In addition, while the technology industry continues to grow, smaller communities have a vested interest in growing a culture for collaboration between students and local software developers. We formed a local open source organization to collaborate on a product by combining efforts from students and professionals. This paper describes the localized free and open source software (LFOSS) organization and reports initial findings from software engineering students' involvement.

Keywords—computer science education; software engineering; industry collaboration; free and open source software (FOSS); humanitarian free and open source software (HFOSS); team projects.

I. INTRODUCTION

Teaching software engineering in traditional educational settings poses the challenge of teaching principles and practices with limitations imposed by academic calendars and budgets. In particular, common fifteen (or fewer) week academic terms restrict students from producing large-scale projects from scratch even when an entire term is dedicated to a single project. Consequently, students in computing disciplines may not be exposed to projects with long enough lifespans nor large enough scale to appreciate software qualities such as maintainability and reusability. Meanwhile, learning software development methods and conventions in a classroom setting alone may feel contrived and detached from actual professional applications.

A hindrance of contemporary computing education is that programming projects usually produce “toy applications”—those with little practical use outside of the classroom and whose lifespans rarely extend past the academic term in which they are assigned. However, in an effort to mature from “toy” to extensible and useful software projects, some software engineering instructors advocate incorporating Free and Open Source Software (FOSS) projects [1]. These projects offer publicly available code where students can often contribute to software products that aim to solve real problems and will

continue to be used and maintained beyond the completion of school calendars. The following *Background* section discusses general advantages and challenges to integrating FOSS projects in the classroom.

In Chico, California—a city with a population of approximately 100,000 and with no *Fortune 500* software companies [2]—we organized Chico Open Source Consortium (COSC) to help bridge a disconnection between the university students and the local software professionals. Independently, both students and professionals had expressed frustration of a missing “technology culture” or “software community” despite the resources available.

COSC formed as a localized FOSS organization comprised of a professor and eleven software professionals who worked at three different companies within the city; its mission is “fostering a collaboration between CSU Chico students and Chico, CA software companies on open source projects” [3]. Students in an upper-division software engineering class were given the option to use this project as their semester-long team assignment. However, students in the class were provided leniency and agency to choose their team projects, including options to contribute to remote FOSS projects or to propose their own products.

We used surveys to gauge students' experiences with their respective projects at the end of the term. In this paper, we compare student experiences and opinions from a variety of projects and discuss implications of local and remote FOSS collaboration. Lastly, we identify other benefits and lessons-learned from the first semester of student collaboration with a localized FOSS organization.

II. BACKGROUND

Thanks to the contributions of worldwide software developers, many Free and Open Source Software (FOSS) products have gained popularity, including Mozilla Firefox web browser [4]. Just like the commercial software it often competes against, FOSS products require software design, development, validation, and maintenance with care not normally afforded to traditional educational computer science assignments. Consequently, introducing FOSS projects to software engineering students exposes them to challenges like those they will face as professional software developers. In

addition, by collaborating with the FOSS community, students potentially gain insight and mentoring from more experienced developers.

Nevertheless, involving students in FOSS projects also introduces new challenges, such as working with geographically remote (non-classmate) collaborators whose active participation and communication in the project may be unpredictable. However, despite its challenges, there are strong pedagogical and curricular rationales for using FOSS projects in software engineering courses.

Auer, Juntunen, and Ojala describe FOSS projects as a viable application of constructivism learning theory. Constructivism explains learning as a processes of building (or *constructing*) new knowledge based on connecting new information to learners' prior knowledge. Additionally, project-based learning contextualizes learning new skills by directing students to solve real-life problems. Experts (i.e. experienced software developers) may scaffold students' learning by following an apprenticeship model whereby the novice students gradually develop and adopt the experts' skills through mentorship [5].

However, Auer, Juntunen, and Ojala acknowledge that connecting suitable projects with experienced software developers can be challenging. Meanwhile, In an effort to connect students with "education-friendly open-source projects," the Repository for Open Software Education (ROSE) collects a list of projects that may be suited for classroom use [6].

Moreover, the Humanitarian Free and Open Source Software (HFOSS) Project advocates contributions to humanitarian projects that "intrinsically benefit a non-profit organization pursuing some kind of public-service mission" [7]. As an example, they submit Sahana, an application to help manage disaster relief. However, the potential benefits of HFOSS extend beyond the altruistic nature of the projects.

ABET accreditation criteria specify that student outcomes include "an ability to analyze the local and global impact of computing on individuals, organizations, and society" [8] and involvement in HFOSS certainly lends itself to analyzing its social benefit. In addition, the HFOSS Project reports that experience with their projects influences positive perspectives of computing majors and careers, particularly among students with less programming experience [9].

A preliminary experience report also suggests that HFOSS Projects could help recruit underrepresented minorities in computing who may have a stronger interest in "applications that benefit society" [10]. If true, integration of HFOSS in computer science curricula could begin to address the lack of diversity in the discipline, particularly concerning the disproportionately few women.

III. METHOD

A. Localized Free and Open Source Group

After talking and identifying a mutual desire to organize collaboration between software engineering students and professionals in the local area, a group of twelve individuals formed through existing professional and personal networks.

The group comprised of the software engineering professor and eleven professional software professionals who worked for three different employers in Chico, California and named itself the *Chico Open Source Consortium* (COSC).

Over the summer, COSC met and discussed project ideas that we thought would be useful to their respective companies as well as to the general software developer population. Together, COSC brainstormed the idea for *BossyUI*, a web toolkit that would include a collection of widgets (common components used on websites, such as calendars and data grids) that could be reused and adapted for different web pages with adaptable visual styling and automatic data binding. The idea for *BossyUI* developed from a common appreciation for existing web toolkits like Bootstrap [11] and jQuery [12] while avoiding frustrations and limitations that the team found with existing products.

In addition to identifying *BossyUI* as its first FOSS project, COSC set expectations for the core members of the team. COSC scheduled a weekly one hour meeting at which the members would share updates and discuss issues with the project. In addition, each member agreed to devote two hours per week to the project. In recognizing the value of the project, two of the three employers agreed to donate their employees' two hours per week workload so that they could support the project. Once the product had been identified and the COSC team solidified, the next task was to find software engineering students who wanted to collaborate.

B. Student Teams

In an upper-level, undergraduate software engineering course, teams of students were assigned a semester-long project to practice and demonstrate the software development techniques taught in lecture. According to the suggestion that ideally, students' involvement in FOSS should be voluntary [5], we gave the teams the option to choose their own projects. Although HFOSS shows promise of attracting new audiences, we recognize that different students may have different motivations. In particular, a student with an entrepreneurial motivations may be more interested in creating a commercial product that is not freely-available to the public.

Accordingly, we allowed teams to either identify an existing FOSS project or propose an original product to maintain on an either public or private repository. During the first week of the semester, students formed groups of 3-7 members based on the projects and technologies that interested them the most.

Altogether, there were 75 students divided into 15 teams. Three of the teams (n=17 students) chose to pursue original commercial products in which they could keep their code private within the team (and overseen by the professor). Nine teams (n=41) also identified unique products that they wanted to develop but without aspirations to profit from them and consequently chose to make their products free and open source.

One team (n=4) chose to contribute to Spyral, a library specific to the XO "One Laptop Per Child" non-profit initiative [13]. Spyral was an existing library but its original authors had

identified new features that the software engineering students could add to it.

Finally, three teams (n=13) chose to contribute to *BossyUI*, the COSC project. Each of the three teams needed to produce independent deliverables for the class (since teams belonged to different sections of the software engineering course). Consequently, with some guidance from COSC, each team identified a subset of the *BossyUI* widgets that they would work on. Once the semester began, the student teams were given prominent roles in developing the widgets, while the COSC team agreed to mentor the teams and to help provide specifications. Effectively, the COSC team became both clients and technical supervisors for the student teams who assumed the lead in development.

C. Course Overview

The software engineering class used for this project is a upper-division class for computer science majors after they have completed the three-course sequence of Introduction to Programming, Programming 2, and Algorithms and Data Structures. Software engineering concentrates on students learning Agile software development methods, version control, testing, software quality metrics, and design patterns. Teams were required to have (at least) weekly meetings. The project grade specifically required teams to demonstrate that their software was ethical, well-designed for maintainability and extensibility, and was tested thoroughly with software tests. However, since students chose their own projects, the programming languages, platforms, and libraries used varied considerably, including mobile development in Java, full stack web development, and lower level C programming for breadboard hardware.

The teams presented their product at the end of the term and were assigned team grades (with adjustments made when the instructor deems necessary due to imbalanced contributions and peer-reviewed ratings). Every team's code was maintained in their own GitHub [14] repository, which tracks each individual members' code contributions through version control. Most groups' repositories were public but two teams (both with commercially aspired projects) chose private repositories to keep their code proprietary. The instructor was a member of the private repositories for grading purposes and classmates were sometimes added temporarily as members to private repositories during peer-review class activities. At the end of the term, there was also a project showcase on campus that was open to the public so teams could demonstrate what they contributed.

D. End-of-Term Survey

At the conclusion of the semester, students were asked to complete a survey to summarize their opinions, expectations, and experiences with their team projects. The survey included the following questions:

- Outside of lecture and lab, estimate how many hours you spent per week on your team project.
- (T/F) I plan on continuing to contribute to my team project after this semester is over

Rate the following from 1 (Strongly Agree) to 5 (Strongly Disagree)

- After the end of the semester, I expect other programmers (besides my team and instructor) to use my project's code
- After the end of the semester, I expect my project to become a commercial (for sale) product
- I believe my project can help serve my school (and/or affiliated groups)
- I believe my project can help serve the local community
- I believe my project can help serve national or international communities
- (T/F) What I have done in Computer Science and Software Engineering has made a positive impact on the world.

The survey had 66 (88% of 75 students) responses and students identified to which team they belonged so their responses could be associated with what type of project they worked on.

IV. FINDINGS

The team projects were grouped into four categories: commercial, HFOSS (Spyral project only), LFOSS (localized FOSS BossyUI project only), and FOSS (open source projects started from scratch not categorized as HFOSS nor LFOSS) and survey responses were aggregated accordingly. First, we investigated the responses for the estimated amount of time spent per week and the true/false questions, as shown in Table I:

TABLE I. REPORTED HOURS PER WEEK, EXPECTATION TO CONTINUE, AND POSITIVE IMPACT

Category	Hr/Wk	Continue	Pos. Impact
Commercial	M=6.86 sd=4.30	64%	93%
FOSS	M=8.17 sd=7.39	36%	72%
HFOSS	M=3.63 sd=1.60	100%	50%
LFOSS	M=4.04 sd=2.57	75%	83%

In Table II, we summarize the Likert scale responses (1 strongly agree to 5 strongly disagree) by category for each question: expectations for other programmers to use the code, expectations to become commercial product, and serving school, local, and international communities.

TABLE II. LIKERT SCALE RATINGS AGGREGATED BY CATEGORY

Category (M, <i>sd</i>)	Other Prog	Comm	Serve School	Serve Local	Serve Intn'l
Commercial	3.57, 1.34	2.43, 1.45	3.21, 1.47	2.36, 0.93	2.50, 1.22
FOSS	3.58, 1.02	3.78, 1.24	3.11, 1.24	3.11, 1.19	3.22, 1.27
HFOSS	3.00, 1.41	4.50, 1.00	4.00, 0.82	4.25, 0.50	2.25, 0.50
LFOSS	1.50, 1.00	3.58, 1.68	2.25, 1.14	1.83, 0.94	2.25, 1.06

When analyzing these findings, one must keep in mind that this study was *exploratory* and *not* intended to explicitly test hypotheses. There are several limitations and confounds that would make any attempt to generalizable conclusions inappropriate from this data alone. First, the sample size for the Commercial, HFOSS, and LFOSS categories were very small and consequently, the aggregated data could be dramatically skewed by even just a single student's response.

Perhaps even more importantly, one should keep in mind that the students chose their own projects so the results are confounded by any personal characteristics that may accompany the selection bias. In particular, we anecdotally observed that in general, the students who chose either Commercial or LFOSS projects tended to be stronger self-starters and generally higher-motivated (to either create a profitable product or contribute to a FOSS project while networking with professionals). While these confounds hinder the experimental design of comparing end-of-term attitudes, they also illustrate the attraction that both commercial and LFOSS projects have to students.

While we will continue to monitor the lifespan and activity of these projects for future longitudinal studies, it is also worth noting that two of the three commercial projects have publically released their products (one as a mobile phone application [15] and the other as a website [16]) and that BossyUI (the LFOSS Chico Open Source Consortium product) [3] is preparing its initial release for Summer 2015. Unfortunately, Spyral (the HFOSS project) [13] was trumped by a similar product that rendered it obsolete for all practical purposes. Although the HFOSS team met their goals for the semester, the parent product itself was unexpectedly abandoned approximately at the same time the semester was concluding. The exact timing and communication to the HFOSS student team is imprecise so we do not know if it influenced their survey results.

We also observed several valuable outcomes from the LFOSS project. Foremost, one of the students from an LFOSS team was recruited and hired as a paid intern as a direct result of his interaction with the professional developers on the COSC team. That networking and mentoring between the LFOSS students and the COSC was very positively received by both sides. Although the HFOSS students had mentors to guide their project, the weekly in-person interaction between

the LFOSS students and COSC seemed invaluable and unmatched. Anecdotally, we noticed the LFOSS students mature most distinctively as software developers as they adopted the habits and the language of their professional mentors. From the first semester of this study, we are inclined to believe that the in-person interaction of LFOSS projects may offer more impactful learning experiences than collaborating with a distributed team can. These promising anecdotal observations give us reason to continue studying the impact of LFOSS projects.

Although the preliminary data must be accompanied with caveats of multiple confounds, the general trends seem to suggest that options to pursue both commercial and LFOSS may compliment HFOSS opportunities for students with different motivations.

Nurkkala and Brandle identified the lack of software maintenance and lack of customers as vital limitations of traditional ("toy application") software engineering projects [17]. Any projects that start from scratch at the beginning of the semester will suffer from the former. In that regard, existing and active open source projects (of any variety) will have a distinct advantage over students who begin development of a new product regardless of whether it is intended to be commercial or not. In this study, the *new* FOSS (but not HFOSS nor LFOSS) projects lacked both maintenance and a customer. Many of these new FOSS projects could be considered "toy applications." Consequently, we discourage allowing students to pursue *new* FOSS products as they tend not to bridge the gap between education and industry.

Both HFOSS and LFOSS types of projects appeared to particularly benefit from interaction with external, professional software developers. Consequently, the students were held to high standards and received quicker feedback than instructors can achieve reasonably at scale. For these projects, the teams followed a "fork & pull" model of committing their code to the repositories—that is, they created copies of the existing repositories in their own space (forks) and created "pull requests" for their customers to review before their work was merged with the main repository (when deemed satisfactory). As the students were learning Agile development methods in the software engineering class, it took some practice for some students to adapt to getting quick (and occasionally negative) feedback. However, the experience is useful in preparing students for working in real project environments.

ACKNOWLEDGMENT

We extend a special thanks to Build.com and LuLu*s for their sponsorship of Chico Open Source Consortium by donating time to the project. Even more importantly, the BossyUI core team provided essential guidance and mentorship for the students. The core team includes: Carly Culver, Andrew de Sena, Dani Dirks, Dan Green, Tauseef Jamadar, Geoff Lawson, Erik Mellum, Jason Merino, Adrian Miller, Tuhin Shukla, and Daniel Sluis. We greatly appreciate their effort and contributions. Thanks also to GitHub for providing educational accounts for hosting online repositories and to ChicoStart for providing meeting space.

Teaching Digital TV Programming for Engineering Students

An Industry Oriented Proposal

Abstract— One of the most important problems of the engineering courses in Brazil is that they do not cover subjects related to computer science deeply enough to attend the needs of the modern industry. It is uncommon to find young electrical engineers able to deal with programming techniques for applications like web engineering, embedded systems, mobile devices, or new digital TV systems. Indeed, that is a new problem for engineering educators, to keep teaching the classical approaches as well as to keep path with new technologies. One of these actual hot topics in Brazil is the programming for Digital TV Systems. The goal is not only to produce basic software but also applications that may be used in new smart TV devices. In fact, we need a novel academic program that could introduce new subjects without changing the official curriculum. This kind of program would help to keep the students aligned with novel themes and help them understand the linkage of fundamental topics with new technological trends. Moreover, this program also helps to bring the industry closer to the university. Complete analyses of the adopted curriculum as well as the activities done are going to be presented in this paper. We will also present some examples of the developed software.

Keywords –University and Industry Collaboration; Extra-Curricular Programs; Educational Experience.

I. INTRODUCTION

In Brazil, the curricula of engineering courses are defined following strict rules from the ministry of education. There are some mandatory points that must be obeyed prior to the accreditation of any engineering course. In one hand, curricular modifications must be submitted for evaluation what starts a long administrative process that may takes years to be concluded. On the other hand, many modern industries need to hire engineers with knowledge of new technological trends [1], which demands the introduction of new curricular components in the existing engineering courses in a very quick way. Most of these curricular modifications could not be implemented or, sometimes, take too much time to be integrated to the official curriculum, what reduces the possibility to start any profitable cooperation between the local industry and the universities. Moreover, the universities have been facing many problems to keep up-to-dated with the even faster technological changes, for example, it is not easy to construct and maintain laboratories in areas like embedded systems, digital TV, or

related topics. The contents of the classical engineering majors are not capable to attend these new demands.

Trying to solve these problems, some lecturers from UFAM proposed a flexible extra-curricular program (extension) for electrical and computer engineering students [2]. The whole program, its subjects, duration, and topics of each particular course were discussed previously with the industry partners in order to attend their actual needs. The extension programs contain two mandatory parts: one that covers the most significant theoretical concepts, and another one that focuses on the practical aspects of the technologies being taught, that is where the students are supposed to solve real problems. This concept is flexible enough to cover any new trend in electrical engineering and computer engineering and to be adapted to the needs of the companies installed in the local industrial pole.

