way is a difficult NP-hard research problem with high complexity; and to achieve the best results, such grouping can be very time consuming and tedious for the teachers to perform manually, especially when local cultural context (for instance, gender parameter) has to be taken into account, such as in the Middle East region. So the ability of allowing educators to define rules describing groups is very important for both homogeneous and heterogeneous grouping capabilities. This paper thus describes a smart grouping tool portal which is easy to access and user friendly, and aims to assist teachers to automatically group students based on different criteria. This portal has been trialled at Khalifa University of Science, Technology & Research (KUSTAR). A case study of the trial has also been analyzed to illustrate the derivative benefits of our smart grouping tool portal.

Keywords—cooperative/collaborative learning; student grouping; learning analytics

I. INTRODUCTION

Research into the efficacy of cooperative learning (as defined in [1-3]) in education has primarily taken place within a “conditions” paradigm, where factors such as group composition, task features, collaboration context and means of communication, are investigated for their causal role, if any, in the development of domain expertise among group members, with results most often interpreted within the framework of Piaget’s developmental model and the social-constructivist’s model from Vygotsky (see [4] for review). Briefly summarizing these models, the cognitive development of a learner proceeds through definite stages, with each characterized by the manner in which the learner constructs meaning about the world and solves problems [5]. Development and learning are often triggered by cognitive conflict with and facilitated by social interactions with peers of greater task-relevant knowledge, but with such skill differences being within an optimal “zone of proximal

development” [6]. In other words, skill differences among members that are too small are unlikely to produce conflict, while skill differences that are too great can lead to confusion, demotivation, or create perceived authority figures within the group or other counter-productive behaviors among members.

For this reason, conditions of group composition in general and the distribution of the group’s task-relevant skill levels in particular, have been investigated more than any other factor [4]. However, the question of ‘what represents the ideal group formulation?’ remains an active area of investigation, partly because of a lack of wide agreement on (1) the definition of a “collaborative group”, particularly in terms of proximity (e.g. do we include 1,000 students in a project-based MOOC as forming a ‘group’?) and (2) how to measure relevant learning specifically resulting from peer interactions [4]. These issues are difficult to resolve partly due to the difficulty in studying large populations with a consistent methodology, large numbers of different definitions of ‘group’ and different teaming recipes, and analyzing large sets of assessment data for the individual learners.

To address this issue, we have designed a standalone grouping tool application based on a set of user-defined rules under the iCampus initiative (<http://intelligentcampus.org/>) at the Etisalat BT Innovation Center (EBTIC) [7,8]. To make it more easily accessible and applicable for further learning analytics, we have also upgraded it into web portal termed as “Smart Grouping Tool”. To maximize the practicality and usefulness of the tool, we have focused the functions offered around solving the problem of creating student groups within one class or section of a course (i.e. one instance of a course where students would be physically present with one another during a scheduled contact time). This approach is practical because teaming students in such a setting is a recurring task of instructors using team-based pedagogies. And it is a useful approach because this specific teaming task is, when done manually, often very time consuming and difficult to apply consistently, for a given rule set or teaming recipe. This approach is also very relevant for research purposes, since providing an algorithm that gives the ability of following user-defined teaming recipes consistently will help other investigators eliminate systematic errors and better compare data sets collected under different settings. Lastly, the teaming recipe itself, when constrained by many rules, can present a tricky non-deterministic, polynomial-time-hard (or “NP-hard”) problem.

A sample of representative research suggests that task-relevant, skill-homogeneous groups are good at narrowly defined, more analytical tasks, while heterogeneous groups perform better in extended, more synthetic tasks requiring learning, creativity and ideation [9-14]. Research in recent years has also seen many efforts aimed at defining student spaces and learning styles [15, 16]. Algorithms based on feature distance have been used on grouping tasks [12,17-20], however is difficult to be adapted to apply on rule set based grouping tasks. In addition, as previously mentioned, grouping is an NP-hard problem, so complexity and speed are two important considerations. Some optimal algorithms might not be practical in the real scenarios, while for the most existing algorithms, the user is not allowed to define the rule set and therefore they become inflexible for real world usage.

The paper is organized as follows: In Section II we describe our smart grouping tool portal and show the prototype with some user interfaces snapshots. In Section III, we report a case study with University Physics I students at Khalifa University of Science, Technology & Research (KUSTAR). We then conclude with current progress and future work in Section IV.

II. SMART GROUPING TOOL PORTAL

The culture in the Middle East is very much different with other regions. For example, Gender needs to be considered seriously in some place, so does Nationality. So the class grouping has to be more flexible to allow some defined rules. That means the class grouping tool must have both homogeneous and heterogeneous grouping capabilities. From the point view of the Middle East Culture challenge and our research, we built up our smart teaching assistant class grouping tool web portal platform. Our motivation is to have a class grouping tool that both “Smart” enough to handle the practical constraints in the Middle East and “Flexible” enough to understand user requirements and make the results understandable to the user. Figure 1.A describes the workflow of our smart grouping tool portal. Our motivation is to have a class grouping tool that is both “Smart” enough to handle the practical constraints in real classrooms (e.g. incomplete data sets) and “Flexible” enough to understand user requirements and make the results understandable to the user. A server database will store registered user information (instructor’s class data) and monitor the user’s login status. The user uploads student data files (.csv format) as the system input. The final grouping results will be generated and downloadable as an Excel™ file (.xls).

Figure 1.B shows the upload file interface as seen by the user. The file is allowed to include any attributes/features of the students. The example file we use includes the student information like Identifier, Course Section, FCI Pretest (%), UAE National, Gender, IELTS, KU Math Placement Score (%), Lecture Quiz (1-3) Avg (%), Midterm Exam (%), Round 1 Team No., Round 2 Team No. which are used in Khalifa University of Science, Technology & Research (KUSTAR).

Figure 1.C shows the rule/force interface. Column headings are taken as variables and rows as student identities by the algorithm. Any alpha-numeric data types are allowed, including numerals like boolean, integer, and reals, and

non-numerics like gender, ethnicity, etc. A user can upload their student data, then construct custom rules for carrying out the grouping calculation using the rule/force interface. The user may also specify on a student-by-student basis, special exceptions, hence the “force” in “rule/force” interface. For example, if two students are known for having personal conflicts, but are likely to be grouped based on their skills, the user can force the grouping algorithm to keep looking for solutions that do not include those where the two students in question are in the same group.

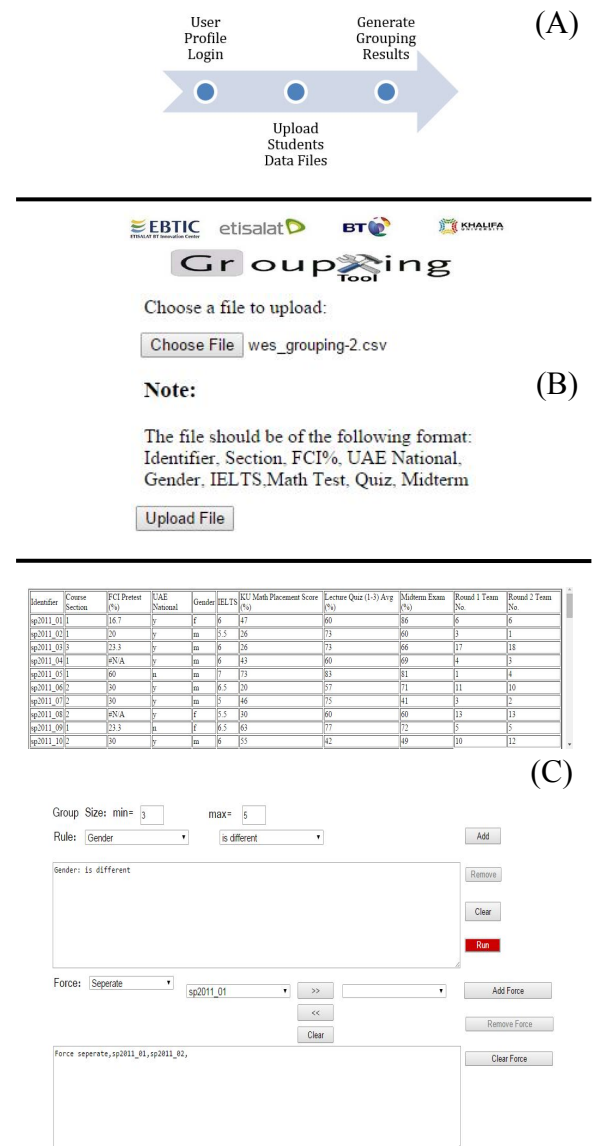

Fig. 1. Workflow for the smart grouping tool portal (A). The upload file interface page (B). The rule/force interface page (C).

Table I shows the operator options available for users to construct grouping rules, depending on the data type. The grouping tool is intelligent and able to automatically identify the type of the data; Boolean values, integers, reals, and text strings. Based on the properties of the data type, the tool then automatically creates and populates drop-down menus of operators (verb-phrases), for each column/data field, that can be used for flexible construction of nearly-natural language rules.

For example, an instructor might upload data that indicates in a column if a student is repeating the course or not and indicate this with a Boolean value; 1 – for repeating the course, 0 – for first-time registration. The grouping tool will automatically populate a pull-down menu for this column, with the following options; “is at least one”, “is the same”, “is different”, and “new member more than one”. If the user selects “1” for the value and “is at least one” for the operator then, when run, the algorithm will search for a solution where all groups formed from the uploaded roster have at least one member who is repeating the course. Multiple rules can be defined on the same data and multiple data may have rules defined for them, so that these rules can be combined together as user wishes. For real number data types, alternative options of “is at least one highest”, “is at least one lowest”, “difference is larger than”, and “difference is less than”. For rules constructed with either the “...highest...” or “...lowest...” operators, the tool determines how values for the real data field are distributed among the students, determines the top, bottom, and middle thirds, then assigns membership in groups accordingly. For rules using “...difference is...” operators, the tool searches pairwise among students, to find grouping solutions that have satisfactory differences between members’ values. For example, an instructor might include student age data in a column and define a rule for the age value with “is at least one highest”. When run, the algorithm will return a grouping solution where every group has a member from the top third of the age distribution in the class. Table II shows the user options for grouping rule construction in our case study for University Physics I students at Khalifa University of Science, Technology & Research (KUSTAR).

TABLE I. USER OPTIONS FOR GROUPING RULE CONSTRUCTION

Data Type	Operator Options for User Rule Construction
Boolean	{“is at least one”, “is the same”, “is different”, “new members more than”}
Integer	{“is at least one”, “is the same”, “is different”, “new members more than”}
Real	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}
Text String	{“is at least one”, “is the same”, “is different”}

TABLE II. CASE STUDY OF USER OPTIONS FOR GROUPING RULE CONSTRUCTION

Rule	Options	Value
Identifier	{“is at least one”, “is the same”, “is different”}	non-numerical
Course Section	{“is at least one”, “is the same”, “is different”}	non-numerical
FCI Pretest (%)	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}	numerical
UAE National	{“is at least one”, “is the same”, “is different”}	non-numerical
Gender	{“is at least one”, “is the same”, “is different”}	non-numerical
IELTS	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}	numerical

KU Math Placement Score (%)	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}	numerical
Lecture Quiz (1-3) Avg (%)	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}	numerical
Midterm Exam (%)	{“is at least one highest”, “is at least one lowest”, “difference is larger than”, “difference is less than”}	numerical
Team	{“New partners more than”}	numerical

Figure 2 shows the final generated grouping results according to the defined rule set. The result is downloadable as an Excel™ file.

III. CASE STUDY

Trials were performed using the smart grouping tool portal in Spring 2011 and Fall 2011 term offerings of the University Physics I course at Khalifa University (populations A and B, respectively), using the recently developed Collaborative Workshop Physics (CWP) pedagogy, described in detail in [22]. Population A consists of 75 students and population B consists of 85 students.

Identifier	Course Section	FCI Pretest (%)	UAE National	Gender	IELTS	KU Math Placement Score (%)	Lecture Quiz (1-3) Avg (%)	Midterm Exam (%)	Round 1 Team No.	Round 2 Team No.

Total No. of Groups is 14

Fig. 2. On-screen display of an example solution, in this case, for 14 groups of 3-4 students each, satisfying five user-defined rules on a variety of data. The result is downloadable as an Excel™ file.

The Force Concept Inventory (FCI) [23] was administered both as a pre-test and a post-test to measure learning gains and was used, along with other data, in the grouping rule definitions. Strict matching between FCI pre-test and post-test was applied, so that only individual students with both scores were included in the analysis. This defined corresponding Samples A and B, consisting of 62 students (32 male and 30 female) and 68 students (35 male and 34 female), respectively.

The CWP pedagogy, both its rationale and efficacy, are described in detail in [22]. For the sake of brevity, here we only point out that it is largely based on Cooperative Group Problem Solving (CGPS) in physics [10,11], a pedagogy which calls for students in teams of 3-6 to conduct lab experiments and problem-solving recitations/tutorials on open-ended, context-rich problems, rather than traditional

‘recipe labs’ and ‘end-of-chapter’ problems. The pedagogical goals are to emphasize deep conceptual learning over rote memorization and formula usage, and shift classroom norms away from an emphasis on ‘answer-making’ and toward an emphasis on ‘sense-making’ [24], consistent with the larger body of findings in physics education research (PER) [25]. Another important component of maximizing the pedagogy’s effectiveness is designing and assigning students to heterogeneous teams and reassigning them multiple times over the course, maintaining heterogeneity with aggregated performance data, such as exam and quiz scores. Students are typically re-grouped in this way 3 to 5 times over the semester, and consequently, it is a labor-intensive task for instructors to continuously create teams based on a consistent recipe for high-heterogeneity, with an ever-growing amount of performance data to work with.

Table III shows an example of the grouping rules used for creating the first set of student teams in both Populations A and B. Teams for Population A were created by section instructors manually, by hand, following these rules. Whereas, the smart grouping tool portal was used in Population B. In both sets, all groups were 3-5 students, for 14 to 24 total groups on any given round of (re)-grouping.

TABLE III. EXAMPLE OF USER-DEFINED GROUPING RULES, FOR SAMPLE A AND SAMPLE B STUDENTS IN THE CASE STUDY

Data	Data Type	Grouping Rules Constructed with the Tool
FCI Pretest	Real	Groups have “at least one highest” FCI Pretest Score
Gender	Text String	Groups are “(is) the same” Gender
UAE National	Boolean	Groups have “at least one” not a UAE National
IELTS ^a	Real	Groups have “at least one highest” IELTS score
Math Placement Test	Real	Groups have “at least one highest” Math Placement Test

^a. International English Language Testing System (IELTS) is a test of English proficiency.

Comparison of Teaming Methods

Fig. 3. Comparison of teaming methods, for few (0-2; red) versus many (3-4; blue) experiences solving problems with skill-heterogeneous teams, in the Collaborative Workshop Physics session [22].

Table IV shows results from FCI pre/post-test data, analyzed to determine the efficacy of skill-heterogeneous teaming, in terms of normalized learning gain, $\langle g \rangle$ [26]. Here, we define a team as “Skill-Heterogeneous” in narrow terms, by (1) whether or not Rule 1 (“Groups have at least one highest FCI Pretest Score” (top-third as determined by the smart grouping tool portal) is satisfied, which was not always possible, and (2) if the team also contains a member with an FCI pretest score from the bottom-third of the distribution. In Table III, N gives the number of individual students in the Sample, in terms of how many times they were members of a skill-heterogeneous team.

In both Samples, the fraction of students experiencing the course content in large numbers of skill-heterogeneous teams (3-4 out of 4) was comparable (50% and 40% respectively). Most interestingly, there is a relatively strong ($r = 0.87 - 0.89$), and significant (0.06 – 0.08 two-tailed p -value) correlation between the number of such experiences and normalized learning gain. Figure 3 shows learning gains data from Table III, from manually (left) and grouping tool-created (right) teams. Red columns show normalized FCI gain for students having 2 or less experiences in skill-heterogeneous teams and blue columns shows that same for student having 3 or more. Most relevant to the present study, is the ease of determining the groups. Sample A contains a total of 80 teams which a total of 12 person-hrs to determine. Sample B contains 72 teams which required a total of 40 person-min. a substantial time saving.

IV. CONCLUSION

Our smart grouping tool portal is very useful in the Smart Teaching area and could be a very good teaching assistant to help teachers to conduct cooperative and collaborative learning. Our tool is easily accessible and flexible with user defined rules. It can be used to re-group students based on the educator’s requirement so as to fit his/her teaching purpose. Our motivation is to have a grouping tool that is both “smart” enough to handle the practical grouping constraints and “flexible” enough to understand user requirements and, as such, make the results understandable to the user. It is also very useful for researchers to understand the group dynamics and the co-construction of knowledge using trial results. The trial results presented here add to evidence in the literature that skill-heterogeneous teams promote greater learning in individual students. Further study, to replicate and deepen our understanding of this result is greatly enhanced by the grouping tool, allowing researchers to maintain consistent teaming recipes over multiple settings and large population sizes. Our future plan is to do large-scale user testing and get feedback to do learning analytics in the future.

TABLE IV. USAGE CASE DATA FOR MANUAL VS. SMART GROUPING TOOL PORTAL-GENERATED TEAMS IN COLLABORATIVE WORKSHOP PHYSICS

Teaming Method	N	No. of Skill-Heterogeneous Team Experiences	FCI <g> _{Hake}	N	No. of Skill-Heterogeneous Team Experiences	FCI <g> _{Hake}
Manual (Sample A)	7	0	0.10 ± 0.05	31	0-2	0.13 ± 0.03

Smart text-classification of user-generated data in educational social networks

Di Wang, Ahmad Al-Rubaie, Ahmed Al Dhanhani, Jason Ng

Etisalat BT Innovation Center

Khalifa University, Abu Dhabi, UAE

{di.wang, ahmed.al-dhanhani, jason.ng@kustar.ac.ae} and ahmad.al-rubaie@bt.com

Abstract — Nowadays, face-to-face interpersonal communication has been gradually replaced by communications via virtual social network platforms, which applies to the new generation of education. The amount of user-generated data in social networking sites is increasing day by day. Understanding and consuming this great amount of data has become a harder task. Classifying the user-generated data (mainly text) can help simplify the user experience by providing them dynamic personalized recommender. Filtering the data, and providing users with what is relevant to them, will help them utilize this data more effectively. In education, recommending relevant learning content to learners in educational social networking sites saves them the arduous task of sifting through a huge amount of information.

This paper introduces the partial-supervised learning for Hierarchical Dirichlet Process (HDP) for text classification with inherent hierarchical structure in education. This enables the use of partial known model structure and labels as expert knowledge to guide the model learning procedure from the text without labels. Compared with the existing partial/semi-supervised HDP, the proposed method is able to make use of the known labels for not only structure construction, but also parameter learning. This enhancement provides a more flexible way and better guide for the model learning from the unlabelled documents. We experimentally investigate the contribution of partial knowledge to guide the model learning process. The proposed partial-supervision for HDP is applied to student micro-blog automatic classification and adds intelligence to our student social media platform (ELSE).

Keywords—*Hierarchical Dirichlet Process (HDP), semi-supervised learning, partially-supervised learning, document classification, text mining, social networks, informal learning*

I. INTRODUCTION

We currently live in a digitally connected world, where the amount of information available is increasing at an unprecedented rate. Information sharing has become significantly simpler, and the creation of content, its decimation, availability, and distribution is expanding at a record pace. All these, have been made possible through advancements in ICT in general and the Internet, social media and Web 2.0, in particular. Web applications have penetrated & reached almost all walks of life. Moreover, the increase in processing power, quality and availability of mobile devices have further contributed to this digital content exchange bonanza, providing instant access, as well as user alerts, ubiquitous access and simpler ways of managing information. Cloud Computing on the other hand, is now providing us with

cost effective reliable and scalable data handling & processing capabilities to manipulate and analyse this valuable information.

Enterprises and businesses have embraced such technologies, and are leveraging them to help them on all levels, business development, people development, value creation, marketing, collaboration, innovation, customer management, supply chain management, and so forth.

In education, the picture is not different, “The Internet, social media, and Web 2.0 are becoming important components of students’ education as schools increasingly provide a laptop or other portable device to each student, but just how these new ICTs should be used is still a topic of debate [1].”

A substantial amount of work and research is being undertaken to enhance education and learning, identifying new opportunities, and tackle old challenges with new methods, and addressing new arising ones. Today’s students are changing in capabilities, and expectations (both in what they expect and what is expected from them). Fluency in ICT, is almost implied for students who are expected to survive, and excel in a global digital, and connected economy. Traditional collaboration boundaries have come tumbling down, and a new set of drivers and rules have emerged. Educational institutes are becoming more complex in terms of their setup and pedagogical requirements. They are also becoming more capable in terms of data collection and analysis, mostly due the fact that the new systems provide educators, as well as learners, with more information that can be studied to help them improve.

Hence, we see a growing trend globally focusing on the use and impact of these technologies on education. Studies are ongoing to ascertain how traditional learning methods and techniques can be adapted to deal with the new complexities, in order to leverage them to deliver a more effective learning for the 21st century student.

We are witnessing an increasing use of social network applications in education, whether this is the use of well-established systems such as Facebook and Twitter, or specifically developed systems such as Ning and Mixable. The primary driver for such systems, whether they are for formal or informal learning is to encourage collaboration and knowledge sharing to achieve better learning.

However, “Till now, the success of social applications for collaboration has not been consistent and the ability of these social applications to stimulate their subscribers to contribute varies greatly. The work on encouraging the participants to contribute has been more of an art than science [2].”

One such project that is looking at using social networking to drive collaboration, and information sharing, in an informal

learning setting, developed by the Etisalat BT Innovation Centre (EBTIC), in collaboration with Khalifa University in the UAE. The project, which is known as EBTIC's Learning and Social Environment (ELSE), is part of EBTIC's overall education initiative; the Intelligent Campus (iCampus). ELSE, forms the foundation for the iSocial pillar within iCampus. It is aiming at leveraging advances in social networking and intelligent systems to augment learning. It is to be achieved through collaboration between students as well as faculty and create a user centric, user & time relevant collaboration platform, for creating, sharing and distributing knowledge. EBTIC is using its research and development work on semi-supervised and Hierarchical Latent Dirichlet Process (HDP), which is a document/micro-blog classifier to add intelligence to the ELSE platform.

This paper will use the user input data (comments and posts) gathered during the ELSE platform 3 months trial at Khalifa University campus in Abu Dhabi, and classify them by topics using EBTIC's micro-blog LDA engine. This work demonstrates the engine's effectiveness within an education environment. The ELSE platform is introduced in Section II. Our proposed partial supervised learning for HDP is explained in Section III. We show how the proposed partial supervised HDP work for the student posts from the ELSE platform in Section IV. Last, the conclusion is given in Section V.

II. ELSE PLATFORM

ELSE is a system that leverages advancements in social networking, and intelligent systems, to create a proactive, and adaptive platform that promotes informal collaborative learning. ELSE provides the usual social networking tools such as activity wall, groups, file sharing, etc. However, it is different in that, it does not solely rely on the user to find content, search for groups and identify friends and collaborators. It aims to use various techniques that are being researched and investigated to automatically identify content, collaborators and groups that are relevant to a particular user at that point in time and then make appropriate recommendations. Therefore, it supports the user in achieving his/her learning and social objectives more efficiently.

ELSE aims to automatically populate and maintain part of the student profile with available data from the university systems (integration is required). This ensures the changes in the studied subjects are taken into account as the student progresses through the academic year, and avoids spamming him/her with no longer needed material. It will also monitor user contributions, and activities, to enrich the profile through current data reflecting current user interests. The user will naturally retain the manual ability to modify and change the profile (learned by ELSE) as needed.

In summary, the recommendations will not be based on a static list of interests and common friends, but rather on current interests derived from user activities, educational needs, expertise level and even social activities and club memberships where appropriate. For example, a student who is studying astronomy and in need of help might be put in touch with another student, who is a member of the astronomy club, and is known to have contributed in that subject, even though he

might be an engineering student. The environment also considers various motivation theories to incentivise users, to collaborate and share information in a fair and objective manner, to ensure its long-term sustainability.

To achieve active recommendations, an intelligent and flexible document classifier is needed. The classifier should be able to deal with not only formal long documents (which is comparatively an easy task), but also short informal messages (e.g. comments & status updates), and the mixture of long and short text (the length of forum post varies). In addition, the classifier should be able to deal with complex problems with inherent hierarchical logic structure which is a reflection of the real world. Hence we propose to add partial supervised learning to Hierarchical Dirichlet Process (HDP) [3], because HDP itself has the capability of dealing with complex problems with inherent hierarchical structure. Our introduction of partial supervision adds flexibility to the user control and as a result improves the final accuracy. The proposed partial supervised learning is explained in the next Section.

EBTIC and Khalifa University ran a 3 months live user trial of ELSE. The trial included about 100 students and their lecturers. The system was available on the world wide web and accessible from within as well as outside the campus, it also included and IOS 6 native application for the iPhone and iPad devices. The native mobile application provided immediate and quick access to the platform on the move as well as user notification capabilities. We collected the data from the ELSE trial and analysed the collected data by using our proposed method (see Section III). The analysis results are shown in Section IV and will be used to realise dynamic profiling and smart recommendation.

III. THE PROPOSED IMPROVED HDP

A. Hierarchical Dirichlet Process

Hierarchical Dirichlet Process (HDP) [3] was proposed after Latent Dirichlet Allocation (LDA) [3] by Blei to investigate and represent more complex corpus/data with inherent hierarchical structure. HDP does not need the number of topics as user input and it is assumed that there is always a possibility that there exists new topic(s) for new documents. Parameter γ is introduced and it indicates a possibility of introducing a new topic, which is the number of imaginary documents belonging to a new topic that does not exist in current model.

Collapsed Gibbs sampling [5] is usually used to build up the HDP model, which is divided into two iteratively cooperative sampling stages: sampling for the path and sampling levels for each word along the sampled path. The path sampling for document d is based Equation (1), where the prior probability $P(\mathbf{c}_d | \mathbf{c}_{-d}, \gamma)$ for path \mathbf{c}_d is calculated by Equation (2) and probability of the data $P(\mathbf{w}_d | \mathbf{c}, \mathbf{w}_{-d}, \mathbf{z}, \gamma)$ for \mathbf{c}_d is calculated by Equation (3). n_i is the number of documents having path getting through $node_i$. γ is the parameters indicating how many imaginary documents do not belong to any existing nodes. \mathbf{c}_{-d} and \mathbf{w}_{-d} in the equations mean that the influence (word counts in document d) for d has been removed and will be re-sampled. $n_{l,-d,w}$ is the count of word w at level l without considering the word counts for

document d . $n_{l,w}$ is the number of word w in document d at level l . W is the total number of vocabulary in the dictionary. η is the Dirichlet distribution parameter for words. Γ is standard gamma function defined as $\Gamma(z+1) = z \times \Gamma(z)$.

$$P(\mathbf{c}_d | \mathbf{w}, \mathbf{c}_{-d}, \mathbf{z}, \eta, \gamma) \propto P(\mathbf{c}_d | \mathbf{c}_{-d}, \gamma) \times P(\mathbf{w}_d | \mathbf{c}, \mathbf{w}_{-d}, \mathbf{z}, \gamma) \quad (1)$$

$$P(\mathbf{c}_d | \mathbf{c}_{-d}, \gamma) \propto \begin{cases} \prod_{i=1}^{L-1} \frac{n_{i+1}}{n_i + \gamma} & \text{if all nodes along } \mathbf{c}_d \text{ is existing nodes} \\ \prod_{i=1}^p \frac{n_{i+1}}{n_i + \gamma} \times \frac{\gamma}{n_{p+1} + \gamma} & \text{if first } p \text{ nodes along } \mathbf{c}_d \text{ is existing nodes} \end{cases} \quad (2)$$

$$P(\mathbf{w}_d | \mathbf{c}, \mathbf{w}_{-d}, \mathbf{z}, \eta) \propto \prod_{l=1}^L \frac{\Gamma(\sum_w n_{l,d,w} + W\eta)}{\prod_w \Gamma(n_{l,d,w} + \eta)} \times \frac{\prod_w \Gamma(n_{l,w} + \eta)}{\Gamma(\sum_w n_{l,w} + W\eta)} \quad (3)$$

Given a path sampled through equation (1), word level sampling is calculated based on equation (4), where $P(l_{d,z,w} | l_{d,-w}, \alpha)$ is the level distribution and calculated by Equation (5), and $P(w | l_{d,z,w}, c_d, \mathbf{w}_{-d,-w}, \eta)$ is the probability of the given word w based on a possible assignment and is calculated by Equation (6). $n_{l_{d,z,w}}$ is the word count in document d at level z along the path c_d . $n_{c_d,l,w}$ is the word count for word w at level z in all documents along the path c_d . W is the total number of vocabulary in the dictionary.

$$P(w_z | l_{d,z,-w}, c_d, \eta, \alpha) \propto P(l_{d,z,-w} | l_{d,-w}, \alpha) \times P(w_z | l_{d,z,-w}, c_d, \eta) \quad (4)$$

$$P(l_{d,z,-w} | l_{d,-w}, \alpha) \propto n_{l_{d,z,-w}} + \alpha \quad (5)$$

$$P(w_z | l_{d,z,-w}, c_d, \eta) \propto \frac{\eta + n_{c_d,l,w}}{W\eta + \sum_w n_{c_d,l,w}} \quad (6)$$

B. Partial Supervision

The proposed Partial-Supervised learning for HDP has the advantages of: model structure partial definition, parameter partial-supervised learning, and consistent process sampling within the sub-space constrained by the defined labels.