Particularly, in this work in progress paper we are going to present a specific program demanded from Samsung Company. They have a huge production plant installed in Manaus that assembles television-sets, mobile phones, and other consumer electronics devices. In order to keep the production running they need qualified people and their demand is still growing. Many of the particular desired skills for the engineers being hired by the company are not discussed during the college period and therefore they asked UFAM to develop a specific training for these people.

Despite the inflexible curricula, we decided to propose an alternative way to insert those new interesting topics on the undergraduate studies path. It was possible by the offer of extra-curricular modules taught after the official class hours. This are the so-called extension programs and the choice of their content was done in a close cooperation with the industry.

One of the demanded topics dealt with software development for Digital TV. Indeed, the technology used to construct digital TV systems is already covered in the traditional engineering curriculum of any classical electrical engineering program. However, those topics are distributed in many disciplines all over the undergraduate course. In the next paragraphs we will describe particularities of the educational program developed by UFAM in cooperation with Samsung, we believe this model may contribute to other similar experiences.

Some of the results presented here were obtained through the research and training of human resources project, at the undergraduate and graduate level in the areas of industrial automation, software for mobile devices and digital TV, funded by Samsung Electronics Amazon Ltda. under the Law. 8387 (art. 2) / 91.

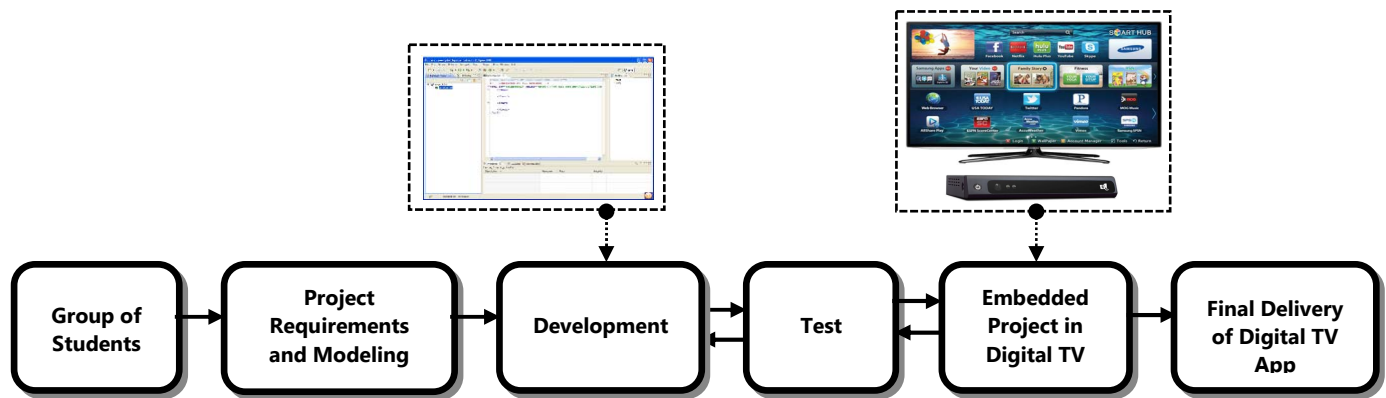

Fig. 2: Block diagram of the project phases.

Fig. 1: Block diagram of the Digital TV Technologies program.

II. PROGRAM DESCRIPTION AND METHODOLOGY

The program follows the steps presented in Fig. 1, where we can observe all its stages in a macro way. In general, according to the block diagram, the project starts with the planning of the desired topics. In this case, the chosen theme was Digital TV Technologies, specifically the programming for this kind of system. Professors from the Federal University of Amazonas together with the researchers and technical staff from the company developed the whole program. In this planning, the following points were established:

- Objectives and milestones of the complete program.
- Common technologies from the industry that could be used in the program.
- Program organization in two different sub-phases called *training* and *project*.
- Definition of the desired modules of the *training* phase and the requirements of the digital TV applications in the *project* phase.
- Workshop with the participating students presenting their final work to researchers and managers.

After concluding the planning phase, we started the selection of students. In this step, students from different institutions of the State of Amazonas (in Brazil) were enrolled. The criteria for selection were: (1) current semester in the University; (2) scholar performance (cumulative grade); (3) overall academic performance; and (4) available time to dedicate of the program. At the end of this process, twenty students were selected to take part in the project.

Another important aspect of this project is that the instructors are not necessarily the same lecturers that work in the University. Indeed, it is more interesting if the instructors come from the industry in order to pass for the students another point of view on the topics being studied. In this project, we could select five industry researchers that agreed to work as lecturers for the selected topics. The selection criteria were: (1) practical experience in Digital TV; (2) academic experience in the Digital TV; and (3) provided training experience in general.

As soon as the project started, two meetings were held with students together with the researchers and with the professors in order to present the whole program objectives. The specific goals in respect to the training, the use of laboratory infrastructure, a detailed description of the modules, the period and duration of the modules, and other general information about the program were also discussed. Additional subjects discussed at these meetings were the classroom place, time schedule of modules, delivery of software artifacts, and program approval criteria.

In the training phase, five modules were defined with twenty/thirty hours each, the total duration of this phase was 110 hours (see Table I). The topics covered the most important aspects of programming for Digital TV systems [3, 4, 5, 6]. The selected industry researchers taught the modules, whose took in consideration theoretical and practical aspects of the art. The practical classes occurred in an appropriate laboratory that hosted all students at one time containing appropriated Digital TV equipment. During the theoretical and practical classes, students worked out several assignments in order to exercise the taught content. Details of each module are presented in Table I.

TABLE I. MODULES OF THE TRAINING PHASE OF THE DIGITAL TV TECHNOLOGIES PROGRAM.

Module Title	Duration (h)
Fundamentals of Digital TV and Software Development	20
Java and Java TV	30
Software Development using Digital TV Middleware	20
C/C++ Programming	20
Embedded Systems Programming and Embedded Linux to Digital TV	20
Total amount of hours	110

The topics covered in each module were previously discussed among the professionals from the company and the university staff. As said before the choice of the person in charge for teaching each module were based on the academic competence and on the practical experience in solving real problems. The following subjects were covered in each module:

- **Fundamentals of Digital TV and Software Development** - Digital TV Fundamentals. Concepts of video systems. Analog television systems. Video scanning. Decoding techniques used in Digital TV. Components of Digital TV systems. System Block Diagram. Software Environments. Hardware and Application. The context of Interactive TV. The Set-top Box. Constitution of the Set-top Box. Introduction to software engineering. Life cycle of software development. Software Quality. Techniques and methods for design and software testing.
- **Java and Java TV** – Introduction to object-oriented programming languages. Java virtual machine. Data types. Control structures. Object orientation. Classes and interfaces. Java class libraries. Packages of the Java language. AWT. Creating Java applications. Exception handling. Events and Threads. Java TV programming. Paradigms of implementation. Software emulation and authoring. Xlets and NCL: presentation engine. NCL formatter. Objects and media players. Structure of an NCL document. LUA execution engine. NCL-LUA integration.
- **Software Development using Digital TV Middleware** - Interactivity concept and interactive content for DTV. Definition of Middleware. Existing middleware standards. Typical architecture of a middleware and types (declarative and procedural). Carousel of objects. Hardware architecture and software of a Set-Top-Box. Definition of a transport stream and tables. Conventional Broadcast. Broadcast of Interactive applications and the Internet. Introduction to the concept of interactive applications. Software Emulation. Concept of graphical interface and usability design. Interactive applications based on Java for TVD. Interactive applications based on NCL-LUA.

- **C/C++ Programming** – History of the C language. C compilers. Program Structure in C. Data Types. Logical Data, Variables and Constants. Operators and Arithmetic Expressions. Relational and Logical Operators. Repetition structures. Structure of Matrix. Functions and Procedures. Using Libraries. Functions of application. Parameter Pass, Pointers, Vector Pointers, File Pointers. Introduction to C++ programming. Algorithms of structures. Functions and Recursion. Operator overloading. Object-oriented programming in C++. Objects, Classes, and Polymorphism. Templates. I / O Stream. Exception handling in C++.
- **Embedded Systems Programming and Embedded Linux to Digital TV** - Hardware and software architectures of embedded systems. Operating Systems for embedded platforms. Understanding of design methodologies and programming languages for minimal systems. Hardware synthesis application. Software and communication. Validation of mixed hardware-software systems. Design based on platforms and low power system design. Introduction to Linux. Process model and overview of the kernel. Real-time scheduling. Linux boot process. Interrupt process on Linux, device drivers. Kernel modules and boot sequence. File system. Shared and static libraries. Graphical environments for Linux embedded systems. Real-time Linux. Business solutions for embedded Linux.

After completing the modules, those students that obtained the minimal average grade were admitted to start the project phase. The planned workflow of this phase is presented in the block diagram shown in Fig. 2, and it has six different steps. First, the students are supposed to create working groups with six/seven members each and establish their own responsibilities. One of them plays the role of the leader; the others will work as developers and testers. Each group is responsible to define the project requirements and to submit their proposal to the supervisors. After the approval, the students start modeling and developing the software.

Here is the point where the students begin to exercise their professionalism, one of the most important characteristic of an engineer. In the steps *Development*, *Test* and *Embedded Project in Digital TV*, we used the Scrum development methodology with weekly sprints [7]. This methodology is very popular among software developers now a day and wide spread among mobile developers. It also proved to be effective for the development of software for Digital TV systems.

Every week, the groups must deliver a set of document reporting their progress, as well as, the faced difficulties. One of these deliveries must be made directly on the set-top box device (see in Fig. 2, on top of the box *Embedded Project in Digital TV*) which allows real monitoring of what has been developed. In these three steps, we used several tools like Ginga NCL [8], Eclipse [9], and Git [10] to develop the proposed work. In fact, the students should start the implementation by using a simulation tool and afterwards they should move their applications to the real Digital TV device.

Fig. 3: Screen inside of a Digital TV, in the digital TV laboratory, of the groups that are developing the project Interactive Application of Points of Interest of Brazilian Cities (Fig.3(a)) and the project Interactive Educational Game: Search the Treasury (Fig.3(b)).

III. PARTIAL RESULTS

The results obtained in our last execution of this project (December 2014) were very interesting. After the last phase, the groups could deliver three functional digital TV applications. The title of the developed applications were:

- a) Interactive Application of Points of Interest of Brazilian Cities. This software searches in a database the most relevant touristic points of a specific city and present them on a TV screen. Particular interest was given to the 12 host cities of the 2014 Soccer World Cup.
- b) Digital TV Interactive Application for the Soccer World Cup. The goal of this application was to display the information about the status of the Soccer World Cup. Games scores, best players, national teams' classification, and other relevant information were presented on-line.
- c) Interactive Educational Game: Search the Treasury. That was a quiz game developed for the Ginga Middleware. The questions were presented in a very attractive way and the difficulties increased as the number of correct answers grew.

All those projects were successfully developed in a simulation environment inside of a digital TV laboratory. After a long period of tests, they were embedded in the digital TV set-top-boxes. That means that all groups were able to reproduce a development environment commonly used in the local research and development companies. Fig. 3 shows two examples of the developed software applications.

IV. CONCLUSIONS

At the end of the project, the students presented their work in an open workshop at the University. All applications worked well and proved to be good experiments for demonstrating the importance of Digital TV technology. The student groups were supposed to present their products as real professionals trying to impress customers or investors. The company's staff took part in their presentations; they judged the quality of each application, and choose the most interesting which won a prize given by the company.

The most important result was that the totality of the students was able to conclude successfully the training. The teaching model proved to be a good extra-curricular approach. In fact, the students learned a lot about topics related to Digital

TV and learned how to develop software in a real world approach.

From the professor's point of view, we had to manage many new pedagogical situations. For example, teaching at the evening is quite different from doing the same job during the day. We needed to supervise the students in a very closer way keeping their progress under constant attention. Another challenge was to work with students having quite different backgrounds; in fact, we received students from other universities and in different stages (seniors and fresh man) that needed to work together.

Finally, we may affirm that we have learned a lot by working closer to the industry professionals. The practical aspects and the industrial way of doing could be taught not only to the participating students but also to the professors coordinating the whole program.

Abstract— *In this report we will describe our first steps in understanding the characteristics of individuals enrolling and completing MOOCs. The learner characteristic we focus on is the deep versus shallow learning dimension. We will use the revised two-factor study process questionnaire of Biggs in our study [1]. To our knowledge, there is no comparable research either reported in the literature or currently under way. Our focus is on Learning How to Learn (LHTL), currently the most heavily subscribed course on the Coursera platform. The last offering of LHTL, completed in January, 2015, attracted just under a quarter million learners. In the fourth and final week of the course, the R-SPQ-2F survey instrument was made available to all students on the LHTL site. Approximately 1,600 students completed the survey. We believe our research to be of interest widely because of the confluence in our research of (a) MOOCs, (b) the deep versus surface learning dimension, and (c) a methodology that can lead to better understanding of MOOCs.*

Keywords—MOOC; online learning; deep learning; surface learning

I. INTRODUCTION

Massive open online courses (MOOCs) have been a rapidly growing part of the educational space since 2008. MOOCs have been saddled by both overly optimistic expectations and overly pessimistic warnings. On the optimistic side, MOOCs have been touted as a vehicle for democratization of educational opportunities on a global scale. On the pessimistic side, some have pointed to the current very low “graduation rate” of students. The ground truth about MOOCs is dependent on the factors distinguishing a given MOOC. This is where serious research about MOOCs and the learning potential they may offer should start. Analyzing MOOCs as a whole is difficult without first coming to an agreement on the dimensions they will cover. At that point we will begin to understand strengths and weaknesses of each type of MOOC. What draws individuals to enroll in a given

MOOC? What holds a learner’s attention over the duration of the course? The subject matter of the MOOC and the pedagogical approach underlying the MOOC are part of the story. But part of the story must be in the characteristics of the learners and this study focuses on that aspect.

As part of our investigation, we will be looking at students enrolled in Learning How to Learn (LHTL), a MOOC offered on Coursera by Drs. Barbara Oakley and Terrence Sejnowski. LHTL consists of a series of 41 brief videos, each with a clear and concise focus on one learning “principle.” Students who take LHTL in a session-based platform view these videos over a one month period. Although like all massive open online courses, the LHTL MOOC has a lower completion rate than would be desirable, statistics from Coursera indicate that the offerings of LHTL have attracted hundreds of thousands of “students” and that the participation rate for LHTL is high.

While most students become more efficient learners as they mature and progress through school, “most college students have not developed a systematic approach to study skills” [2]. According to the most recent Noel-Levitz report, approximately 60% of incoming first-year students nationwide report positive study habits used in high school [3]. While students with better study skills, attitudes, and time management skills tend to achieve higher academic results, the converse is also true [2]. There is evidence to suggest that students will not learn study skills unless those skills are explicitly taught [4]. However, such training can significantly improve academic performance in at risk college students by changing students’ academic behaviors [2]. Bender et. al., suggests that “the at-risk student may be more successful in college than in high school if academic behaviors that contribute to college achievement are acquired, whatever the reason for poor performance in the past” [5].

While the students enrolled in LHTL, may or may not be college students, the course emphasizes techniques that can be applied to any learning environment. The course description states: “We’ll learn about the how the brain uses two very different learning modes and how it encapsulates (“chunks”) information. We’ll also cover illusions of learning, memory techniques, dealing with procrastination, and best practices shown by research to be most effective in helping you master tough subjects” [6].

At the end of their course sequence students were asked to complete a 20 question survey, The Revised Study Process Questionnaire (R-SPQ-2F) to assess deep and surface approaches to learning to determine which learning styles the students are using at the end of the course [1, 7]. In addition to the R-SPQ-2F data, also available to this research team are the results from a preliminary survey which explores the student’s intentions of course participation and expectations in LHTL. Our primary result presented here is the scoring on the deep versus surface learning dimension for those who completed the survey. While extrapolation to the entire population will be difficult, we will attempt to characterize the similarities and differences between the population taking the survey and the general population taking LHTL on the preliminary survey results. Finally we will examine correlations among the preliminary survey and the results of the R-SPQ-2F survey.

II. SURVEY INSTRUMENTS

The preliminary survey begins by asking about the student’s personal participation expectations in the course. They are asked how many lectures they intend to watch and how many assessment activities they intend to complete. They are also asked to rank the importance of the course topics on a 5 point Likert type scale (5 = very valuable, 1= not valuable). Finally, students are asked to describe their common study techniques and approaches and explain why they are taking the course.

The R-SPQ-2F survey is broken down into 6 measures. *Deep Approach: Method, and Strategy*; and *Surface Approach, Method, and Strategy*. Each of the subscales is a set of 5 questions. The *Approach* measure is the sum of the *Method* and *Strategy* scores as shown below [1]:

A. Deep Method

- I find that at times studying gives me a feeling of deep personal satisfaction.
- I feel that virtually any topic can be highly interesting once I get into it.
- I find that studying academic topics can at times be as exciting as a good novel or movie.
- I work hard at my studies because I find the material interesting.
- I come to most classes with questions in mind that I want answering.

B. Deep Strategy

- I find that I have to do enough work on a topic so that I can form my own conclusions before I am satisfied.
- I find most new topics interesting and often spend extra time trying to obtain more information about them.
- I test myself on important topics until I understand them completely.
- I spend a lot of my free time finding out more about interesting topics which have been discussed in different classes.
- I make a point of looking at most of the suggested readings that go with the lectures.

C. Surface Method

- My aim is to pass the course while doing as little work as possible.
- I do not find my course very interesting so I keep my work to the minimum.
- I find I can get by in most assessments by memorizing key sections rather than trying to understand them.
- I find it is not helpful to study topics in depth. It confuses and wastes time, when all you need is a passing acquaintance with topics.
- I see no point in learning material which is not likely to be in the examination.

D. Surface Strategy

- I only study seriously what’s given out in class or in the course outlines.
- I learn some things by rote, going over and over them until I know them by heart even if I do not understand them.
- I generally restrict my study to what is specifically set as I think it is unnecessary to do anything extra.
- I believe that lecturers shouldn’t expect students to spend significant amounts of time studying material everyone knows won’t be examined.
- I find the best way to pass examinations is to try to remember answers to likely questions.