Although HDP does not require the number of topics as user input and determines the number of topics automatically, the resulting model usually has more topics some of which are not interpretable by a human. The user needs to control the number of topics/sub-topics for better understanding of each node (topic/sub-topic). We can see from Section III.A, whether a new node/topic/sub-topic is added to HDP depends on the path sampled to one document which is controlled by Equation (2). In Equation (2), if not all nodes on the sampled path are existing nodes; then a new tree branch is created and added to the existing model. The path sampling process is done step by step from the root node down to the leaf node. Each lower-level path node sampling is dependent on its higher-level path sampling. At each level, say the $(i+1)$ th level sampling, there is a chance of $\frac{\gamma}{n_i + \gamma}$ to sample out of the existing nodes/topics/sub-topics and create a new branch. The way to stop new branch creation is to set the parameter of γ as zero. Then the chance of sampling out of existing branches is $\frac{\gamma}{n_i + \gamma} = 0$. Then the step-by-step sampling, can be written as Equations (7) and (8):

$$P(\text{child_node}_i | \text{parent_node}, \gamma) = \frac{n_{\text{child_node}_i}}{n_{\text{parent_node}} + \gamma} \quad (7)$$

$$P(\text{new_child_node} | \text{parent_node}, \gamma) = \frac{\gamma}{n_{\text{parent_node}} + \gamma} \quad (8)$$

To control the number of children for each node; we need to reset the parameter of γ as zero when the number of child nodes reaches its defined maximum number. Then Equations (7) and (8) can be rewritten as Equations (9) and (10);

$$P(\text{child_node}_i | \text{parent_node}) = \frac{n_{\text{child_node}_i}}{n_{\text{parent_node}}} \quad (9)$$

$$P(\text{new_child_node} | \text{parent_node}) = 0 \quad (10)$$

Hence to control the model structure a monitor and intervention is added to use either Equations (7) and (8) or Equations (9) and (10) for the next-level path node sampling.

Now we consider a problem as a collection of M documents, $\mathbf{D} = \{d_1, d_2, \dots, d_M\}$, which is composed of M_L labeled documents $\mathbf{D}_L = \{d_1, d_2, \dots, d_{M_L}\}$, and M_U unlabeled documents $\mathbf{D}_U = \{d_1, d_2, \dots, d_{M_U}\}$, where $M_U + M_L = M$. We assume we have K defined topics $\mathbf{T} = \{T_1, T_2, \dots, T_K \dots\}$ in current model (and initially $K = 0$), each document d_i in \mathbf{D}_L has one or more assigned topics $\mathbf{T}_i = \{T_{i_1}, T_{i_2}, \dots, T_{i_k}\}$, where either $T_{i_k} \in \mathbf{T}$ or is a new topic to be added. In the Gibbs sampling process, the target topic for any labelled document d_i in \mathbf{D}_L is restricted to belong to the set of labels $\mathbf{T}_i = \{T_{i_1}, T_{i_2}, \dots, T_{i_k}\}$, and the target topic for any unlabelled document d_j in \mathbf{D}_U is restricted to belong to the whole topic domain $\mathbf{T} = \{T_1, T_2, \dots, T_K, \dots\}$ and possible new topics.

For documents with defined labels, to guarantee that we always get a valid label constrained to the defined labels, Equations (7) and (8) for path sampling is modified to Equations (11) and (12). If the defined topic/sub-topic has been included in the existing model then equation (11) is used to sample the path; otherwise new nodes (path branch) are created and added to the model according to Equation (12).

$$P(\text{child_node}_i | \text{parent_node}) = \begin{cases} \frac{n_{\text{child_node}_i}}{\sum_{\text{child_node}_j \in \text{defined path}} n_{\text{child_node}_j}} & \\ 0 & \text{otherwise} \end{cases} \quad (11)$$

$$P(\text{new_child_node} | \text{parent_node}) = 1 \quad (12)$$

For documents without defined labels, the Gibbs sampling process follows Equations (7) to (10). Given the sampled path $\mathbf{c} = \{c_1, c_2, \dots, c_L\}$, the word level sampling process is exactly the same with HDP: Equations (4) - (6) as discussed in Section III.A.

IV. EXPERIMENTAL RESULTS

We are applying the proposed partial learning for HDP to education recommender system. We need a document classifier to identify relevant learning contents which is a comparatively easier task (for formal document classification) and not discussed here. The second task is to identify the group of students who are interested to the identified documents from their user-generated text hence we need to classify students' posts/comments. We ran the ELSE platform trial for a 3 months period and involved students from two classes studying C++ and English. Totally 1615 posts/comments were collected ranging from short messages such as "test" or "hello world" to

full paragraphs of programming code. This data unbalance presents a great challenge in achieving satisfactory accuracy. After cleaning the messages (non-English posts/comments are removed) we were left with 1200 English posts/comments. We then manually classified the 1200 English posts/comments to 2 high-level categories and 3 sub-categories in each high-level category (as shown in Figure 1).

We ran the 10-fold cross-validation to test the accuracy by using different percentage of labelled information and the result of average accuracy is as shown in Figure 2. We can see a small percentage of labelled posts/comments (0.1 labelled ratio) provides a guide to map the model output to the realistic outputs however cannot provide a satisfactory accuracy. When we improve the ratio of labelled posts/comments, we can see the improvement in accuracy. The tendency of accuracy improvement is obvious before the labelled ratio reaches 0.5. Beyond a ratio of 0.5 of labelled posts/comments, the accuracy improvement in relation to the increase in labelled posts/comments ratio is very limited. In other words, for this application to function properly, 50% of manually labelled posts/comments is good enough for training/testing accuracy.

Figure 1. Hierarchical topic structure for students' post/comment

In addition, note that HDP itself without partial supervised learning can only address clustering, not classification. So another advantage of introducing partial supervised learning to HDP is that, the modelled categories are automatically mapped to the real world categories. Otherwise, it will be a trial & error to find the best match from the model categories to the real world categories (in this small application we need 72 tries).

Figure 2. Accuracy by using different ratio of tagged posts/comments

The accuracy of the student's posts/comments classification is not very high (between 0.6 to 0.7). The reason for the low accuracy is due to the low number of training documents and the overlapping of topics. We can see from Table 1, the most confusing category is 'daily chat' which covers a broad range of free topics and tends to be close to any possible topic. For example, system bug and performance messages are exchanged in an informal way which is very close to 'daily chat', which creates the confusion between the category of 'daily chat' and 'system test'. The accuracy for other categories is better, above 0.83.

Table 1. Result of one running in 10-fold cross-validation

Model output Target	daily chat	system test	other code	E: discussion	C: discussion	C: code
daily chat	15	6	4	2	5	1
system test	1	9	1	0	1	0
other code	1	0	12	0	0	0
E: discussion	0	0	0	12	0	0
C: discussion	2	4	2	0	29	2
C: code	0	0	0	0	0	7

V. CONCLUSION

In this paper, we proposed partial supervised learning for HDP which enables HDP to make use of partial known knowledge to guide the model learning process. This partial learning enables HDP which is aimed at solving clustering problems to tackle classification problems and meanwhile partial supervised learning helps improve the classification accuracy.

We applied the proposed partial supervised learning for HDP to classify posts (micro-blogs) in an educational environment. The proposed partial supervised learning proves to perform reasonably well. This directly contributes to dynamic profiling and recommendations within the ELSE platform. The next step is to expand the usage of the ELSE platform and carry out further data analysis. The accuracy is expected to be greatly improved provided having access to more training data.

Our work in this paper provides an accurate classifier which works well for both long documents and short messages with comprehensive hierarchical structures and this is the key work to realise dynamic profiling and smart recommendation in today's smart learning and smart education.

Abstract—An Industrial Electronic discipline, involving different topics and technologies was designed to improve the sequence of activities within the available time and learning resources. The b-learning new methodology, applied in the University of Vigo, Spain, is composed of lectures, self-study sessions, quizzes, design problems, emulations, and laboratory sessions, integrated to achieve a better pedagogical environment.

Most of the resources are available online without time restrictions, thus providing the students the opportunity to choose where and when they can learn, interact with the emulators, the remote laboratory and self-evaluate.

Five flexible and powerful emulators have been developed for the buck, boost, buck-boost, forward and flyback converters. Emulation sessions provide a fast and easy path to understand the required concepts.

The laboratory sessions are implemented by means of existing automatic test equipment (ATE), drive by a dedicated online server with new specific custom made software.

The students provided positive evaluations of the methodology, and achieved a better degree of knowledge acquisition.

Nowadays students from the University of Minho, Portugal, are also using remotely the set of resources available. The future work on this methodology will integrate the resources developed in both universities, to include more aspects of power electronics converters.

Keywords—Power engineering education; Educational activities; Problem-solving; Electronic learning; Remote Laboratories.

I. INTRODUCTION

In recent years, higher education institutions in Europe have undertaken major educational reforms focused to improve the learning process of students. An important change in approach with regards to traditional model of teacher-centered learning is presented. In this traditional model, it is the teacher

who defines and organizes knowledge to be transmitted to the student to achieve the expected results. Students often take a passive role, limited to perform memory learning with very little critical or creative component.

Moreover, under the new educational trends, the focus moves from teacher to student emphasizing the active role in his own learning process. In this model, learning is interpreted as a natural and constructive process where the student uses personal processes to strategically regulate the behavior and immediate environment of learning [1].

Therefore, an important objective was to enhance the process of self-regulation, so the students activate different strategies in order to plan, to control and to assess their own learning process to approach it successfully [2]. Although this learning model is centered on the student, the teacher's role is crucial. One of the key is mentoring, therefore, it is the teachers's responsibility to design an appropriate learning environment and another key is that students express a high degree of motivation for learning.

As a whole, engineering education is a complex task. Specifically, power electronics disciplines involve different fundamental topics and technologies, so that power electronics courses contain plenty of previously learned topics on mathematics, physics and other technological skills [3]. Usually, a high load of lectures and tutoring sessions are essential due to the high amount of information related to all the technological and functional aspects implied. Simulation sessions provide a fast and easy path to understand the required concepts, but simulated results do not adequately represent real-world systems and behavior. The laboratory sessions complete the knowledge acquisition process [4]; offering the students a rich set of experiences that cannot be acquired by any other means.

The fundamental objective of laboratory experiments is to improve students' creativity and capability in real-world problems solving. However, conduct experimental activity in-class involves a series of drawbacks:

- The equipment for power electronics test and laboratory is often sparse and expensive [5] [6]. Also the circuits under study integrate expensive components and complex drivers.
- Laboratory's measurement equipment can be easily damaged under misuse by inexperienced students.
- The students have little time to interact with the power electronics labs; and as consequence the acquisition of new competencies by the students is curtailed [7].
- Due the tight schedule of lectures and laboratories time slots, the student does not have the opportunity to repeat the design process for a given component if the theoretical results and the measurements do not match.
- Usually, laboratory sessions are carefully prepared by professors so that the probability of student success is high. But this approach does not allow the student to develop skills relate to creativity, autonomous learning and self-regulation.
- Frequently, laboratory sessions are designed for full-time students. They are not conceived for students who try to balance their studies with a job.

Added to which, one of the goals of the European High Education Area (EHEA) [8] is that students can combine work with their studies; and the solution is to establish mechanisms that allow communication between students and teachers through virtual systems.

In order to develop an integrated training system based on the previous premises, the authors have developed a new b-learning model [3]. This new model is composed of lectures in classroom, self-study sessions, quizzes, design problems, emulations, emulations problems and laboratory sessions, organized and coordinated to achieve a better pedagogical environment.

The central element of the planning methodology is the sequential exposure of the whole set of activities and tasks for guiding the experiences that the student has to cover along the process of teaching-learning. The proposed activities are supervised by the teacher, giving a new dimension to the university tutoring.

The laboratory sessions are implemented by means of existing automatic test equipment (ATE), drive by a dedicated online server with new specific custom made software. The server allows students to share the ATE resources for testing DC-to-DC converters. The laboratory sessions can be made local or remote [9]. More tools were added from other closely related developments [10]-[15].

The feedback of professors is very important regarding the achievement of skills, because different evaluation strategies are used. In this way, the students are fully aware, at any time, of the degree of achievement of their objectives.

II. COURSE SYLLABUS AND LABORATORY SETUP

The University of Vigo offers a graduate program titled

'Engineering in Industrial Electronics and Automatic Control' (*Ingeniería en Electrónica Industrial y Automática*). It is equivalent to a B.Sc., with a total duration of 240 European Credit Transfer and Accumulation System (ECTS) in four years. ECTS is a standard for comparing the study attainment and performance of students of higher education across the European Union and other collaborating European countries. For successfully completed studies, ECTS credits are awarded. One academic year corresponds to 60 ECTS credits that are equivalent to 1500–1800 hours of study in all countries respective of standard or qualification type and is used to facilitate transfer and progression throughout the Union. In Spain, one academic year is equivalent to 1500 hours (600 attendance hours and 900 student's autonomous work hours).

Inside this program students can choose among two intensifications: Industrial Electronics or Automatic and inside the pool of electives for the Industrial Electronics intensification, the Electronic Technology Department taught a course on Industrial Electronic" (*Electrónica Industrial*), with a total of 6 ECTS credits (60 attendance hours and 90 student's autonomous work hours). It is offered during the second semester of the fourth year as an intensive course during January, February and March.

This course is devoted to switch-mode DC-to-DC power converters and it has four global topics: first an introduction to power converters; second, power converters topologies and circuits; the third topic is modeling and simulation; and the last one is control methods.

The introduction is intended to show the common subjects for power converters, that later will be applied to the different types of circuits. In order to gain insight of the differences, not only mathematical analysis is used, but also some modeling for the power stages. Being one of the latest courses in the program, control loop analysis and design is also included. With these topics the theoretical knowledge will be enough to achieve satisfactory practical skills.

The evaluation of the topics is established into a continuous assessment, providing students with a set of activities that let them perceive the degree of acquisition of knowledge, and also provide the professors with a valuable feedback of the evolution of the course.

A. Course Methodology

To expose the topics in the syllabus and achieve all the goals cited in the introduction, a blended methodology was developed by adding a wide set of resources and ideas positively tested in previous courses [9]. In the course four basic topologies were shown, analyzed and tested in the remote laboratory. For each one, the same set of activities was held, as the one in fig. 1.

Theoretical lectures and problem solving exercises are essential due to the high amount of information related to all the technological and functional aspects implied in power electronics converters. The total dedicated time for the lectures was 18 hours (0.72 attendance ECTS credits).

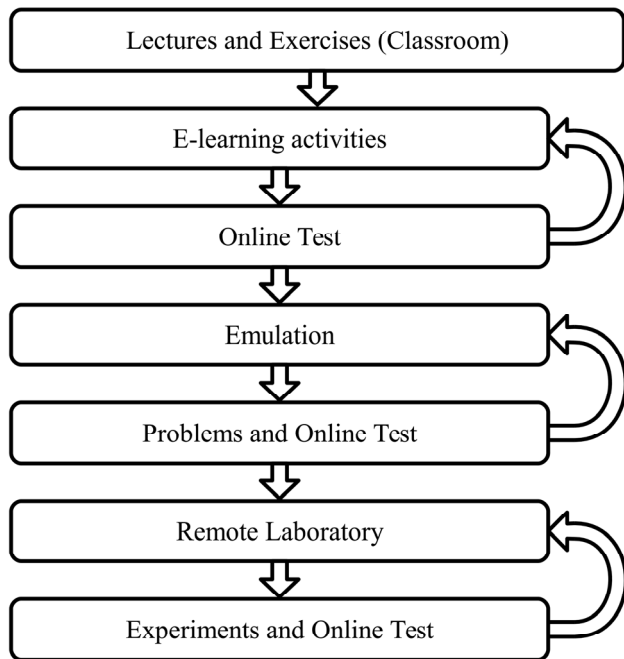

Fig. 1. Sequence of activities to be performed for each basic topology.

Following the lectures for a given converter, online activities were open for students. A set of documents with animated figures and graphics were used as reference. More exercises and design problems help students to reinforce the knowledge acquisition process. Finally, an online test is used to evaluate the students. If they fail to pass the test, then a new round of activities is proposed. During this step of the process it is critical to make the students understand that they cannot go ahead without properly learned concepts. Therefore, in some cases, the next step remains locked.

Emulation sessions provide a fast and easy path to understand the required concepts. For the first time this kind of session is held in a classroom, professor explains how the emulator works. The developed emulators are complex flash animations, based on equations that describe the ideal behavior of switch-mode converters. Five flexible and powerful emulators have been developed for the buck, boost, buck-boost forward and flyback converters [9][14][15]. Associated to the emulators, a set of design exercises are proposed, that must be solved and answered online. For online activities and emulations, tutoring from professors is available face to face on designed hours and via email. Total time dedicated with the professor in classroom and/or laboratory is close to 12 hours (0.48 attendance ECTS credits).

The laboratory sessions provide to the students a set of rich experiences that cannot be acquired by any other means. The first experiments are based on measurements of open loop power stages of each converter. These measurements are to be contrasted against calculated variables provided by the emulator. Then closed loop experiments are held, to demonstrate how a complete converter behaves. The total time dedicated to these activities with the professors is 10 hours (0.4 attendance ECTS credits).

All these steps are included into the evaluation process. Some of them provided direct marks on students' activities and some other provide insight on how the students are acquiring skills and knowledge.

When all these steps are applied to the four basic converters circuits, every student must design parts of the circuit of a predefined prototype. The resulting circuit must be calculated, simulated and tested in the remote laboratory setup. Tutoring in this stage is provided by the professors, in the laboratory. The time employed in this activity is 9 hours (0.36 attendance ECTS credits). The final assessment is composed of a series of design problems of input filters, compensating loop components and snubbers networks for the semiconductors and the magnetic components. Some of these tasks include simulations and other imply the use of remote laboratory setup, to test the selected components on a previously defined converter. For tutoring this task a total of 11 hours (0.44 attendance ECTS credits) are reserved by professors.

B. Methodology Implementation.

Resources available through Internet access are by far the most accepted among students. A Moodle server provided the framework to allocate all documents and also to aggregate some other online tools: the tests, the design problems, the emulators and control the access to the remote laboratory [9].

The main reason for using blended learning is that most of the resources in the server are available online without time restrictions, thus providing the students with the opportunity to choose where and when they can learn, interact with the remote laboratory and self-evaluate. This also gives more flexibility to professors, as some steps of the learning process can be keep open and available during more days along the semester. As consequence, the students are tutored in a more positive way, because they know that tutoring time is not scarce nor crowded.

Using emulation instead of simulation was a choice made on the available time and required effort of students. Simulation programs are powerful mathematical tools [16], but for switching circuits, like the ones in this course, can be too complex to use. Emulators provide easy to use interface and fast results, allowing the students to focus their attention on the converter behavior knowledge rather than in simulation problems, like convergence. An example of an emulator is shown in fig. 2 [14].

There are two reasons for using a remote laboratory setup. The first one is that the use of programmable remote instrumentation implies that an ordered sequence of actions, programmed on a script, is needed to make experiments. Indirectly, this requisite demands a pragmatic and organized sequence of actions in order to execute the experiment. The second one is that the laboratory sessions are held partially in the school and later from home, if needed. This feature removes pressure to finish the experiments, and even provide a late opportunity to change the experimental measurements from home if something wrong is detected. The remote laboratory setup [9] is shown in fig. 3.

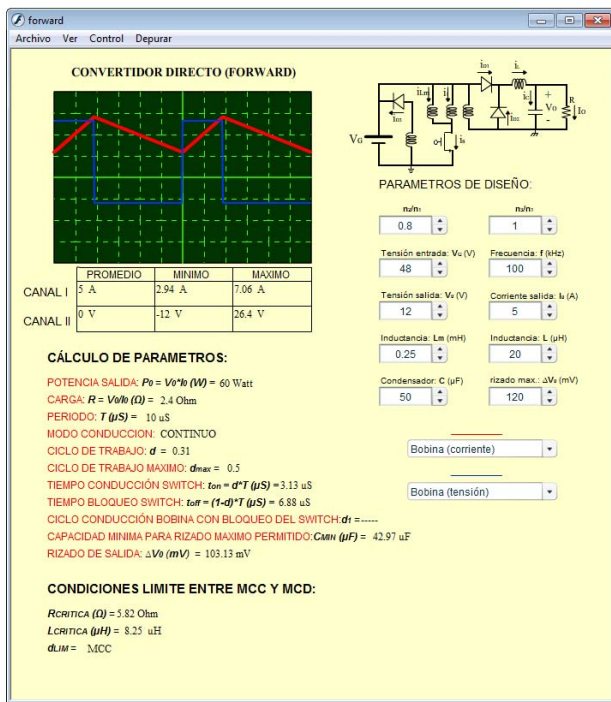

Fig. 2. Forward dc-to-dc converter emulator showing continuous current mode operation.

The students were requested to calculate, with the help of emulators, the voltages and currents for each converter, and contrast with measurements, for the open loop test. When the control circuit is added to the loop, they are asked again to come up with theoretical results. And as some of the passive elements of the control can be changed, some of the questions involved modifications in the desired dynamic response.

As a final assessment, each student is asked to design parts of a pre-defined converter. The circuit must be emulated and/or simulated, physically assembled and tested in the remote

Fig. 3 The automatic test equipment in the remote access laboratory.

laboratory. To simulate the converter design, SPICE and PSIM simulators are available. Once these results have been evaluated as correct by the professors, the student receives a prototype with the main components already assembled and empty sockets to place the designed components.

Specifically, the student must complete the input filter, the snubber networks and the feedback loop. This way, topics that are studied only on lectures are completed and reinforced by practical application. Some technological related topics, as losses in high frequency transformers or loop stability constrains due to the selected components values are added to the knowledge acquisition process. The converter behavior is tested not only by the student, but also by all others classmates. As an example, in fig. 4 it is shown a flyback module with indicated places where the students can change the components of the input filter (A), the compensating loop (B) and the snubber networks for the semiconductors and the transformer (C). A report and a brief oral exposition of the design is the final part of the assessment.

The five task evaluated as marks are the online tests for each topology (T1), the power stage design with the use of the emulators (T2), the control loop design with the use of simulation tools (T3), the results of laboratory tests for input filters, compensating loop and snubber network (T4) and the final report with oral exposition of the assessment (T5).

III. STUDENT ASSESSMENT AND FEEDBACK SURVEY.

The number of students enrolled in the course over the two last academic years (2013/2014, 2014/2015) was 25. This number is not very high due to the environment in which the subject is located. As discussed in section II it is an elective course of an intensification. From the set of 25 students, 20 were men and 5 women, aged between 21 and 24 years.

The following performance indicators, are used to measure progress of the student assessment:

Fig. 4 The flyback module showing the components that students can change to test their design.

- A. Performance Rate: number of students who passed a task vs. number of students presented (%). This indicator is related to student motivation and to the transfer of knowledge.

- B. Efficiency Rate: number of students who passed all tasks vs. number of students presented (%). This indicator measures student achievement of the acquired knowledge to design a predefined prototype

- C. Success Rate: number of students who passed the course vs. enrolment (%).

- D. Assessment Rate: number of students who passed the course vs. number of students presented (%).

- E. Dropout Rate: number of students who dropped the course (%).

The indicators B, C, D and E show the results obtained by the proposed methodology in this subject versus the average results obtained by students in the graduate program.

With the aim of know the degree of satisfaction of students related to the new b-learning approach and compare their opinion with the results obtained by the above indicators, a survey was elaborated. The authors have help in the design of the questions from the Department of Didactics, School Planning and Research Methods, of the University of Vigo.

The survey consists of 20 questions grouped into three blocks; and one observations field, for the students freely write all they consider important but not previously asked.

The first block is devoted to know the satisfaction degree of the students on the use of the didactic platform and how adequate is to the learning methodology.

The second set of questions is to determine the degree of satisfaction of students in lectures. Also values the support it can bring to learning through this methodology.

The last block comprises a group of questions about the satisfaction of the students related to the professors.

The most important questions are shown in tables 1, 2 and 3.

The answers to all these questions were measured using a six points Likert scale: 1- Totally Disagree, 2- Disagree, 3- Partially Disagree, 4- Partially Agree, 5- Agree and 6- Totally Agree. The survey data was collected during the last course week, prior to the final exams. All students answered all questions.

IV. RESULTS AND DISCUSSION

Taking into account the small number of students and that responses in different academic courses are alike, the authors have decided to include 25 polls into a single study.

A. Analysis of Performance Indicators.

The figure 5 shows the results of the performance rate. A high percentage of students have completed all the tasks.

TABLE 1
RELEVANT QUESTIONS ABOUT THE DIDACTIC PLATFORM

Number	Question
1	Your motivation towards the course has increased during this experience.
2	The sequence of topics blocks and their formative relevance are adequate.
3	The objectives of the course are coherent with the training plan.
4	The length of the course promotes the mastery of all the topics in the course.
5	The proposed learning activities are consistent with the required difficulty level.
6	The laboratory sessions have a correct timing and resource design.
7	There is coherence between activities and the evaluation criteria and objectives.
8	The clarity and appropriateness of the methodological guidance has been consistent with the approaches of the experience.
9	There were major technical difficulties for the development of laboratory sessions.

TABLE 2
RELEVANT QUESTIONS ABOUT LECTURES FOR SUPPORTING THE LABORATORY

Number	Question
10	During lectures to support the laboratory sessions there was: communication, assertiveness, neatness, conceptual clarity and correct exposition rhythm.
11	The printed and/or audiovisual materials used have been useful for taking the laboratory sessions.
12	There is a good climate of coexistence in the course.
13	The tutoring sessions favored the adequate acquisition of contents and help clarify any doubts.
14	The supervision of the tasks and the received aid was adequate, and the information received was clear and adequate.

TABLE 3
QUESTIONS ABOUT PROFESSORS

Number	Question
15	The assessment tools types and adequacy: are consistent with the objectives, the knowledge content, and competencies.
16	The professors' specific knowledge of the subjects is relevant and considered adequate.
17	The professors offered guidance on improving learning strategies when presented difficulties.
18	The professors demonstrated adequate and up to date skills on the technology.
19	The professor has prepared the lectures.
20	The professor is on time for lectures and laboratory sessions.

Fig. 5. Performance rate.

Special mention for the first two tasks (T1, T2) in which the student uses the emulator. It is confirmed that the use of this tool helps students to successfully pass the desired objective.

It must be emphasized that the value obtained in the last task (T5) of 95% is obtained on the total number of students who have passed the previous task (T4).

In order to establish a comparison frame between our course and the fourth year of the Industrial Electronics and Automatic Control graduate program, statistical data provided by the Industrial Engineering Scholl is used. The students enrolled in the graduate program in the two last academic years was 48.

Figure 6 shows the efficiency rate. This indicator is compared with of the graduate program and an improvement of 7 points is observed. The efficiency rate of 86.36% is obtained on the total number of students who have presented the finished tasks.

Fig. 6. Efficiency rate.

The results of the success rate, assessment rate and dropout rate compared with those of the graduate program are shown in fig. 7. The first two rates include the results of students in the laboratory sessions using the remote ATE laboratory. The increasing success and assessment rates and the decreasing dropout rate confirm the improvement in knowledge transfer.

The data provided by the school is the same used for quality assessment of the graduate program. Highlight that decreasing the dropout rate by 10 points confirms that the use of the proposed tools improves student motivation, helps to achieve the goals outlined in the proposed methodology and reinforce the quality of the program.

Fig. 7. Comparison between the success rate, assessment rate and dropout rate of the course and the degree.

TABLE 4
SURVEY DATA

Points on Lickert Scale	Block 1	Block 2	Block 3
Totally Agree	246	180	282
Agree	440	265	375
Somewhat Agree	108	132	100
Somewhat Disagree	93	27	9
Disagree	46	0	0
Totally Disagree	15	0	0

B. Analysis of Feedback Survey.

The Cronbach's alpha coefficient from the variances is calculated to measure the reliability of the survey. The survey has obtained a coefficient $\alpha = 96\%$. It can therefore be considered that the survey has a good level of reliability. The score of students' satisfaction of the three blocks is show in Table 4 and graphic in fig. 8.

A 72.4% of the students totally agree or agree that the methodology used and the resources from the learning platform are useful for this course.

Fig. 8: Poll results data grouped by blocks of questions.

Questions 3, 4 and 8 are the most significant for evaluating the satisfaction degree related to the use of the platform and the skills acquired by using it. A 77.2% of the students agree or totally agree (73.29% agree) that the platform helps them to master the knowledge of the course.

The results for the second block of questions, relative to lectures, indicate that a 73.2% of the students agree or totally agree that these sessions provide valuable help to solve doubts and clarify concepts. The global results of the questions are depicted in the second column of Figure 8. The questions 13 and 14 are the most significant to know the degree of satisfaction with tutoring and task supervision. The satisfaction degree reaches a 70.42%. These results indicate that above the importance of the online learning experience is the supporting presence of tutors, being this fact more important for complex activities in laboratory.

The last block of the survey is to evaluate the students' satisfaction with the professors. The global results of the questions are depicted in the third column of Figure 8. The 85.8% of the students totally agree or agree with the knowledge and performance of professors. In this block the professors can be scored with two subsets of questions: the knowledge of the course contents with questions 16 and 18, and how this knowledge was transferred by professors to students with questions 17 and 19. For the first subset, the satisfaction degree is 82.78%, and for the second subset is 84.76%.

Finally, in the remaining questions of block 3, students were asked about the evaluation procedure. The question was intended to evaluate the consistency and coherence of the assessment tools with the course objectives, the knowledge content and the acquired competencies. For this single question, the students agree or totally agree in a 76.67%.

V. CONCLUSIONS, PRESENT AND FUTURE LINES

In this paper, a b-learning approach in the implantation of a practical course in the power electronic field is shown. The major effort is devoted to coordinate and integrate a set of previously successfully tested tools for e-learning, emulation, remote laboratory access and evaluation procedures with the classical lectures and laboratory sessions. These resources are sequenced as a set of activities and tasks, in order to give the students a better knowledge acquisition framework, promote students' autonomous work and improve students' motivation. As a whole the authors aimed to achieve a better pedagogical environment.

Several conclusions can be drawn:

- It is confirmed that the use of the implanted methodology helps to successfully achieve the desired objectives.
- Using emulation the students can focus their attention on the converter analysis and study. 100% of students passed the tasks in which they must use the emulator.
- Online access to the laboratory facilitates the use of time and self-pace progress of students. No laboratory session was unfinished due to the lack of time.
- Online and face to face tutoring sessions provide a better

human interaction among participants.

- The performance indicators of this course are higher than the average of the graduate program courses. A 94.43% of the students enrolled passed the course. The efficiency rate of this course is 7 points higher than the whole graduate program and the dropout rate indicator is less than 10 points compared to the graduate program.

- A 72.4% of the students agree or totally agree that the methodology used and the resources from the learning platform are useful for this course.

During the months of June and July 2014, students from the University of Minho, Portugal, used remotely the set of resources available. The objective was to share the available b-learning tools to implement a similar methodology in cooperation with the professors of the Industrial Electronics Department. Another future action will be to integrate the remote laboratory into the PILAR project. The aim of this project is an Iberian Peninsula Universities Federation of remotely accessed laboratories, part of an educational innovation action, where a unique repository and online showroom will allow students to use different setups on participating departments.

ACKNOWLEDGMENT

The authors want to thanks Prof. Margarita Pino, from the Didactics, School Planning and Research Methods Department of the University of Vigo for the provided guide and assistance on the survey questionnaire design.

Abstract— The middle years of college-level engineering have been identified as an area that needs increased research attention. To date, little has been done to understand how students' learn conceptual knowledge in engineering science courses. This study examines how students use conceptual knowledge during the learning of control systems engineering. This work in progress will discuss the initial findings of a study examining junior-level mechanical engineering students solving controls homework and laboratory problems, exploring topics such as PID control, state feedback, and pole placement.

Keywords—controls; middle years; conceptual knowledge; engineering education

I. INTRODUCTION

The middle years of college-level engineering have been identified as an area that needs increased research attention [1]. In between the freshman cornerstone [2] and senior capstone projects, these middle years are when students take courses in core disciplinary subjects. To date, little has been done to understand how students learn conceptual knowledge in engineering science courses [3].

This work in progress is the beginnings of a project examining exactly how students use conceptual knowledge in the solving of homework and laboratory-based problems within a typical controls course. Over the past ten years, a number of new innovative methods of instruction have been proposed and leveraged in engineering classrooms. These methods include project based learning [4], flipped classroom model [5], and even purely online experiences (Coursera, Khan Academy, edX). While these innovators are prevalent in the forefront of educational research circles, the majority of established instruction continues to use a lecture teaching method with problems sets and laboratory exercises as learning tools and exams as evaluation. While there is some acknowledgement this is not the best form of instruction [6] proposed alternatives are typically material intensive and more

laborious to evaluate, thus providing a barrier to entry for teacher looking to transition.

Despite lecture-based methods being the most prevalent for teaching engineering science course at the university level, little research has actually been done on student learning in these courses. This project aims to understand better how students are developing and applying conceptual knowledge, through examination of homework and laboratory problems in a typical controls system course. This research will optimistically lay the groundwork for supporting further innovations in engineering teaching methodologies.

II. LITERATURE REVIEW

Student learning in traditional engineering science courses during the sophomore and junior years has received less research focus than design and team based courses. As of late, many universities have adopted a “bookend” [7] model of engineering education, with cornerstone and capstone design courses in the first and final year with core content courses delivered in the middle years. Despite this period containing the largest portion of conceptual knowledge learning, limited research applied to studying these middle years [1] with more attention given to retaining freshman and measuring the skills of graduating seniors.

A. Conceptual Knowledge

The study of conceptual knowledge has received significant attention within physics education (e.g. [8]) and in that field served as a foundation for instructional curriculum reform. Streveler, Litzinger, Miller and Steif [3], in their literature of prior studies on students conceptual knowledge of mechanics, thermal science, and direct current circuits, call for more studies about the conceptual learning of engineering students. Litzinger et. al. [9] began this work with one investigation of students' problem solving in statics. In think-aloud sessions, they asked strong and weak performing students to solve a number of different statics problems, simulating the process of completing homework. These were then scored by six expert instructors and coded by the research team for evaluation of the

students' metacognitive processes of monitoring and evaluation. They found weaker students were poorer performers in creating free body diagrams and students able to use self-explanation as a strategy to guide them through the problem were mostly the strong performers.

B. Controls Education

In the past 20 years research on controls education has been more focused on incorporating new tools and technologies into the teaching methodology, especially within laboratory experiences. While research agrees the laboratory section is an important part of the course as it links the theory students learn in lecture to the real world hardware and construction of control systems [10], the literature debates the best delivery method of this material. To ensure every student has access to laboratory experiences, professors more recently have designed take home labs [11-13] and online experiments [14-16]. Others have preferred to keep the laboratory on campus, but innovate by integrating new technologies into the course [17-19]. Others have called for pedagogical enhancements such as the open lab concept [20], inquiry based instruction [22], and new graphical user interface (GUI) designs [23]. While these innovations keep teaching methods up to date with new technologies, little is reported in this work of how these improvements affected student learning. This work hopes to fill this gap in the literature to better understand how the use of these tools and technologies in laboratory problems aid students in learning conceptual knowledge.

III. COURSE DESCRIPTION

System Dynamics and Controls is a junior level course taught every spring semester at a small private university in the northeast of the United States. This course is a requirement for students to graduate with a bachelors degree in mechanical engineering. The two sections of the course are taught by two different members of the faculty, loosely coordinated but each in their own style. Each section is taught lecture style over two 75- minute blocks twice a week and averages about 24 students per class. In spring 2015, each course required one homework assignment (problem set) due per week, excluding exam weeks, and five laboratory exercises that were done in class throughout the semester. Laboratory exercises were completed using Arduino Uno boards and various LEDs, sensors, and actuators assembled in kits for students to assemble in breadboards for different kinds of labs.

Both professors' lectures were traditional lectures that involved collaborative learning between professor and students. The professor of Section A used real world examples to communicate processes of analyzing and tuning controls systems. He discussed personal experience with creating and tuning controls systems to illustrate many different practical methods in system design. The professor of Section B leveraged outlined "skeleton notes" students completed and flushed out during lecture that broke down important equations and analytical processes. For some parts of the lecture, the professor gave the students 2-5 minutes to solve a part of a problem or complete a portion of a derivation before he presented the answers.

TABLE I. COMPOSITION OF COURSE SECTIONS

Course Section	Total Students	Males	Females	Research Participants
Section A	24	20	4	11
Section B	24	15	10	6

Students self-selected to participate in research and were not given any incentives to participate. Laboratory and homework groups were formed by students prior to the beginning of the research study. Students were not grouped by grade point average or perceived ability in the course. No changes were made to the course instructions due to the research except grouping research participants in the same groups for two laboratory exercises in Section A. The research team purposely made no intervention to the course in order to record the course activities as is. The researcher attended one lecture per week to keep current with the material.

This study examines the two types of problems found in these controls courses. Homework problems are those usually found in textbooks. These normally present the student with a system for them to evaluate by finding specific values of system elements and improving the theoretical system performance through mathematical derivation. An example of a homework problem is shown below.

A system has the transfer function

$$G(s) = \frac{2}{s + 3}$$

where the input is in the units of Newtons and the output in units of m/s.

- Plot the Bode plot for this system. It is fine to use Matlab in any way you want. Please show the commands you used to generate the plot.
- If I drive the system with a 3 Newton peak force at 20 Hz (Hz! Not rad/sec!!) at steady state (after any transients have died out) what will be the:
 - Frequency of the response
 - Magnitude of the response
 - Phase of the response relative to the drive

Figure 1: Example homework problem

Laboratory exercises typically ask students to set up (construct) a physical system and execute a program (code) to take initial data. Students modify this initial program based on the collected values leveraging different methods of control to improve the performance of the system. Both of these types of problems were given to students in these two courses.

Figure 2: Diagram to aid students wire up their motor and encoder

IV. RESEARCH DATA COLLECTION

Video data of students solving both homework problems and laboratory exercises were collected. All data is of pairs or groups of students working together in order to encourage discourse about the problems. Homework problem were collected by meeting undergraduates in classrooms and conference rooms in the engineering school as they were working collaboratively on their homework. Multiple cameras and angles were needed to simultaneously capture students' paper, discourse, and overall context.

Laboratory exercises were completed each during scheduled class periods (one period per lab) at various points throughout the semester. 24 hours of homework and laboratory session were collected. Six hours were collected of student homework sessions with up to five cameras capturing different views of students and student tools during each one of the hours. Five groups total were filmed completing three or four laboratory exercises (see Table II below) for a total of 18 hours of video data.

The authors collected data in this manner to capture authentic student activities. While past studies have been successful with think-a-loud protocols in laboratory settings [9,23], the authors aimed not to alter the natural environment and process of student work. A goal of this study was to evaluate this protocol as a way to identify conceptual knowledge without hampering students.

TABLE II. LABORATORY EXERCISES IN COLLECTED DATA

Section A	
Lab	Topic
Control Actions as Difference Equations	Low pass filter, proportional control, interregal control, derivative control
Vehicle Control Using IR Distance Sensor	Proportional control
Motor Velocity Control	Using Simulink for motor control
Temperature Control	Proportional-integral (PI) control

Section B	
Lab	Topic
System Control Using a Motor with an Encoder	Proportional control, proportional-integral (PI) control
Control Using a Motor win an Encoder Continued	Proportional control, proportional-integral (PI) control
Step Response	Step response of a system

V. INITIAL OBSERVATIONS

Analysis of video is currently in the early stages. The majority of the data collected was around the completion of laboratory exercises. Initial observations indicate student discourse between partners mostly revolves around procedural activities, interpreting results, and solving issues with hardware and code, rather than the actual application of concepts. When the system performance was unlike the students' predictions did conceptual knowledge begin to enter the discourse, only as means to analyze the system performance. Conceptual knowledge also is used to discuss expected performance and real performance of the system and then to make adjustments to modify this performance. Presence of the professor or teaching assistants, either checking in or to resolve issues, occasionally also began discourse around the conceptual knowledge.

VI. FUTURE WORK

The research team will continue to analyze the data collected within these courses. During the analysis, the research team will identify moments of application of conceptual knowledge within the data to assist in building a case library of these instances and the associated types of problem solving related to each. Video clips from the courses related to these occurrences will be used with both instructors in connection with discussions around teaching strategies to also incorporate their view of conceptual knowledge use into the analysis. Attention will also be given to differences between application of conceptual knowledge in the two different sections and if these can be attributed to differences in teaching style. The research team will work to develop a list of conceptual knowledge in controls to be reviewed by experts, for refinement to then be used in further analysis here and in future data. Findings from the data will also be used in a redesign of the study methodology (data collection and analysis) before the next academic year begins. Findings from all these activities will be shared with the academic community with hopes of better supporting the educational innovations around teaching methodologies in the field of controls.

ACKNOWLEDGMENT

The authors would like to acknowledge funding and support from Tufts University Center for Engineering Education and Outreach, Tufts University Department of Mechanical Engineering, Tufts University Department of Computer Science, and the Center of Science and Mathematics in

Context at the University of Massachusetts Boston. This work was also supported by the National Science Foundation DRK-12 program, grant # DRL-1020243, and grant # DRL-1253344. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation. We would also like to thank Professor William Messner and Professor Robert White for their support of the project and the student participants.

Abstract - This paper presents an optimal control design methodology used in a graduate electrical engineering course. The proposed methodology was applied and used on the double inverted pendulum system. The regulators presented are based on the state-variable feedback with Linear Quadratic Regulator (LQR) design. An asymptotic observer was designed to estimate the state-variables of the system. A Kalman Filter was designed as an alternate estimator to include sensor and process Gaussian noise. The Loop Transfer Recovery technique was used to recover some of the robustness properties that can be lost when implementing the Kalman filter. The Kalman Filter resulted in a better state estimator with less estimation noise on the velocities state variables, compared to the velocities state variables that were estimated with the asymptotic observer. Furthermore, Loop-Transfer Recovery allowed for a better tuning of the Kalman filter based controller and resulted in a better time response of the system. Theoretical aspects were experienced and confirmed in a laboratory setup as each design technique was applied and implemented sequentially in the real system. This is an innovative practice because the students learn by doing in a deductive way, as they build upon their design.

Keywords – *Double Inverted Pendulum System, Kalman Filter, Linear Quadratic Regulator (LQR), Loop Transfer Recovery, Asymptotic Observer, Optimal Control, State Variable Feedback.*

I. INTRODUCTION

This paper describes a term project used in a graduate control course designed to enhance the learning of optimal Linear Quadratic Regulator (LQR) design techniques. The course is on Optimal Control and follows the book by Lewis, et al. [1]. A design and implementation methodology is proposed to complete the design project successfully. The system chosen to illustrate the proposed methodology is the double inverted pendulum. The design methodology may be applied to other systems if the steps presented in this paper are followed.

The term project tasks were developed and evolved

along the semester as the theoretical aspects were discussed in class. Using a design project as a teaching and learning tool, provided the students with an interactive framework that facilitated the understanding of a complex theory. The design and implementation of the controllers allowed the students to reinforce the theory and the design techniques. This is an innovative practice because the students learn by doing in a deductive way, as they build upon their design.

The controllers for the system are designed in four stages. The first controller was a simple LQR design assuming that all state variables were available for feedback, then an asymptotic observer was designed and implemented to estimate all the state variables of the system. Later, a Kalman Filter was designed to reduce the noise that appears on the estimated state variables. Adding an asymptotic observer or a Kalman filter can cause the system to lose its robustness properties [1]. To recover these properties, a regulator using the Loop Transfer Recovery technique was designed and implemented.

Section II presents the double inverted pendulum system model used for the implementation of the regulators designed. Section III presents the design techniques used for designing the regulators. The results are presented and discussed in Section IV and conclusions are given in section V.

II. DOUBLE INVERTED PENDULUM SYSTEM

The double inverted pendulum system, consists of an upper pendulum and a lower pendulum, connected to a cart that slides along a linear track. See Fig. 1. The mechanical system has three degrees of freedom: the position of the cart, the angle of the lower pendulum with respect to the cart and the angle of the upper pendulum with respect to the lower pendulum. The actuator that moves the cart is a DC servomotor equipped with a gear system. The sensors that read the position of the cart, and the two angles of the pendulums are quadrature optical encoders. The system used was developed by Quanser [3]. The system was controlled via a Q4 data acquisition card and the QUARC® program, both developed by Quanser. A state-space nonlinear model of the system is derived from the Euler-Lagrange equations [2]. These equations are then linearized about an operating point. The linearized state-space model is

then used to design all of the state-feedback controllers. The performance of each controller is simulated and evaluated via Simulink. Once the simulated performance is deemed satisfactory, the controllers are implemented in the real plant to validate their performance.

A. Double Inverted Pendulum Linearized Dynamic Model

A Double Inverted Pendulum system is illustrated in Fig. 1, where $x(t)$ is the cart position, $\alpha(t)$ is the angular position of the lower pendulum mounted on the cart with respect to the vertical axis, $\theta(t)$ is the angular position of the upper pendulum with respect to the lower pendulum. The corresponding velocities are $\dot{x}(t)$, $\dot{\alpha}(t)$, and $\dot{\theta}(t)$.

Fig. 1. Simplified Model of the Double Inverted Pendulum System

The state-variables are defined as,

$$\begin{aligned} x_1 &= x(t) & x_4 &= \dot{\alpha}(t) \\ x_2 &= \dot{x}(t) & x_5 &= \theta(t) \\ x_3 &= \alpha(t) & x_6 &= \dot{\theta}(t) \end{aligned}$$

The nonlinear differential equations were linearized about an operating point defined as zero for all state variables. The resulting linearized model is of the form

$$\dot{x}(t) = Ax(t) + Bu(t) \quad (1)$$

$$y(t) = Cx(t) \quad (2)$$

The nonlinear state equations and the system parameters may be found in [3]. The linearized model is

$$\begin{bmatrix} \dot{x} \\ \dot{\alpha} \\ \dot{\theta} \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & -13.7315 & -5.96 & 0 & 0.136 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 95.1 & 109.19 & 0 & -50.95 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & -98.64 & -113.25 & 0 & 131.68 & 0 \end{bmatrix} \begin{bmatrix} x \\ \dot{x} \\ \alpha \\ \dot{\alpha} \\ \theta \\ \dot{\theta} \end{bmatrix} + \begin{bmatrix} 0 \\ 3.07 \\ 0 \\ -21.28 \\ 0 \\ 22.07 \end{bmatrix} u(t) \quad (3)$$

$$y(t) = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} x \\ \dot{x} \\ \alpha \\ \dot{\alpha} \\ \theta \\ \dot{\theta} \end{bmatrix} \quad (4)$$

III. DESIGN TECHNIQUES

A. Linear Quadratic Regulator

The Linear Quadratic Regulator (LQR) is a special case of the optimal control problem which minimizes the performance index

$$J = \int_0^\infty (x^T Q x + u^T R u) dt \quad (5)$$

The solution of the LQR problem reduces to solving the Algebraic Riccati Equation (ARE) [1]

$$0 = A^T P + PA - PBR^{-1}B^T P + Q \quad (6)$$

Where Q is a positive semi-definite ($Q \geq 0$) state weighting matrix and R is a positive definite ($R > 0$) control weighting matrix. LQR controller tuning is achieved by varying the Q and R matrices until the controlled system performs as desired. Matrices Q and R penalize the magnitude of the state variables and the magnitude of the control action respectively. Bryson and Ho [4] suggested a way for choosing starting values for the Q and R matrices. For the double inverted pendulum system we chose Q to be diagonal and R to be a scalar

$$Q = \begin{bmatrix} q_{1,1} & 0 & 0 & 0 & 0 & 0 \\ 0 & q_{2,2} & 0 & 0 & 0 & 0 \\ 0 & 0 & q_{3,3} & 0 & 0 & 0 \\ 0 & 0 & 0 & q_{4,4} & 0 & 0 \\ 0 & 0 & 0 & 0 & q_{5,5} & 0 \\ 0 & 0 & 0 & 0 & 0 & q_{6,6} \end{bmatrix} \text{ and } R = r$$

Where $q_{i,i}$ is the weight attributed to state variable x_i and r is the weight attributed the control action $u(t)$. The initial weights for the Q matrix are assigned as

$$q_{i,i} = \left(\frac{1}{x_{i\max}} \right)^2$$

The initial weight for the control action is assigned as

$$R = \left(\frac{1}{V_{\max}} \right)^2$$

Where $x_{i\max}$ is the maximum allowable value for the position of state variable x_i and V_{\max} is the maximum allowable value for the control action. In our case, V_{\max} is the maximum voltage allowed to be applied to the motor. After choosing the Q and R matrices, the ARE (6) is solved for P and the feedback gain is computed as

$$K = R^{-1}B^T P \quad (7)$$

The control action is defined as

$$u(t) = -Kx(t) \quad (8)$$

Fig. 2 shows a block diagram of the regulator when the LQR is implemented assuming that all state variables of the system are available as measurements.

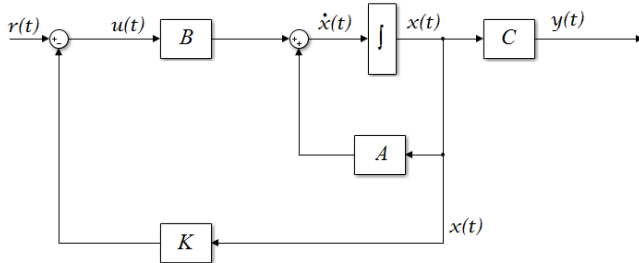

Fig. 2. System Block Diagram for the LQR Implementation

As is usually the case, not every state variable of a system is available as a measurement. Therefore, it is not possible to implement an LQR as illustrated in Fig. 2. It is often necessary to add state estimators to implement a state-feedback controller. For the double inverted pendulum system, the most basic controller is an LQR with feedback gain K , where the angular positions of the pendulums and the linear position of the cart are measured by sensors while the unmeasured velocities are estimated using first-order derivative filters given by

$$G(s) = \frac{as}{s + a} \quad (9)$$

Where,

a –The pole of the first-order derivative filter.

s –The complex frequency.

B. Asymptotic Observer

The problem of implementing the LQR controller with gain K by estimating the unmeasured velocities of the system with first-order derivative filters is that it results in a noisy estimation of the state variables. This can be problematic since it adds high frequency noise to the control action applied to the plant which in turn may damage the servomotor brushes and the gear system if the situation persists for a long time. The asymptotic observer is presented and designed as an alternative to this method.

An asymptotic observer can be designed and implemented if the system is observable [2]. Observability of the system implies that the poles of the asymptotic observer may be assigned arbitrarily, provided they are a self-conjugate set. The state observer state-equation is given by

$$\dot{\hat{x}}(t) = (A - LC)\hat{x}(t) + Bu(t) + Ly(t) \quad (10)$$

Where $\hat{x}(t)$ is the state vector estimate. Fig. 3 shows the block diagram of the LQR implemented with an

asymptotic observer. When designing the asymptotic observer, its gain matrix L is chosen in such way that the poles of the observer matrix $(A-LC)$ are faster than the poles of the plant with feedback $(A-KB)$, so that the poles of the observer do not affect the dynamics of the closed-loop system. Matrix L of the asymptotic observer may be assigned by using the “place” command in MATLAB®, which is based on the pole placement method develop by Kautsky, Nichols, and Van Doorens [5]. A usual starting point that produces good results is to select the poles of $(A-LC)$ to be negative real numbers, 10 times larger to the left of the poles of the closed-loop system. If such a selection does not produce satisfactory results, then choose different positions for the poles and assign them with the “place” command until the system is controlled satisfactorily.

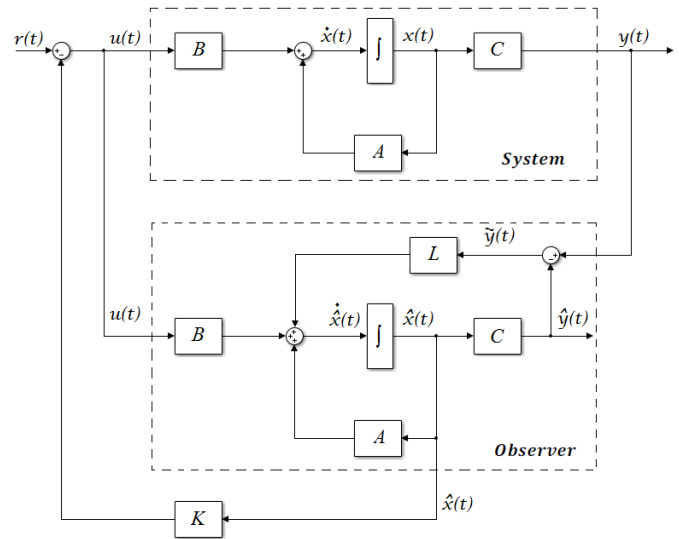

Fig. 3. System Block Diagram for the Asymptotic Observer, Kalman Filter, and Loop Transfer Recovery Controllers.

The controller for the system with the asymptotic observer is designed in the same way as the LQR problem with the exception that in this case, the control action $u(t) = -K\hat{x}(t)$ is used instead of $u(t) = -Kx(t)$. That is, the state-vector estimate is used for feedback instead of the real state-vector.

C. Kalman Filter

The control implementations of the LQR and observer problems have been done assuming that there was no noise in the measured states. Those implementations have not taken into account the complete dynamics of the system, disturbances, and the noise coming from the measuring sensors. The Kalman filter is an alternative that uses probability theory to treat the inaccuracies inherent in the linearized system models used [1]. The Kalman Filter can also be implemented as in Fig. 3. The system with process and measurement noise is described by

$$\dot{x}(t) = Ax(t) + Bu(t) + Gw(t) \quad (11)$$

$$y(t) = Cx(t) + n(t) \quad (12)$$

$$x(0) \sim (x_0, P_0), w(t) \sim (0, Q_k), n(t) \sim (0, R_k)$$

Where $w(t)$ and $n(t)$ are white noise processes orthogonal to each other and to $x(0)$. The Q_k and R_k matrices in this case are not the same as those used for the LQR design. The subscript k , as in Kalman, is used to distinguish them from the Q and R of the LQR problem. Moreover, Q_k and R_k are not weighting matrices but noise spectral density matrices [1]. The Kalman filter is designed as follows:

Initialization: set

$$\hat{x}(0) = \bar{x}(0)$$

Solve the error covariance Kalman filter ARE:

$$AP + PA^T + G^T Q_k G - PC^T R_k^{-1} CP = 0 \quad (13)$$

Compute the Kalman gain:

$$L = PC^T R_k^{-1} \quad (14)$$

Implement the state estimate dynamic equation:

$$\dot{\hat{x}}(t) = (A - LC)\hat{x}(t) + Bu(t) + Ly(t) \quad (15)$$

D. Loop Transfer Recovery

It is well known that the guaranteed robustness properties of using the full state feedback is generally lost when using an observer or even a Kalman filter [1]. A technique for designing Kalman filters, called Linear Quadratic Gaussian/Loop-Transfer Recovery (LQG/LTR) may be used to recover the robustness properties that the LQR feedback control has [1]. This is accomplished simply by tuning a scalar parameter v . For the system described by (11) and (12) with

$w(t) \sim (0, M)$ – White Process Noise

$n(t) \sim (0, v^2 N)$ – White Measurement Noise

M – Process noise spectral density matrix

N – Measurement noise spectral density matrix

v – Scalar parameter (Nu)

The process noise spectral density matrix is defined as

$$M = v^2 M_o + BB^T, \quad M_o > 0 \quad (16)$$

The Kalman filter using the loop-transfer recovery technique is designed as follows:

Solve loop-transfer recovery (LTR) Kalman filter ARE:

$$AP + PA^T + (v^2 M_o + BB^T) - PC^T (v^2 N)^{-1} CP = 0 \quad (17)$$

Compute loop-transfer recovery Kalman Gain:

$$L = PC^T (v^2 N)^{-1} \quad (18)$$

The following procedure, described by Lewis et al. [1], is used to design a Kalman Filter using the Loop-transfer

recovery technique:

1. Use the LQR control ARE (6) to design a state-feedback gain K with desirable properties. Which involves an iterative design varying the Performance Index weighting matrices Q and R .
2. Select $G = I$ (Identity Matrix), $M = v^2 M_o + BB^T$ – Process noise spectral density, and $v^2 N$ – Measurements noise spectral density

For a positive definite matrix M_o , and a positive definite matrix N . Fix the design parameter v (Nu) and then solve the LTR Kalman filter ARE (13) for P and compute the Kalman gain L (14).