The R-SPQ-2F rates the items on a 5 point scale where A = this item is never or rarely true of me (1 point) to E = this item is always or almost always true of me (5 points) [1]. Therefore, within each subscale there is the possibility of 25 points and within each main scale, the possibility of 50 points.

III. ANALYSIS AND RESULTS

A total of 2,081 students completed the preliminary survey out of 223,428 participants (0.9%). From the preliminary survey, we can see that the students enrolled in LHTL for a variety of reasons (Table I) and have an affinity for various professional areas (Table II). For both of these questions, students could select more than one answer. According to our

survey results, it would appear that the top two reasons to enroll in LHTL are to assist with personal and professional development. It also seems that STEM fields as well as the humanities and education are the most popular affinity areas for students. In terms of expected participation, approximately 78% of students (N = 1648) planned to participate in the course discussions, with only 48% (N=1002) planning to complete the course assessments and 22% (N = 365) planning to watch most of the course videos.

TABLE I. REASONS FOR ENROLLMENT IN LHTL MOOC (N = 2081)

To assist with personal development	85.6%
To assist with professional development	60.9%
Curiosity about the course materials	55.6%
To improve my academic performance	52.0%
Other	12.2%

TABLE II. WHICH OF THE FOLLOWING AREAS DO YOU FEEL YOU HAVE A "NATURAL AFFINITY" FOR? (N = 2081)

Math, science, engineering	55.0%
The social sciences (psychology, sociology, anthropology, etc.)	45.6%
The humanities (art, music, literature, history, etc.)	44.4%
Athletics/sports	20.4%
Business/entrepreneurship	28.2%
Education/teaching	40.8%
Medicine/health sciences	19.9%
Other	12.3%
None	2.60%

While only 48% of students who completed the preliminary survey stated they would complete both course assessments, 77.4% (N =1,638) actually completed the R-SPQ-2F survey as well (0.7% response rate). For analysis and classification purposes of the R-SPQ-2F survey results, those students with a Deep Approach score greater than 35 (average 3.5 on methods and strategy questions = items true more than half the time) and a Surface Approach score less than 25 (items true less than half the time) were classified as learners who applied a primarily Deep Approach. The opposite is true for learners applying a primarily Surface Approach. Students with both a Deep and Surface Approach score greater than 35 were classified as Mixed. Students who scored below 25 on both were classified as using Neither Deep or Surface Approaches.

Shown below in Fig.1, 44.6% (731) of the 1638 students were classified as using a Deep Approach to learning, 54.5% (892) are not readily classifiable as using either Deep or Surface Approaches, so were designated Mixed, only 0.4% (7 students) would classify as using primarily Surface Approaches and 3.5% (58) used neither approach.

Fig. 1. Learning Approach Profile

Each Approach Scale has a total of 50 points that can be earned. To classify students in the subscales, we used a similar rating as with the approach scales. An average of 3.5 or higher on the subscale questions meant that the student used this more than half the time. These students were classified as using a Deep Method, Deep Strategy or a combination of both depending on their scores on these scales. For example, students who scored higher than a 3.5 on the Deep Method scale, but not the Deep Strategy scale were classified as using Deep Methods. Those students who averaged 3.5 or higher on both scales were classified as using both Deep Methods and Strategies.

An average of 2.5 or lower on the subscales meant that students used the method or strategy less than half the time. Students who scored in this group were classified as not using deep strategies or methods. Between these two groupings, greater than 2.5 average and less than a 3.5 average, students were classified as Mixed Deep which meant they used either Deep Methods and/or Strategies about half the time. An identical classification scheme was used to classify students according to the Surface Approach subscales.

Looking at the Deep subscales in Fig. 2, 71.2% (1166) strongly use deep methods and/or strategies. This total includes all those classified as deep learners (731) as well as 96.6% (435) of those students who use mixed learning approaches. An additional 24.4% (399) employ some deep method and/or strategies. Only 4.5% (73) use no deep methods or strategies. The Surface subscales, shown in Fig. 3, are almost a complete reflection of the Deep subscales. Fig. 3 shows that only 4.6% (75) use surface methods and/or strategies, while 69.1% (1132) use no surface methods or strategies and 26.3% (431) use mixed surface methods.

These results seem to imply that those student who are classified as Mixed Surface or Mixed Deep are truly using both equally. However, looking closer at the data, only 146 students (34%) are common to both groups. Therefore it seems that most of those classified as Mixed Surface or Mixed Deep are still more one than the other and we may need to update our classification scheme.

Fig. 2. Deep Approach Usage

Fig. 3. Surface Approach Usage

One option available for those students who enroll in LHTL is to earn a course grade or certificate. In order to pass the course, a 70% average must be obtained. In order to earn a certificate, an 85% average must be earned. Looking at the entire set of data, only 5% of those students enrolled in the class passed the course (11,229), while only 1.8% (4,008) passed with distinction. A substantial group (81.5% or 182,088 students, did not take quizzes or earn a score in the class. Within our survey group, 22.7% (372) scored a passing grade in the class and 47.6% (177) were deep learners. 70.6% (1157) of students did not complete any graded work in the class.

Table III below shows the correlation between overall grade in LHTL and the overall scale and subscale scores for the R-SPQ-2F survey. As shown, only the Deep Method subscale seems to be a significant predictor of final course grade ($p < 0.05$). The Deep Approach approaches significance, but the other measures (Deep Strategy and Surface Approach, Method, and Strategy) do not appear to be significant predictors of success in this course. Although, as always with such a small sample size from this population it is difficult to draw meaningful conclusions.

TABLE III. CORRELATION OF LEARNING APPROACH WITH LHTL GRADE

Learning Approaches	Passing Score Correlation(p-value)	Distinction Score Correlation(p-value)
Deep Approach	0.047 (0.059)	0.048 (0.066)
Deep Method	0.063 (0.011) ^a	0.067 (0.009) ^b
Deep Strategy	0.023 (0.358)	0.021 (0.426)
Surface Approach	-0.034 (0.171)	-0.04 (0.118)
Surface Method	-0.037 (0.138)	-0.039 (0.134)
Surface Strategy	-0.026(0.300)	-0.035 (0.171)

^a Significant to $p < 0.05$

^b Significant to $p < 0.01$

IV. CONCLUSIONS AND FUTURE WORK

This paper investigated the different learning approaches used by students completing the Learning how to Learn (LHTL) MOOC offered through Coursera. While survey responses are low, they do offer an interesting snapshot of the students enrolled in this course. The majority of students are enrolled in this course to develop their personal and/or professional skill set. Course participation through assignments and discussion are low, however within the students that did participate in our survey, about half seem to be employing a Deep Approach to learning, while the majority of the remainder are using mixed methods in their learning approach. Very few students apply a purely Surface Approach to their learning. With regards to grades, it appears that very few students are completing the course for a grade, but of those that do, using a Deep Method for learning was significant predictor of student's success or final course grade in this measure.

In the future, the authors plan to investigate the learning approaches used by students in the LHTL course and the effect the course has on these approaches. Using a simple pre-post-test, we can get a better understanding of individual changes.

Scaling Youth Development Training in IT Using an xMOOC Platform

Martin Löwis*, Thomas Staubitz†, Ralf Teusner†, Jan Renz†, Christoph Meinel† and Susanne Tannert†

*Beuth Hochschule

Berlin, Germany

Email: loewis@beuth-hochschule.de

†Hasso Plattner Institute

Potsdam, Germany

Email: firstname.lastname@hpi.de

Abstract—The paper at hand evaluates the Massive Open Online Course (MOOC) *Spielend Programmieren Lernen (Playfully learning to program)*, an effort to scale the youth development program at the Hasso Plattner Institute (HPI) for a larger audience. The HPI has a strong tradition in attracting children and adolescents to take their first steps towards a career in IT at an early age. The *Schülerakademie*, the *Schülerkolleg*, the *Schülerklub*, and the support for the *CoderDojo* in Potsdam are some of the regular activities in this context to take youngsters by the hand and supply them with material and guidance in their mother tongue. With the emergence of MOOCs and the success of HPI's own MOOC Platform—openHPI—it was a natural step to develop a course to address an audience that is only marginally represented in openHPI's regular courses: school children and adolescents. A further novelty for openHPI in this course was the focus on teaching programming with a high percentage of obligatory hands-on tasks. Particularly for this course, a standalone tool allowing participants to write and evaluate code directly in the browser—without the need to install additional software—has been developed. We will compare this tool to a small selection of similar approaches on other platforms. As it will be shown, the course attracted a far more diverse audience than expected, and therefore, also needs to be seen in the context of spreading digital literacy amongst wider parts of society. In this context we also will discuss the significant differences in the usage of the forum between the course *Spielend Programmieren Lernen* and the course *In-Memory Databases*, a more traditional openHPI course.

I. INTRODUCTION

The Hasso Plattner Institute (HPI) in Potsdam, Germany is a university-level institute offering study programs in IT-Systems Engineering. Since its early days, youth development training has been a strong focus of the HPI. In order to raise IT-skills and interest of (junior-)high school students in programming subjects, the Hasso Plattner Institute has established the *Schülerakademie* (lit. "academy for pupils") offering various activities in this area. Part of these activities are organized by the *Schülerklub* ("pupils' club"). Bachelor and master students at the HPI are encouraged to participate in so called *Klubs*, which are self-organized by the students, alongside their regular studies, as a part of their socio-emphatical education

at the Institute. The *Schülerklub* is one of those. The members of this Klub are working with school children to raise the enthusiasm for computer science amongst this clientele. They organize events and activities for children and adolescents who are interested in getting first hand information about studying IT Systems Engineering at the HPI. These events include e.g. a summer camp of several days' duration for girls and boys from all over Germany and the HPI CodeNight. The HPI also sponsors third party events, such as the CoderDojo, with locations and support. The *Schülerkolleg* is a special program for school children from 7th to 12th grade, who are particularly interested in computer science and mathematics. For one year, every Tuesday afternoon, the participants of the program meet to experiment with new information technologies and their foundations. They are supported by faculty and students of the HPI as well as four teachers who are sent by the school authority of Brandenburg. Even though the HPI facilitates those numerous activities for high-school students, they are limited by given capacities, such as staff, room size, and number of available computers.

openHPI started in 2012 and, thereby, is one of the first platforms that transferred the idea of MOOCs to Europe and Germany. Run by the HPI, it has offered about 20 self produced courses on various ICT topics since September 2012—hosting between 5,000 and 17,000 enrolled users per course. Typical openHPI courses follow a classical xMOOC schema of a six-week course with several ungraded self-tests and one graded assignment per week. The courses are concluded with a final exam, which also is graded. For each of these graded assignments, the participants can achieve a certain amount of points. To be eligible for a graded record of achievement, a participant has to achieve at least 50% of the overall maximum course score [1]. In this specific course (Python2014), the setting was a little different as the focus was moved to hands-on exercises. The only way to gain grade relevant points was by solving practical programming exercises. Weekly assignments and a final exam have not been offered, ungraded self-tests were available, however.

A number of improvements on the platform enabled us to implement a new course model with a focus on hands-on tasks and practical exercises. A standalone tool has been developed that allows the participants to write, run, and evaluate Python code in the browser. The tool stores the submitted code for each user and automatically grades the submissions.

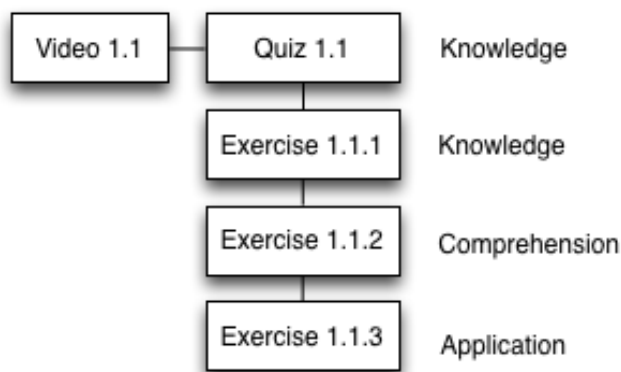

Fig. 1. Exemplary structure a *building block*. Each week contained four of these blocks following the same structure.

The remainder of the paper is structured as follows: The first section will give some information about the course itself and its participants. The second section will give more information about the programming tool, the experiences with it throughout the course, and how it has been connected to the openHPI platform. Furthermore, similar solutions offered on other MOOC platforms will be compared to our approach. The third section will deal with a non-technology-related scaling issue that has been encountered while the course was running: The participation in the forums and the usage of the help-desk, which was noticeably higher than in regular openHPI courses. The final sections will discuss some of the steps we are going to take next and conclude our findings.

II. COURSE STRUCTURE

To scale the HPI's activities in the area of youth development training, a prototypical MOOC to teach children and adolescents the basics of Python programming has been designed throughout summer 2014 and was realized on openHPI in October 2014. The 4-week course consisted of teaching videos, self-tests in quiz-format, and graded hands-on programming exercises. For each week, four videos were offered. Linked to each video were one ungraded self-test and three graded exercises in different levels of difficulty. According to Bloom's

Fig. 2. Total user distribution (8-80).

Fig. 3. User distribution of the actual target group (8-18).

taxonomy [2] the exercises can be classified in the categories: knowledge, comprehension, and application. Figure 1 shows such a building block—exemplary for the first video in week one. All others followed the same structure. The deadline for the graded exercises of each week was at 10:00pm(CEST) on the following week's Monday.

The course had about 7400 enrolled participants. The specified target group were children from the age of 11 to 17, but the course attracted users from a wider range of ages. Some parents enrolled in the course together with their children, also teachers enrolled with their classes. Additionally, the course attracted a vast variety of programming beginners of all ages. Many of them have expressed in the forum, that the promise of understanding basic computer programming, persuaded them to join this course. Figures 2 and 3 show the distribution of the participants age, as far as it is known. The participants are not obliged to enter their age—in the case of Python2014 we have this information for 2379 participants (32%). This course provided the users with a tool to write, run, and evaluate programs in the browser. From here on we will refer to this tool as WebPython. It was very well accepted amongst the participants. Table I shows some of the numbers in the context of user activity with regard to this tool. In the context of our regular courses, active participants are defined as those users, who have submitted at least one discussion post or one assignment [3]. In previous courses the percentage of active participants during the first week was about 40% (see e.g. [4]). In Python2014, due to the different setting, we defined an active participant as a user that at least has started one exercise in the respective week. According to this definition, Python2014 sported 68.73% of active users during the first week (derived from the number of registered users (Table III) and active users (Table I).)

	Users	Started	Submitted
Week 1	4961	51209	48764
Week 2	3696	37597	34115
Week 3	3078	28862	26118
Week 4	2392	23780	21725
RoA	2523	-	-

TABLE I. ACTIVE USERS, STARTED EXERCISES, AND EXERCISES WITH SUBMITTED (NOT NECESSARILY CORRECT) SOLUTIONS PER WEEK. THE LAST ROW SHOWS THE NUMBER OF ISSUED RECORDS OF ACHIEVEMENT.

	Total	Active
Average openHPI courses	18.3%	51.11%
Python2014	34.22%	50.86%

TABLE II. COMPLETION RATES IN RELATION TO THE TOTAL OF REGISTERED USERS AND THE NUMBER OF ACTIVE PARTICIPANTS DURING WEEK ONE

Figure 4 shows the decrease of the number of active participants over time. High dropout rates are a common issue that is shared by most MOOCs. Courses on openHPI have generally rather low dropout rates compared to other MOOCs [3]. To compare Python2014 to other courses on openHPI, we employed the same methodology as Meinel et al [3]. They observed the participants' engagement throughout the course and took the number of submitted homework assignments as measured value. The submission number for the first week's homework is taken as a reference (100%) [3]. In this course multiple submissions per participant and exercise were possible. We, therefore, normalized the number of submissions by counting only one submission per participant. We calculated the average value of the courses Meinel et al have listed and compared this average to the number of active participants in Python2014 based on their methodology. The dropout rates of Python2014 seem to be a little higher than in the average openHPI courses especially in week four (see Figure 5).

Comparing the completion rates of the average, regular openHPI course and Python2014 shows a different image: The completion rate in relation to those users that have been active in week one is almost the same as for the average openHPI course. The completion rate in relation to the total of registered users is even better (see Table II.) At the end of the course we also conducted a survey amongst the participants. The results of this survey indicate two explanations for this phenomenon:

- 1) A substantial amount of participants took the course with their school class, some of them not by choice. Teachers required a Record of Achievement to pass the class. So, as soon as those students had achieved 50% of the points, they quit.
- 2) The workload of the course was perceived as getting increasingly higher from week to week. More details will be discussed in one of the following sections.

Fig. 4. Decrease of active participants from week one to week four.

III. SCALING THE TECHNOLOGY

As participants kept dropping in during week one, we decided to extend the deadline for the exercises of this week until the end of week two. During week two, we faced increasing load problems, culminating into a tightened version of another common problem that we are facing at openHPI: load peaks before deadlines. In this case the participants had to hand in the exercises for two weeks instead of one, additionally they did not have to hand-in simple multiple choice tests but running code. Particularly, in week two—the *loop* week—this caused technical problems, which forced us to extend the deadline for the first two weeks for another day until Tuesday. Figure 6 shows the load peaks on that particular Tuesday. At some point we had a CPU outage but could take measures to recover before the end of the deadline.

Figure 7 compares the number of started exercises, submitted solutions, and active users before and after the deadline of week three. The numbers on the left have been extracted a day before the exercises' deadline. The exercises were available

Fig. 5. Active participants in Python2014 compared to average openHPI courses.