3. Plot the maximum and minimum singular values of the regulator loop gain $L_r(s)$ and verify that the robustness bounds are satisfied. If they are not, decrease v and return to 2.

Since in our course we did not cover robust control topics, step 3 was accomplished by observing how the system response improved or deteriorated as the design parameter v was decreased.

IV. RESULTS

A simulation of the system with the regulator was performed with MATLAB® and Simulink® before implementing it on the real system. Virtual Instruments were then created in QUARC® to implement the LQR, Asymptotic Observer, Kalman Filter, and Loop-Transfer Recovery controllers on the real system. Next we will present the results obtained after implementing each controller on the real system.

A. Linear Quadratic Regulator Results

The first-order derivative filters (9) were used to estimate the unmeasured velocities with $a = 20$. The initial values chosen for the Q and R matrices were determined by choosing the maximum allowable values of the state variables and the control action as: $X_{max} = 0.1$ meter, $\dot{X}_{max} = \infty$, $\alpha_{max} = 0.105$ rad (aprox. 6°), $\dot{\alpha}_{max} = \infty$, $\theta_{max} = 0.105$ rad, $\dot{\theta}_{max} = \infty$, $V_{max} = 5$ Volts. When those maximum values were used, the Q and R matrices become

$$Q = \begin{bmatrix} 100 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 90 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 90 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \text{ and } R = 0.05$$

Then the value of gain K was found by using the “lqr” command ($K = \text{lqr}(A, B, Q, R)$) in MATLAB®, resulting in

$$K = [50.0000 \quad 35.0725 \quad 146.8321 \quad 36.0010 \quad 270.0862 \quad 32.7691]$$

However this K caused the cart to react too fast to control the system and there was too much noise fed to the motor. Thus, it was decided to reduce the amount of weight

attributed to the positions of the cart and pendulum angles to reduce the reaction of the cart, allowing for a more relaxed control action. Also, it was decided to increase the weight attributed to the control action so that it would apply a lower voltage to the motor. With those changes, the system performed better. After various changes, it was realized that the weight assigned to the position of the cart could be much less than what we started with. Finally, we ended up with the following Q and R matrices

$$Q = \begin{bmatrix} 0.75 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 35 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 30 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \text{ and } R = 0.04$$

The final value of gain K and the poles of the closed-loop plant ($A-KB$) are

$$K = [3.8730 \ 3.2136 \ 45.3633 \ 13.6046 \ 131.5116 \ 14.9450]$$

$$\text{LQR poles} = \begin{bmatrix} -23.7816 + 16.5569i \\ -23.7816 - 16.5569i \\ -7.0555 + 2.7091i \\ -7.0555 - 2.7091i \\ -1.1264 + 0.2362i \\ -1.1264 - 0.2362i \end{bmatrix}$$

This K value kept both pendulums in a vertical position, with the least amount of oscillation and with the best reaction in response to disturbances. The experimental results of the LQR implementation are shown in Fig. 4 and Fig. 5. It can be seen from Fig. 4 that the velocity estimates contain high frequency noise signals. When those signals are used for feedback control, they cause high frequency noise to appear in the control action signal $u(t)$ as shown in Fig. 5. The presence of noise in the control action can even be perceived by the sound generated by the DC servomotor.

Fig. 4. Measured State Variables of System using LQR

B. Asymptotic Observer Implementation Results

When implementing the asymptotic observer, the value of gain K used was the same as the one found for the LQR

implementation. The Observability Matrix of the system was computed with the “*obsv.m*” command of MATLAB® to evaluate the observability of the system. The Observability Matrix is determined to be full rank using the “rank” command of MATLAB®. This proves that the system is observable and that an asymptotic full-state observer can be designed and implemented.

Fig. 5. Noisy Control Action (Vm) using LQR.

When designing the asymptotic observer, the poles of the observer matrix ($A-LC$) were chosen to be faster than the poles of the closed loop plant ($A-KB$). Matrix L was found by using the MATLAB® “place” command ($L = \text{place}(A', C', P_o)$), where P_o is a vector that contains the location of the desired observer poles. The initial choice for observer poles locations was

$$P_o = [-100 \ -102 \ -104 \ -106 \ -108 \ -110]$$

The resulting L matrix was

$$L = 1.0e+04 * \begin{bmatrix} 0.0196 & -0.0001 & -0.0002 \\ 0.8294 & -0.0134 & -0.0222 \\ 0.0094 & 0.0206 & -0.0003 \\ 1.8479 & 0.0001 & -0.0633 \\ -0.0100 & 0.0001 & 0.0214 \\ -1.9463 & -1.9463 & 1.1792 \end{bmatrix}$$

However, when the observer implemented with this L matrix was not able to keep the pendulum stable. Thus, it was decided to assign slower observer poles. After various trials, we ended up with P_o and L matrix that resulted in the best system behavior

$$P_o = [-30 \ -60 \ -62 \ -64 \ -66 \ -68].$$

$$L = 1.0e+03 * \begin{bmatrix} 0.0685 & 0.0038 & -0.0036 \\ 0.2304 & 0.1845 & -0.1805 \\ 0.0225 & 0.1349 & -0.0069 \\ 1.8833 & 5.0005 & -0.8359 \\ -0.0226 & -0.0074 & 0.1329 \\ -1.9065 & -0.9597 & 4.8851 \end{bmatrix}$$

Figs. 6 and 7 show the experimental results of the asymptotic observer implementation. It can be seen from

Fig. 6 that there are still high frequency noise signals in the velocity estimates, but with lower frequency content than the estimates in the LQR case of Fig. 4. These state variable estimates produce a control action $u(t)$ with less noise than the previous LQR implementation, as it can be seen from Fig. 7 when it is compared to that in Fig. 5. However, this level of noise in the control action is still unacceptable since it can still be perceived as sound generated by the DC servomotor.

Fig. 6. Measured State Variables of System using LQR with Asymptotic Observer

Fig. 7. Control Action (Vm) using LQR with Asymptotic Observer

C. Kalman Filter Results

For the double inverted pendulum system we did not have any information of what values to use for the spectral density matrices Q_k and R_k , but we had the position of the poles and the value of the L matrix that produced good results when implementing the asymptotic observer. Those could be used for comparison. It was decided to start with intuitive and reasonable values for the spectral density matrices Q_k and R_k . Our starting value for R_k was

$$R_k = \begin{bmatrix} 1/20 & 0 & 0 \\ 0 & 1/20 & 0 \\ 0 & 0 & 1/20 \end{bmatrix}$$

To choose a starting value for the spectral density matrix Q_k , we started by looking at the state variable measurements of Figs. 6 and 4 and noticed that the signals with the highest amount of noise density were the angular velocity estimates. Thus, the elements in Q_k matrix that represent those state variables should have values with a greater magnitude than the ones of the angular position state variables. We also noticed from Figs. 4 and 6 that the state variables representing the position and velocity of the cart show small amount of noise compared to the angular velocity state variables. Thus, smaller numbers were used for these state variables. Based on the described analysis, the initial spectral density matrix Q_k was assigned to be

$$Q_k = \begin{bmatrix} 15 & 0 & 0 & 0 & 0 & 0 \\ 0 & 20 & 0 & 0 & 0 & 0 \\ 0 & 0 & 5 & 0 & 0 & 0 \\ 0 & 0 & 0 & 100 & 0 & 0 \\ 0 & 0 & 0 & 0 & 10 & 0 \\ 0 & 0 & 0 & 0 & 0 & 100 \end{bmatrix}$$

With those choices for matrices Q_k and R_k , and defining G as $G = I$ (Identity Matrix), we solved the Kalman filter ARE with the MATLAB® “lqe” command ($[L, P, E] = \text{lqe}(A, G, C, Q_k, R_k)$). This resulted in the Kalman gain L and poles for the observer matrix $(A-LC)$.

However, this first L value did not control the system well because the control action did not have enough strength to maintain system stability. However, our intuitive values looked promising. Changes were made by trying out different values in the diagonal elements of the spectral density matrices Q_k and R_k and comparing the resulting L and poles for the observer matrix $(A-LC)$ to those found with the Asymptotic Observer. We knew we wanted the poles for the observer matrix $(A-LC)$ to have their real negative parts as farther to the left of the poles of the plant with feedback $(A-KB)$ as possible. This was taken into consideration when we ran the “lqe” command in MATLAB®. When we saw that the resulting observer matrix $(A-LC)$ poles generated by changing the matrix Q_k and matrix R_k were promising, we ran simulations and then tested it on the real system to see how it responded. Taking those steps, resulted in the final value that were used for the spectral density matrices Q_k and R_k that produced a Kalman gain L that produced enough control action strength to maintain the stability of the system. The final values for Q_k and R_k , Kalman gain L , poles of the Kalman filter are

$$Q_k = \begin{bmatrix} 500 & 0 & 0 & 0 & 0 & 0 \\ 0 & 506 & 0 & 0 & 0 & 0 \\ 0 & 0 & 12 & 0 & 0 & 0 \\ 0 & 0 & 0 & 50000 & 0 & 0 \\ 0 & 0 & 0 & 0 & 6 & 0 \\ 0 & 0 & 0 & 0 & 0 & 50000 \end{bmatrix}$$

$$R_k = \begin{bmatrix} 1/10 & 0 & 0 \\ 0 & 1/10 & 0 \\ 0 & 0 & 1/10 \end{bmatrix}$$

$$\text{Kalman filter poles} = \begin{bmatrix} -70.7032 \\ -19.656 \\ -20.7147 + 16.7508i \\ -20.7147 - 16.7508i \\ -19.9185 + 17.6866i \\ -19.9185 - 17.6866i \end{bmatrix}$$

$$L = \begin{bmatrix} 70.7398 & 0.1109 & -0.1629 \\ 2.0759 & 4.2701 & -9.6560 \\ 0.1109 & 43.4210 & -3.7564 \\ 8.9965 & 889.7540 & -138.8682 \\ -0.1629 & -3.7564 & 43.7332 \\ -9.4068 & -188.5399 & 933.3635 \end{bmatrix}$$

Figs. 8 and 9 show the experimental results of the Kalman filter implementation with LQR. It can be seen from Fig. 8, when compared to Figs. 4 and 6, that the estimated state variables generated by the Kalman Filter essentially do not contain high frequency noise signals on the velocity estimates. When those state variable estimates are used in the control law $u(t) = -K\hat{x}(t)$, they no longer cause high frequency noise to appear on the control action, as can be seen from Fig. 9. When this controller design was implemented on the plant, there was no perceived sound generated by the DC servomotor. Also, the movement and reaction of the cart and pendulums were more fluid and it was observed that the system was kept stable with more ease.

Fig. 8. Measured State Variables of System using LQR with Kalman Filter.

Fig. 9. Control Action (Vm) using LQR with Kalman Filter.

D. Loop Transfer Recovery

To implement the loop-transfer recovery technique we started by assigning spectral density matrixes Q_k and R_k found for the Kalman filter, as the corresponding starting values of the spectral density matrixes $M_o = Q_k$ and $N = R_k$ so that the iteration process explained by Lewis [1] could start.

In the previous step, both M_o and N are required to be positive definite matrixes ($M_o > 0$) and ($N > 0$). The procedure described by Lewis [1] and reproduced in section III.D was used to design a Kalman Filter using the Loop-transfer recovery technique. This procedure was performed first off-line with the system model to determine how it would change the gain L and the observer matrix ($A-LC$) poles compared to those found with the Kalman filter and then we ran simulations. Later, the procedure was performed while the system was running with the data acquisition system displaying the graphs of the estimated state variables to find out how it was affecting the system. Start with the same Kalman gain K used for the previous controllers. Set design parameter $v = 1.0$, then solve the LTR Kalman filter ARE (18) for P and compute the Kalman gain L (19) by using the "lqe" command of MATLAB®. Observe the resulting gain L and the observer matrix ($A-LC$) poles, and compare them with those found with the Kalman filter. If we saw no appreciable change on the system performance, we returned to step 2, reduced the design parameter to v , and made the same observation.

Repeating steps 2 and 3 of the procedure and updating the Virtual Instrument gains while the system was running, allowed us to see the effect of reducing the design parameter v . We finally arrived at design parameter $v = 0.02$ because it produced the best results. Those are shown in Figs.10 and 11. However, if the design parameter v was reduced too much, the loop-transfer recovery would begin to produce high frequency noise in the velocity state estimate variables, causing a control action that had too much noise. Those results are shown in Figs. 12 and 13 when the design parameter $v = 0.001$ is used.

Figures 10 and 11 show the experimental results of the Loop Transfer Recovery implementation when the design

parameter $\nu = 0.02$. The estimated state variables generated by the Loop Transfer Recovery were used and applied with the feedback gain K . It can be seen from Fig. 10 that the estimated state variables generated by the Loop Transfer Recovery essentially have no high frequency noise signals on the velocity estimates. Also it can be seen from Fig. 10, when compared to Fig. 8, that the amplitude of the velocity estimates oscillations was reduced. When those signals are used in the feedback control law, they basically cause very little high frequency noise to appear in the control action signal $u(t)$ as shown in Fig. 11.

Again, there was no perceived sound generated by the DC servomotor, as the system was running. It was observed that the movement and reaction of the cart and pendulums were more fluid and the system was keep stable with both pendulums in an even more vertically straight position and with more ease than with the regular Kalman filter. There was less swing movement on the pendulums and the reaction to stabilize the system when it was disturbed was done faster, with more ease and fluidity than with the previous asymptotic observer or the Kalman filter.

Fig. 10. Measured State Variables of System using LQR with Kalman Filter and Loop Transfer Recovery ($\nu=0.02$).

Fig. 11. Control Action (Vm) using LQR with Kalman Filter and Loop Transfer Recovery ($\nu=0.02$).

Figures 12 and 13 show the experimental results of the Loop Transfer Recovery implementation with LQR when the iterative value of the scalar constant ν is reduced too much, without considering the effect it might have on the estimated state variables and control action of the system or

whether or not the robustness bounds of the system are satisfied. Figure 12 shows an extreme amount of high frequency noise signals on the velocity estimates. When those signals are used for feedback, they cause high frequency noise to appear on the control signal $u(t)$ as shown in Fig. 13, which is even worse than what was observed for the case of the LQR implementation (Fig. 5).

V. CONCLUSIONS

An LQR design methodology that may be used as a technologically-based educational and learning tool for teaching a graduate optimal control course was presented. The methodology was applied by a team of two graduate and one undergraduate student in the course term project. The methodology starts with the most basic LQR design using MATLAB® design tools. Then, an asymptotic observer, a Kalman Filter, and a Kalman Filter with Loop transfer Recovery are designed and implemented sequentially to obtain increasingly improving performance of the regulator. The methodology served to enhance the teaching practice while providing effective learning opportunities since the students were discovering the improvements of each additional design method while they were confirming theoretical aspects in an experimental setting.

flavio_toribio@hotmail.com, rafaalvesum@gmail.com, iaione@facom.ufms.br

Abstract—The first digital circuits course becomes a lot more interesting for students when it involves practical experiments in the laboratory. Motivation is higher when students use old digital integrated circuits, such as the TTL7400 or CMOS4000 families, and construct circuits on solderless breadboards. The handling of these circuits containing logic gates is more motivating than using a digital circuit simulator software or an FPGA, which looks like a black box for beginner students. To verify the built circuit's operation on the solderless breadboard, with a digital integrated circuit, it is necessary to generate input signals and display the output signals, as well as a probe in order to check the logic level at any point in the circuit. For this, there are two options: using didactic modules for experiments with digital circuits, or generating input signals with switches and showing the output signals with LEDs. The former has the disadvantage of relatively high cost. The latter has the drawback of inserting many other problems when building a digital circuit using breadboards. As a low-cost alternative, this paper presents a virtual instrument that consists of an Arduino and a software, which allows experiments using digital integrated circuits.

Keywords—computerized instrumentation; digital circuits; low cost;

I. INTRODUCTION

Practical experiments with digital circuits are very important for teaching computing and engineering because they act as a bridge between theory and practice, not only solidifying the concepts shown in class [1] but also being highly valuable to one's curriculum [2]. The first course for digital systems education becomes much more interesting to students when it involves practical experiments in the laboratory, which undoubtedly increase motivation in class and improve the extent to which students understand and remember the laid out concepts.

Conducting experiments using simulator software is much more interesting than teaching a class based only on the blackboard. However, the use of simulators does not arouse much interest in students due to their lack of physical components to be handled when assembling the circuits. In addition, many interesting problems arise when a project is implemented in hardware, and as such, these hands-on experiments are necessary to develop essential skills [2].

Currently, practical experiments involving physical components use two approaches. In the first one, the circuits are assembled on protoboards using logic gates (AND, OR, NOT, etc.) contained in SSI and MSI integrated circuits, such as the old TTL74 and CMOS4000 families. In the second approach,

the experiments are performed using hardware boards containing programmable logic devices (VLSI and ULSI), such as FPGA-based prototyping [3].

The second approach has several benefits, such as: the possibility of assembling more complex circuits; the student does not need to manage wires to interconnect the logic gates; no issues arise from bad contacts and shorts; the circuits are assembled more quickly; and more [3]. However, when considering the first course in digital systems—taught to beginners—it appears that these benefits are somewhat diminished, and the first approach that allows the handling and physical interconnection of logic gates becomes more appealing. In [4], it was found that discrete components are fundamental in the initial courses and the FPGA is an economical alternative to subsequent courses.

To verify the operation of the protoboard-assembled circuit using SSI and MSI integrated circuits, we need to generate input signals and display the output signals, as well as have a test probe to check the logic level at any point in the circuit. This may be accomplished using specific teaching modules for experiments with digital circuits, whereas this solution has the disadvantage of a relatively high cost, around US\$1000 per module in Brazil. Another much cheaper solution is to generate the input signals using switches, and display the output signals using LEDs and resistors. This last solution has the drawback of inserting several other problems in addition to those which already naturally occur when assembling a digital circuit using protoboards and wires. Besides, the increased number of wires—which will cause more bad contacts—plus the switch bouncing and LEDs with inverted terminals can complicate the experiment for the beginner student. For example, an LED connected incorrectly at the output of a logic gate (inverted anode and cathode terminals) will erroneously display the output level as always 0 (LED always off) to the student.

Given the above, and considering that currently the use of virtual instruments has received considerable attention in the literature [5, 6] and the great popularity and low cost of open-source platforms for electronic prototyping, such as Arduino [7]–[9], the objective of this paper is to develop a virtual instrument consisting of an Arduino and a computer application, which allows the realization of practical experiments using SSI and MSI circuits at low cost. The proposed system is a solution that does not present the problems associated with the use of switches and LEDs to generate and display the logic levels, respectively; and it does not present the inconvenience of the

high cost usually associated with the use of specific didactic modules for experiments with digital circuits.

II. METHODOLOGY

The system is designed to be simple to use at first, and so its requirements for running are just:

- connecting an Arduino Mega 2560 board to a USB port;
- opening the software and letting it detect the board automatically (Figure 1).

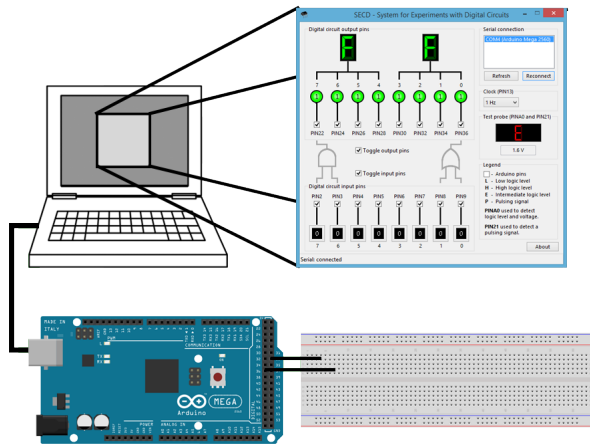

Fig. 1. How to set up and use the system.

By pressing the virtual circuit buttons in the program, the user sends LOW or HIGH digital state signals to the specified pins on the board. To receive signals, the user must use one of the available pin numbers shown in the program. For instance, a signal can be sent from button 7 to LED 7 by connecting a jumper from PIN2 to PIN22. This I/O system provides a method of manipulating real-life signal processing circuits without dealing with how to visualize the output states in hardware.

A. Hardware

The prototyping platform chosen for developing the system is the Arduino. The model used in this project is the Arduino Mega 2560¹, which has a proper pinout compatible with the system. Currently, this is the only model supported.

The Arduino platform has undergone a major refinement, becoming better, simpler, more accessible and cheaper for electronics students, generating a large number of possible projects. The Arduino Mega 2560 is based on the *Atmel AVR ATmega2560* [11] microcontroller, featuring 54 digital I/O pins (15 of these are used as PWM outputs) and 16 analog inputs. The major user base of this platform for the most part are beginner designers who, perhaps, would not be able to get more sophisticated prototyping controllers because of their price and/or complexity. Its accessibility associated with its great performance, plus its extensive community and

documentation, make the Arduino one of the main platforms used worldwide [12].

The role of the Arduino in the system is to perform the analysis and study of a particular digital circuit project through the signals that are generated by the Arduino, and the signals—not necessarily logical—which are generated by the circuit. The system can generate inputs with static logic levels according to a project specification, and can also analyze its output through the logical levels; all of this using the input and output pins from the Arduino. The system is also capable of generating square waves through the digital outputs, in certain pre-determined frequencies, using the built-in timers on the microcontroller.

A great strength of the system is that it is capable of making a more precise analysis of a digital circuit by measuring the voltage and signal type at any point in the circuit using the analog input and the interrupts system as a test probe. This probe checks whether a signal is low, high, indeterminate or pulsing. To determine whether a signal is high, low or indeterminate, the Arduino does the signal pre-processing using the built-in A/D converter, turning the signal into data that the software is capable of translating. If the analyzed signal has variations in a frequency equal to or above 10 Hz, our firmware will define this signal as pulsating. If the signal is below 10 Hz, it is expected to see the changes between LOW and HIGH on the interface. Every hundred milliseconds, the firmware checks whether there was any change in the signal's logic level. If there is more than one logic level change during these hundred milliseconds, the signal is determined as pulsing; if there was just one change, the firmware analyzes the time difference between each state. If there was no change in these hundred milliseconds, the signal is one of the other three types, but not pulsing. To identify a change in the signal's logic level, hardware interrupts are used as a feature within the microcontroller.²

B. Software

The software part is responsible for quickly exchanging messages with the Arduino board, using serial communication to automatically upload the firmware and to process input and output signals for the virtual buttons and LEDs.

We developed the software using C++ and *wxWidgets* for the graphical user interface (GUI). *wxWidgets* is a programmer's toolkit for writing cross-platform applications with GUIs and contains a large library for handling standard controls, events, databases, multi-threading and general communications [10]. Currently, the software uses two threads for its inner workings, the main one processing the window events and other general calculations, and the second for the USB-virtual serial port communication loop.

When performing a new serial connection, the program tries to identify the firmware and, if it is missing or else is not the same version, an automatic upload is done using the third-party uploader *AVRDUDE*.³ With the new firmware, the next connection attempt will succeed when an identifier string is sent to the program, which verifies it for authenticity, and

¹<http://arduino.cc/en/Main/arduinoBoardMega2560>. Accessed on Apr. 10, 2015.

²<http://arduino.cc/en/Reference/attachInterrupt>. Documentation for `attachInterrupt()` Accessed on Apr. 12, 2015.

then the user may fully use the interface and start physically prototyping the circuit.

C. Communication Protocol

The serial protocol used to communicate between the Arduino and the software is relatively simple. It is composed of a three-byte packet, for both sending and receiving data, which contains information about (Figure 2):

- the inputs which are provided from the Arduino to the digital circuit;
- the square wave frequency that the Arduino should generate;
- the data analyzed by the test probe (voltage or pulsing signal);
- a checksum/hash to detect communication errors.

The three bytes sent from the software to the Arduino contain information about the logical level of each input generated from the Arduino, the square wave frequency and a XOR (eXclusive OR) byte, which is essentially the XOR operation on all the other bytes. The response from the Arduino to the software contains information about the logical level of each output generated from the digital circuit, the test probe signal information and also the XOR operation on the other bytes.

This XOR operation is a method of preventing data loss. It is not the most secure means, yet it is very simple and effective for simple applications. The option for simplicity in this case is chosen because the system must process communication very quickly. The analysis for the pulsing signal, which requires a fast processing time, is done within the hardware initially, before the Arduino can pass the information to the software. Therefore, if any data loss or bit-swapping occurs during communication, this information should be easily retransmitted on the next packet without the user noticing any difference in behaviour on the interface due to its fast speed (which is set to 115200 bps).

To keep track of when a packet starts or ends—in case an error occurs during communication—all the bytes have their high-order bit set to 0, except for the first byte, which has its most-significant bit set to 1.

	7	6	5	4	3	2	1	0
$byte_1$	1	bt_6	bt_5	bt_4	bt_3	bt_2	bt_1	bt_0
$byte_2$	0	bt_7	$clock_index$					
$byte_3$	0	$byte_1 \text{ XOR } byte_2$						

	7	6	5	4	3	2	1	0
$byte_1$	1	ld_6	ld_5	ld_4	ld_3	ld_2	ld_1	ld_0
$byte_2$	0	ld_7	$probe_value$					
$byte_3$	0	$byte_1 \text{ XOR } byte_2$						

Fig. 2. Data packet format. (Top) Packet received by the Arduino. (Bottom) Packet sent by the Arduino. *bt₇–bt₀* are the bits generated by the Arduino and *ld₇–ld₀* are read bits. The *probe_value* contains the voltage mapped from 0 to 50. A pulsing signal is any value above 50 (limited to 63 due to the 6-bit width).

D. Graphical User Interface

The GUI design is shown and explained in detail for better understanding (Figure 3).

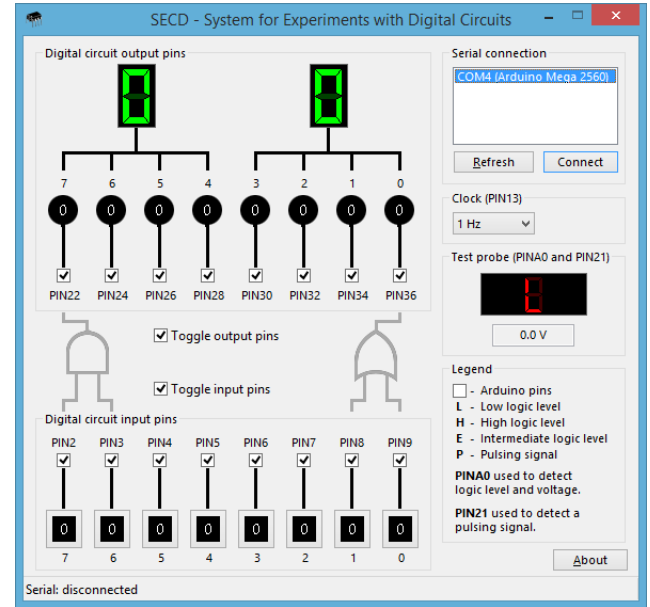

Fig. 3. The software when idle.

1) *Connection*: When the software is opened, it will check if an Arduino Mega 2560 is connected through the window shown in Figure 4. If an Arduino is connected or if the user connects the Arduino while the automatic search is executing, a dialog will ask if the user wants to do an automatic firmware upload if it is not already present, as shown in Figure 5. The user may cancel the automatic search and manually connect to a serial port, as shown in Figure 6.

Fig. 4. The automatic Arduino search dialog.

Fig. 5. The automatic firmware upload dialog.

³<http://www.nongnu.org/avrdude/>. AVRDUDE—AVR Downloader/Uploader Accessed on Apr. 12, 2015.

Fig. 6. The manual connection box.

2) *Digital Circuit Input*: These are the eight virtual buttons on the software as shown at the bottom of Figure 7. In this example figure, the button number '7' is pressed, sending a HIGH signal through PIN2 on the Arduino to the digital circuit. The user can toggle each pin to clarify which pins are being used in a project.

3) *Digital Circuit Output*: These are the eight virtual LEDs on the software as shown at the top of Figure 7. In this example figure, the LED number '4' is receiving a HIGH signal through PIN28 on the Arduino. The user can toggle each pin to not only clarify which pins are being used in a project, but also because the default state of every virtual LED is HIGH, so that it becomes less confusing. There are also two seven-segment displays for each four bits, showing an hexadecimal representation of these LEDs.

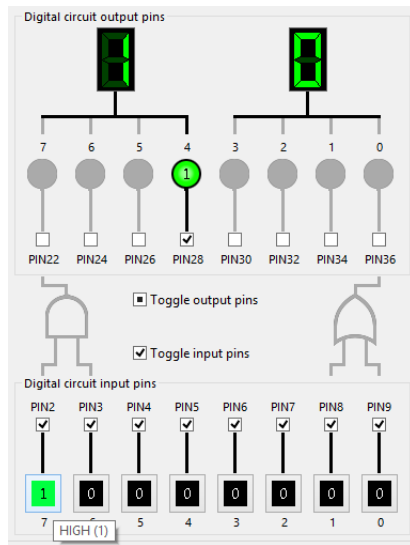

Fig. 7. The digital circuit inputs (bottom) and outputs (top).

4) *Clock Generator*: In Figure 8, the user can select an output clock frequency to be sent to PIN13 on the Arduino (0.5 Hz, 1 Hz, 10 Hz, 100 Hz and 500 Hz).

Fig. 8. The clock generator drop-down frequency list.

5) *Test Probe*: The test probe (Figure 9) can be used to read a voltage and to detect the type of signal anywhere in the circuit. PIN21 is used to detect a pulsing signal (displayed as P) and PINA0 to read a voltage and detect it as L for low, H for high, or E for indeterminate.

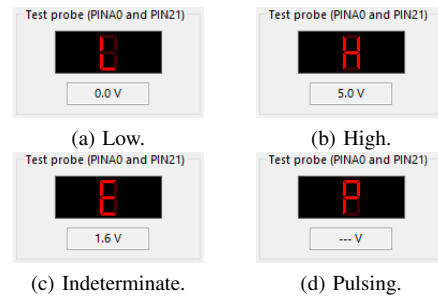

Fig. 9. The test probe box.

III. RESULTS AND DISCUSSION

The following subsections show the results obtained in the tests.

A. Signal Visual Delay

These two tests calculate the I/O visual delays using a *GoPro HERO3+ Silver Edition* video camera filming at 119.88 FPS (Frames Per Second). Note that this is a visual delay test—hence the decision to not only use a relatively high FPS camera but also to maintain simplicity and get a more practical and usable result.

The camera was set up to record both a computer screen and an *ATTEN ADS1102CAL+* oscilloscope in order to count the frames by a visual trigger between both devices.

To convert frames to milliseconds, the following equation was used:

$$delay_{ms} = \frac{1000}{119.88} \times delay_{frames}$$

1) *Software Output to the Arduino*: The values below are the delay length—in frames—for each output tested out of a total of 14. An output in this case is the change of a state button in the program, which sends a signal to the hardware part.

The delay counter starts when the software changes the state of a button after receiving a user command, and stops when the oscilloscope displays a change in signal.

LOW→HIGH	5, 9, 6, 2, 4, 9, 11, 9, 15, 9, 7, 11, 13, 12
HIGH→LOW	11, 6, 4, 5, 1, 3, 8, 15, 6, 10, 1, 8, 12, 15

It takes 72.6917 ms (8.7142 frames) on average to output a HIGH signal; and 62.5625 ms (7.5 frames) for a LOW signal. Therefore, the average output delay is approximately 67.6 ms.

2) *Software Input from the Arduino*: Once more, 14 tests were made for the input. 'Input' here is defined as the signal received by the software from the Arduino board.

The delay counter starts when the oscilloscope displays a change in signal, and stops when the software turns the respective virtual LEDs on.

LOW→HIGH	14, 4, 5, 16, 5, 6, 2, 6, 2, 4, 8, 2, 2, 1
HIGH→LOW	2, 8, 5, 6, 16, 6, 5, 2, 3, 3, 6, 1, 5, 1

It takes 45.8792 ms (5.5 frames) on average to receive a HIGH signal and 41.1125 ms (4.9285 frames) for a LOW signal. Therefore, the average input delay is approximately 43.5 ms. The largest value is 133.5 ms (16 frames), which is imperceptible to a human user.

B. Probe Measurement Accuracy

Using a *Hikari HF-3003S* adjustable DC power supply and a *Victor 88B* digital multimeter, we tested various voltage readings on 4 different Arduino boards. Knowing that our system was designed to display only one decimal place for the voltage, we set a resolution of 0.1 and obtained the results shown in Table I.

TABLE I. PROBE MEASUREMENT ACCURACY RESULTS. VALUES ARE MEAN \pm STANDARD DEVIATION.

Multimeter (V)	System's probe (V)	System's display
0.0	0.0 \pm 0.0	L
0.4	0.4 \pm 0.0	L
0.6	0.6 \pm 0.0	L
0.7	0.7 \pm 0.0	L
0.8	0.8 \pm 0.0	L
0.9	0.9 \pm 0.0	E
1.0	1.0 \pm 0.0	E
1.4	1.4 \pm 0.0	E
1.8	1.8 \pm 0.0	E
1.9	1.9 \pm 0.0	E
2.0	2.0 \pm 0.0	H
2.1	2.1 \pm 0.0	H
2.2	2.2 \pm 0.0	H
2.6	2.6 \pm 0.0	H
3.0	3.0 \pm 0.0	H

Considering the resolution of 0.1, it can be seen that the probe measurement error is negligible.

C. Probe Pulsating Signal Detector

Using a *Minipa MFG-4221* function generator and a *In-strutherm OD-275* oscilloscope to precisely measure the generated square wave, the system was able to detect frequencies starting from the 10 Hz mark. Below this mark, the test probe display periodically changes its state from LOW to HIGH, instead of detecting the signal as pulsating.

This is due to our detection code being used in the Arduino, as explained in section II-A. Therefore, it is a predetermined behaviour and limitation on the system. Any "pulsating" signal below 10 Hz is more likely to be a varying signal than a real square wave frequency.

D. Square Wave Generator Accuracy

Using an *ATTEN ADS1102CAL+* oscilloscope, for each square wave frequency the system can output and based on the readings of four different Arduino boards, the results obtained are shown in Table II.

TABLE II. SQUARE WAVE GENERATOR ACCURACY RESULTS. VALUES ARE MEAN \pm STANDARD DEVIATION.

System's clock (Hz)	O-scope's freq. (Hz)	O-scope's volt. (V)	Main time base (ms)
0.5	0.49725 \pm 0.000433	2.40 \pm 0.0	800
1.0	0.99600 \pm 0.0	2.40 \pm 0.0	800
10.0	9.87375 \pm 0.149389	2.46 \pm 0.034641	40
100.0	99.5500 \pm 0.0866025	2.46 \pm 0.034641	4
500.0	497.625 \pm 0.216506	2.46 \pm 0.034641	0.4

The average accuracy error for the measured frequency is 0.6275% with a standard deviation of 0.32117%, which is sufficient for this application.

IV. CONCLUSION

This paper presents a low-cost system, consisting of an Arduino (US\$ 45) and an application to be used in practical experiments with discrete digital components.

It is reasonable to assume that the main goal of a first course in digital circuits is to present important concepts and to fix them in the students' minds through experiments that motivate and spark interest in them, rather than presenting the latest technology in implementing digital circuits, such as FPGAs. Furthermore, a beginner student typically implements simple digital circuitry, and thus the main advantages in using FPGAs begin to diminish. Therefore, it is believed that the use of FPGAs is of great importance, but mainly so for more advanced courses on digital systems. For a first course, it is believed that the use of discrete components and the developed system shown here is a better solution.

The tests performed in our system showed satisfactory results, considering the application in question. The delays presented by the system are virtually imperceptible to a human user, who sees the changes in logic levels as instant changes, both in signal generation and reading.

Hopefully, this work has contributed to the teaching of digital systems in starter courses, with its advantage of being a low-cost alternative.

The Exploration for Computer System Capacity Training in Experimental Teaching

Li Shan-shan, Quan Cheng-bin, Chen Yong-qiang

Department of Computer Science and Technology

Tsinghua University

Beijing, China

lishanshan,quancb,chenyongqiang@tsinghua.edu.cn

Abstract—Computer system capability is an essential capability for the computer professional undergraduate students, and the system capacity training becomes an important target for the computer professional education. Computer system design experiment is the key method to achieve this target. This paper introduces the exploration in training computer system capability of the Dept. CS&T Tsinghua University, which establish a series of course experiments to form a computer system experiment. This paper focuses on the experimental teaching, from the course contents adjustment to course experiments integration, to achieve an experimental teaching system for system capacity training. And this paper presents some key points for the computer system experiment, and gives a sample experiment embodiment of the computer system experiment for the computer system capability training.

Keywords—Computer System Capacity; Experimental Teaching

I. INTRODUCTION

For the computer professional students, the systematic view of the computer system becomes more and more important. In their eyes, the computer should be a completed organic whole which can work coordinately, not just the software or hardware part working separately.

In Computer Science Curricula 2013(CS2013), the System-level perspective becomes one of the expected characteristics of the computer science graduates. It requires the graduates of a computer science program think at multiple levels of detail and abstraction. This understanding should transcend the implementation details of the various components to encompass an appreciation for the structure of computer systems and the processes involved in their construction and analysis. They need to recognize the context in which a computer system may function, including its interactions with people and the physical world.[1]

In China, the Guidance Committee of Computer Professional Education of Ministry of Education also requires to enhance the system ability training in computer education and practice. It listed four main abilities of the computer professional, which are computational-thinking ability, algorithm design and analysis ability, program design and implementation ability and system ability. The system ability includes system cognition, system design, system application and system implementation.[2]

In order to meet these requirement, computer professional students are required to have the capabilities of the system design and system application. These capacities requires the students to master basic computer system knowledge, understand the interaction between computer hardware and software systems. It is just the computer system capacity training requirements.

The computer system capacity is a comprehensive ability, which includes the use of the system level view consciously, understanding the integrity, relevance, hierarchy, dynamic and opening of the computer system, and also requires the students be able to use a systematic approach to master the collaborate of the computer hardware and software, understand the mechanism of interaction between them[3].

In order to meet the needs of computer system capacity training, the core courses of the computer science undergraduate curriculum system should be adjusted to make the correlation between the course content closer, and let the courses connections smoother. Similarly, the experimental teaching of these courses should be carried out around the computer system capacity training. It requires the course experiments connected seamlessly, that is the course experiment should undertake the content of the previous course experiment and at the same time prepare for the subsequent course experiment. Thus all these experiments will eventually form an integral experimental teaching system.

In China, many universities have made attempt for system training target. Nanjing University and Zhejiang University reforms the curriculum to link the related courses content to form a system course, which has been carried out for several years. The students' system ability have been improved greatly.[4][5] And University of Electronic Science and Technology completed a demo computer hardware platform, which can support a simple educational computer with a monitor program. On it the student can design and implement a open CPU, and the student have made more deep understanding of the principle of the computer hardware.[6] But these reform only focus one aspect of the computer system, software or hardware, lack of whole computer systematic level consideration.

II. EXPERIMENTAL TEACHING IN SYSTEM

The experiment or practice training is an important method to help the student to understand the knowledge of the courses. In the CS2013 the Project Experience is listed as the characteristics of the computer science graduates. It mentions that all graduates of computer science programs should have been involved in at least one substantial project. Such projects should challenge students by being integrative, requiring evaluation of potential solutions, and requiring work on a larger scale than typical course projects. Students should have opportunities to develop their interpersonal communication skills as part of their project experience[1]. The experiment of computer system is a good project for this requirement, which need the students to complete by team work and is an integration practice of several courses in experimental teaching .

The current computer curriculum system includes a large number of computer systems related courses, such as Digital Logic Circuits, Assembly Language, Computer Organization, Computer Architecture, Compile Theory, Operating Systems, Embedded Systems, etc. Each of these courses has its own separated experiment contents, but these experiments are not good or enough for helping students to build systematic knowledge of the computer hardware and software systems. Through these courses learning and experiments practice, the students have in-depth understanding of the subsystem introduced in these courses, but they have not such understanding on the interaction between the various subsystems of other courses or on how these subsystems integrated to one computer system. That is the students have not really grasp the computer knowledge in systematic level.

The main reasons for this situation we think are the following two aspects:

(1) In the teaching process, these courses are planned and carried out independently. And these courses emphasize the integrity and systematic for their own self-knowledge system, thus it causes the redundancy of the knowledge, and meanwhile it also leads to insufficiency of the interconnection content between the consequent courses, so it is difficult to form a complete computer system knowledge system for the students.

(2) In the experiment process, these courses focus on the study of their own content, so the experiment is lack of the continuity of the leading course experiments, as well as the supports for the subsequent course experiments. And most of the experiments are mainly the simple verification of the principle, lack of the practice for complex integrated system design.

Computer experiment teaching is an integrated process, which need high correlation between the courses. The experiments need overall planning from the systematic level, in order to effectively develop and training students' ability in computer system capabilities[4]. Therefore it is demanded to adjust the experiment teaching system.

First of all, on the teaching principle, the courses should focus on how to improve the level of the system capability training. Based on the idea of "Focus system, Emphasizing

experiments, Building capacity", the related courses should adjust the courses' content to fit for the system level teaching.

Second, experiment teaching content need to be planned unified, in order to set up a complete knowledge system on systematic level for the students, from the underlying hardware to the operating system and the compiler, to form a complete experimental teaching system.

Furthermore, it is needed to establish a unified teaching experiment platform, thus each course experiment will be on the same implementation carrier, which is helpful for the coherence in these experiments, and also convenient to carry out the experiments.

Finally, the target of the experiments is that the students can design and implement an educational computer system, which is based on a certain instruction set, and on it they can run an operating system kernel and implement a compiler for this system. The computer hardware, OS and compiler are all implemented by the students themselves. Through the practice on this system experiment, the students will comprehend the computer on systematic view and the system capability will be improved greatly.

III. COMPUTER SYSTEM EXPERIMENT

In order to make up the deficiencies of the students system capacity in the teaching of computer professional courses, the Guidance Committee of Computer Professional Education suggests several universities to attempt the system experiment project, in order to explore an approach on the integration of course experiments using the methods of the engineering education, to form a systematic experiment of the computer professional. The computer departments of Tsinghua University, Beihang University, Zhejiang University, etc all joined this project, and have made some progress in the exploration process.

In Tsinghua university, the Computer Experiment Teaching center is the National Demonstration Center[7], in order to achieve the objectives of the system experiment, we made following changes in the system related courses and experiments: adjust and optimize the courses content, integrate the experiments, design the experimental system and develop the experiment platform. In the past three years, we continuously improve our system experiment, and gradually formed a prototype of the experimental teaching system for the goal of system capacity training.

A. Planning Experimental Teaching Unified

Based on the computer professional curriculum system, we analyzed the knowledge points of each courses related to the system experiment, and listed the overlapped teaching content in each courses, found back the connection content missed before between the consequence courses. In the teaching process, these courses are planned unified and cooperated with each other.

The computer system experiment mainly involves Digital Logic Circuit, Assembly Language, Computer Organization, Operating System, Compiler Theory, these five courses. In order to meet the requirements of the computer system

experiment, the experiments of these courses were analyzed and adjusted, focusing on the interconnections of the contents between the course experiments. The detail adjustment contents is shown in Table I.

These adjustment of the entire experiments is intended to link up the experimental teaching contents in each courses to form a complete computer system experiment. This system experiment will strengthen the training of computer system capability.

B. System Experiment Design

The computer system experiment is a complex system level experiment. The students need to design and implement a complete computer system. They should complete several stages in each course, and in the Computer System Design

TABLE I. ADJUSTMENT AND OPTIMIZATION IN EXPERIMENTS

Course Name	adjustment or optimization content
Digital Logic Circuit	<ol style="list-style-type: none"> 1. Strengthen the experiments of using programmable logic device, including gate level to component level design 2. Emphasis on the experiment of the computer component. 3. Learn how to use the corresponding EDA tool for complex system design.
Assembly Language	<ol style="list-style-type: none"> 1. Introduce the assembly language as the interface and connection of the hardware and software system. 2. Add MIPS instruction set experiments, including interrupt and exception handling, virtual memory management, etc. 3. Add the experiment of typical C code expressed in assembly language level and the disassembly experiment.
Computer Organization	<ol style="list-style-type: none"> 1. Design and analysis of instruction system based the MIPS instruction set 2. The design and implementation of a simple computer systems, in which the CPU at least supports the subset of the designed instruction set with Multi-cycle or pipelined. 3. The designed CPU should support interrupts, including soft interrupt and hardware interrupt. 4. Add the TLB experiment of the virtual memory management.
Operating System	<ol style="list-style-type: none"> 1. The designed instruction set / processor in Computer Organization course is the target platform of the operating system. 2. Strengthen the combination of operating system theory and experiment. Require to complete a simplified mini OS that can be able to work on the real hardware platform. 3. Emphasize that the core algorithms of each experiment can form an organic whole. The experiment will use its previous experiments code, and eventually form a complete small operating system.
Compiler Theory	<ol style="list-style-type: none"> 1. The designed instruction set / processor is the target platform of the compiler. 2. Implement a compiler that supports the experimental platform used in previous courses. 3. Add the experiment of optimization for the specific experimental system.

course they will eventually integrated previous experiments to form a complete computer system. So, the relevant courses should adjust the experimental system and experimental content, treat their own experiment as the module or base of the final comprehensive system experiment.

Assembly Language and Digital Logic Circuit is the experimental foundation courses, providing an experimental basis for other courses; the experiments of Computer Organization, Operating System and Compiler Theory will become the parts of computer systems. The experiments of Computer Organization will implement the basic hardware, and Operating System experiments will be the software parts. The following are the experiments of these two courses.

The experiments of Computer Organization will implement the hardware part of the system experiment, with three-level experiment contents: verification level, design level and comprehensive level experiment content. The final experiment is to design a computer hardware which can run an assembly program called monitor program that can manage the hardware resources of the experiment platform.

Lab 1 (Instruction Set Lab). This is a verification experiment, writing the assembler language programs in the simulator using the instruction set for the designed CPU. This experiment is in order to let the students be familiar with the instruction set and understand the function of the simulator and monitor program.

Lab 2 (Component Lab). Design and implement the ALU. Let the students learn the basic ALU design methods and data path, and to be familiar with the hardware experiment platform. The designed ALU will be used as important component of the CPU in the following experiments.

Lab 3 (Memory& IO Lab). Design a state machine to access the memory and IO on the platform. It is a design level experiment, which will help the students to comprehend the memory access timing and learn how the data exchanged on the bus.

Lab 4 (Hardware System Lab). Design and implement a complete computer hardware system on the platform, and the monitoring program can run upon the designed hardware CPU core. A data transfer program will load the binary code of the monitor program directly into the memory, and then the designed computer will run the monitor program, which will communicate with PC. This experiment is a comprehensive experiment that allows students to learn how to design an underlying hardware of the education computer, and this computer should support the OS in the Operating System course.

Operating system is the basic software in the computer system, and it is tightly integrated with the hardware[8]. In order to support the hardware designed in Computer Organization, Operation System course's experiments were based on ucore OS and transplanted to the new platform[9].

Lab 0 (experimental operating system environments and tools).It aims to let the students understand and become familiar with the tools and process in the whole course experiments, including kernel debugging, simulator, etc.

Lab 1 (startup process). It will implement the bootloader for loading and running the operating system, in order to understand the process of starting the bootloader, bootloader's files, the boot process of the ucore OS, and interrupt handling mechanism.

Lab 2 (physical memory management) & Lab 3 (virtual memory management). These labs will help the student to understand how the system manages the memory.

Lab 4 (kernel thread management)& Lab 5 (user process management)& Lab6 (scheduler)& Lab 7 (synchronous mutex). These labs will help the students understand the process of the kernel thread creation and execution, and understand how to implement the context switching.

Lab 8 (File System). It requires the students to understand the file system and its implementation technique.

After these labs, the students will grasp a simple operation system of ucore in the simulator, and in following course they will run it on their designed hardware.

C. Experiment Platform

The unified planned system experiment needs a unified platform to support the experiment deployment. This platform need to support each course experiments, and can support the comprehensive computer system experiment as well. The platform includes not only the actual hardware circuit board, but also the software tools, which contains the debugging tools, simulator, assembler, compiler and other tools. All of the platform should support a simple, standardized instruction set. So we choose about 50 MIPS like instructions as our instruction set, and designed the circuit board, named THINPAD(TsingHua mINi PAD)[10], as the hardware carrier. We also developed some software tools, including system simulator, assembler, compiler, terminal program and etc. And we have run the teaching operating system ucore on this platform. In addition, the corresponding compiler was developed. The program generated by this compiler can be run in the ucore. Thus the system experiment platform was established and has been used in the course experiment teaching.

1) Hardware platform.

Fig. 1. Example of a figure caption. (figure caption)

The figure 1 is the composition of the hardware platform. The circuit board uses the programmable logic device as the experiment carrier. This programmable device is a FPGA, which is the experiment chip that will act as the CPU of the experiment computer system. The students need to design and implement a CPU using the EDA tools, and configure the design into the experiment chip. The platform provides two separate memory sections(Base Memory and Extend memory), act as the instruction memory and data memory. The flash is used to store the operation system and RS232 interface is the input/output of the experiment computer. And there are several peripherals to help debugging, such as LEDs, switches. these devices like SRAM memory, Flash memory and other peripherals are all connected to the experiment chips via several buses.

2) Software tools

For the system experiment and the hardware platform, we developed several software tools to help the students completing the experiment. The following is the main tools:

a) *Instruction simulator.* This simulator can help students complete software simulation and debugging. The students can use this simulator debug their assembly program, avoiding directly debug on the hardware platform.

b) *Assembler.* This assembler can convert assembly language to binary code of the hardware platform. This tool can help the student to write some simple assembly program for their designed computer system.

c) *Data communication program.* This program can load/store the data or program into the memory/Flash on the board.

d) *Monitor program.* Before running the operating system on the hardware, this program is a relatively complex program which can be a preliminary test on the hardware system implementation. It can work as a mini operating system to manage the platform's resources and testing programs.

e) *GCC compiler.* As the operating system is written in C, the GCC compiler can compile the operating system to the instruction set. Of course, this GCC compiler was modified for experiment platform, and it only used for the operating system (ucore) compilation.

f) *Hardware simulator:* This simulator is a hardware simulator which is specifically designed for our experiment CPU. In this simulator, the student can get the signal value of the designed hardware.[11]

D. Computer System Design Course

In order to integrate the experiments of system related courses, we add a new course in the curriculum called Computer System Design course, which is an experimental opening course. This course has been selected as the Challenging Courses of Tsinghua University.

After completion of previous courses, the students will use the knowledge learned in Digital Logic Circuit, Assembly Language, Computer Organization, Operating System and

Compiler Theory, etc. to design and implement an integral simple computer system independently in this course. It will improve the students' problem solving skills and the computer system capacity.

E. Experiment Process and Evaluation

The system experiment involves several courses' experiment. In each course, the students need to finish a part of experiment which will be prepared for the next course experiment. As the system experiment is very complex, so it need the students to complete in team work. They will keep working together in the whole system experiment, which will improve their communication and collaboration skills.

The final experiment evaluation contain two aspects:

One is on-site checking, the teams need to show their experiment to the teacher or TA, that is running their experiment computer on the platform. The teacher or TA will check whether they have implemented the basic function required and validate whether their computer can run the operation system (ucore) and the testing programs successfully. And if they have completed some additional functions, they will get some extra points on their scores. At last the teacher or TA will give an evaluation result of their experiment.

The other is presentation, each team will give a presentation to other teams, and these teams will give a evaluation result for this presentation. Because the students doing the experiment together, they will know each other more clearly. And the presentation will improve their express ability.

Thus, Combined these two evaluation result, our evaluation will be relatively fair.

IV. ACHIEVEMENTS

The computer system experiment has gradually carried out in the undergraduate teaching of the Department of Computer Science& Technologies, Tsinghua University. The teaching experimental platform has been used in the course experiments, and got good results. Some students has completed the system experiment: the ucore has run on their

Fig. 2. Computer system implemented in experiment

designed CPU, and some applications can be compiled by their own compiler and running successfully in the system. After complete the real first computer system, the students have an enormous sense of achievement. Figure 2 is a computer system implemented in the experiment course, which is running a slide shown program.

Through the computer system experiment, the students generally reflect that they understand the computer system more deeply and this experiment is good for their comprehending the knowledge in these corresponding courses. All courses use the unified experiment platform brings more convenient for the students experiments. The computer system experiment gave them a platform to use their knowledge and skills, and it helps them get more profound understanding of the mechanisms and principles of computer system.

V. SUMMARY

Computer system capacity training is an important target for computer undergraduate teaching, in which experimental teach plays an important role. Dept. CS&T Tsinghua University explored several years on it and established an experimental system, which has been deployed and got some achievement in the teaching process. Through this experimental system, the students' computer system capability has effectively improved.

ACKNOWLEDGMENT

I would like to recognize LiuWei-dong for guiding us on the experiments of Computer Organization, Xiang Yong for guiding us on the experiment of Operation System, Wang Sheng-yuan for guiding us on the experiment of Compiler Theory, Liu Cong, Wang Ning-ping, Jia Kai for implement the system experiment.

Helping Undergraduate Engineering Students Discover Their Interests (and Reduce Their Fear of Research)

Mary R. Anderson-Rowland, Armando A. Rodriguez, Anita E. Grierson
Arizona State University

Mary.Anderson@asu.edu, aar@asu.edu, Anita.Grierson@asu.edu

Abstract – In recent years, there has been an increased emphasis on undergraduate research. High tech companies need research to keep them competitive. This paper addresses the issue of getting engineering and computer science students interested in focused engineering and computer science areas so they are excited about these topics and want to learn more by doing research in that area. Our method is to encourage the student to research and write an interest paper as a first step to writing a proposal to seek and do organized research. In order to evaluate this approach, a survey was completed by 57 students in an Academic Success and Professional Development class who were assigned the writing of an interest paper in engineering or computer science. Results show that the assignment was successful for some students in leading them to an area of research in which they were interested and in other cases learning that they were not that interested in a particular area. Other students found a second interest. In this assignment, some students used an engineering data base for the first time.

Index Terms – Undergraduate Engineering and Computer Science Students, Research, Increasing Interest in Engineering Topics

I. INTRODUCTION

In the past, most undergraduate engineering and computer science students would earn a Bachelor's degree and go to work in industry without having interests in any particular subfields or having done any organized research. However, in recent years, there has been an increased emphasis on undergraduate research. Companies relying on good research to keep them competitive want students who are interested in their type of work and research. Although students used to use internships to help determine their interests, many company recruiters are now asking perspective interns about their interests. Some recruiters do not pursue students who do not know what interests them.

This paper is written in the context of an upper division Academic Success and Professional Development two

semester credit class with 66 students. The class is supported through an NSF S-STEM grant 1060226 and STEP grant 0856834. The course is taught within the Ira A. Fulton Schools of Engineering at Arizona State University (ASU) and includes all engineering majors, as well as computer science. Henceforth in this paper the term "ENGR" will include engineering and computer science. The students who attend this course are S-STEM and STEP scholarship students, transfer students directed by academic advisors, and students who have heard of the course from friends or by general word-of-mouth. The course credit does not count on a Program of Study, but the grade does count in the GPA.

The students are taught academic, professional development, and management-like (soft) skills that are often times left out of normal class sessions due to time constraints. These topics include: detailed time management, learning how to learn through the Guaranteed 4.0 Plan [1], career planning, how to prepare for and work a career fair, portfolios, internships, graduate school, and research. Although the authors are convinced that doing research is good for all ENGR students, it is difficult for many students to get involved in research because they do not know what really interests them, they do not understand what research is, and they believe that they will never have to do it. If a student is interested in a particular topic, it follows that s/he will be much more likely to want to learn more about that topic, schooling becomes more relevant, and the student is more likely to be retained. The Academic Success students are taught that "if you don't decide on an interest, someone else (industry) will decide for you, and you may not be too excited about their choice." Our emphasis on research is to help a student find a career doing something about which they are challenged and excited.