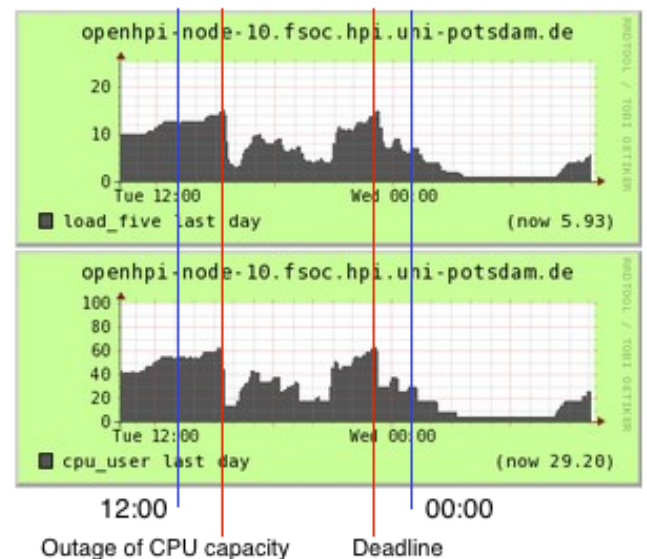

Fig. 6. CPU usage and load on a node shortly on the day of the deadline.

Fig. 7. Submission peak before deadline (week three, Python2014).

for exactly one week. During the remaining last day before the exercise's deadline the number of submissions almost doubled, which increased the load on the system remarkably. Unfortunately, we do not have these numbers for the first two weeks, but the trend would undoubtedly be the same there.

A. Python Programming Tool

The course objective was to teach programming with Python to people with no prior programming experience. As programming is learned primarily by exercise, we set a list of requirements for the infrastructure:

- There should be practical exercises along with the video teaching material.
- Participants should not be required to install additional software on their systems, to avoid hassle with broken software installations.
- There should be support for graphical output, following the turtle graphics programming model.
- There should be fully automated assessment of the programming exercises.

The second requirement resulted in the necessity to offer Python programming in the web browser. Our system features a web server that allows to edit Python source code in a programming editor, based on the CodeMirror¹ package. In

¹CodeMirror: <http://codemirror.net>

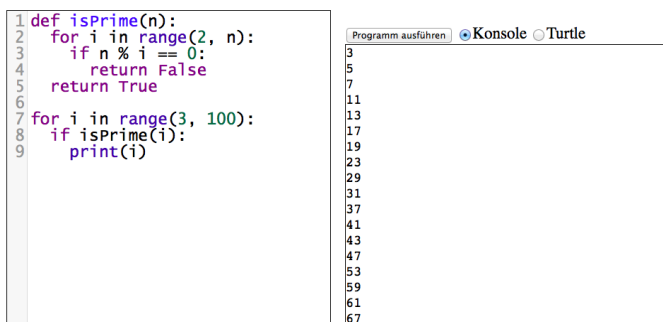

Fig. 8. WebPython in console mode.

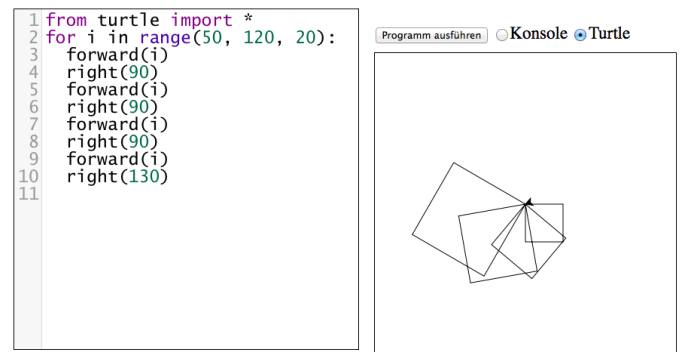

Fig. 9. WebPython in turtle mode.

order to test their programs, users can submit their source code to the server for execution and view the results in a console output window (see Figure 8). After completing the exercise, users can submit the code for assessment, resulting in a grade for the exercise. To allow for long-running Python processes that produce output in an ongoing manner, while also consuming user input of their own, a web socket connection is established between the web browser and the Python process.

As the course title and the target group suggest, we intend to attenuate prejudices against computer science amongst children. Therefore, we designed exercises with visual—and not only numerical or string—output. Turtle graphics [5] is a programming model developed by Seymour Papert in the 1970s, which targets this goal. Various projects have demonstrated its practicability in teaching programming to children (see e.g. [6] and [7]). Turtle graphics is a core part of the Python standard library and Python programming literature for children typically leverages this support [8] [9]. An exemplary output of a turtle script is shown in Figure 9.

Automated assessment of programming exercises is the most challenging aspect of this project, and previous work has demonstrated inherent limitations of automated assessment when compared to a human teacher's assessment [10]. On the other hand, automated assessment also has advantages over human assessment, such as instantaneous feedback, scalability to a large number of participants, and objectiveness.

We decided to allow participants to submit each exercise as often as they want, grading each attempt, and finally taking the best result into account. The assessment code is written in Python as well, running it, and then evaluating the output (not just the printed output, but also side effects on variables, function definitions, and other changes that were expected from running the program). In addition, for a few exercises, the source code was analyzed, primarily to determine whether the solution was using an undesired shortcut.

Running the Python script either for the user's testing purposes or for assessment requires a working Python implementation. For that purpose, several implementations of Python that allow to run code in the web browser itself are available. Unfortunately, none of them is production-ready in the sense that it provides sufficient compatibility with the *official* Python (aka CPython) installation. Therefore, we opted to provide a server-side installation of CPython.

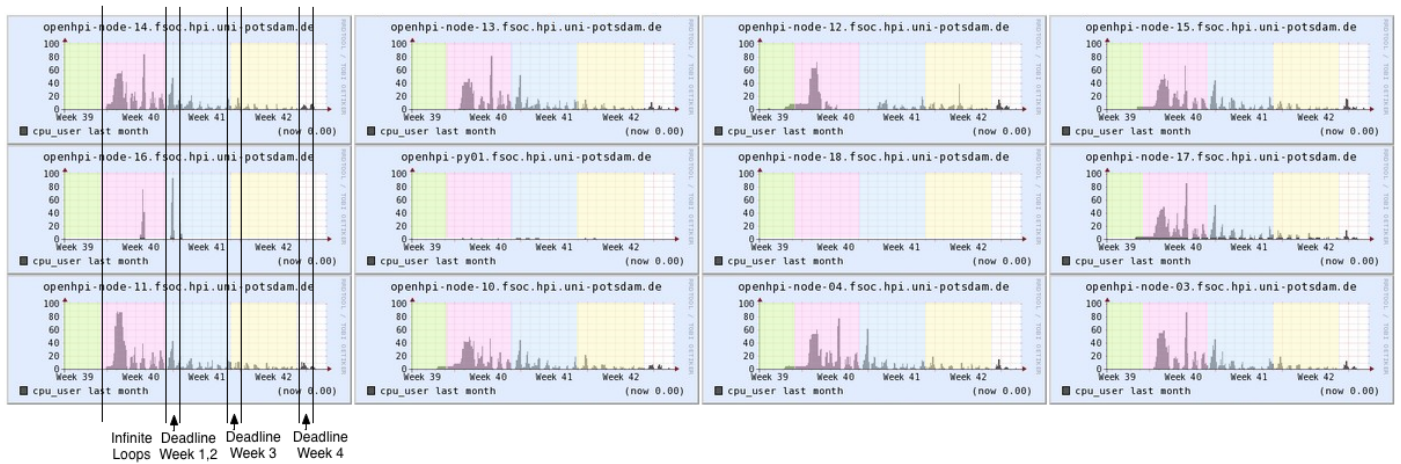

Fig. 10. Load on some of the nodes in our private cloud at the Future SOC Lab during the course. There are two nodes in the middle of the figure that have no or only very little load. The one on the left is the head-node that only runs the web-server. The one on the right did not want to join for unknown reasons.

B. FutureSOC

Providing a server-side CPython installation produces two challenges: first, it is necessary to provide sufficient CPU and memory resources to accommodate a large number of concurrent users. Second, the system must be protected against abuse and user mistakes.

To allow for a large number of participants, we set up a private cloud in the HPI's Future SOC Lab².

The Future SOC Lab is a cooperation of the HPI and a couple of industrial partners. It provides a complete infrastructure of state of the art hard- and software to researchers—free of charge—for a certain period of time. Python2014 was running in between two lab periods, and therefore, we had the chance to use some of its computing power. The code submission system consists of several server processes as shown in Figure 11. The head node runs the nginx web server, to provide for static files and TLS encryption. It delegates to a number of Python servers written with the Twisted framework³ which perform user authentication, templating of the exercise descriptions, and delegation to worker processes running on the cluster. Each node in the cluster runs a Twisted Python server, which in turn launches a Docker⁴ container that ultimately runs the Python process.

²<http://hpi.de/en/research/future-soc-lab.html>

³<https://twistedmatrix.com/trac/>

⁴<https://www.docker.com>

Fig. 11. WebPython's architecture.

The cloud consists of 18 machines in the HPI FutureSOC Lab infrastructure. Each machine has 24 CPU cores and 64GiB of memory.

As kind of a coarse-grained load balancing, we initially had set a limit of 10 processes to be run per core. This arbitrary limit caused a shortage on available process slots within week two, where we dealt with the concept of loops. As expected, several users created infinite loops by error, which blocked a process slot for the maximum allowed runtime of 10 minutes per process. This issue could luckily be solved by setting the limit to 50 processes per core, resulting in a more efficient scheduling, capable of enduring some infinite loops without running out of available process slots. We have not gotten any CPU or main memory outage since this increase. This overload situation can be seen in Figure 10 as the block of higher CPU usage in week two and the pike at the beginning of week three. Afterwards, only minor peaks show up—also due to decreasing numbers of active users—but no more longer lasting high load situations.

As expected and clearly visible in the peaks, most load always occurred close to the closing dates of the respective exercises. With regard to the different charts, it stands out that some nodes hardly show any load at all. Node 18 seemed to be simply broken, while node *py01* was responsible for rendering the web front-end of the python editor, which was a comparably simple task requiring only little CPU capacity.

The protection against abuse and mistakes is primarily achieved by using Linux containers, and the Docker infrastructure that builds on it. Users are isolated against each other and the system, and state is not persisted across program invocations. Docker also allows to limit the CPU share and memory that a process may consume. However, it currently does not provide sufficient support for setting a maximum process run time, which becomes necessary as programming beginners will inevitably write programs that perform endless loops. External monitoring is used to kill processes that exceed the maximum acceptable run time of 10 minutes.

IV. COMPARISON TO SIMILAR COURSES ON OTHER PLATFORMS

In this chapter, we provide a short description of similar courses. The selection is based on the following criteria: First, we only consider courses on MOOC platforms as most of the issues we are focussing on in this paper are to some extent specific for this format. Second, we focus on Python programming courses and third we focus on courses that claim to be addressing programming novices. Finally, we do not claim that the following list is exhaustive.

Programming for Everybody⁵—A first programming course, teaching Python, applies an open-source, web-based development environment⁶ for writing and assessing practical programming exercises. The tool is based on CodeMirror and Skulpt, an in-browser implementation of Python, providing client-side code execution. Since no request to the server is required, the tool's client-side code evaluation approach has the advantage of short response times. Infinite loops also turned out to be problematic, as they eventually rendered the browser window unresponsive. Affecting the client side only, at least they did not affect the performance of the tool for other users than those that caused the problem. Program errors are reported using native browser alert dialogs. Error messages are reduced to the essential. They neither contain a traceback nor provide additional clues to the error's origin. Whenever code is executed, it is also checked against the exercise specification. The programming tool performs automatic grading, based on I/O matching and basic invocation checks at runtime. The grading approach can only grant full score or zero points. Partial solutions, however, are not awarded. Besides auto-graded programming assignments, the course contains two optional peer-graded essays.

Intro to Computer Science⁷—An introductory Python course aiming to build a basic search engine. The course makes use of a lightweight web-based development tool, which is based on CodeMirror and seamlessly integrates into the Udacity platform. The editor is easy to operate, but it provides no means for editing more than one unit of code. Exercise instructions are provided as comments in the skeleton source code and sometimes in the form of a short introductory video. Learners can restart the exercise from scratch, execute their code for exploration, submit their code for evaluation, or view a sample solution, which is presented in a step-by-step fashion. During program execution, Python's standard traceback is presented in case of an occurring error, which might be too cryptic for beginners. During test execution, basic hints pointing to corrective actions are provided, however. The result of successful test-based code assessment is briefly presented in natural language, which benefits comprehensibility but lacks valuable details, such as expected and actual program behavior.

V. BETA-TESTING THE COURSE DESIGN FOR LEARNING ENVIRONMENTS AT SCALE

As a course of this kind was new terrain for all members of the teaching team, we conducted a beta test with six high-school students, who participated at one of the HPI's on-site

⁵<https://www.coursera.org/course/pythonlearn>

⁶<https://github.com/csev/tsugi>

⁷<https://www.udacity.com/course/cs101>

Fig. 12. Workload as perceived by the participants.

youth development activities. The main reason for this effort was to get a feeling about the necessary amount of time that participants would require to cover the workload. The pupils in the beta test were able to work through the exercises of week one in very short time. It took the fastest pupil about ten minutes the slowest had to invest about twenty minutes. Another test was conducted with first semester HPI students. While these students did not notice a higher workload for the following weeks, a survey at the end of the course, and some discussions in the forum, showed that the participants perceived this differently. While in weeks one and two the majority of the users stated that the workload was below three hours, in weeks three and four this shifted towards three to six or even six to nine hours with an increasing dropout rate. See also Figure 12. Therefore, we investigated if our analysis tool⁸ would also reveal that the time that the users have spent on openHPI has increased, which was not the case. See Figure 13. Instead, we can see again the recurring pattern of activity peaks shortly before approaching deadlines.

VI. SCALING THE SUPPORT

At openHPI, the user forum is an important part of scaling the support for the users. The help-desk, openHPI's one-to-one support tool, turns out to be overwhelming the teaching teams, particularly in hands-on courses on beginner's level. Many participants do not realize that personal support is not manageable for a small team facing the massive amount of users. Too often requests cannot be answered during the runtime of a course. Monitoring the forum alone and providing appropriate support is often already taking the teaching teams to their limits. In general, our teaching teams consist of the professor, four to eight research assistants, and one or two

Returning Visits

Fig. 13. Average session length during the course.

No. of	Python2014	IMDB2014
Users total	7373	8641
Users active (avg)	about 3700	1191
Users(Q)	700	139
Users(A)	670	56
Users(C)	770	104
Questions	1404 (0.19/2.01)	219 (0.03/1.57)
Answers	2178 (0.30/3.25)	203 (0.02/3.63)
Comments	3571 (0.48/4.64)	385 (0.04/3.70)

TABLE III. COMPARISON OF FORUM AND HELP-DESK USAGE BETWEEN PYTHON2014 AND IN-MEMORY DATA-MANAGEMENT (IMDB2014)—TWO PARALLEL COURSES ON OPENHPI. USERS(Q,A,C): AMOUNT OF USERS THAT POSTED A QUESTION, ANSWER, OR COMMENT. THE NUMBER IN BRACKETS SHOW THE AVERAGE AMOUNT OF POSTS PER USERS TOTAL/POSTING USERS.

students. Participants are encouraged to support each other in the forums. The teaching team only intervenes if discussions get rough, or go down the wrong track. In Python2014 it could be observed that this style of offering support to the course participants has worked very well. Naturally, as the course had way more participants than the on-site youth development activities at HPI, an increased demand for support had already been expected. The factor, however, by which the forum usage of Python2014 has increased in comparison to other openHPI courses really came surprising. Table III compares the forum activity of Python2014 to a IMDB2014, a regular openHPI course that was conducted in parallel. The numbers in brackets show the average amount of forum posts per total participants and the average amount of forum posts per users that actually have posted a question, answer, or comment in the forum.

The forum usage in Python2014 was significantly higher compared to other openHPI courses (exemplary IMDB2014). The average number of questions per participant was six times higher in Python2014, the average amount of answers was even more than fifteen times as much. The amount of comments was about twelve times higher in Python2014. The majority of the questions were about problems with the programming exercises. Often, the participants started with a complaint about the automatic grader while asking for help. Having received an answer enabled them to finally solve their problem. Common complaints were about tests being too restrictive, e.g. being case sensitive.

We came up with a couple of hypotheses for this significant difference between the two courses.

Fig. 14. Age of the participants who were active in the forum

- 1) The age of the participants: Python2014 sported a high percentage of very young participants. Younger users are more used to expose themselves on the internet and therefore have less problems to publicly post in a forum.
- 2) More posts due to "misusage" of the forum, such as duplicated questions due to a "post first, search for similar topics later (or never)" tactic by the less experienced participants, fun posts or irrelevant posts, and user to user communication via the forums.
- 3) Optimized forum usage by the more experienced users of IMDB2014.
- 4) The professional level and background in IT of the participants: IMDB2014 participants are at a higher level of their career and, therefore, have the notion that they have more to lose when they show the gaps in their knowledge by posting.
- 5) The language barrier: Python2014 participants were mostly German native speakers, while IMDB2014 participants come from all over the world.
- 6) The possible benefit that could be achieved by actively taking part in the forums was much higher in Python2014 as graded homework could be done over and over again. Asking for help in the forum was likely to improve the grade. Due to the short and strict time limits for graded assignments in IMDB2014, in this course, it was rather unlikely to find direct help in the forum.
- 7) As the course itself afforded more active participation, the threshold to actively participate in the forums was less high.
- 8) The forum was identified as the second most important learning material, next to the course videos, in the survey at the end of the course. Way in front of books, even relegating the internet to the third position.