A majority of students in this class are upper division transfer students from local and rural community colleges. Many of these students only recently decided on engineering and do not have any particular interest areas. For most of these students, research is not in their background. For many, the transition to a large university is challenging and survival is on their minds, not particular engineering interests. Although talking about interests and research may motivate some students to pursue a research project, getting students actually

involved in research has proved to be difficult. Being able to come up with a new technique, a new idea, or an improvement on an idea seems overwhelming to most students. Encouraging students to talk with professors whose work interests them seems to be difficult since the student doesn't know what interests them. This is true even if they are instructed that just comparing two different ways of solving a problem can be "research." Along with a fear of not being able to do anything new, there is also a general attitude of "I did research once and I don't like it." Upon examination, the authors learned that usually the student was not really involved in research, but was merely a project helper and was not given anything meaningful to do. The authors have tried to engage the students in research by assigning them a research paper or proposal, with references, and giving them an outline on how to write it. [2] For some students this was overwhelming and they dropped the class rather than having to write such a paper. In fall 2014, a different approach to the assignment was tried by calling the assignment an "interest paper" and relaxing the requirement that the student propose a new research step at the conclusion of the paper.

A survey was given at the end of the semester to the students to determine if the new assignment was helpful. The survey asked if the assignment helped the student to learn to find engineering references and to find or to change a particular engineering interest. The students were also asked for suggestions on assignment changes that would help the student. As expected, the outcomes are mixed, but the majority of the class found the assignment to be useful and some students were able to find an interest.

A literature search to highlight work that has been done on undergraduate and graduate students doing research is included.

II. Background

A question that is commonly asked by students is why should I have to do research? I don't plan to go to graduate school. I plan to get a job in industry and I don't expect that I will ever do research. As an answer to these questions, we talk to them about research and why it is likely to be a part of their life someday as ENGRs.

Student involvement in research is good for ENGR and it is good for the individual student. It is good for ENGR in that students who become interested and involved in their major are more likely to stay in their major. [3] Research can be part of a retention strategy. If a student becomes involved in research in an area that is interesting, challenging, and fun, that student is very likely to stay in engineering and go on to graduate school.

However, our emphasis in the course and this paper is to help the student understand the advantages of learning how to do research and to actually do research.

For students going on to graduate school, research seems to be a reasonable activity in which to become involved as an undergraduate. Certainly students understand that if they seek a PhD, they will have to do original research. If students can become involved in research with a professor as an undergraduate, perhaps that research can continue into graduate school for the student and the research work can be funded and pay for graduate school. If the student finds an area in which they are interested, then this may take care of two major graduate school concerns: a topic and funding. Students doing a Master's degree with a thesis, report, or applied project, are ahead of the game if they have identified a research area before they begin graduate school. We recognize that doing research is not a prerequisite for a Master's degree. Many colleges and universities have a pathway to the Master's degree that requires some 30 hours of appropriate credit hours of classes and then a written comprehensive exam in lieu of a thesis or thesis substitute. Becoming involved in research early can also be very helpful for the Honors College student who writes an honors thesis. Knowing how to do research and finding areas of interest can make the writing of a thesis easier.

Another advantage of research is that there are research awards to help fund undergraduates and graduates. At ASU, for example, we have FURI (Fulton Undergraduate Research Institute) awards of \$1,500 per semester. Students find a faculty advisor (who advertise on the web that they are willing to work with undergraduate students in certain areas of research), write a proposal, and, if selected, obtain funding for approximately 10 hours of work per week during the semester. [4]

There are many other advantages of doing research. Having done research and having publications make a strong resume to help in obtaining an internship or job hire. Research and publications are considered minimum requirements for some graduate fellowships and scholarships. We have seen our students singled out for an interview and position because the research listed on their resume complements a research area of the industry or graduate school.

Having done research either as an undergraduate or as a graduate student should also help the student to be able to do more research in their career, if they desire, in industry, government, or a lab. Research is good training for industry. Companies are always looking for better ways to do things. When an engineer puts forth ideas on how something can be improved, he/she will need to do research to understand the status quo, what other ideas have been tried, and show that the suggested improvement is viable. Engineers may be given an assignment for which they do not have much background. They may need to do research to learn more about the project and to determine what solutions are already available.

Research is fun. The excitement of new discovery, of using your background to develop something new and helpful to

people, is fun and exciting. Our students give testimony to this over and over and make excellent role models for others students to follow.

III. Literature Review

Amekudzi and Meyer [5] develop research and information skills in Civil Engineering undergraduate students through a 300-level course that they teach. They emphasize the importance of students gaining information knowledge and skill sets through information structure, information access, and information integration. These skills are needed for the students to be able to write a paper on comparative systems analysis with project examples. The authors learned that students are eager to learn where and how to find scholarly or authoritative information if opportunities are provided for them. They also suggest that “to benefit every student, it is would be helpful for some students, especially transfer students, to attend a library basic introductory class before coming to the course-specific information workshops. [5] They note that their methods are applicable in any area of engineering.

Another paper along these same lines was written by Rockland. [6] “Because of the vast amount of data currently available, students need assistance developing an approach to gather this information. Without a proper plan on how to obtain information, they will waste countless hours, and become very frustrated at the process.” [6] The paper suggests a hierarchy in using various methods, depending on the type of search required. The author suggests that for general technical information, students check the *National Engineering Information Center*, which is part of the ASEE website (www.asee.org/neic). Additional sites are also recommended. Specific insights are given for product information, company searches, patents, mathematics, and biomedical engineering. [6]

There are several ways for students to actually get involved in research. One common way is through summer research programs such as the Research Experience for Undergraduates (REUs) sponsored by the National Science Foundation at universities across the nation. This is a great experience for the students, but may be an actual “brain drain” for minority-serving institutions. Summer research programs certainly benefit the host institutions in terms of research done at that time and the potential to bring the participants back as graduate students. On the other hand, for minority-serving institutes this may be an “erosion of the capacity to develop talent.” [7] It should be noted that, in general, there are many more applications than positions for these awards.

How to prepare students for engineering research is a problem of broad concern, without much research on the subject. For example, at a Software Engineering conference, a session was held entitled, “Preparing Students for Software Engineering Research.” The discussion included the needs of industry and

the preparation of graduates for professional careers, as well as how to support students who plan to do research in a particular area. [8]

Rogers and Goktas explored the research proficiency of engineering graduate students. In 2007, more than 25 percent of PhD students did not complete their program, suggesting that research for them was not a good experience. Although many reasons can be given for this attrition, lack of written and communication skills, inadequate mentoring, and barriers for certain underrepresented demographic groups, and little attention paid to the actual research experience are included. [9] They administered a survey for two years to both master’s and PhD students. Their primary conclusions were that “many students indicated that they lacked research preparation upon beginning graduate study and during the first year of study, lacked development in important research skills like statistics and communicating in writing, and were somewhat hindered in research organization and progress. Regarding academic motivations, students generally valued personal advancement and enrichment over paper publication. Doctoral students overall indicated more preparation with respect to several aspects of research and more value placed on paper publication than did master’s students.” [9]

A team of researchers looked at student’s beliefs about research, relative to sex differences, personality, and career plans. They were particularly interested in learning if understanding how students consider research could explain the low percentage of women in undergraduate engineering programs and academia. [10] Woodstock, Graziano, et. al looked at Person-Thing Orientation which has been shown to be a factor in gender differences of vocational interest. [11] In addition, Thing Orientation has been found to be a dispositional predictor of persistence in engineering. [12] Woodstock’s team surveyed 297 engineering major students. They found that there was no statistical difference between men and women in the percentage of Person Orientation. [10] However, there was a statistical difference between men and women in that a larger percentage of men had Thing Orientation. A second conclusion of their research was that “engineering students’ beliefs and expectations about research and researchers will be associated with their desire to pursue a research career” and that “Thing Orientation will influence students’ beliefs and expectancies about research.” [10]

Studies have also been done on the effect of research on the student including self-efficacy, satisfaction with the major, confidence, motivation, recruitment, and retention. For example, Ragusa and Lee [13] showed that focused degree projects resulted in increased efficacy in the area, as well as increased student satisfaction, and increased student retention. Seevers et al [14] showed that undergraduate research and internships increased student confidence and motivation. Further, Rabb, Nowicki, and Bristow showed that

early research experience had an impact on recruiting and retaining students in engineering. [15]

While these studies are related to our study, it should be noted that when we speak of a student with an interest area, we do not imply that the student is necessarily interested in a career in research.

IV. The Survey/Methodology

We built our survey using grounded theory. We have worked with upper division ENGR students for 13 years. During these years we have had many conversations with these students about their reasons for choosing and staying in ENGR. In addition, we have researched and surveyed ENGR students over these years. For example, we know that a third of our community college (CC) transfer students only decided on ENGR after they were at the CC. [16] We also know that next to lower tuition and proximity to home (to save money on room and board), not having decided on a major is the largest reason for attending a CC. [16] A major goal of our work with these students is to graduate them and to have them go right on to graduate school. Our efforts with both native and upper division transfer students have resulted in a current graduation rate of 95% and a rate of 50% for students going directly to graduate school in ENGR (rather than a 70% graduate rate and about a 12% graduate school attendance rate for upper division transfer students). A part of the success has been due to our stress on the importance of research and graduate school.

The students in the Academic Success and Professional Development class were asked to complete a survey in order to evaluate the assignment of writing an interest paper. Of the 66 students in the class, 57 (86%) of the students responded. The purpose of writing an interest paper was to help students define a special area of interest to help guide their career. The students were asked to research and to write a paper about an interest of theirs, but were not required to propose actual new work as in an actual research proposal. We note that writing an interest paper is not “doing real research” in the traditional sense, but it is hopefully getting students interested in new areas and to think about doing research.

We asked the students several demographic and background questions, including their participation in internships, research, and intent to go to graduate school, since this is an emphasis of the Academic Success Class. Relative to the interest paper, we wanted to know if the student had an area of interest before writing the paper, and if not, did the interest paper help to define an interest area. We also asked if the paper helped define an interest area for the first time, defined a new interest area, or the student discovered an area in which there was no interest. We also asked for suggestions on improving the paper assignment. The last two questions were how important the student thought it was to find at least one area of interest as soon as possible and how the student would

judge the interest paper assignment relative to their professional development.

V. Analysis of Survey

Some students did not complete each question, so the number of responses per statement varies. Of the 57 students who completed the survey, 10 (17.5%) of the students were females. Forty-five (78%) of the students were transfers. The distribution of students by academic level were: 11 sophomores, 25 juniors, 13 seniors, and 8 graduate students. Most of the “sophomores” were transfer students who were in at least their third year of college, but who were considered at the sophomore level in regard to engineering courses. The average age of the students was 25 with a range from 19-49 years. Twenty-seven (47.4%) or nearly half of the students had had an engineering or computer science-related internship, most of them during a summer.

We then asked the students how many semesters they had been at ASU and for how many semesters they had taken the FSE 394 Academic Success Class. Also included in this count were semesters spend in a similar one credit Academic Success Class for lower-division students, primarily native students. The results of this tally are shown in Table 1. It should be noted that most of the transfer students start this class in the fall which is their first semester at ASU, although a few postpone the Academic Success Class until their second semester at ASU. A few transfer students start ASU and the success class in the spring. For these reasons, there are fewer students at the second and fourth semester level. Note that only 23 of the students were in their first or second semester of the class and thus writing their first interest paper.

Semesters	1	2	3	4	5	≥6	Total
Number Students At ASU	13	2	12	2	14	14	57
Number Students in Class	17	6	15	0	8	11	57

Table I. Semesters at ASU and in Academic Success Class of Survey Takers

To the question, “Have you done Research?” Forty percent (23) of the 57 students said yes. Seven of these 23 students had published a paper (4 graduate students and 3 undergraduate students). Table II shows the type of research setting for the students. The WAESO research grants are offered regionally and each student team must include at least one underrepresented minority student (Black, Hispanic/Latino, Native American). It should be noted that several of the 23 students who did research had more than one research experience; hence the number of experiences is more than the number of students who had done research.

Type of Research	Number of Students
Fulton Undergraduate Research Institute (FURI)	10
Lab	8
Western Alliance Expanding Students Outreach (WAESO)	5
Research Experience for Undergraduates (NSF REU)	2
Other: Independent or based in Industry	7
Total	32

Table II. The Number of Research Type Experiences by the 23 Students Who Did Research

Next we looked at the number of students who did research according to the number of semesters at ASU and the number of semesters in the Academic Success Class. Table III gives these statistics.

Semester	No. Researchers per Students at ASU	Number Researchers per Students in Success Class
1	3/13	4/17
3	4/12	7/15
5	6/14	3/14
≥6	10/14	9/11
Totals	23/53	23/57

Table III. Number of Students Doing Research According to Semester at ASU and Semester in the Academic Success Class

There were no students doing research that were in either their 2 or 4th semester at ASU or in the Success Class. In general, we see that the longer the students are in the class, the more likely they are to do research. The students hear about getting interested in a topic, doing research, and going on to graduate school continually throughout the Academic Success classes.

As part of the class assignments, the students are told to visit an engineering librarian to learn how to access ENGR data bases if they do not already know how. For the interest paper assignment, they need to have 10 references. Using data bases will help the student find more appropriate references, but a student could find references through Google or other means. We asked the students if they knew how to access engineering data bases before they wrote the interest paper and if they knew how to do this after they had written the paper. Table IV shows the results.

Know how to access engineering databases?	Yes	No
Before interest paper	35	20
After interest paper	50	3

Table IV Number of Students Who Knew How to Use an Engineering Database to Find References “Before” and “After” The Interest Paper

Looking at Table IV, it is clear that we were successful in having almost all of the students understand how to access information through an ENGR data base. Only 3 of the students still did not understand this activity after the assignment. It is surmised that these students did not take the time to visit the engineering librarian. Two of the papers [5, 6] in the literature review emphasized that students need help in this area.

Next we wanted to learn if the assignment helped students find an interest area for the first time, or found an additional interest, or determined an area in which they are not interested. Seven of the students who said that had no area of interest in ENGR, said that they had an interest area after the paper assignment. Other good results from this exercise are that 21 students learned of a new area in which they are interested and 9 students learned of an area in which they are not interested. See Table V for details.

Have an area of interest in engineering or CS?	Yes	No	No Response
Before interest paper	41	15	1
After interest paper	46	8	3
Helped find an additional interest	21	35*	1
Learned of an area in which they are not interested	9	46	2

Table V. Number of Students Who Have Interest in One or More Areas of Engineering or Computer Science

*One of these students went into more depth in area of interest

As an additional check on the students’ interests, they were asked if, at the time of the survey, they had an area of interest in ENGR (independent of an interest paper). Only 6 students said they did not. Most of the students (87.5%, 49/56) intended to go to graduate school.

The students were asked if the interest paper assignments could have been better constructed to better help the student find an interest or additional interest area. See Table VI for the results.

	No	Yes	No Response
Better Constructed?	40	15	2

Table VI. Student Responses to the Question: Could the Interest Paper Assignment Have Been Better Constructed to Better Help Find an Interest or Another interest?

Although 70% of the students seemed satisfied with the assignment as given, it is interesting to note the suggestions for improvement given by the students. The students were also encouraged to give comments about the assignment at the end of the survey. Only a few had suggestions and they mostly related to making the assignment easier, although one student implied that they could have been asked to do more research.

The student suggestions for improvement of the Interest Paper Survey can be put into two categories as seen in Table VII. The comments in the two columns of the table are independent. The first category is changing the assignment. A first suggestion in this category is that students without an interest area be asked to do several smaller papers. It is not clear to the author how this would help the student to really explore the steps that are needed in research, but breaking the assignment up into smaller steps and cover more of the semester is certainly a legitimate suggestion. The suggestion of having the assignment be different for different students is valid. The instructions need to be clear that the second time a student does this assignment for this class, they should write an actual research paper or proposal.

The second suggestion of using only an outline may make it easier for the student, but again allows the student to go in less depth. Suggestions 3 and 4 under this category both have to do with making sure there are enough references for a topic, since the paper requires at least 10 references. If the students follow the instructions to use an ENGR database, they can quickly discover how many references are available. Usually the student will need to use this tool to narrow down their topic, since an inquiry, say into “solar energy,” can produce thousands of references.

Improvement Ideas for Interest Paper Assignment	
Alternate Form:	More Help with Paper
1.Allow those who haven't found an interest to do several small papers	1.Outline trigger questions
2.Writing an outline for a paper comparing several potential interests would be more beneficial and less mind numbing	2.Provide topics from which to choose
3.For first assignment pick 5 areas and do a brief search to see if there are plenty of references	3.Maybe a little clearer details needed. I ended up doing it wrong twice
4.Encourage a consultation with a professor about the topic; it would be very helpful to narrow on a topic and see if it relates fully to research I could be doing	4. Better instructions
5. If you have an interest, you have probably looked into it already; it should make you look at other things to expand horizons	

Table VII. Improvement Ideas for the Interest Paper Assignment

A goal of the assignment was to get the students to apply for a research grant such as the FURI, WAESO, or REU. If they have not done this, then we want the student to research their interest and to be able write about a contribution that they

could make in the field. The students were also told that if they were already doing research in an area and were interested in exploring another area, then this paper is a good opportunity.

The first two suggestions for making the assignment easier are asking for more directions. An outline of a research paper is made available to the students. Suggestion 2 is contrary to our intent to make the student think about their own interests, not follow someone else's. The two suggestions asking for better instructions will be noted. The paper is discussed in class, but perhaps a more detailed written description of the assignment is needed. In the instructions for these students, they were asked to first write an interest paper based on 5 references, then to add 5 more references and expand the paper. One student commented in the survey, that it would be easier to have the first assignment be to find at least 10 references and then to write the paper in a second assignment. This suggestion will be incorporated with the next assignment. We believe that if we can help a student write one research proposal, then it will be much easier for them to write a second one.

The students were asked how important they thought it was to find at least one area of interest as soon as possible. Table VII shows these results and suggests that the students understood the importance of the assignment.

How important is it to find at least one area of interest as soon as possible?					
Importance	Very Important	Some what	Neutral	Un Important	No Response
Number of Students	35	18	2	1	1

Table VIII. Number of Students by Level of Importance of Finding at Least One Area of Interest in Engineering or CS

A final question the students were asked was: “How would you judge the interest paper assignment relative to your professional development?” Their responses are in Table IX.

How would you judge the interest paper assignment relative to your professional development?						
Rating	Excellent	Very Good	Neutral	Not Good	Negative	No Response
Students #	12	27	14	1	2	1

Table IX. Ratings by Students of Interest Paper Assignment Relative to Their Professional Development

The positive responses in Tables VIII and IX would make it appear that most of the students understood the importance of the assignment and research, although some were not convinced.

Finally, the students were asked to comment. The comments in general corresponded to their rating. Those who felt the assignment was good for them stated: "It was insightful," "I would love to take my interest paper and put it into my portfolio," "It was interesting," "It was very helpful in further preparing me for my honor's thesis," "I like the assignment, it helped me really think about what I want to do," "Great, forces you to get out of comfort zone," "I enjoy the interest paper, it is a lot of great information," "I enjoyed learning about research and how to research topics, different topics that I am interested in," "It was useful to get interested in a topic in multiple ways, it was good for interview scenarios, and finding something to be passionate about," and "Thought it was great."

Those who had difficulty with the assignment were of course more negative: "I didn't really learn anything from the paper since my interests aren't very well defined," "It became an annoyance rather than something that excited me to action," "Just make sure it is more clear on Blackboard. No worries though," "I had no idea where to start and the instructions were unclear," and "Split up the assignment weighed the same each week."

The maturity shown by most of the students on this type of assignment is encouraging. Some students need to take the course a couple of times in order to be convinced that the assignments are all designed for their own good. The interest paper assignment is only given in the fall semester. Even though it is a difficult assignment for first semester transfer students, we want to get them involved in research as soon as possible in order to help them to get research funding, to strengthen their resume, and to help with interviews for internships. One student commented, "All of the assignments have been helpful."

VI. CONCLUSIONS AND FUTURE WORK

The "interest paper" assignment will be given again in the Academic Success Class next fall. Some changes will be made in the assignment. The students will again first be asked to visit an engineering librarian to learn about using ENGR data bases, if they do not already know. Their first assignment for the paper will be to find a list of 10 appropriate references.

The students will be encouraged to talk with the transfer students who work in the Transfer Center, who are available to help students, have taken the course, and have completed the assignment. They will also be reminded to talk to the course instructor if they are stuck or overwhelmed by the assignment. As a result of this survey, the instructor will make a point to talk more with the students about the interest paper assignment and try to determine if they need additional help. Sometimes new transfer students have a difficult time asking for help when they need it. The instructor will also review the assignment to make sure that the instructions are appropriate for students by how many times they have already done it.

For the students who want more help with choosing a topic, they will be reminded to look on the web for professors who are willing to work with students on a FURI grant proposal and whose area of research is listed. The students are also told to look up the research of professors that they are particularly interested in and to read about their research on the ASU web.

The conclusions drawn from the survey show that the assignment is working quite well in accomplishing its goals. Only 23 of the students in the class were doing the assignment for the first time. Before the assignment 20 students did not know how to use an ENGR data base. After the assignment, only 3 students in the class said they did not know how to use such a data base. Only 15 students did not have an interest area before the assignment; five of these students had an interest area after the assignment. Another nice result of the assignment was that 21 students, who already had at least one interest area, were helped by the assignment to find an additional interest. Nine students learned of an area in which they are not interested, which is good information when deciding on the type of industry in which they might have a career. Using some of the suggestions by the students should make the assignment even more effective.

ACKNOWLEDGEMENT

Special thanks go to Ms. Maria Sanchez Telles, graduate assistant, and Lindsay Brown, undergraduate assistant, who put the survey into EXCEL to aid analysis

Abstract—The University of Texas-Pan American (UTPA) faces some unique regional challenges that hinder retention, success, persistence, and progression. These regional challenges include reduced college preparedness, a high incidence of poverty, low educational attainment, and a language barrier. In particular, first-year, first-term UTPA students are largely unprepared to take Calculus. This places an undue burden on the students, lengthens their time to graduation, and hinders their performance in many gatekeeper courses. The shortcomings that result in gatekeeper courses are especially acute and significantly hinder success in upper-division courses. To overcome these, the authors have identified four proven practices that will accelerate math-preparedness of incoming freshman, overcome misconceptions that hinder progression from lower to upper division, and enhance sustained student engagement throughout. Together these practices form a strategy intended to engender a sustainable ecosystem of student success in Engineering and Computer Science in the Rio South Texas Region.

I. INTRODUCTION AND BACKGROUND

Driven by the emergence of Rio South Texas as a leading manufacturing hub that requires increasing numbers of engineering graduates, the University of Texas-Pan American (UTPA) has established collaborations to increase participation of high school and college students in Engineering. It serves a population of students that present both challenges and enormous potential. To address both, faculty members from the College of Engineering and Computer Science, the College of Science and Mathematics, and the College of Social and Behavioral Sciences have devised a series of coordinated activities intended to instill a sustainable culture of student success in the College of Engineering and Computer Science.

UTPA is located in Edinburg, Texas, where it offers degree programs leading to professional careers, continuing education, and services designed to improve the quality of life in the seven-county Rio South Texas Region through research and community engagement. With a recent (Fall 2014) enrollment exceeding 21,000 including approximately 2,300 Engineering and Computer Science majors, the university is the eleventh largest in the state and the sixth largest in the University of Texas System. UTPA has the nation's fourth highest enrollment of undergraduate and graduate Hispanic students and is

ranked eighth in the number of Engineering bachelor's degrees awarded to Hispanics [1].

Three key challenges this project is designed to overcome are

- 1) Rio South Texas Region public school students lag behind in rigorous course-taking and accomplishment essential for success in postsecondary STEM coursework;
- 2) Rio South Texas has a high incidence of poverty and low educational attainment, which negatively impact persistence in postsecondary education, especially in STEM coursework; and
- 3) The Rio South Texas Region is predominantly Hispanic, a population severely underrepresented in STEM majors and careers.

High school students from Rio South Texas are significantly less likely (34.2%) to meet the criterion score of "3" on Advanced Placement tests than students across the state (51.2%) [2]. Significant gaps in average college entrance exam scores (SAT/ACT) also exist between the Region's schools and statewide and national outcomes. There is an even more pronounced regional (10.0%) and statewide (26.9%) performance gap for students scoring at or above the Texas Education Agency's "criterion" scores indicative of "college readiness" (an SAT of 1110 for Critical Reading and MATH or composite ACT of 24) [2]. Nationally, Hispanics consistently lag behind their white counterparts on standardized tests, which are used in Texas for first-year Math placement. Amongst the Fall 2010 and 2011 cohorts, 27% and 34%, respectively, of the first-time, first-term Engineering and Computer Science students qualified to take Calculus I or II. In recent years, approximately two thirds (or greater) of incoming students are not Calculus ready. Finally, the percentages of Class of 2009 graduates from the area schools who met both of TEA's "college readiness" standards (English Language Arts/Mathematics) are significantly lower at 35% compared to 47% statewide. These measures are predictive of the number of students entering postsecondary education needing remediation.

Rio South Texas includes two of the poorest Metropolitan Statistical Areas in the nation, but is also one of the fastest growing areas in the US aspiring to sustain a growing manufacturing sector. 34.8% of its residents are below the poverty level, more than twice the State and national rates. The percentage of economically disadvantaged public school students in the region is even higher, at 85.6% [2]. Low levels of educational attainment also characterize the region. 85.1% of residents over the age of 25 have education completion levels below a baccalaureate degree, as compared to the state (74.7%) and national rates (72.5%). This means that only 14.9% of the target area residents have earned a four-year college degree. However, 34% of the population is under the age of 18 compared to 27.8% statewide and 24.6% nationally. Many parents of school-age children lack first-hand knowledge of the American public school and higher education systems. 80.2% of the population principally speaks Spanish [3]. Language, cultural, and educational barriers prevent many parents from providing the support needed by high school students to successfully avail themselves of opportunities for rigorous mathematics and science coursework.

According to the 2010 U.S. Census, 91.0% of the Rio South Texas' 1,544,713 residents are Hispanic [4]. The Hispanic population of the area's public schools is even higher, at 95.2% [2]. UTPA and STC have been engaged in efforts to facilitate student engagement and success in STEM which has led to a steady increase in STEM majors and graduates over the past dozen years. These activities have resulted in a number of articulation agreements that facilitate the transition of STEM students from regional two-year institutions to UTPA, and have enabled more low-income and non-traditional individuals to pursue Engineering degrees. The regional population demographics have provided a unique environment for identifying and implementing strategies that support the success of students in STEM, and, in particular, the success of low-income, first-generation Hispanic students. There is still, however, a significant need for more extensive interventions to reach the levels of success in STEM participation that would constitute closing the gaps. For these interventions to be sustainable, they must leverage existing activities that target recruitment, retention, and persistence. Both UTPA and STC have several existing programs that target recruitment and success of STEM majors.

II. PROJECT OVERVIEW AND DESIGN

This project is establishing a sustainable ecosystem of success in Engineering and Computer Science in the Rio South Texas Region by targeting major barriers to student achievement and creating opportunities for enhanced student engagement. To do so, the project leverages existing programs and resources. It brings together these resources in a holistic manner previously lacking and builds upon this foundation through four interventions. The interventions include

- 1) A targeted, STEM-focused, concurrent-enrollment program;
- 2) An entering-first-year, summer-bridge program;

- 3) Just-in-time, inquiry-based, supplemental instruction; and
- 4) Peer-led, mentoring and teaching.

These activities are intended to attract a greater number of quality students into the Engineering and Computer Science majors at UTPA, accelerate the preparedness of entering students who are not otherwise Calculus-ready, reduce the bottleneck in existing gatekeeper courses, and establish a sustainable peer-mentoring structure to support all the interventions. This will serve as a model for establishing and sustaining STEM success at minority serving institutions.

Activity 1: Targeted Concurrent Enrollment Strategies for Potential Engineering Majors. This activity establishes a streamlined process for providing precollege students already participating in a summer Engineering and Computer Science camp – the Texas Prefreshman Engineering Program (Tex-PREP) – the opportunity to partake in the summers prior to their Junior and Senior years in an Engineering-focused, concurrent-enrollment program that includes a residential experience and an engineering design project. This program, dubbed UPREP, provides precollege students an opportunity to advance and/or enhance their preparedness for an engineering or computer science program while earning college credits. Two special courses were offered to U-PREP students (College Algebra and English I) that considered the needs and special interests of future engineering students. The College Algebra section offered to these students catered to engineering applications and focused on skills needed later in Calculus and beyond. The English I section was designed to help develop technical writing skills.

Activity 2: A Summer Bridge to Calculus. The purpose of this activity is to accelerate the Calculus readiness of incoming students who do not test into Calculus. During the spring prior to their first-year of college, based on their math placement, students are offered the opportunity to participate in a Summer Engineering Bridge Program that includes accelerated Math preparation, a specialized college-preparedness curricula, and engineering design projects. Many students who have high school credit for Pre-Calculus or even Calculus do not place into Calculus based on entrance or college readiness exams. To leverage their prior experience in these areas and reward them for those concepts they have mastered, a special section of Pre-Calculus employing an emporium approach was implemented.

Activity 3: Enhanced Student Engagement and Guidance in Engineering "Gatekeeper" Courses. To improve persistence and timely progression, the authors have established, for key "gatekeeper" courses, specialized online and in-person recitations that target common misconceptions and improve mastery of key fundamentals. During the first year of this project, the authors have worked with instructor for Calculus I, Statics, Circuits I, Engineering Statistics, Chemistry for Engineers, and Computer Science I. Each instructor was tasked with creating and implementing interventions and supplemental course material. This was based on work previously conducted in Statics which included

- Lectures developed to review prerequisite material,

- Online homework designed to review prerequisite material and prepare for a pre-test,
- A pre-test to assess mastery and recall of prerequisite material,
- The development of metrics to identify at-risk students, and
- The implementation of an online course inventory conducted at the beginning and end of the course.

Activity 4: Student Peer Mentoring, Recruitment, and Teaching. Each of the activities will be supported through the work of peer mentors. As students progress, they will be taught and mentored by specially trained, upper-division students, many of who previously partook in the activities. They serve to connect the activities and provide a shared link that supports long-term sustainability.

As Figure 1 illustrates, Activities 1 and 2 provide two precollege paths – one targeted at increasing the number of high-achieving students who enter Engineering and Computer Science and another aimed at those who declare an Engineering or Computer Science major but who are not Calculus ready. As both cohorts transition into the lower divisions, Activity 3 provides interventions to help them master the fundamentals. High performers entering the upper division can become mentors in Activity 4 and serve as role models. This activity is a “feedback” to each of the others closing the precollege-college loop and lower-division-upper-division loop. The mentors supports Activities 1-3 through peer teaching. The interaction of students involved in Activities 3 and 4 supports the transition from novice to expert or mentee to mentor.

Fig. 1. Activity pathways and connections.

III. PRELIMINARY RESULTS AND OUTCOMES

The summer of 2014 was the first implementation of Activities 1 and 2. At this stage, it is rather early to gauge the longitudinal impact of Activities 1 and 2 on the matriculation and persistence of students in Engineering and Computer Science programs at UTPA. Nonetheless, participants are presently being tracked, especially those who completed the Bridge to Calculus.

Twenty two TexPREP students participated in Activity 1. Each completed six hours of college credit courses that contribute to a degree plan in Engineering or Computer Science. All but one of the students lived in the dorm for the duration of the program. The one student who opted out began staying at the dorm toward the end of the program as she recognized it was a comfortable and supportive learning environment. Six tutors, four mentors, and four resident assistants provided supervision, academic assistance, and social activities for the students. Eleven of the students were declared as engineering majors, four were undecided, and majority of the balance were other STEM majors. As we track these students over the coming years, we will determine how many remain or matriculate to Engineering and Computer Science majors. Additional details regarding preliminary results are presented [5].

Twenty two entering first-year students participated in the Activity 2 in the summer of 2014. All but five students successfully completed the course, four of which had significant job workloads. Of those that successfully completed, all but one went on to take Calculus I in the fall of 2014. The Calculus I pass rate – measured as the percentage of students who pass the course with a grade of “C” or above – for the Activity 2 participants was 63% compared to 49.3% in the general population. Still, the anticipated pass rate was higher. Hence, we are currently assessing what adjustments can be made to help the students optimize their performance in subsequent courses. Nonetheless, it should be noted that, based on their college readiness scores, most of the participants would have been placed into College Algebra fall of 2014. Instead, they successfully completed Pre-Calculus, and, as a cohort, performed comparably well in Calculus I relative to the general population. Additional details regarding preliminary results are presented [6], [7].

Regarding Activity 3, several key outcomes have resulted thus far due to the preliminary efforts conducted in Statics. A pre-test has long been used in Statics to assess students’ mastery of prerequisite material, and to identify students that may be at risk. However, historically, the average performance on these pre-tests has been poor, and there was little correlation between the pre-test results and general performance in the course. To better address the needs of this project, several co-authors experimented within interventions preceding administration of the prerequisite knowledge test (pre-test). These interventions include an online review and web-administered pre-test assignment and practice problems. This and careful design of the pre-test instrument has since led to a high correlation between the pre-test and final course grade. This was important because it serves as a key metric for identifying at-risk students who would most benefit from interventions include the supplemental instruction. Several other key factors for identifying at-risk students were also used. They include grades on the pre-test review assignment, GPA, performance in prerequisite courses, and class repetition due to failure or drop. Similar pre-test instruments are currently in development for Engineering Statistics, Electric Circuits I, Computer

Science I, Calculus I, and Chemistry for Engineers. During the summer of 2014, nine faculty members who have been involved with Activity 3 participated in a two-day workshop aimed at extending the practices adopted in Statics to the other courses previously mentioned. The practices used in Statics has resulted in improved pass rates. Previously the pass rate lingered around 60%. The pass rate in recent semesters has been around 75%. Details regarding related results can be found in [8], [9].

Peer mentors have been trained and imbedded in each of the previously mentioned courses. However, results show that while mentorship helps, it is not statistically significant due to small sample size. More results will be obtained in the coming semesters. Qualitative analysis has revealed, though, that more training is needed to teach the peer mentors best practices. All too often, the interaction between the mentors and mentees resorts to little more than tutoring. We have experienced challenges in recruiting and retaining well-qualified students as most are often being recruited into research assistantships and other opportunities. Hence, we are seeking ways to improving training and optimize the peer-mentoring model.

IV. CONCLUSION AND FUTURE WORK

We are currently reaching a critical mass of data in the various activities that will allow us to conduct more definitive analyses to better inform our practices and assess the success of our interventions. Some preliminary results are further detailed in [6], [5], [8], [9].

Based on experiences during the first summer of implementing Activities 1 and 2 we have made some adjustments to our strategies for recruiting participants and will soon be able to assess the influence of these changes. Additionally, we are planning to expand some of these practices in collaboration with regional community colleges. In particular, we are seeking to focus the efforts of these collaborations on facilitating the transition of transfer students into our Engineering and Computer Science programs. Though articulation agreements already exist that insure transfer of nearly all the students credits, other issues exists that would be well-served by adopting some of the activities we have implemented. The programs at the two-year institutions struggle to recruit and retain mentors for key gateway courses because many of those who are qualified have either transferred or are in the process of moving on to a four-year program. Thus, we are seeking ways of providing face-to-face and web-enabled peer mentoring sessions.

Currently, through Activity 3, we are already working with one faculty member at South Texas College in Engineering. Our hopes are to expand that into Mathematics and potentially Chemistry and Physics. It has been our observation that many transfers to the College of Engineering and Computer Science struggle integrating themselves into the preexisting cohorts and learning communities. Moreover, they are often unaware of or not acclimated to the supplemental resources at our campus. Hence, we plan to leverage extended versions of our existing activities to address these challenges. For instance,

the Bridge to Calculus model could readily be adopted by the Mathematics departments at the community colleges. Also, a similar model could be used to offer a Bridge to Engineering or Computer Science where transfer students come in during the summer and take a sophomore level course or junior level course not offered at the community college. We can embed or connect various extracurricular activities that better connect the students with the local student success resources and integrate them into existing cohorts and learning communities. In other words, the various activities can be adjusted to enhance the transition of transfer students from the lower to the upper division.

ACKNOWLEDGMENT

The authors would like to thank the Division of Undergraduate Education at the National Science Foundation for its support through the STEP, "Graduate 10K+," initiative under grant number DUE 1317661. Special thanks also goes to the UTPA University Transportation Center for Railway Safety for providing additional support to incorporate railway safety applications of Trigonometry and Pre-Calculus in the Summer Bridge to Calculus. Additionally, we would like to acknowledge the contributions of the various UTPA faculty members participating in Activity 3 including Drs. Mohammad Azarbajani (Civil Engineering), Douglas Timmer (Manufacturing Engineering), Julius Marpaung (Electrical Engineering), Emmet Tomai (Computer Science), Timothy Huber (Mathematics), and Tina Thomas (Chemistry) and Mr. Martin Knecht (Engineering) from South Texas College.

Metacognition involves an ability to reflect upon a learning episode, understand what strategies provoked learning, and gauge one's current level of understanding. This paper details preliminary evidence regarding the University of Texas at El Paso (UTEP) Metacognitive Learners course, a pre-engineering course structured to develop metacognitive strategies and habits through scaffolded collaborative group work, small and large group discussions about learning, and guided writing exercises designed to support learner reflection. Course curriculum addressed metacognition and metacognitive skill development in three explicit ways: a) team problem solving, b) student goal setting, and c) reflective writing about group process, project progress, and individual learning. Following this course, student survey data across all 4 sections suggests initial success in creating a learning environment that supports developing metacognition—students considered how they learned best, described their knowledge to others, and were asked to check their own understanding and progress throughout the course via dialogue and reflective writing.

Keywords—*metacognition, introductory engineering courses, community of learners*

Metacognition involves an ability to reflect upon a learning episode, understand what strategies provoked learning, and gauge one's current level of understanding [1]. The research literature suggests metacognition may be vital to developing high-level expertise in a domain—studies of experts and novices indicate metacognition is a key difference between the two groups [2,3]. This paper details preliminary evidence regarding the University of Texas at El Paso (UTEP) Metacognitive Learners course, a pre-engineering course structured to develop metacognitive strategies and habits through scaffolded collaborative group work, small and large group discussions about learning, and guided writing exercises designed to support learner reflection. This course was developed as part of a United States Department of Education Minority Science and Engineering Improvement Program (MSEIP). Research questions this study addresses are the following:

Do students perceive the entry level general education course as a learning environment that supports metacognitive learning? If so, in what ways?

I. METACOGNITION IN ENGINEERING

Metacognition involves an ability to reflect upon a learning episode, understand what strategies provoked learning, and gauge one's current level of understanding. A related conception of metacognition is that it involves knowledge about how to learn, the skill and awareness needed to gauge what one has learned, and the ability to manage new learning opportunities for optimal learning [4]. The research literature suggests metacognition may be vital to developing high-level expertise in a domain—studies of experts and novices indicate metacognition is a key difference between the two groups [2,3].

Students with metacognitive abilities are more likely to be aware of their academic strengths and weaknesses and use feedback to improve future learning. This may be particularly important in a field like engineering, in which rigorous coursework in a fast paced higher education setting can overwhelm students who are less prepared. Studies of metacognition in engineering contexts suggest that inquiry based design experiences such as capstone courses may provide opportunities for developing metacognitive capabilities, yet it is unclear whether open-ended problem based learning alone can lead to greater self-regulation—as an example, Lewanto [5] found disciplinary differences in the development of cognitive self-appraisal and cognitive self-management during senior design courses.

A. Designing for metacognition-curricular supports for developing student thinking about their thinking

Metacognitive learners take time to reflect upon what they know and how they learn best, and consider strategies that would help them improve their knowledge. Metacognitive learners are reflective about what they are experiencing in learning contexts, and consider connections between what they learn in classes over time and how they might transfer to application in the engineering field. While some students seem to have innate abilities and inclinations to study their own learning, this is not evident across the undergraduate student body.

Traditional instructional and assessment in schooled settings do not tend to promote reflection, nor provide opportunities to learn in a variety of ways. However, evidence suggests that classroom practices that emphasize reflection, provide timely, specific feedback to learners, and promote

learning strategy development could heighten students' attentiveness to their own learning. Korgel [6] initiated journals in a course setting in which students developed personally relevant analogies to describe important concepts in chemical engineering, thus eliciting student reflection. Newell, Dahm, Harvey, and Newell [7] asked students to monitor in writing how their group was progressing and detail barriers they faced in their progress. Students stated they valued this activity, and that by monitoring their progress in group meeting, they were able to advance more quickly in their design work.

Reflective journals can promote deeper learning, particularly when students are prompted through carefully crafted journal assignments to reflect on their conceptual understanding, monitor their progress in learning key concepts, and consider a purpose for learning beyond the course grade [8]. Qualitative evidence details how students became more focused on conceptual understanding in the course, learned to assess themselves and their progress in learning content throughout the semester, and became more adept at connecting the content from the course to real world applications. The UTEP Metacognitive Learners effort draws on the work regarding written journals as a means to heighten metacognition and extends the premise that courses can be designed to promote metacognition. The theory of change regarding course design and implementation as well as the research methods for studying the impact of the course on participants are discussed in sections II and III.

II. THEORY OF CHANGE- DEVELOPING A LEARNING ENVIRONMENT THAT FOSTERS METACOGNITION

The Metacognitive Learners team at UTEP designed the course as well as data collection and analysis strategies with a sociocultural view of learning [9]. In this view, learning occurs in social interaction with others, and with tools and artifacts of the discipline. Learning environments such as classrooms afford learning to different degrees, based on the ways interaction is structured, or not structured, to provide all students access to experiences that promote learning outcomes. A goal of the Metacognitive Learners project is to create a community of learners [10], a collection of learners who work together to develop more advanced understanding of a profession, discipline, or content area. In this case, the Metacognitive Learners project aims to create student to student and student to faculty bonds that promote critical feedback mechanisms, reflection on conceptual learning and progress within a content area, and supportive team members poised to learn together throughout their undergraduate studies in engineering.

III. COURSE DESIGN AND INSTRUCTIONAL METHODS

In an effort to ensure all new engineering students had access to the metacognitive learners curriculum, program leadership chose the Engineering 1301 course for this initiative. All entering freshman are required to take a 1301 course at UTEP. The 1301 series of courses promote the following:

“All sections will▪ Strengthen your academic performance and ease your transition to UTEP.▪ Enhance your essential

academic skills.▪ Increase your interaction with faculty members and fellow students.▪ Encourage your self-assessment and goal clarification.▪ Increase your involvement with UTEP activities and resources.” [11]

Writing prompts and activities focused on thinking and reflecting about learning. Pre-calculus mathematics concepts and a robotics project served as focal content areas in this general education course. Pre-calculus was chosen as a focus area because the majority of UTEP engineering students begin their academic careers in preparatory mathematics courses until they are calculus-ready. Mathematics courses serve as a barrier to successful completion of engineering in many institutions—this issue is particularly prevalent in schools with inclusive admissions policies such as UTEP. Course curriculum addressed metacognition and metacognitive skill development in three explicit ways: a) team problem solving, b) student goal setting, and c) reflective writing about group process, project progress, and individual learning. Specific written assignments designed to promote metacognition were the online prompts for reflective writing and engineering notebooks used to document progress in the group robot project.

Some illustrative examples developed from interviews as well as classroom observations of practice appear below. The examples serve to depict implementation of this engineering course.

Example A: It is mid-October. Twenty eight students enter the classroom, which is set up with tables facing forward. Three peer leaders circulate, asking students in Spanish and in English about their weekend. There is light chatter before the class begins. The instructor walks towards the front of the room, and reminds the class that today is a math group day. Students reconfigure the tables in the room to accommodate groups of 4 or 5. Students begin working on becoming experts on their assigned math topic- they collectively solve sample problems, google youtube videos, and consult with the instructor and peer leaders. The instructor reminds them to answer the online reflection question related to their experience of learning math collaboratively in this course.

Example B: It is late October. Students are moving on to their culminating activity for math—a group Jeopardy game. In this game, teams that have worked on math topics together all semester are working together to solve precalculus questions. “Remember,” the instructor calls out, “make sure everyone on your team can reach the answer—we will call one of you from the group to the board.” As questions are read aloud, groups huddle around their tables, negotiating solving strategies. Students who have sketched out an answer on paper begin describing the main concepts to their teammates, walking them through the problem step by step. A team raises hands. “Miguel, pick someone from that team to go to the board.” The peer leader says. Miguel picks Jorge, a quiet student who sits on the periphery of the group. Jorge walks slowly to the board, picks up a marker, and pauses. “Go on Jorge, you got this,” calls Jamal, a member of another group. Jorge begins to sketch out the answer.

Example C: It is mid-November, a robot day. Groups gather their equipment from the storage locker in the classroom—

hardware, the engineering notebook, and the computer they will need to program the robot. “We said we would have the robot built out by now, so we are behind schedule,” says Roberto, reviewing the goals they set for the group the week before. “Right, but I have been practicing the code for making the robot navigate the room, so I think we can make up the time this week,” Marisel tells the group. They schedule a time outside of class to meet the following day, so they can be sure to get back on track.

IV. DATA COLLECTION AND ANALYSIS

The Metacognitive Learners project involves multiple methods of evaluation and research. Internal and external evaluators collect the following: observational notes from course meetings, artifacts of practice including journal entries, engineering notebooks, assignments, syllabi, video of project work, survey data from all students, interviews and focus groups with select participants, including faculty members and instructors. In addition, the evaluators have collected baseline student course outcome data for courses that cross all engineering disciplines- in this case, high level mathematics courses. Future work will involve comparing Metacognitive Learners’ outcomes in these courses following their Engineering 1301 course. This paper focuses on the external evaluation of the project, which to date included observations, interviews with faculty, and student surveys.

Given the sociocultural theory that drives this effort, it was important to gather data at the right level of abstraction. Taking into consideration the focus on social, collaborative, and collective practices, the classroom learning environment itself was considered the appropriate unit of analysis in this case.

TABLE I. CLASSROOM COMMUNITY SCALE RESULTS

Classroom Community (positive items) <i>Strongly disagree = 1; neutral = 3; Strongly agree = 5</i> <i>87% of students averaged more than 3 across items</i>	Mean	Std. Dev
I trust others in this course.	4.1739	.73950
I am given lots of opportunities to learn in this course.	4.1556	.99899
I feel connected to others in this course.	4.1304	.85916
Students in this course care about each other.	4.1087	.87504
I am confident that others will support me in this course.	4.0217	.88164
I am encouraged to ask questions.	4.0000	.94281
I can rely on others in this course.	3.9348	.90436
I receive timely feedback in this course.	3.9130	.98491
This course is like a family.	3.8444	1.10691
Members of this course depend on me.	3.7391	.95300

Rather than measuring students’ perceived metacognitive skills, skills that may or may not have derived from the course, we targeted the learning environment itself for study. We used the validated instrument developed by Thomas [12] called the Metacognitive Orientation Learning Environment Scale

[MOLES], which was developed with a social-constructivist approach towards metacognitively rich classroom learning, in which learning and knowledge building are collaborative, interactional efforts. This instrument best fit the goals of the instructors, which were to create communities of learners who were able to reason about their own learning and meaning-making.

A secondary element of the learning environment of interest to the Metacognitive Learners program was the extent to which the class members felt a sense of community in the course. The Metacognitive Learners project sought to develop strong social ties between students with the assumption that developed relationships would serve engineering in the future—they would gain a sense of community, feel supported in their academic efforts, develop study groups, and feel as though they had a confidante in future courses. To measure the extent to which students felt they developed a community, the evaluator implemented a modified version of Rovai’s classroom community scale [13].

In spring of 2014, initial data was collected from students to understand their experiences of the UNIV 1301 course. That data and analysis informed development of the survey completed by students in four sections of UNIV 1301, all receiving some version of the Metacognitive Learners curriculum. For example, all participated in math review in teams, all received the UNIV 1301 college readiness curriculum (e.g., time management, study skills), and all participated in a robotics project with various themes for their work.

V. RESULTS

Forty seven of the 98 students enrolled in Engineering 1301 in the fall of 2014 participated in the survey (48%). Details of the classroom community and Metacognitive Learners survey data are provided in this work in progress paper, along with qualitative responses to open ended survey items related to metacognition.

A. Classroom community

This report highlights the positively worded items from Rovai’s classroom community scale, as negatively worded items showed skewed and irregular patterns. Overall, Engineering 1301 students in the metacognitive learners program viewed their classroom as connected, caring, encouraging, and trusting. Average scores were all in the “agree” range, at or near 4.0. A closer look at each student’s average score indicated that 87% of survey participants had a mean greater than 3, or neutral. Evidence suggests that Metacognitive Learners courses were successful in fostering ties among students and other stakeholders.

B. Metacognitive opportunities in UNIV 1301

The research-based instrument is made up of 8 subscales that describe a classroom environment that is supportive of metacognitive learning. First, students must interact with “thinking about thinking” as part of the content of the course—in other words, students must consider the course do be one in which individuals model their learning processes (teacher

modeling and explanation) and where they view part of the learning objectives to be related to their metacognition (metacognitive demands). Secondly, metacognitive learning environments assume flat distributions of power and responsibility, in which student ideas are valued and discussed in the class openly (student–student discourse, student-teacher discourse, student voice). Learning objectives and experiences develop over time with input from students (distributed control). Finally, in a learning environment in which students are admitting to misunderstandings or disclosing a lack of learning strategies they must feel emotionally safe and supported by colleagues and peers (teacher encouragement and support, emotional support).

The following table indicates the results from the post test for MOLES in all 4 sections of Engineering 1301 engaged in Metacognitive Learners. No scale differences were statistically significant across gender, course section, or instructor. Each scale had at least 4 items, making each measure more robust than one item alone. Averages for all scales are in the “agree” range, in this case between 3.97 and 4.38. There were slight differences that did not reach statistical significance in this small sample by instructor. The emphases on encouragement, student voice, and emotional support were slightly higher for a professor who noted in an interview these were his/her goals in the Engineering 1301 course. Another professor who focused more on metacognitive demands and student-student discourse saw slightly higher scale means for those elements of the MOLES survey.

TABLE II. METACOGNITIVE LEARNING ENVIRONMENT SCALE RESULTS

Scale Name	Sample scale item Strongly disagree= 1; neutral = 3; Strongly agree = 5	Mean out of 5	Proportion of students who average 3 or above (neutral- positive)
Student-student discourse	“Students discuss with each other about how they can improve their learning.”	3.97	83%
Metacognitive demands	“Students are asked to think about how they learn.”	4.00	79%
Student voice	“It is OK for students to speak out about activities that are confusing.”	4.04	85%
Instructor encouragement and support	“My professor encourages students to try different ways of learning.”	4.19	83%
Emotional support	“Students’ efforts are valued.”	4.38	87%

C. Qualitative description of the benefits of Metacognitive Learners

Two themes emerged from the qualitative data regarding course experiences. One was that students felt they learned how to work together in this course. This is important in the field of engineering because early engineering courses are traditionally lecture based, and because engineering design courses often do not take time to describe or scaffold students’

cooperation. Engineering 1301 was unique in that it valued group work for freshmen and was designed to provide students specific roles in every group such that cooperation was supported. The first quote focuses on the structured preparation of learning to work in groups, the second quote highlights the intentional focus on collaborative practices, and the third mentions that learning occurs in teams, rather than just “work”—in other words, students talked about what they knew and how they learned it. The third quote also shows that students met many other peers in the group work.

“This class teaches you how to be successful working with other students.”

“Other courses are based on an individual but Engineering 1301 revolves around group work.”

“There is a lot of learning and discussing in teams, which is not something you do in every class; working in teams is very helpful and you get to know a lot of people.”

The second theme was related to reflection on learning and the ways in which the course was designed to support group reflective leaning practices supportive of metacognitive capabilities. The first quote indicates the class was perceived as one that was open to multiple ways of learning, the second quote shows how students had opportunities to consider their progress in the course before moving onto another set of learning objectives, and the third quote is indicative of a developing community of learners.

“I believe this course is very different from other classes because it does not really support any (specific) way of thinking but encourages you to explore other ways, other than your own.”

“There’s a reflection about how it is that we learn instead of just learning the material and not understanding it at times in other classes.”

“It gives us different ways of thinking and allows us to discuss which path we took to learn. They support group learning as we would learn from and teach each other.”

VI. CONCLUSIONS AND NEXT STEPS

Following this course, student survey data across all 4 sections suggests initial success in creating a learning environment that supports developing metacognition—students considered how they learned best, described their knowledge to others, and were asked to check their own understanding and progress throughout the course via dialogue and reflective writing. Students’ ratings of their course showed high marks. The majority of students rated the course with a 4 or 5 out of 5 across all scales. The metacognitively-focused curriculum provided student voice, an opportunity to build metacognitive skill, encouragement and emotional support for learning, and opportunities for rich student-student discourse. Longitudinal student data analysis with institutional records of course grades planned for summer 2015 will show whether this preparation has academic benefits beyond this course, specifically whether the students involved in the Metacognitive Learners program outperform other engineering cohorts in their mathematics course completion.

Agile Learning Through Continuous Assessment

Kevin A. Gary and Suhas Xavier

Computing, Informatics, & Decision Systems Engineering

Ira A. Fulton Schools of Engineering, ASU

Mesa, AZ, USA

{kgary,sxavier2}@asu.edu

Abstract—This work explores the impact of teaching and learning if the rate of learner engagement outside the classroom is continuously measured and available to the instructor and students. We describe an ongoing implementation of a monitoring tool built within a software engineering continuous integration and testing (CI & Test) platform that integrates multiple streams of student activity and performance on yearlong junior software engineering projects. The CI & Test platform allows for continuous and instantaneous feedback, which we will use to inform student behavior change. In the work-in-progress we describe the technology, its impact on the teaching process for the instructor, and preliminary results observing impacts on student engagement behavior.

Keywords—agile; project learning; continuous assessment

I. INTRODUCTION

This work-in-progress is an application of agile process concepts from software engineering to learning assessment. *Agile* is the overarching theme, taken in the software engineering context (and derived from industrial engineering) of *empirical process control* [6]. In a forward-engineered, defined process model, the steps of a process are elaborated and arranged using tools such as task activity networks. Participants in the process execute the scheduled tasks, with expected process output if the tasks are completed within the specified constraints. Most courses are planned in this predictive, forward-engineered way. Learning outcomes are supported by learning activities (whether active or passive), and typically laid out on a course calendar or syllabus, which guides both the teacher and learner through the process. In contrast, empirical process control suggests that complex processes are not amenable to a predefined set of scheduled steps, as the environment is too fluid. Instead, the process should be driven by a feedback loop where small adjustments are constantly made based on continuous feedback.

The popular *agile* software engineering process models are based on this empirical process principle. In prevailing agile software engineering practice, processes are instrumented with continuous and visible feedback mechanisms. For example, *daily standups* are short (less than 5 minute) meetings to share individual progress and hurdles to success. *Scrumboards* are

information radiators [1] meant to provide a highly visible, continually updated representation of project requirements and associated tasks. *Continuous Integration and Test* (CI & Test) tools provide an instantaneous view of product quality, and reduce the risk associated with long gaps of development without validating system integration (“big-bang integration”). There are several other practices and extensions to mainstream agile practices (such as *Kanban*) that are beyond the scope of this work. Suffice to say this project is motivated by the potential for engineering an instrumented learning process for the purpose of providing visible continuous feedback to students and instructors. The hoped for result is behavior change in the manner in which students conduct long-term (semester or yearlong) projects.

II. BACKGROUND

A. Continuous Assessment

Continuous assessment refers to a field in educational research devoted to the practice of performing frequent assessments in a course context [6]. The concept has become somewhat popular with the rising popularity of constructivist approaches to learning, as frequent assessment provides a feedback mechanism ensuring students are properly aligned with a scaffolded learning process. It remains an active area of research, with an ongoing debate surrounding the utility of formative versus summative continuous assessment [2][6]. From a practice perspective, frequent assessments are becoming more common with the support of technology. Badges and micro-certificates used in some MOOCs are, in our view, examples relying on finer-grained and more frequent feedback mechanisms.

We do not present a new validated vehicle for continuous assessment nor do we have a specific perspective to advance in the debate over formative versus summative assessment. This work instead offers a specific instance of continuous assessment in the context of a project-centric student experience with the support technology-based tools.