We tried to find indicators for these hypotheses in our data. Table IV gives an overview about the socio-demographic

	Python2014	IMDB2014
Background IT		
Beginner	43.8%	14.7%
Advanced	58.7%	49.8%
Expert	18.7%	35.5%
Professional life		
None / not set	81.6 %	61.6%
Up to 5 years	4.7%	10.4%
Up to 10 years	2.9%	8.5%
More than 10 years	10.9%	19.5%
Highest degree		
High school	23.4%	10.4%
Bachelor, Diplom, Master	42.7%	76.0%
PhD	3.7%	4.9%
other	30.1%	8.7%
Gender		
Male	77.2%	87.5%
Female	22.8%	12.5%
Country		
Native German	96.2%	48.8%
Native English	0.8%	14.2%
India	0.3%	14.9%
Other	2.7%	22.1%

TABLE IV. SOCIODEMOGRAPHIC COURSE DATA.

data of the course participants in comparison to a regular course on openHPI. As mentioned before in the context of the participants' age distribution, we only have this data available for those participants who voluntarily entered this information in their profile page (25.6% in Python2014 and 41% in IMDB2014). Generally, those users, which have a longer relation to the platform and have taken more than one course (and, therefore, are not in the actual target group of this course) are more likely to have completed their profile. So the actual circumstances might be a little distorted. Figure 14 shows the age distribution of the active participants in the forum. Most of the posts are from users that have not completed their profile information. Where we have this information, it seems to be the 40 - 50 year olds who were most active. There were some patterns that we observed amongst the younger participants. For instance, we can say that some inappropriate posts that had to be removed, were definitely written by younger participants. After deleting the threads we wrote to the culprits in private and asked them to stop such behavior. They apologized and the number of this kind of posts was reduced remarkably. Technical or performance problems at peak hours generated a lot of forum posts. We could observe, that especially among younger and not as experienced online-learners, the forum mirrored frustrations over-exceptionally. Discussions in IMDB2014 mainly revolved around three topics: general questions and comments concerning the content, seeking for clarification if the participants understood it correct, in-depth questions on applying the presented principles on real-world problems and organizational questions concerning the course. Since technical issues were mainly targeted towards the helpdesk, and organizational questions accounted for only the minority of threads, most discussions were content oriented. The fact that the in-depth questions usually were too specific to be answered by fellow students, such threads typically ended up in a 3-5 post status, with one post asking the question, a teaching team member answering it and the original poster either saying thank you or asking for further clarification of a certain detail and then thanking the team member. Comparing the numbers per active or posting user, the gap becomes noticeable smaller. While the participants of IMDB2014 in average were less likely to be active in the forum, those who did participate did not show a different communication pattern than the participants of Python2014.

A potential reason for the, generally, more reluctant behavior within IMDB2014 is the fact that substantial parts of the audience did not have English as their mother tongue and, therefore, felt uneasy to pose questions potentially exposing them in front of other adults or even professionals and colleagues. Matching our hypotheses to the data presented in Table IV, it becomes apparent that the language hurdle is most likely to be the main reason for the lower post count within IMDB2014. Above 85% of the participants were non native speakers with regard to the course language. Also the second hypothesis, taking the professional career into account, is backed by the data. While the majority of users did not answer this question at all, the fraction of participants with higher progress in their career in IMDB2014 is about twice as high as the corresponding one in Python2014.

VII. FUTURE WORK

Coming up next on openHPI is another hands-on programming tool that will allow to set up courses in a wider variety of programming languages. This tool also allows to define test cases for these languages—in the language's native testing framework, e.g., RSpec for Ruby, JUnit for Java, etc. Courses, such as Python2014 require additional forum support and monitoring. A possible solution might be to involve experienced and active participants. In an earlier survey we had very encouraging results from users that would be willing to mentor in future iterations of a course [11]. Making these people recognizable as mentors could ease the high demand for individual support. Already during the registration phase of Python2014 an opportunity to scale the support for participants in future iterations of this kind of courses evolved. We received many requests from teachers who intended to use the course in a flipped classroom setting and asked if the platform supports mechanisms to enroll whole classes or to monitor the results of the students in their class. Enabling teachers to give optimal support for their pupils seems to be a promising way to relieve openHPI's teaching teams from at least a part of their workload. For this use case enabling teachers to create learning groups, supervise their students within the group, and being able to check their results will be very helpful for both sides. A very important step is to enable users to go on from where they are when the course has ended. Particularly, it is important to enable the users to step forward from the restricted learning environment that has been employed during the course to a more self-determined way of coding. Therefore, we plan to enhance our next programming course with a supplementary course introducing the participants to the world of compilers, interpreters, and IDEs.

VIII. CONCLUSION

The MOOC format certainly offers a valuable means to scale the youth development efforts of an institution such as the HPI. Offering MOOCs for a very young audience—or more general for novices—however comes along with a couple of challenges. Particularly, a significantly increased amount of support needs to be taken into account when planning the human resources for such courses. Despite several technical hiccups at the beginning of the course, we conclude that the course can be considered as successful. It was well received by the participants and had a comparably very high rate of user participation. In the survey at the end of the course, 84.33% of the users stated that they would recommend the course to other people, and 71.10% asked for a sequel of the course. The age distribution turned out to be more widespread than we had intended. Concerns that this could turn out to be problematic did not come true, rather quite the opposite was observed. Participants of all ages worked very well together and supported each other. Particularly, programming courses at a beginner's level should support a tool that liberates the participants from having to install a programming environment of their own to ease the initial pain. Towards the end of the course, the participants need to be introduced to more powerful tools, however, to enable them to transfer the knowledge they gained to real life challenges.

IX. ACKNOWLEDGMENTS

We thank Kai Fabian, Nicco Kunzmann, and Hauke Klement for their help with the help-desk, forum, and platform. We additionally thank Bernhard Rabe for supporting us at the Future SOC Lab and the pupils and students who helped to beta test the course.

Abstract — The frequent advances in Information and Communication Technologies (ICTs) represent an opportunity to rethink teaching and learning in the context of virtual education. In this perspective, MOOCs (Massive Open Online Courses) have been promoting research in the technological and educational areas, since they serve as an emerging and powerful knowledge-building platform for anyone, anytime and anywhere. However, limitations in the current development of MOOCs have required the search for strategies to support their personalization in order to enhance the users' learning and others skills, such as the ability to self-regulate and to work in a collaborative way, and not just to replicate the content already taught in the traditional classroom, through videos or other passive learning activities. Considering the need for changes in the MOOC's pedagogical model, this research aimed to investigate and promote a reflection about the possibility of using Flipped Classroom Teaching Model principles to design this type of virtual and massive environment. The paper starts with a description of MOOCs, Flipped Classroom and some related works used to support personalized learning in MOOCs. As a result of this investigation, we present some conceptual strategies for educators to design MOOCs from FC ideas and principles. We envisage that adaptation and incorporation of concepts of Flipped Classroom, already applied in face-to-face classroom, can also act as an effective intervention to support personalized learning in MOOCs, helping students to take the active role in their own process acquisition of skills and knowledge construction.

Keywords—Massive Open Online Courses (MOOCs); Flipped Classroom; Personalization; Learning Design.

I. INTRODUCTION AND MOTIVATION

The adoption of Information and Communication Technologies (ICTs) has been highlighted as an important mechanism for improving the quality and learning effectiveness. Among the benefits pointed out, ICTs can also contribute to make students more creative, motivated and

critical, capable of solving problems in a more autonomous and, at the same time, in a collaborative way.

However, there is still little evidence if the isolated use of computational technologies can really change educational practices [3]. Actually, effective learning occurs when computational technologies and teaching methods are applied in an integrated manner, contributing to student's knowledge construction process.

Considering this perspective, some research studies in the Computers and Education field have suggested MOOCs (Massive Open Online Courses) and Flipped Classroom as new trends in order to better achieve the requirements and outcomes of the emerging learning scenarios [5].

MOOCs are characterized as online courses, with unlimited participation of students and open access (e.g., Coursera, edX, Veduca). Although promising, most of the MOOCs produced are still based on traditional classroom formats. Furthermore, the number of students that successfully finish a MOOC is very small, motivating the research for alternative pedagogical designs to deal with the dropout rates.

Flipped Classroom Model [4], in turn, is an inverted version of the traditional learning model. Basically, there is an inversion between in-class and out-of-class activities: firstly, students learn new content by reading texts or watching videos wherever they are, and whenever they want; and then, exercises, group activities, and other active learning strategies are performed in the classroom with instructor mentoring.

Some people are using MOOCs to support out-class Flipped Classroom activities. However, despite of the works already done [31, 33], there is a need for research on mechanisms to support the integrated adoption of these strategies in virtual learning contexts, providing the necessary support for educators to manage their classrooms and for students to develop autonomy and creative skills.

Considering this context, this work fits in this new perspective, investigating how Flipped Classroom ideas can be used as an approach to create personalized learning experiences in MOOCs, in order to achieve initial findings to support an answer for the following research question:

“How the Flipped Classroom teaching model can be incorporated into the MOOCs project in order to contribute to the learning and student’s engagement?”

In a general way, three main factors motivate our research: i) the current model of MOOCs, which basically replicates the traditional classroom; ii) the low completion rates for MOOCs, particularly due to the lack of motivation and student’s engagement; and iii) the large amount of information produced by the interaction among MOOCs and their users. Considering these issues, we propose a preliminary approach based on Flipped Classroom which can be used as an intervention in MOOC project.

This paper is organized as follow: Section II provides information about other projects we have used as motivation to develop the current idea. In Section III, we present some conceptual strategies to be used by educators to describe and design MOOCs from FC ideas and principles. Finally, section IV shows the discussions and future works.

II. THEORETICAL FRAMEWORK

The theoretical framework for this study draws upon three groups of investigations connected by the perspective of learning: i) MOOCs, pedagogical design and its limitations; ii) Flipped Classroom teaching Model, its origin, meaning, characteristics and some experiences on its application in the context of face-to-face classroom; and iii) current personalization approaches in MOOCs. Together, they provide insights to explain an initial conceptual framework for educators to describe and design MOOCs based on Flipped Classroom fundamentals and related theories.

A. Massive Open Online Courses (MOOCs)

As previously discussed, MOOCs have emerged as an important mechanism for democratizing the access to education. In general, the massive and open distribution of learning resources and materials contributes to the dissemination of knowledge and facilitates access to information, benefiting society as a whole.

Nevertheless, despite the enthusiasm raised by MOOCs, there is also much skepticism. In fact, several problems should be addressed to incorporate MOOC as part of formal education [6, 7].

One of the most important challenges in the first generation of MOOCs is how to ensure a minimum participation, avoiding the (relatively) high dropout rates throughout the course [8, 9, and 10]. In general, the dropouts are associated with difficulties in the required autonomy level, the ability to deal with the adopted technological environment and the lack of physical presence of teachers and peers, among others.

Although extremely promising, current MOOCs still reflect traditional class formats with few personalization features and adaptation to their users. For Blanco et al. [11], personalization and content adaptation, assessment and learning strategies, considering the diversity of the audience are gaps that require investigation by researchers.

As highlighted in Guàrdia, Maina and Bleeds [12], the need for the development of new pedagogical approaches that are able to provide consistent support on how should be designed the personalized teaching and learning strategies for this emerging educational setting must be greater than the debate about technological, economic and MOOCs’ institutional aspects.

In general, the presented limitations motivate the search for new ways of understanding the construction of knowledge in virtual learning environments on a large scale. This, in turn, triggers challenges in order to design educational experiences, demanding innovative and appropriate teaching and learning approaches.

B. Support for Personalized Learning in MOOCs

Personalization in learning environments is crucial to the learning of each student being effective, especially in informal education, which requires motivation, determination and users’ self-control [13].

Krafcik, Santos and Apothecary [13] also argue that personalization approaches can be built from different perspectives and applied in various educational contexts, such as face-to-face classroom or virtual environments, formal or informal education, among others.

Personalization in virtual learning environments has been developed for years, and has been evolving as new technological and pedagogical innovations appear. In addition, there is no unique, formal and widely accepted definition. Essalmi et al. [14], for example, highlight some basic principles commonly used in the literature about personalization in e-learning systems, such as personalization parameters, personalization strategies, combining operators, learning scenarios and learning objects.

In this work, the personalization idea is based on Blom [15], which defines it as a process that can change the functionality, user interface, content or the distinctiveness of a system in order to increase its relevance in favor of a certain individual.

Considering these issues, investigations about MOOCs and personalization aspects are still limited. In general, the first generation of MOOCs uses the same content, activities and assessments for all students, ignoring the diversity of learning styles, academic background, learning objectives and cultural/social aspects.

The following strategies change, according to the definition identified above, functional, interface, content, or mainly, the distinctive character of the virtual learning environment. They try to leverage many personal aspects, such as motivation, engagement, self-regulation, effective learning, and

collaboration, among others. In addition, such related works investigated the incorporation of theoretical aspects of collaborative learning, game elements or social aspects in the design of virtual learning environments, including MOOCs.

1) Collaborative Learning

Ronaghi, Saberi and Trumbore [16] presented the MOOC provider called NovoEd¹. His instructional model is supported by many learning theories, such as project-based learning, team-based learning, collaborative learning and social aspects. It is, therefore, a user-centered online environment that attempts to promote the engagement of students, i.e., the focus is not on the content delivery, but on the student's learning. NovoEd supports two types of formation teams: algorithmic and organic. Algorithmic teams are formed automatically, based on criteria defined by instructors. In organic teams, students form their own groups. The Figure 1 highlights the main page of a MOOC available in NovoEd provider. It is aimed at people who have access to a face-to-face classroom where science content and scientific reading are being taught. The MOOC users, which are teachers in the face-to-face class, must complete a series of tasks, such as watching videos, performing tasks embedded in videos, participating in discussion forums, reading research articles and engaging in activities in the classroom where it operates (practical project).

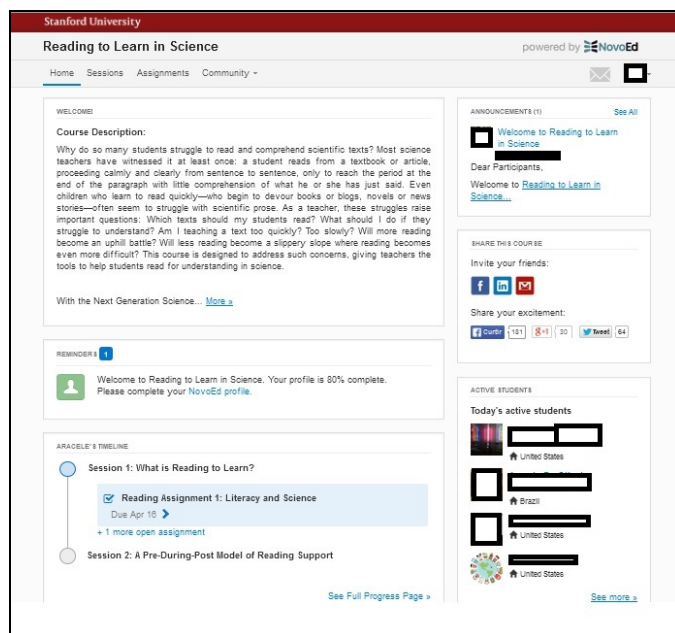

Figure 1 - MOOC “Reading to Learn in Science”, available in NovoEd.

In another strategy, Collazos, Gonzalez and Garcia [17] argue that MOOCs can be understood as an extension of existing online learning approaches, but they also offer an opportunity to think about new models of open online education. Thus, the authors analyzed as collaborative elements should be incorporated into MOOCs, in order to increase students' interest in content related learning. They proposed an

open online course model that integrates collaborative aspects content, activities and assessments, considering the elements highlighted in Figure 2. Teachers are responsible for generate and build contents and activities, but using a collaborative environment. A technology platform supports teachers in the development of collaborative learning activities, defining which task should be performed in order to achieve the rapid and real collaboration among the participants. However, the model has not been validated, and therefore does not measure the level of learning acquired during the collaborative activities.

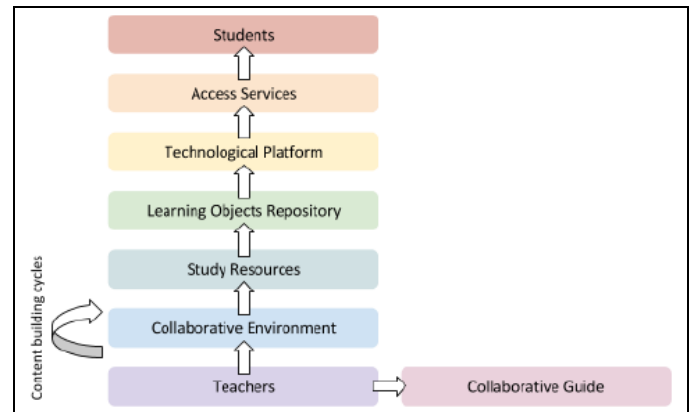

Figure 2 – Collaborative MOOCs supported by a computer model (Collazos, Gonzalez and Garcia [17])

2) Gamification

The addition of game elements in environments that are not related to games, that is, gamification has been used in the design of virtual learning environments in order to enhance some student's personal aspects, such as motivation and engagement.

Considering the high dropout rates in MOOCs, Gené, Núñez and Blanco [18] proposed a model based on gamification to promote students' intrinsic motivation. The model includes an additional layer to MOOC projects, based on game theory and collaborative aspects. This layer includes various elements such as distribution points and ranking, volunteer activities, promote cooperation among peers, information about student' progress, among others.

Additionally, Vaibhav and Gupta [19] conducted an experiment to compare the results obtained from a traditional virtual learning environment and another based on gamification ideas. These results indicated that if the learning platform is based on gamification, not just the subscriber's numbers increase, but also the involvement of users throughout the course.

3) Social Aspects and User Profile

According to Nawrot and Doucet [20], MOOC's platforms, their pedagogical paradigms and business models are still in the early stages of development. This situation and possible connection with low completion rates require different and

¹ <http://novoed.com/>

adapted directions for the construction and use of MOOCs. After investigating the causes of evasion, their results indicated that one of the main motivations and meanings of abandonment is related to bad time management. They presented features that can be incorporated into MOOCs platforms to allow users to optimize their learning process, increasing engagement and reducing the dropout rate. In general, these characteristics should support the prioritization of activities, the development of strategies to achieve the learning objectives, time allocation and schedule. They should provide the user with action plans; activities of driving suggestion, with its priorities and time allocation based on users profile; reports on overall progress in the course, among others. However, the effectiveness of the proposed solutions has not been tested empirically. It is therefore recommendations for MOOCs developers.

Nkuyubwatsi [21] investigated strategies to achieve or incorporate cultural and recontextualization aspects in MOOCs. Using an observation protocol focused on cultural issues, data were collected from videos, quizzes, surveys, discussion forums and five MOOCs descriptions available on Coursera provider. The main practices identified were: i) the translation of courses for certain languages and ii) the creation of local or geographic groups (virtual or face-to-face) to conduct collaborative activities. A small number of MOOCs incorporated activities and projects to encourage students to reflect on the application of the concepts studied in their own environment or work space. The authors consider that project-based activities are important and should be used as a strategy to allow students from different cultures to adjust their learning to their reality of life or work, since they received the opportunity to choose the project theme and which individuals will profit from the implementation of this project. MOOCs designers can use these achieved theoretical results to reflect and build customized interventions to promote diverse and multicultural experiences in MOOCs.

So, developing a personalized learning is one of the most important challenges of the twenty-first century, according to Perry et al. [22]. It is focused on student's success and try to develop in them various skills such as creativity, innovation, critical thinking, problem solving, communication and collaboration. In general, any personalization strategy should consider differing personal characteristics to achieve these skills. The customization in large-scale virtual learning environments must therefore consider different characteristics of learning, such as learning styles, academic background, learning goals, and different social, economic, cultural and media types used by the students.

As the technological evolution happens, different personalization strategies in virtual learning environments appear. In this section were highlighted some studies which incorporate the use of basic fundamentals of collaborative learning theory, games, time management, cultural issues and recontextualization as an intervention in the MOOC pedagogical design. However, these are recent strategies and more investigation about the positive and negative aspects of each of them still need to be performed by the scientific community.

The strategy instigated in this work is based on practices of Flipped Classroom Model already used and investigated in face-to-face classroom teaching. The idea aims at investigating how the principles of Flipped Classroom can be used/adapted to achieve the personalization requirements for MOOCs. The main Flipped Classroom fundamentals are discussed next.

C. Flipped Classroom

Concerns about education reform to provide appropriate subsidies for students to acquire the needed skills for the twenty-first century suggest the adoption of ICTs as an important perspective to improve the quality of education and the search for an effective learning. That is, learning mediated by technologies can significantly contribute to the formation of students more creative, innovative, critical and able to solve problems independently, but in a collaborative way.

Durall et al. [23] investigated the use of emerging technologies to predict their impact on the Latin American context. They compiled a list of pedagogical trends that comprise the main impulsion of technology adoption in Ibero-American education between 2012 and 2017. As stated by the authors, the Flipped Classroom (FC) is the new paradigm of modern pedagogy for both secondary and higher education.

Considering the FC origin, it is likely that this teaching model has been adopted at other times or circumstances, but was not widely used and disclosed in the academic and scientific community [26].

In addition, FC became a popular term [24], mainly from the year 2012. This fact was motivated, in general, from reports about trends in education [23] and by the increased academic interest, noticed by the amount of scientific publications and events that have discussed this subject [25].

With the evolution of mobile devices and the communication media types, since 2012 Bergmann and Sams [4] are constantly referenced in scientific papers of the area as those who popularized the concept of Flipped Classroom. The definition of FC in Bergmann and Sams [4] and Lage et al. [27] establishes the "inversion" of the classroom as the conversion of events that traditionally occur inside the classroom to events that occur outside the classroom and vice versa.

Regarding the concept of FC, according to Bishop and Verleger [25] there is no consensus on a formal and widely accepted definition of Flipped Classroom by the community and, to Bachnak and Maldonado [28] there is no single strategy to apply it.

On the other hand, Bishop and Verleger [25] also argue that such simplistic definitions, in general, can suggest that the Flipped Classroom model is only a re-ordering of the classroom and the activities that are carried out elsewhere. However, as can also be identified in Keengwe [29], FC represents an expansion of the curriculum, rather than a mere re-ordering of activities.

For example, according to Galway [30], the Flipped Classroom model can represents a broader shift in how we think about the learning process. It is based on several theories

about learning and pedagogy. An explicit attention is given to interactive and collaborative learning, based on Piaget's active learning theory, which emphasizes that learning occurs when we act and apply in practice new ideas and learned theoretical concepts.

Galway et al. [30] also points out that, taking into account the influence of (Revised) Bloom's Taxonomy about thinking and learning, the inverted classroom model allows high and low levels of cognitive work. Specifically, students take a lower-order cognitive work, i.e. the acquisition of knowledge, independently and outside of class form; while the higher-order cognitive work, including the application of knowledge, analysis and synthesis, occurs during the class time, with the support of class friends and teachers.

In addition, Flipped Classroom helps instructors or teachers to develop different learning experiences appropriate for each student, considering their regional or local context [4].

The Table 1 highlights some approaches used to achieve the classroom inversion, based on FC general ideas. The main strategies adopted in and out of the classroom, and the main forms of assessment are presented.

TABLE 1 - EXAMPLE OF FLIPPED CLASSROOM EXPERIENCES

Ref	Subject	Out-class activities	In-class activities	Evaluation
30	Master of Public Health	-MOOC -Quizzes	-Short-classes -Active Learning activities -Talks between students-teacher	-Final text -Diary -Online participation -Final project in groups
31	Undergraduate Health. Department of Basic Pharmacy.	-Textbooks -Videos -Virtual Learning Environment Sakai	-Revision Questions -Pairs activities -Discussion mediated by two students. -Quizzes -Short-classes	-Tests -Quizzes -Projects -Engagement
32	Undergraduate Software Engineering. Discipline Introduction to Scrum Methodology.	-Videos (YouTube) -Resolution of some issues before going to class time.	- Group activities - clarification of doubts	- Formative evaluation - Group talks - Summative evaluation
33	Graduation of Teacher Training.	-Sophia Learning Platform -Quizzes -Learning objects interaction	- Project-based learning activities	-Diagnostic evaluation - Sophia learning participation - Project

These and other analyzed works suggest that FC can improve the student's learning and their problem solving skills. FC can also promote engagement and motivation to learn.

Consider and analyze such experiences may be relevant to think over a Flipped Classroom application approach MOOCs project, issue highlighted in this work.

The review also provided a set of findings: i) students can learn at your own pace; ii) the curriculum can be customized; iii) the time in the classroom can be used in an efficiently and creatively way; iv) there is evidence that such model contributes to increase the students levels of interest, engagement and achievement; v) the model supports new strategies and teaching and learning approaches; vi) among others.

This findings were used to support conceptual ideas described in the next section, which can be useful for educators to describe and design MOOCs from FC principles.

III. IDEAS TO ADAPT AND INCORPORATE CONCEPTS OF FLIPPED CLASSROOM IN MOOCs DESIGN

This work argues about the possibility to adapt and incorporate concepts and principles of Flipped Classroom as an intervention in MOOCs design.

Initially, Honeycutt and Glory [34] presented in their blog a reflection about Flipped Classroom model to design more interactive and personalized online learning experiences for virtual learning environments, in general. They suggest that the course project proposal could be planned considering the Flipped Classroom ideas in order to develop learning experiences needed to engage students in theoretical activities or application of concepts, with focus on expected learning outcomes for the related course context.

Based on this first reflection, we present some more explored ideas and new initial strategies to incorporate concepts of Flipped Classroom in MOOC project. The first two descriptions were presented from the perspective of Learning Design (LD). The others could follow the same perspective, but were presented using text model, for reasons of space.

Learning Design (LD) is an approach that aims to support the explicit design of course learning activities with regardless of pedagogical approach [1]. This research field has stimulating the development of useful tools and methods to represent the design process of learning experiences. In this current work, the CompendiumLD tool was used to visually represent guidelines to apply personalized learning activities from the Flipped Classroom perspective. According to Conole [2], Learning Design methods and tools have been shown benefits when employed to design complex learning contexts, as is the case of MOOCs, in which a significant number of resources and stakeholders are involved. However, more investigations about MOOCs and Learning Design are still needed.

For each scenario we highlight i) when the strategy (or idea) could be applied, considering the MOOC outline, ii) some guidelines to apply it, regardless the MOOC platform that will be used, iii) what kind of skills, learning or personal features are stimulated by the strategy, considering the Flipped Classroom related theories, among others.

Scenario 1: In the first week of the MOOC course, or as soon as possible, students (MOOC users) are asked to find important data related with the syllabus, such as material to be learned, course organization, warnings, teaching strategies,

deadlines, among others. Thus, instead of performing a reading of these current features, students have the opportunity to build their own mental or mind map related with the MOOC course (or another kind of conceptual diagram), considering the scenario described (Fig. 3).

According to Willis and Miertschin [36], this kind of strategy is a form of active learning and can be used to engage students in meaningful learning activities, for instance, writing, problem solving, visual thinking, analysis, synthesis, creativity, evaluation, among others, considering the theory related with mind maps.

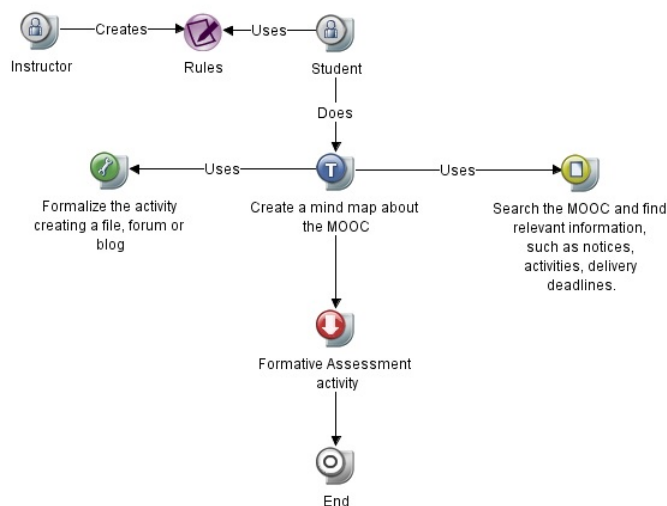

Figure 3 – An application of Flipped Classroom ideas in MOOC project – visual representation from the perspective of Learning Design.

The instructor can also use some final results or shared mind maps to verify and clarify common student's misconceptions early, which could prevent possible high drop-out rates. However, further investigation about this relation needs to be performed.

A way to formalize the activity can be adjusted according to the used MOOC platform, for example, using forum, blog or posting a file. There are many available free and online tools which can be used by the students in order to develop their mind maps, such as the MindMup², what can be used in an integrated way with Google Drive and some browsers.

In addition, the mind map can be changed by a video, text, or audio, considering the student's learning styles, in order to achieve personalization.

About the activity evaluation, benefits can be offered to those who complete the task. In this case, our proposal is a formative assessment activity. However, the instructor can also use a summative assessment with multiple choice test for a more individual and prompt evaluation.

² <https://www.mindmup.com>

Scenario 2: In general, this scenario is related with the use of social media to support learning. There are many ideas or possibilities.

Firstly, the instructor can create an unique hashtag for the MOOC course and share it, before the course start date, in order to promote the upcoming course.

Following on, according to Fig. 4, the instructor can advise the students to use this resource in social media to share interesting materials and stuffs related to the course topics. Many MOOC platforms already provide support for the use of external social tools. In this way, they can feel engaged and motivated for sharing information to their colleagues. It is also important encourage the student to share materials created by himself, such as video tutorials. In this way, a student can act as a teacher to another student.

Finally, the MOOC team can use all the statistics from the hashtag to analyze the results and to take future decisions about the course.

Personalized learning is achieved by enabling students to choose what (video, text, softwares, etc.), when, and where (Facebook, Twitter, etc.) to share, in order to make use of the enrichment resources and undertake the extended learning activities [37].

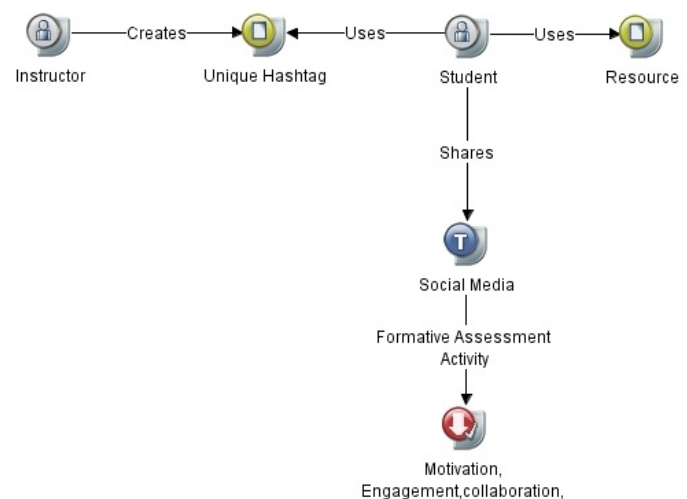

Figure 4 – Using social media to support learning.

Scenario 3: Request students to reflect on how they learn, what are their learning goals and main desires or limitations about the current MOOC course. This can help them to think critically about themselves and encourage them to act to overcome their obstacles or difficulties, which would also be related to the self-regulated learning.

The students have the opportunity to choose how to share their feeling or perceptions about this particular issue. In addition, they can express reflections considering their own learning style. A range of digital media formats (or types) can also be used to represent the reflections, using a discussion forum, figure, text, or shared video, among other ways.

Scenario 4: Students could receive - for example, by their e-mails - interesting and useful learning materials (video, text, games, etc.) and some organized and specific instructions to be performed outside the MOOC platform. Both, materials and instructions (and their related activities), are given according to their learning styles, defined from a survey completed during the enrollment period.

When a user feel ready, he/she needs to perform a quiz designed to test his/her ability about the previous context or activities. According to the result, he/she goes into what we call "active learning room". In this virtual room - the MOOC course - he/she would perform active learning activities based, for instance, on the project-based learning, problem-based learning, among others.

These "rooms" could contain people with similar interests and profiles. Considering another idea, these "rooms" could being opened whenever a number of students is reached. In this way, would not be necessary to wait by future dates in order to begin a course.

To conclude this section, according to Alario-Hoyos et al. [35], teachers and the instructional design team should be aware of the affordances provided by the existing MOOCs platforms at the time of designing courses in this kind of environment, since those may determine for instance the format of learning contents or the types of assessment activities that can be supported.

However, this current work did not consider this perspective because we believe that all the scenarios could be apply in the many available MOOCs platforms. So, considering this question, the present stage of these ideas is its instantiation under an available MOOC platform in order to create some implementation examples about the feasibility of creating personalized learning experiences using them. MOOCs platform is any environment that allows an individual or organization to create a MOOC, providing them with the necessary tools to do so. It can also be called Massive Open Online Education Platform (MOOEP). According to Fassbinder, Delamaro and Barbosa [39], the main MOOCs platforms are Google Course Builder (<https://code.google.com/p/course-builder/>), EDX Platform (code.edx.org), OpenMOOC (openmooc.org) and OpenHPI (https://openhpi.de). Other future perspectives are outlined next as well as the final discussions.

IV. DISCUSSIONS AND FUTURE WORKS

Despite the great enthusiasm instigated by MOOCs, they have also led to many skepticism. There are still several problems to be addressed to ensure that MOOCs be effectively incorporated as part of academic education on a large scale. The high dropout rates, for example, have triggered discussions about students' difficulties in the level of autonomy required, the ability to deal with the adopted technological environment, and the lack of physical presence of teachers and classmates.

Considering the need for changes in the educational and instructional structure of MOOCs, this research work is related with the context of an investigation about personalized strategies in MOOC project. Some ideas for the application of

FC concepts and principles in the project, development and delivery of such massive environment are presented.

In the next step of our research, we will focus on the investigation of new ways to map the main ideas and success stories of using Flipped Classroom in face-to-face environments into open online environment's projects, specifically in the context of massive education.

Future empirical investigation is envisaged using the Educational Design Research [38] with the intention of producing new theories, artifacts, and practices that represent and potentially affect learning and teaching. We envisage that the adaptation and incorporation of concepts of Flipped Classroom, already applied in classroom education, can also act as an effective intervention in supporting personalized learning in MOOCs, helping the student to take the active subject of role in the process acquisition of skills and knowledge construction.

In order to explore the impact of an intervention based on the use of Flipped Classroom strategies on large-scale virtual learning environments, a major experiment will be conducted. For this, two MOOCs will be created (MOOC control and experimental MOOC) in order to determine the impact that Flipped Classroom ideas have on the student's perception, their engagement with the content and the proposed activities, and the acquired knowledge. The control MOOC will be based on xMOOC type, i.e. using traditional learning teaching techniques such as videos, quizzes, discussion groups, among others. The experimental MOOC will be developed using the approach proposed in this paper.

Specific techniques will also be used to analyze i) quality of the MOOC instructional design proposed from the approach established in this work, ii) learning effectiveness, and iii) learner satisfaction.

ACKNOWLEDGMENT

The authors are grateful to the Federal Institute of Education, Science and Technology of the South of Minas Gerais (IFSULDEMINAS) and the Brazilian funding agencies (FAPESP, FAPEMIG, CAPES and CNPq) for their financial support.

Abstract—In this paper, we present a big data software architecture that uses an ontology, based on the Experience API specification, to semantically represent the data streams generated by the learners when they undertake the learning activities of a course, e.g., in a course. These data are stored in a RDF database to provide a high performance access so learning analytics services can process the large amount of data generated in a virtual learning environment. These services provide valuable information to teachers and instructors such as predict the learner's performance, discover the real learning paths, extract the learner's behavior patterns and so on. The proposed architecture has been validated in the Educational Technology undergraduate course of the Degree in Pedagogy at the Faculty of Education of the University of Santiago de Compostela.

Keywords—Big data architecture, Learning analytics, Experience API

I. INTRODUCTION

In the last two decades a huge effort has been made for developing Virtual Learning Environments (VLEs). Aimed to promote students' anytime, anywhere learning, VLEs include tools for participants synchronous and asynchronous interaction, management of learning content, evaluation of the performance of students, and so on [1]. Nowadays, VLEs have evolved to even support different learning strategies, such as collaborative learning, informal learning with social networking support, adaptive learning through trading patterns, etc. However, in spite of the effort, most of VLEs do not provide the tools to analyze what is happening in a course. VLEs are like black boxes and thus teachers are unaware of what learners are doing, making difficult to improve or correct any deficiencies that might take place during the teaching and learning process.