B. Embedded Assessment

Embedded assessment is a concept related to continuous assessment, with an emphasis on the context in which the assessment is delivered. Typically the embedded assessment happens as part of the learning process, not as a discrete

This work is supported by a grant from the State Farm Foundation.

external activity. Some embedded assessment techniques obey similar principles to continuous assessment. Classroom assessment techniques and technologies (clickers, in-class polls, 1-minute papers, tablet-based activity monitoring etc.) support frequent assessment to give the instructor feedback on learner absorption of material. Automated online assessments not only ease grading workloads, they also offer the opportunity for instant feedback, remediation, and personalization of self-study outside a classroom. Embedded assessments within e-content or newer print textbooks give the student immediate feedback on the content just consumed.

C. Continuous Assessment from an Agile Perspective

Despite the rise in popularity of continuous and embedded assessment, the prevalent delivery model is to push students through a predefined amount of content and assess the student at the conclusion of that activity. Even descriptions of continuous or embedded assessments tend to follow a scaffolded, discrete event learning process, albeit at a much higher rate of frequency than traditional course-grained learning processes. What if we drive the time of assessment to time of learning gap limit to zero?

As discussed in the introduction section, agile software engineering methods derive from empirical process control, or simply put the ability to enact an heavily instrumented process so continual minor adjustments (“tweaks”) keep the process within desired control parameters. Active research and practice in agile methods attempts to drive the feedback loop to zero, thereby eliminating the need for process scaffolding such as frequent short iterations (or “sprints”).

Our work conveniently overloads the term *continuous* from both the educational and agile software engineering perspectives. Conceptually, our work is an example instance of continuous assessment. In practice, it applies mechanisms from agile software engineering, specifically continuous integration and testing, to engineer a learning process resulting in greater engagement in a yearlong project experience. This specific instance and its mechanics are described next.

III. PROJECT-CENTERED LEARNING AND THE SOFTWARE ENTERPRISE

A. Projects as a Professional Spine

Sheppard et al. [6] proposed an integrated development thread in undergraduate engineering programs called a *professional spine*. The professional spine is realized by the Software Enterprise as a *project spine* in the context of undergraduate and graduate software engineering degree programs [5] (see Fig. 1). Instead of traditional dedicated courses in each phase of the software engineering lifecycle (requirements, design, verification & validation), the Enterprise-as-spine promotes learning each of these phases as themes in a integrative project context.

The Enterprise pedagogy combines project-centric and traditional models for course delivery resulting in a just-in-time, contextual learning experience. Software Enterprise courses are a required part of the degree programs from the sophomore year through 1st year of the graduate program at

Arizona State University. The Enterprise is currently in its 10th year, and details of the pedagogy have been presented elsewhere [1][4]. In the context of this work, a short summary of the approach is needed, which we do in the context of the junior year project experience, as this is where we have piloted continuous assessment practices.

B. The Software Enterprise

In a Software Enterprise course, software engineering concepts are broken into discrete modules and sequenced over the course of a semester to synch up with project activities. In this *just-in-time* approach, students are exposed to a concept, practice it, apply it on a scalable project, and then evaluate the applied technique *all within a three-week project iteration* (see Fig. 2). The goal here is to avoid situations where students understand a solution *in the small*, and instead understand problems and their solutions *in context*.

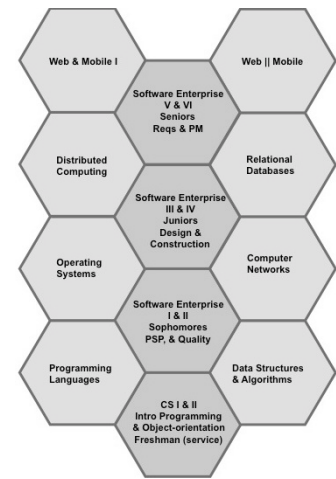

Fig. 1. Enterprise undergraduate spine

Fig. 2. Software Enterprise Pedagogical Model

Example modules in the junior year spring semester course include *source code control*, *unit testing*, *static analysis*, *code reviews*, *metrics*, *refactoring*, and *defensive programming*. Additionally, agile concepts such as *sprint planning with user stories*, *continuous integration and testing*, and *burndown charts* are covered. Again, for each of these concepts, students iterate through *preparation* (typically a reading), *discussion* (in a traditional lecture setting), *practice* (a lab or discovery activity), *learning-in-context* (put in practice in a scalable project), and *reflection*. The key to the Software Enterprise approach is that all of these stages happen at the point of discovery in a single three-week sprint.

C. Challenges and an Opportunity for Assessment

Perhaps the most challenging aspect of implementing the Software Enterprise pedagogy is the expectation that the

student constantly the integrate software engineering concepts (in the form of current modules) into their team's project workflow. This is antithetic to how students typically work on project coursework; projects are deadline-driven, with the majority of the work coming just before the project due date. There are a variety of reasons for this, from student time pressures to a simple inability to properly plan and estimate work over a long time period. Simple mitigation strategies include defining intermediate milestones, though this typically results in a microcosm of the larger problem; students do not pay attention to the milestone until it is almost due.

It is imperative in any project course that students make a consistent effort throughout the semester on the project. Students that defer work to the last minute usually shortchange the concepts they are to discover and apply in favor of just "getting it done". In agile software engineering projects, it is even more important to make consistent progress, the very nature of agile processes suggest developing a constant rhythm so constant feedback is available; without constant activity no work is completed, no feedback can be generated, so no adjustments can be made. The nature of empirical process control breaks down. Finally, in the Software Enterprise is it critical to have consistent activity so that concepts may be integrated in the project at the point of learning.

In the Enterprise, students are given the directive to work on their projects for 8 hours per week, and save 1 hour out of class for preparation activities. Students are asked not to go beyond 8 hours even if their project is falling behind, as the intent is to have the students rely on a team process, not heroic efforts, to complete the sprint goal. Students are assessed each sprint (4 times per semester) on their process-related activities, code-related activity, integration of modules into the project, and team process activities. Individual process activities include updating a scrumboard and participating in standup meetings (3 per week). Code activities relate to individual velocity measured by frequency and significance of commits to the source code repository. Module integration is determined by a student journaling evidence and presenting it as part of a sprint individual reflection. Team process activities are based on adherence to Scrum principles such as user story development, estimation and tracking on burndown charts, and sprint reviews and retrospectives. A student's final grade is the aggregation of each of the 4 sprint grades plus 20% reserved for the end-of-semester product deliverables.

IV. CONTINUOUS ASSESSMENT IN THE ENTERPRISE

A significant hurdle in the Software Enterprise is getting students to work in a constant rhythm. A phenomenon we observed is that students tend to do a burst of work at the beginning of a sprint and at the end of a sprint and not in-between. The burst at the beginning of a sprint aligned with when students received their prior sprint grade, while the end of the sprint is the milestone-driven mentality discussed above. Anecdotally, it seemed the students were more motivated just after receiving feedback (a partial course grade), and just before, but in-between fell into the same bad habits. The premise for this project then, is that continuous assessment, where the student always has visibility into her/his project grade, will motivate students to adhere to the

"consistent work rhythm" expectation, thereby increasing the student's ability to learn in context. The Software Enterprise provides a good vehicle for continuous assessment due to its highly modularized curricular organization, emphasis on highly iterative software development and pedagogical processes, and expectation of continuous, consistent work on the project.

We borrow from the concept of continuous integration and testing (CI & Test) in agile software engineering. CI & Test promotes continual integration and verification of software by performing a software build and regression test for each commit to a software repository, or at least on a nightly basis. This practice avoids the problem of infrequent integration testing and long build processes. CI & Test *dashboards* in tools such as TravisCI (travis-ci.org), Cdash (cdash.org), or Jenkins (jenkins-ci.org, see Fig. 3) provide pervasive visibility of product quality status. Used in conjunction with a *scrumboard* and a mature source code control platform like GitHub (github.com), the project team and all stakeholders have full visibility into the rate of product development, project activity toward requirements, and product quality.

S	W	Name ↓	Last Success	Last Failure	Last Duration
		Project F cubicCoins	20 hr - #106	27 days - #71	9.2 sec
		Project I Entrepreneur Sim	26 days - #30	26 days - #29	10 sec
		Project J Sports	8 hr 7 min - #98	15 days - #81	1 min 7 sec
		Project Team C Gamers	21 hr - #93	17 days - #72	48 sec
		Project Team D Gamers	1 hr 10 min - #68	N/A	1.2 sec
		Project X thefailedandthefurious	5 days 20 hr - #113	20 hr - #123	39 sec

Fig. 3. Example Jenkins dashboard. The traffic light and weather metaphors on the left provide a simple short-term and long-term feedback mechanism.

Our goal in this project is to create a dashboard similar to CI & Test platforms showing the continuous assessment view of a student's grade components – individual process activity, code activity, module integration, and team process activity. We have created a web-based tool that dynamically displays three of these perspectives (all but module integration) and made it available to Software Enterprise students in the Spring 2015 semester. The views this tool provides are shown Fig. 4.

The top chart in Fig. 4 shows team process progress. It measures, as a stacked area chart, the number of To-Do, In Progress, To Test, and Done tasks per day on the team's scrumboard. This particular chart shows good team process over the sprint, as the tasks are getting moved across the states of the scrumboard at a fairly consistent rate. The middle chart is an view of individual code activity. The grouped bar charts show frequency and significance of commits normalized to a common visual scale with a double y-axis chart. This particular student shows decent behavior, though in several cases there a number of insignificant commits, as shown by the blue bar being higher than the orange (commits outweighing code addition, meaning several trivial commits performed).

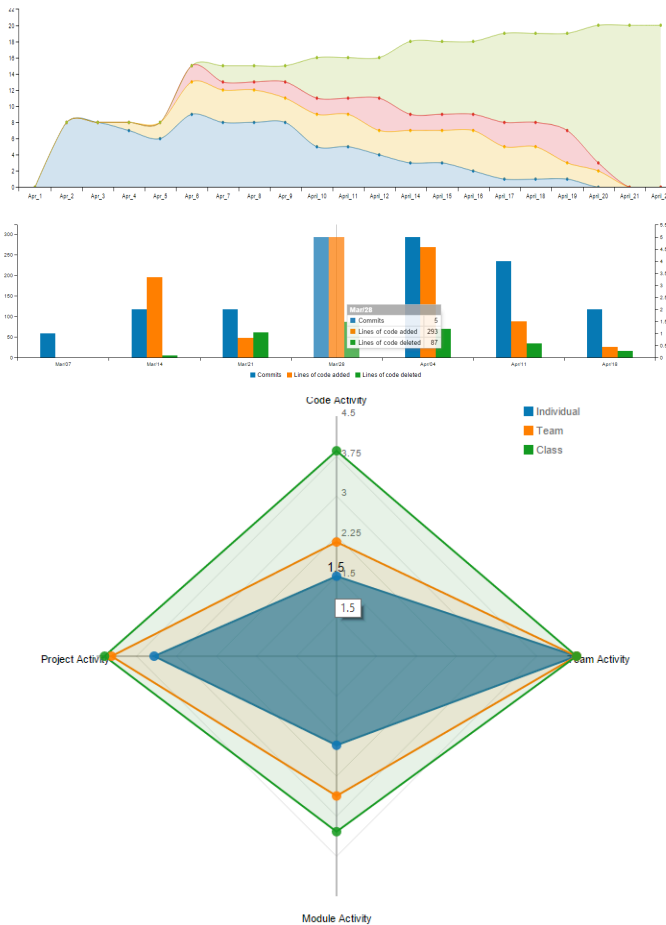

Fig. 4. Continuous assessment of team and individual project performance

The most important chart however, is the bottom chart, as it shows a view of the four components of the sprint grade, laid out on a radial chart. Further, the individual student's component scores (shown in the small dark area) are overlaid with the team's average component scores, and then the component scores of the entire class. The student is able to see, immediately, her/his performance with respect to the class.

These charts are worthwhile in that they show a rate of progress (the top two) and instant comparison to cohorts within the class. They are easily interpreted by the student, and are rendered in one place. This is better than going to the LMS gradebook for textual averages, a scrumboard, or a GitHub pulse diagram. We pull data from the source tools of each component, namely Scrumwise for the scrumboard and GitHub for the code activity, on a daily basis – and are working toward continuous streaming and integration of component data.

The web tool was deployed in Sprint 4 (the last full project sprint), so it was not available in time to use for multiple sprints. Students were asked, in the context of a larger course survey given by the instructor, how useful each of these three views are in the context of team projects. 22 students responded to the survey questions. For the top chart of Fig. 4, 15 students indicated the tool helped them understand team progress, while 1 said it did not help and the other 6 remained neutral. For the code activity (middle) chart in Fig. 4, 10

students indicated it helped, while 8 said it did not help and 4 were neutral. For the bottom (radial) chart, 7 said it helped, 5 said it did not, and surprisingly 10 were neutral. While the results overall were positive, particularly for the top chart, it was disappointing the radial chart did not generate stronger opinions among the students. Of course this is a small ad hoc survey, and we did not in fact have time yet to determine if availability of this data on a daily basis during semester-long project performance would incur the desired behavior change.

Of course, generating reports is useful but alone is of limited utility. We are more interested in behavior change; getting students to pay attention to their rate of progress and seek to work in a consistent manner so the learning process, guided by the pedagogy, has its maximum effect. To this end our technical design goal is to integrate rich views into daily activity through 1) automating assessment data gathering, 2) rendering views in the CI & Test project dashboard and/or in the LMS, 3) adding more and detailed views, and 4) using email, SMS, and/or mobile notifications to remind students as soon as they fall behind on their project expectations.

This project is in a preliminary stage as we prepare to mature the tools for use in the coming academic year. From a theoretical perspective, this project is one data point in agreement with Trotter [9] in that continuous feedback is a tremendous amount of work and sometimes stressful for students and instructors, but is on the whole worth it. Our motivation is to motivate behavior change in students toward consistent project activity, and prepare as instructors for larger project class sizes and a conversion of the Enterprise classes to online delivery. Automated continuous assessment tools is one way, we hope, to address these coming challenges.

Abstract— The teaching and learning process of memory hierarchy is a not simple task. Many topics studied in theory may discourage learning due to its complexity. Resources have been developed to improve learning experiences, and learning objects are resources worth taking into account. This paper presents a learning object called Amnesia, which aims to facilitate the knowledge construction by simulating the structure, functionality and performance of the memory hierarchy in von Neumann architecture, specifically considering the cache memory module. Experimental studies demonstrated an increase in student learning when this object was used. In addition, the students' motivation to use learning objects also increased.

Keywords—education, learning objects, computer architecture, simulation in lab environments, cache memory, amnesia.

I. INTRODUCTION

Being a university lecturer is a great challenge. A university lecturer needs to simultaneously transmit a huge amount of information to students and also pay attention to how this knowledge is being conveyed. One of the factors that may discourage university students is the disconnection between theory and practice [5].

Aiming to bridge this gap, various resources have been developed to improve learning experiences in information technology courses, and learning objects are resources worth taking into account. According to the Learning Objects Metadata Workgroup, learning objects are: “Any entity, digital or non-digital, that may be utilized, reutilized or referred to in technology supported learning” [16]. Another definition, not as specific, says that learning objects are “Any digital resource that may be (re)utilized as a teaching support” [17].

This paper presents the cache memory module from the Amnesia project. The Amnesia project has transformed a tool, also called Amnesia, into a learning object to support teaching and learning in Computer Organization and Architecture courses.

The aim of Amnesia is to simulate the memory hierarchy structure and functionality, and analyze the impact of this hierarchy on the performance of applications. Amnesia is able to simulate internal registers in processors, caches, main

memory and also the use of disks considering virtual memory paging [8].

The practical study of cache memory content using simulations of the concepts presented in theory is an advantage in the learning process. By visual interaction, students can better comprehend the content of the subject, without being discouraged by the traditional teaching method. Furthermore, as the student has to observe the simulation process, it interacts with Amnesia, and actively participates in his/her own learning construction process [6, 15].

The aim of the learning object presented in this paper is not to replace the university lecturer. Instead, it must be used as a support in the teaching process, attempting a more active participation from the student.

This paper is structured as follows: Section II presents related work and Section III briefly describes the main characteristics of the Amnesia learning object. Section IV discusses two experiments conducted: the first, with undergraduate Computing students of a Computer Organization course; the second, with MSc/PhD students in Computing. Section V presents an evaluation of Amnesia considering two perspectives: the students' learning effectiveness, as well as their attitudes towards the use of Amnesia. Finally, conclusions are drawn and future work is recommended in Section VI.

II. RELATED WORK

Some memory hierarchy simulators, specifically cache memory simulators with different complexity and functionality levels, were compared in [12]: KSH [11], Multilevel and Split Cache Simulator (MSCSim) [2], Didactic Cache Memory Simulator (DCMSim) [1], Dinero IV [4], CacheSim [10], LBGCache [7] and SMPCache [14]. Among all of them, KSH, DCMSim, LBGCache and MSCSim performed better, as they had essential functionalities for cache memory learning, in addition to a friendly interface.

Table I shows that MSCSim is the closest to Amnesia. However, MSCSim does not make available lesson plans and tutorials, which are both of them also considered learning objects. MSCSim is also difficult to be reached, because it is not available in a Learning Object Repository (LOR), a place

where it is possible to locate and obtain educational resources for different educational levels and subjects. Amnesia is available in the MERLOT (<http://www.merlot.org/>) LOR. Amnesia has a textual and graphical interface that can simulate different and important concepts to the student learning process. Amnesia can also simulate the execution of a program in a previously configured environment; visualize main memory's contents, the allocation of word blocks in cache and the spread of address bits from each required block, showing byte-offset, word-offset, set and tag. Amnesia has associated learning object lesson plans and tutorials, which will be discussed in Section IV.

Table I contains the following characteristics used to compare the simulators:

- Split: indicates if it is possible or not to simulate split caches;
- Multilevel cache: shows if the simulator is capable of working with different levels of cache;
- Sequence and Parallel access: determines if it is possible to run parallel accesses to the cache memory in addition to sequential access;
- Access time: displays the access times on different levels of cache;
- Associativity: indicates if different levels of associativity can be considered;
- Memory trace: points out if the simulator is capable of generating new traces from each new execution;
- Statistics: indicate if there are metrics showing the performance observed by the execution;
- Graphical User Interface (GUI): determines if the software tool does not only have a user text interface; and
- Download: indicates if the simulator is available to download from a LOR.

TABLE I. TABLE OF THE MAIN CHARACTERISTICS IN THE SIMULATORS

Characteristics	Simulators				
	<i>KSH</i>	<i>DCM Sim</i>	<i>LBG Cache</i>	<i>MSC Sim</i>	<i>Amnesia</i>

III. THE AMNESIA LEARNING OBJECT

First, it is important to explain the origin of this learning object's name. It is a reference to a very common disease in humans that causes a memory deficit called Amnesia. Therefore, Amnesia, the learning object, is a memory hierarchy simulator in von Neumann architecture [9]. Its function is to demonstrate how registers (based on the MIPS processor), caches, main memory and virtual memory work together in a hierarchical view. Amnesia aims to facilitate and improve learning in Computer Organization and Architecture courses.

To start a simulation, the features of the processor, main memory, virtual memory and cache memory must be instantiated. These settings are kept in an xml file read during the Amnesia's startup. The processor setting is just the word size in bytes. Each cache level is set according to the following characteristics: unified/split, size in words, number of words per block, number of blocks per set (i.e., degree of associativity), number of cycles in each reading and writing access, each cycle's duration in time units, replacement policy (FIFO or LRU) and the write policy (write-through or write-back). For the main memory, the settings are according to: its size in words, the number of words per block and the number of cycles in each reading and writing access. Virtual memory settings will not be described here, as they are not in the scope of this paper.

Figure 1 shows that the simulation can be conducted in two ways: firstly (Figure 1a) from a binary code sequence, generated by assembling a MIPS code; and second (Figure 1b) directly from a DIN trace file. The results produced are the simulation statistics. In the first case, the simulation can also produce a trace file with accesses to the main memory in the DIN standard [4]. The simulation may be executed directly or step by step.

Figure 2 shows the output of a program's step by step execution, using a trace file as input. It also shows that this execution type generates a real time detailed log about main and cache memories. It is possible to observe how the bits in a requested address are divided in byte-offset, word-offset, set and tag.

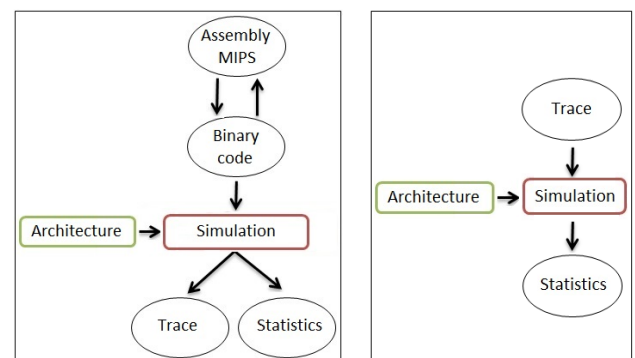

Figure 1. a) Amnesia operation from a binary code; b) Amnesia operation from a trace file.

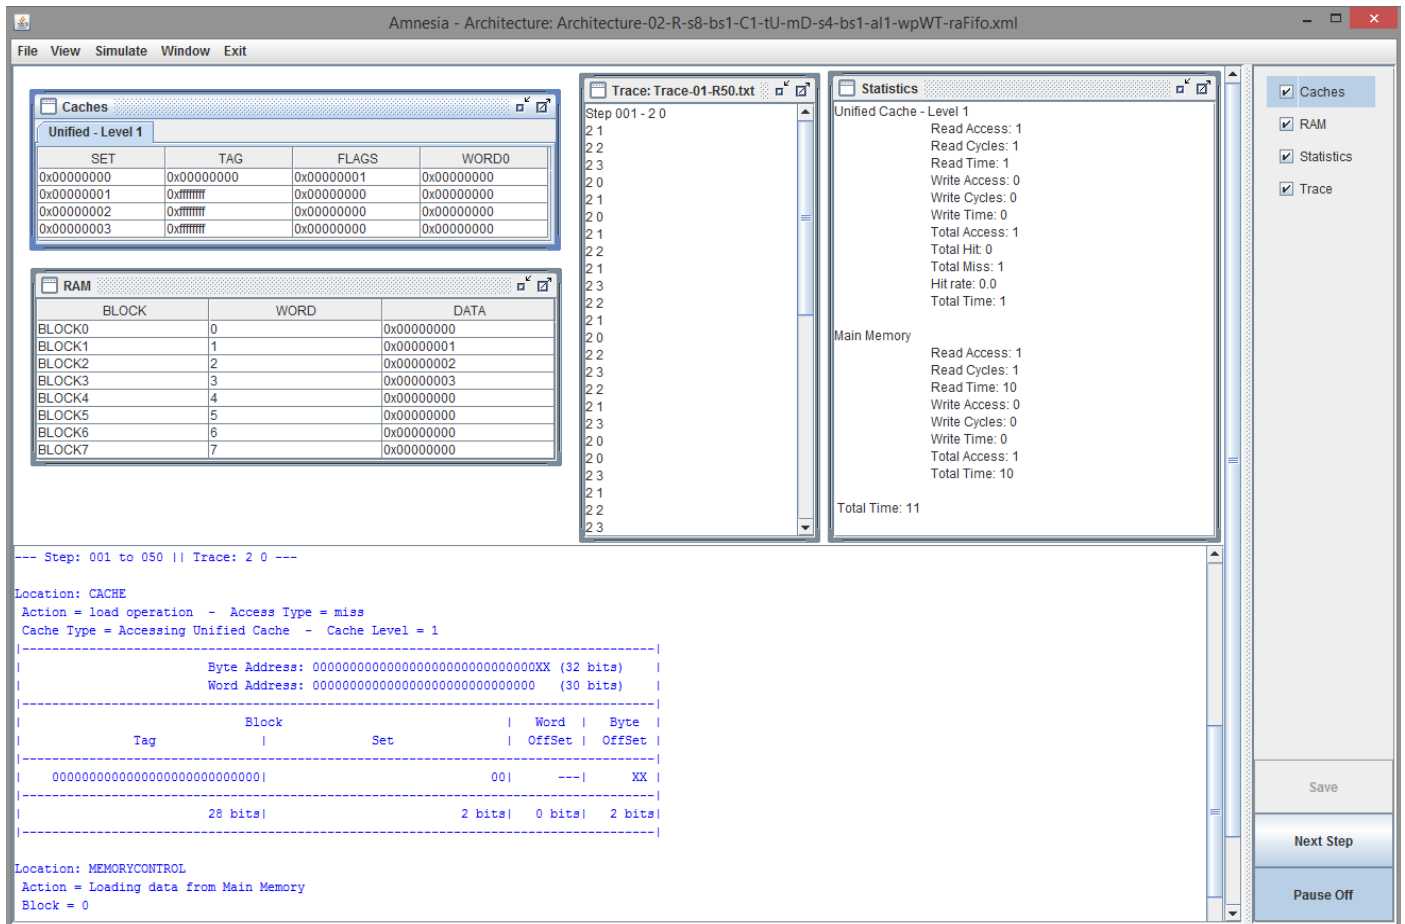

Figure 2. Step by step execution of a trace file.

In Figure 2, the following parts can be observed: program execution (trace), main and cache memory data, and performance aspects (statistics). The statistics are shown for each cache, considering the total amount of accesses, reading, writing and cycles, each cycle's duration (reading and writing), amount of hits and misses, hit rates and cache's total access time. In a main memory, the following information are considered: amount of accesses, total time spent for these accesses and the time spent for reading and writing.

A program can be executed in distinct settings regarding the processor, main and cache. This is important because students can execute a particular sequence of instructions in different environments and then compare the obtained performance.

Each simulation generates an information log containing data about the architecture and program used, the bits spread of each requested address, and the main and cache memories access statistics.

IV. EXPERIMENTATION

Two experiments were carried out using the cache memory module of Amnesia learning object. The aim was: (1) to evaluate whether Amnesia improves students' learning in

cache memory or not; and (2) to find out the students' attitudes toward the use of Amnesia.

Undergraduate students from the Computer Organization course took part in the first experiment. MSc/PhD students in Computing participated in the second experiment. The latter had not worked with cache memory concepts for a while.

In both experiments, two different tests were run, one before (pre-test) and one after (post-test) using the learning object. Both tests had similar complexity levels and consisted of two different sets of 15 questions, which cover all the theory content taught in cache memory during the Computer Organization course.

The pre-test lasted approximately 15 minutes and was it was done by all the students based only on students' previous knowledge. A group of students volunteered in using Amnesia to improve their knowledge. After this group had the practical class using Amnesia, all the students took the post-test, also lasting 15 minutes. The post-test was not applied immediately after the practical class; instead, there was a gap of a few days. If the post-test was run just after the practical class, the knowledge could be recent in students' memory and easy to be remembered, causing a positive influence in the post-test.

The practical class given using the Amnesia learning object was 2 hours long, and the main subjects of cache memory were taught. The subjects were developed with the students in 11 practical exercises, considering functional, structural and performance aspects of caches. More specifically, the following subjects were addressed: motivation and cache concepts, temporal and spatial location principles, mapping function (direct mapping, fully associative and set associative), hits and misses in the access, replacement policies (FIFO and LRU) and write policies (write-through and write-back), reading and writing accesses in caches, performance aspects, multilevel and unified/split caches, bits spreading in requested addresses (in byte-offset, word-offset, set and tag), multilevel cache and miss penalty vs miss rate. For all exercises, performance results were collected from the accesses, as the aim was to analyze and compare hits/miss rate and total duration of accesses, in order to help students understanding and reaffirm the concepts given in theory in a practical way. The exercises were done by the students with a monitor attendance.

Each student downloaded the Amnesia to their local machines and all the exercises were done individually, depending on the interaction of the student to complete it. Thus, the students actively participated in the his/her own knowledge construction.

Besides evaluating the learning effectiveness, the use of the Amnesia learning object was also assessed in these experiments. On the practical lesson day, students were asked to fill in two questionnaires. The first questionnaire asked about the Amnesia using expectation before using it. The second questionnaire was given at the end of the class, asking about the reaction of using it. Some questions are highlighted in Table II.

TABLE II. TABLE OF QUESTIONS IN THE EVALUATION OF USING AMNESIA

Answers: Very good – Good – Regular – Bad – Very Bad.

How was your knowledge on the content before using the object?
How is your knowledge after using the object?

Answers: Yes – Partially – No – Doesn't apply.

Did you increase the level of your knowledge?
Do you think the results obtained in the object were reliable?
Was the class more interesting when using the object?
Would you use the object again?
Are you interested in using any other objects?

V. RESULTS AND DISCUSSION

A. Evaluating the Learning Effectiveness