To address this situation, the concept of learning analytics (LA) arose in the early 2010, understood as the measurement, collection and analysis of data to better understand the teaching and optimize the virtual environment in which it occurs [2]. However, a proper software architecture must be established to effectively store and retrieve the large amount of data generated by learners during a course, which is a clear need in current VLEs. Moreover, this architecture should include intelligent data analysis services and so provide valuable information to teachers and learners. For instance, the automatic discovery of the real learning process followed by the learners [3], [4],

the prediction of learner's performance [5], [6], the automatic annotation of the contents generated by learners in interactive activities or in practical exercises [7], are just some examples of techniques that can facilitate the decision support during the course. An overview of the current state of the art in techniques for intelligent analysis of educational data is available in [8].

Although some conceptual frameworks [9], [10] and/or software architectures [11], [12] have appeared in last years, at present there is no proposal that (i) collects in real time the large volume of information generated during a course; (ii) represents and stores this information following a standard specification to facilitate its interoperability with learning analytics services; (iii) enables these services to effectively access to the information generated in the learner's activities; and (iv) offers a set of intelligent learning analytics services that provide new and valuable information to teachers in order to take better decisions for improving the quality of the learning and teaching processes. The description of such software architecture is the focus of the paper.

In this paper, a big data architecture, called SmartLAK architecture, for supporting learning analytics services is presented. This architecture is composed of:

- A Learning Activity Sensor (LAS), which is a platform-specific component for capturing the sensitive data generated by the learners.
- An ontology, based on the Experience API (xAPI) specification, to structure the data generated by the LAS.
- A semantic data repository, where the data are stored in an RDF graph based on the xAPI ontology.
- A set of intelligent learning analytics services that consume the data stored in the semantic repository through an xAPI implementation.

This architecture has supported the analysis of the data generated by 60 learners enrolled in the Educational Technology undergraduate course of the Degree in Pedagogy at the Faculty of Education of the University of Santiago de Compostela.

II. LEARNING ANALYTICS-AWARE ARCHITECTURE

Figure 1 depicts the main components of the SmartLAK architecture, which supports the extraction and analysis of

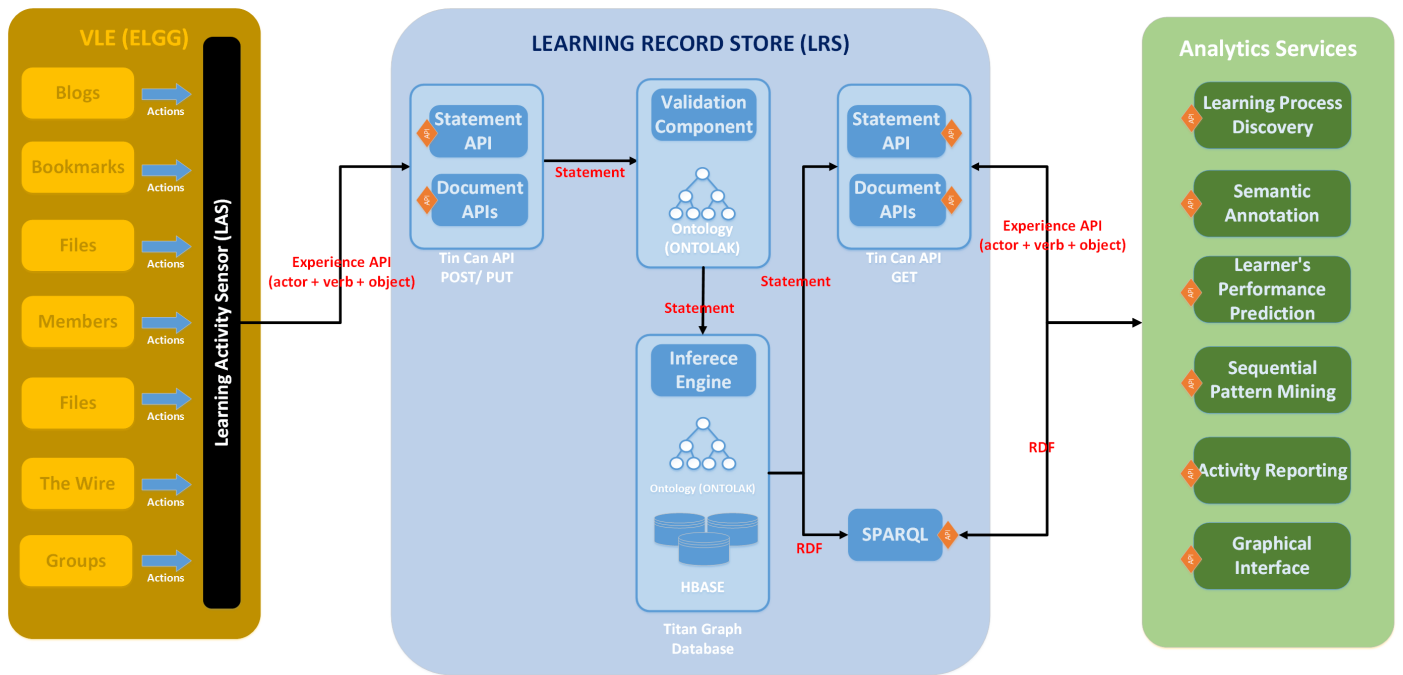

Fig. 1. SMARTLAK architecture

the data generated by the learners in its interaction with the VLE. The development of the SmartLAK architecture has been guided by three key factors: a standard service layer to capture and consume the data flow generated in the VLE (*xAPI services*); an ontology that semantically represents these data to favors the interoperability among the architecture components (*xAPI ontology*); and a high-performance database that enables consume large amount of data (*big data*).

A. Learning Activities Sensor

The purpose of the LAS is to capture the events generated by learners and/or teachers in their interaction with the VLE. In this context, events are atomic pieces of information describing something that VLE users have performed, such as creating a post in a forum, reading an input blog, answering a quiz question, deleting a comment, etc.

Most of VLEs implement event management systems, designed through a publish/subscribe pattern, allowing events to be tracked and represented as *statements* that describe the events and the context in which they occur. In the SmartLAK architecture, events are represented following the Experience API specification, formally known as TinCan API, that defines (i) a data model with the main features of an event, and (ii) an interface of services that will be invoked to store the statement in a Learning Store Record (LRS). Note that tracking events in a continuous way can be considered as an activity stream that requires a high performance infrastructure to effectively store these events when the number of learners (and therefore events) is very high (e.g., in MOOCs).

Taking this into account, the LAS component has been designed as an *event bus* that centralizes every event notification at a single point, where it can be routed as a statement to the LRS where the activity stream is stored.

B. Experience API Ontology

The main classes and relations of OntoLAK [13] are depicted in Fig. 2. The *Statement* class captures sentences in the form: "I spoke with Mike" or "John wrote an essay about surfing". Statements have three *required* properties. On the one hand, the *actor* property represents the subject of the statement. It captures the persons that triggered the event, e.g., the "I" and "John" of the former examples. The second property, namely *verb*, stores the predicate of the statement, e.g., "spoke with" or "wrote". Finally, the range of the *object* property can be an *activity*, an *agent*, a *group*, or another *statement*.

As it is depicted in Fig. 2, a statement can also detail the outcome of the event or the conditions under which it was performed by means of the *result* and *context* properties, respectively. A statement may include the attachments that are part of the learning record. Finally, the *authority* property is used to identify the agent or group who is asserting that statement is true. The remaining four properties of a statement, namely *uuid*, *timestamp*, *stored*, and *version*, are data properties that describe the UUID identifier assigned to the statement, the time when the event occurred, the time when it was stored in the LRS, and the xAPI version, respectively.

C. Learning Record Store

The objective of the LRS is twofold. On the one hand, it efficiently stores learning information (*xAPI statements*) about the events that were generated by learners and teachers in its interaction with the VLE. On the other hand, it facilitates a high performance access to this learning information and enables its processing through big data techniques (e.g., MapReduce). For achieving these objectives, the LRS components are the following:

- *Semantic validation component* is responsible for

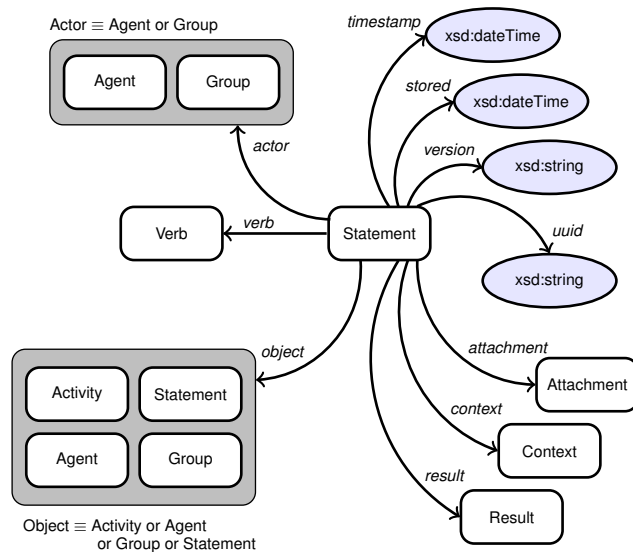

Fig. 2. Experience API ontology

checking whether a statement is compliant with the xAPI specification or not. This component uses Pellet [14], a description logic reasoner, to validate whether a statement that comes from the xAPI service layer verifies both the axioms and rules of OntoLAK, meaning that the constraints of the xAPI specification are fulfilled. In that case, the statement will be stored in the LRS database, guaranteeing that data are compliant with the xAPI specification.

- *Titan* [15] is a high-performance database that facilitates the integration of ontology-based components for conformance checking and semantic querying. In this architecture, Titan stores the information in a graph where data and their relations are explicitly represented, according to xAPI ontology. In addition, Titan provides the ability to expose the graph database as RDF triples through a Sail interface [16], which means that this graph can be exposed and semantically queried by means of a SPARQL endpoint. From the big data perspective, Titan is able to distribute the graph database through various machines in clusters, handling complex crossings graphs in real time and allowing the analysis of large volumes of data through Apache Hadoop.

The LRS interacts with the SmartLAK components through RESTful services that implement the xAPI specification interfaces: to store new statements in the graph database, POST/PUT HTTP methods are invoked from the learner activities sensor, while to access to the database graph, GET HTTP methods are invoked from the learning analytics services.

D. Intelligent Analytics Services

Intelligent Analytics Services (IAS) are independent components that process the LRS data to provide valuable information that enables teachers to better understand what is happening in the course or to facilitate the teaching and learning processes (e.g., assessment). An IAS is composed of

an intelligent algorithm, that provides the functionality of the service itself; a RESTful endpoint, that allow the service to be consumed by other IASs; a set of widgets, that allow visualize the results of the service execution; and a learning analytics sensor, that tracks the user activity when the IAS is integrated as part of a learning analytics dashboard. The current version of the SmartLAK architecture includes a set of IASs that are specially designed to support the learners' assessment. These services are the following:

- *Learning process discovery service* obtains automatically the real learning path followed by the learners during a course. In order to guarantee feasible and correct evaluations of the learning paths, this service retrieves complete solutions while focusing its search towards precise learning paths, i.e., models explaining only what the students did. Last, but not least, it retrieves simple representations of the discovered learning models. This service has been implemented with the ProDiGen algorithm [3].
- *Sequential pattern mining service* detects activity patterns that learners have following during a course. These patterns are understood as sequences of learning activities that occur with high frequency in comparison with other sequences. Thus SPM has been applied to detect activity patterns in self-regulated learning, where the interest is on
- *Semantic annotation service* classifies and annotates the textual content (e.g., blog inputs, posts in forums, comments, etc.) generated by the learners during a course, making easier the teachers access to contents through their topics or annotations. This service has been implemented with the ADEGA algorithm [7].
- *Learner's performance prediction service* obtains the degree of fulfillment of the educational objectives of a course, using as inputs the marks of the assignments of each learning activity that has been performed by the learners. This service has been implemented with the algorithm described in [5].
- *Activity reporting service* provides automatically generated natural language reports built from every student activity data. This service is based on linguistic description techniques adapted from the fuzzy sets field and natural language generation tools. This service has been implemented with the SLAR algorithm [17].
- *Graphical interface service* enables teachers to understand the learner's behavior through the visualization of the data available in the LRS and the results obtained from the IASs execution. Note that typically this component is not independent of the other IASs, since it needs their executions in order to be able to provide valuable information to teachers. Fig. 3 shows a screenshot of the graphical interface of the SmartLAK architecture.

E. Scenario

The current version of the SmartLAK architecture has been used to support the learners' assessment process of the

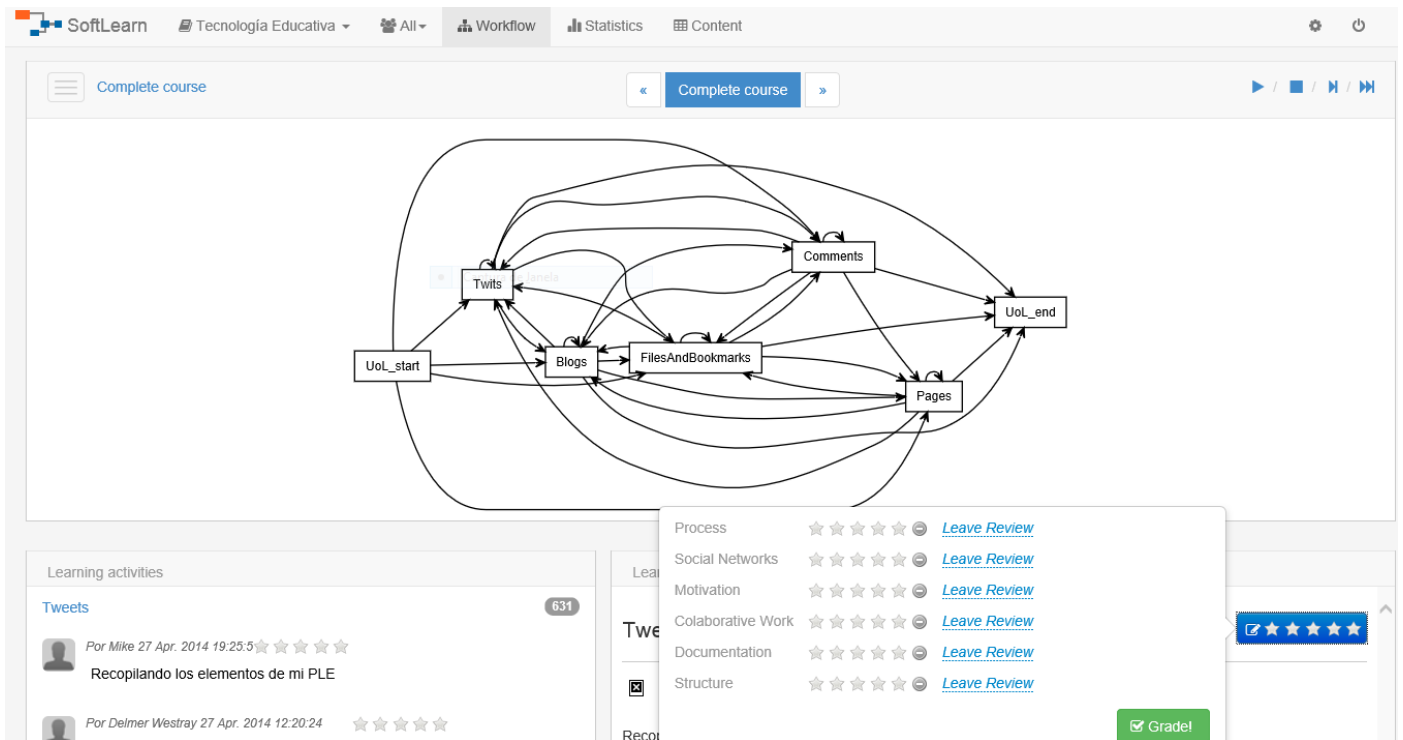

Fig. 3. Graphical interface of the SmartLAK architecture

Educational Technology undergraduate course of the Degree in Pedagogy at the Faculty of Education of the University of Santiago de Compostela. This course has 60 learners enrolled during the first semester 2014 and it was developed in a blended learning mode with virtual activities, where students undertake learning activities through a social e-portfolio with blogs, micro-blogging tools, favorites, pages, etc.

In this scenario, the SmartLAK architecture captured and stored more than 250.000 statements, and its learning analytics services helped teachers to assess the learner's performance based on its learning paths, the classification and annotation of textual content, and the participation statistics supported by a learning analytics dashboard (graphical interface).

III. CONCLUSIONS

We have presented a big data architecture, called SmartLAK, that uses an ontology based on the xAPI specification to represent the activity stream generated by the learners during a course, favoring the interoperability among the components of the architecture. This ontology is also used to check the conformance of the data stream with the xAPI specification, which guarantees that the data in the LRS will be compliant with the xAPI. Once this conformance is verified, data are stored in a high performance database that allow implementing services based on big data techniques.

As future work our intention is to improve the architecture with an Enterprise Service Bus able to integrate different data stream sources and a big data-oriented message queue to increase the activity stream performance. Finally, we plan to experiment with this architecture in several courses with a large amount of learners that would generate millions of data.

Abstract - Information technology has been contributing to various areas of knowledge; in particular, the field of education stands out. In what concerns the teaching of computer programming, literature contains important efforts that aim to assist in the learning process. Teaching algorithms and programming concepts for first year students has always been a great challenge for universities, new Computer Science students usually have difficulties in understanding and abstracting the problem logics. An alternative that has contributed to the teaching-learning process is the use of Learning Objects (LO), which contribute towards mediating and enhancing the teaching-learning process. One of the great difficulties of learning during the initial semesters of Engineering and Computer Science courses is related to the contents of computer programming, which increases the students' failure level and also the dropout rate of such courses. In order to decrease those rates, we have developed a project to create various learning objects to help teach concepts that are considered difficult to understand by students of Science courses, and the results were very positive. This paper presents the qualitative and quantitative results of the experiment we conducted with the development and application of learning objects to help teaching students of Computer Science. The project was conducted in 2013 and 2014 and outcome data showed that the use of learning objects contributes significantly to the teaching-learning process.

Keywords – computer programming; computer science education; educational process; software algorithms; learning objects.

I. INTRODUCTION

Computer programming is a fundamental course taught to Engineering and Computer Science students. Teaching algorithms and programming concepts to first year students has always been a great challenge for universities. Data structures, programming resources, binary trees, sorting, are some examples of very important subjects for students, and several of them do not learn it appropriately. The misunderstanding of programming concepts lead a significant percentage of students to abdicate from their courses.

New Computer Science students usually have difficulties understanding and abstracting the problem logics and transforming it into a step-by-step sequence in order to develop the algorithm later [1].

The primary target of initial programming courses is algorithm design. As these are considered core courses for the Computer Science undergraduate, it is extremely important that students can clearly understand all the concepts covered. However, these courses have experienced the highest failure rates in Computer Science courses.

This fact is due to two factors: a) the paradigm created inside and outside classrooms makes students come to first classes with the fixed opinion that this course will be a great obstacle, extremely difficult to be overcome; and b) some teaching methods used by teachers to present the concepts, because understanding how the computer executes its tasks requires much abstraction ability from the students [2].

Several reasons for student failures in learning algorithms and programming concepts have been described [3], [4]:

- Undisciplined study habits focused on memorizing;
- Unstructured previous knowledge, especially on the domains of mathematics and logics;
- Non-motivating teaching approaches;
- Taught contents are irrelevant to students' day-to-day lives;
- Difficulties in understanding problem wording;
- High levels of abstraction.

The difficulty in learning and teaching algorithms and programming concepts is making coordinators and teachers of Computer Sciences undergraduate courses concerned. These subjects deal with key contents for the formation of the Computer Science professional and present a high degree of difficulty in learning for students.

Many efforts have been made to explore alternative methods of teaching programming concepts to students of the initial years. Teachers have tried the adoption of new tools and pedagogical approaches to help learners engage in a more pleasant learning process.

In the last years, the use of Learning Objects has been experienced as a very important component of instructional tools. A Learning Object can be used in a considerate manner, addressing a part of content that will be worked with students. The instructor can use it as an additional way for teaching.

In this paper we present our experience in using Learning Objects in teaching several basic concepts of computer programming to students of Computer Science first years and the qualitative and quantitative results obtained during the experiments we have conducted with our students during two academic years.

II. BACKGROUND AND RELATED WORKS

Information technology and communication have contributed to various areas of knowledge; in particular, the field of education stands out. With regard to teaching basic concepts of computing, purpose of this study, the literature contains some efforts that aim to assist in the teaching and learning processes: Scratch is an environment that provides the construction of programs and was created with the aim of facilitating learning to beginners in programming. It was developed at MIT (Massachusetts Institute of Technology) using the programming language Squeak; Greenfoot, developed by the University of Kent, in England, and the University of Deakin, in Australia, aims to teach object-oriented programming from the construction of scenarios using the prepared environment for game development.

Greenfoot assumes that the student has previous knowledge of basic programming concepts [5]; the University of Wisconsin-Madison has developed Gamestar Mechanic, an

online platform to build games. The focus is on fostering problem-solving skills and creating motivation for learning science, technology, engineering and mathematics; and finally, ALICE is a 3D programming environment developed specifically for students who have their first experience with object-oriented programming. The software allows the student to learn fundamental programming concepts creating animations and games. In ALICE, 3D objects such as people, animals, vehicles, etc. form a virtual world where students create programs to animate such objects.

Experiments with the use of these software point to the fact that, despite the success of such experiments, much remains to be done in this direction [6].

An alternative that has contributed to the teaching-learning process is the use of Learning Objects (LO). These features tend to facilitate and provide technological support to educational processes.

According to [7], LO are digital or non-digital entities that can be used and reused during a learning process supported by technology.

Applications of Learning Objects can be: animations, videos, simulations, HTML pages, images, among others. Learning Objects can be used discreetly, addressing a piece of content that will be presented to students. The teacher, instead of offering the entire course material through handouts, books, articles or lecture notes, uses the LO which, in turn, will contribute towards mediating and enhancing the teaching-learning process. An LO is a support tool for learning used by the teacher to facilitate deeper understanding of the concept taught [8], [9].

III. LEARNING OBJECTS REPOSITORY

Several repositories for learning objects are available worldwide. Most of them have been developed by the initiative of universities and governmental incentives. A repository of learning objects is an organized collection of digital documents, to which the entire community may or may not have free and open access, and can be seen as a digital library. Students can access these resources made available by the teachers, in order to assist in the course teaching-learning process.

Some examples of Learning Objects repositories are: DOOR, DSPACE, Fedora, EPrints, Edutools, Ariadne, among others. Also the major universities in the world have devoted special attention to the repositories for LO; among them stand out BBC Learning, BozemanScience, Harvard Open Learning Initiative, Khan Academy, Learn NC, Merlot, Math Open Reference, MIT Open Courseware, Nobel Prize Education, Smithsonian Education, among others.

Most repositories store Learning Objects resources to various areas of knowledge, such as mathematics, biology, physics, chemistry, health etc. But there is a very small number of LO developed to teach the fundamental concepts of computer programming, further enhancing the learning

difficulties of students in the early years of Engineering and Computer Science courses.

IV. LEARNING OBJECTS FOR COMPUTER PROGRAMMING TEACHING

The authors of this work have been dedicating to the development of learning objects to help teach computer programming concepts to students in early grades of Computer Science course.

In this sense, learning objects have been developed to teach Pointers, Data Structures, Binary Trees and Data Classification. Such objects are available for use by the entire academic community, and can be accessed through the link: <http://www.fema.edu.br/oa/>

The technology employed for the development of learning objects involves the use of interactive animations created with HTML5 canvas resources, Flash 8 and Javascript. These technologies allow students to have a more intense relationship with the concepts taught in class, facilitating the understanding of the issues addressed by teachers.

V. LEARNING OBJECTS IN TEACHING POINTERS

The first learning object developed aimed to help the teaching process of Pointers to the first-year students of the Computer Science course. With the use of interactive features, the Learning Object works on the basics of algorithms developing, instructions, data and results, and allocation of data in memory. After the student learns the conceptual aspects, the LO applies a series of questionnaires to verify that student's learning level. If the student's understanding was not satisfactory, he or she can return to the previous steps and review the concepts again.

VI. LEARNING OBJECTS IN TEACHING BINARY TREES

The second learning object developed aimed to help the teaching of Binary Trees concepts to the first-year students of Computer Science. Also with the use of several interactive features, the LO covers the concepts of Binary Trees, and the basic procedures of handling the elements of a tree, such as adding and deleting nodes, pathways in pre-order, order and post-order, and the concepts of balanced trees based on AVL trees (Adelson-Velsky and Landis' tree). The processes and algorithms of all operations are explained according to the concepts studied.

As with the other Learning Object, in this case students can also return to the previous steps and review the concepts again, if necessary.

VII. THE PRESENT STUDY

After the development of each of the Learning Objects, the authors of this paper conducted an evaluation process to check the functionality of the tools and to check how useful they were in assisting in the teaching-learning process of students.

The evaluation process was conducted during the academic years of 2013 and 2014, and involved the participation of 106 students from the first year of Computer Science of Fundação Educacional do Município de Assis, FEMA, in Brazil.

For the presentation of the results obtained in the evaluation process, we will describe two case studies, the first of which was held for the implementation of a Learning Object for teaching Pointers and the second was conducted for the application of an LO for teaching Binary Trees.

VIII. CASE STUDY I

In order to know better the effectiveness of the Learning Object for teaching Pointers concepts, we conducted this first case study with 44 students in the first year of Computer Science at FEMA. This study was divided into four steps: identifying the students' knowledge about Pointer concepts, the use of the LO, the assessment of concepts learned after the use of the LO, and the LO environment assessment.

1st Step: Identification of Students' Knowledge about Pointers Concepts

In the first step, we applied the pre-test in order to identify the degree of confidence and knowledge of students about the content of pointer manipulation. The pre-test consisted of objective and essay questions where students should answer the theoretical and practical issues on the use of pointers.

The performance of the students after completing the pre-test is shown in Table I.

Table I – Students' Knowledge about Pointers – before the use of the LO

Right answers	% of students
0.0	13
0.5	32
1.0	23
1.5	14
2.0	14
2.5	2
3.0	2

It can be observed from Table I that 68% of students showed little or no knowledge of the content required in the pre-test, that is, they obtained scores of up to 1.0. Next began the activities regarding the 2nd part of the case study.

2nd Step: The Use of the Learning Object

In the 2nd step the application of the LO was conducted with the target audience. This step was carried out in the computer lab and had the duration of two classes. For its implementation, theoretical and practical activities contained in the LO were planned. It should be noted that the focus of the LO is essentially to present theoretical and practical aspects of using Pointers.

3rd Step: the Assessment of Concepts Learned

The post-test applied in the 3rd stage of the case study aimed to measure the knowledge acquired after completion of activities in the 2nd stage, that is, whether the developed LO fulfills its support role and aids in the learning of contents. The post-test had 4 questions (3 essay and 1 objective) on contents presented in Step 2.

Table II summarizes the performance of students after implementation of the post-test:

Table II – Assessment of Concepts Learned – after the use of the LO

Right answers	% of students
0.0	0
0.5	0
1.0	2
1.5	4
2.0	23
2.5	14
3.0	32
3.5	18
4.0	7

The post-test results show that 94% of students achieved higher accuracy on more than half of the questions to which they were subjected. The post-test was important because it helped us in understanding which concepts and skills were well taught during the 2nd stage and which still require extra time to be worked on.

4th Step: Assessment of the Learning Object environment

Finally, in Step 4, students answered a questionnaire of satisfaction about the contents taught. They could assess how the Learning Object was helpful in their learning, if it really was a feature that offered the support they expected, and how the experience in using the LO was. From the perspective of students, the survey results were encouraging, since 62% replied that the LO facilitates the understanding of the key concepts covered in the case study, and 84% of students see the LO as an important supplement to traditional teaching lessons format used by Computer Science course teachers.

IX. CASE STUDY 2

With the objective of verifying the contribution of the Learning Object on teaching Binary Trees, we conducted this second case study with 62 students of the first year of Computer Science.

These students were in the end of the first year, so they had already been studying algorithms and programming three quarters before, but this was their first contact with the concept of binary trees.

The same strategy adopted on case study 1 was also adopted for this case. The study was divided into four steps: identifying the students' knowledge about Binary Trees concepts, the use of the Learning Object, the assessment of concepts learned after the use of the LO, and the LO environment assessment.

1st Step: Identification of Students' Knowledge about Binary Tree Concepts

In the first step, we applied the pre-test in order to identify the degree of confidence and knowledge of students about the content of Binary Trees. The pre-test consisted of objective and essay questions where students should answer the theoretical and practical issues on the use of binary trees.

The performance of the students, after completing the pre-test, is presented in Table III.

Table III – Students' Knowledge about Binary Trees – before the use of the LO

Right answers	% of students
0.0	64
1.0	20
2.0	11
3.0	5
4.0	0
5.0	0
6.0	0

It can be observed from Table III that 84% of students showed little or no knowledge of the content required in the pre-test, that is, they obtained scores of up to 1.0. Next began the activities regarding the 2nd part of the case study.

2nd Step: The Use of the Learning Object

In the 2nd step the application of the Learning Object was conducted with 62 students. This step was carried out in the computer lab and had the duration of four classes. For its implementation, theoretical and practical activities contained in the LO were planned. It should be noted that the focus of the LO is essentially to present theoretical and practical aspects of using binary trees.

In the end of each stage of the LO, students needed to solve some problems, using the concepts learned. While they worked on the solution of the problems, the students' excitement and how easily they had understood the concepts was remarkable. Most students could successfully solve the proposed problems, and some of them could create new functionalities.

3rd Step: the Assessment of Concepts Learned

The post-test applied in the 3rd stage of the case study aimed to measure the knowledge acquired after completion of activities in the 2nd stage, that is, whether the developed Learning Object fulfills its support role and aids in the learning of contents. The post-test had 6 essay questions on contents presented in Step 2.

Table IV summarizes the performance of students after implementation of the post-test:

Table IV – Assessment of Concepts Learned – after the use of the LO

Right answers	% of students
0.0	0
1.0	0
2.0	0
3.0	6
4.0	34
5.0	42
6.0	18

The post-test results show that 100% of students achieved higher accuracy on more than half of the questions to which they were subjected. The post-test was important because it helped us in understanding which concepts and skills were well taught during the 2nd stage and which still require extra time to be worked on. However, the results were very satisfactory.

4th Step: Assessment of the Learning Object environment

For this fourth step, we conduct an assessment of the entire Learning Objects environment, and the results are presented in the next section.

X. EVALUATION AND RESULTS OF THE LEARNING OBJECTS ENVIRONMENT

At the end of the process of Learning Objects use, students answered a questionnaire of satisfaction about LO. They evaluated whether the LO has the ability to facilitate the understanding of concepts, whether the LO actually helped to better understand the concepts, if the LO has some element that hinders the understanding of the concepts, and if the use of LO can complement the learning of concepts.

Four questions were asked, and the answers given by the students in this LO assessment process are presented below.

Q1. Does the Learning Objects help understanding the concepts?

Answers	% of students
Entirely disagree	0
Disagree	0
No opinion	11
Agree	39
Entirely agree	50

This review has shown that 89% of students believe that the LO is a useful tool that helps in the process of understanding of the concepts presented.

Q2. Has the Learning Objects actually help in better understanding the concepts?

Answers	% of students
Entirely disagree	0
Disagree	5
No opinion	10
Agree	35
Entirely agree	50

This evaluation indicated that 85% of students answered that the LO assisted in the learning process of the concepts studied.

Q3. Does the Learning Objects have any element that hinders the understanding of the concepts?

Answers	% of students
Entirely agree	2
Agree	5
No opinion	19
Disagree	37
Entirely disagree	37

The answers to question number 3 express that only 7% of students found some element that could hinder the understanding of the concepts. Next they answered what these elements were, and that helped to improve the LO. The items most often mentioned by students indicating the elements present in the LO that were hindering the understanding of the concepts were:

- the displayed text is not clear enough for the comprehension of the concepts discussed;
- the graphical layout used for the presentation of content;
- more examples with everyday situations could have been used.

Q4. Can the Learning Objects complement the learning of concepts?

Answers	% of students
Entirely disagree	0
Disagree	0
No opinion	3
Agree	8
Entirely agree	89

The answers to question number 4 indicate that 97% of students believe that the use of Learning Objects can supplement the learning of concepts studied. This result can be proved with the post-test we applied at two case studies, where we can see that most students achieved higher accuracy on more than half of the questions to which they were subjected (Table II and Table IV).

We got very encouraging results, as they showed an important value related to motivation and beliefs of students with the use of Learning Objects. Even considering that this was a subjective assessment, this scenario converged to the importance of the use of learning objects for teaching computer programming concepts.

XI. CONCLUSIONS

This work aimed to present the experiences in using learning objects for computer programming teaching in Computer Science introductory courses. Computer tools were used as pedagogical basis, with the objective of providing practical activities fomenting the study assessment process.

We conducted two case studies. The first one was taken with 44 undergraduate students in the first year of Computer Science, in which we worked with a learning object for teaching Pointers concepts. The second case study was taken with 62 students, in which we worked with a learning object for teaching Binary Trees concepts.

In both case studies we could compare students' knowledge level about the taught concepts before and after the use of Learning Objects. It was evident in the answers gathered on first and third steps of both case studies.

For the first case study, we concluded that 68% of students had very little or no knowledge about Pointers concepts and the third step showed us that 94% of students had more than 50% of success in learning the contents taught. Results set out the growth of students' knowledge about Pointers concepts. Furthermore, it is important to highlight the students' behavior when using the learning object, they felt motivated and had fun solving the proposed problems, and these are essential factors for facilitating the learning. This is also an important factor to contribute for reducing the failure rates in Computer Science and Engineering courses.

In the second case study we concluded that most students (84%) had very little or no knowledge about Binary Trees. It is important to highlight that these students were in the end of the first year, so they had already been studying algorithms and programming three quarters before, but this was their first contact with the concepts of Binary Trees. In the end of this case, we could verify that 100% of students had more than 50% of success in the assessment, and 60% of students had more than 80% of success in the assessment. In this case it was also very clear that the learning object helped students learning the concepts for computer programming.

Finally, the results of the Learning Objects environment were very positive. For the assessment we conducted with the students, we concluded that 89% of students agree that the LO helps understanding the concepts (Q1). With Q2, we saw that the LO helps understanding better the concepts for 85% of students, indicating that the LO is a very good support tool for teaching. On Q3, we concluded that 74% of students indicated that the LO does not have any element which interferes in the understanding of the concepts. And, on Q4, we concluded that 97% of students indicated that the LO is a tool for complementing the concepts learning.

The results gathered on this project are very important and positive. It can serve as a basis for the academic community to start the development of more learning objects for teaching computer programming, making the learning process for first years students less difficult.

Abstract—We present a problem-based approach to teach computational physics to junior-level students with a variety of programming skill levels, many of whom have only 10 weeks of prior programming experience. The students solve tasks, relating to their current class topics, which are mathematically challenging but computationally tractable. The tasks are chosen to develop and reinforce student understanding of traditional physics content. We provide students with minimal code examples (47 lines of python code in a one-year lab sequence) and no textbook, and require students to search the internet for help to achieve the tasks assigned. This is effective through the use of a pair-programming pedagogy, when students are given tasks at a suitable level. This pedagogical approach should be transferable to any mathematical discipline for which computation is appropriate. Because student effort is focused towards accomplishing tasks within their discipline, they gain the practical skills needed to use computation effectively. Because we give students no templates or example code, they are forced to develop the skill of learning a programming language, and debugging code. This gives students confidence, and prepares them to learn other programming languages in their future career: a most important skill!

I. INTRODUCTION

We have set out to develop a computational physics course at Oregon State University that improves student learning of physics content while simultaneously providing students with valuable computational skills. This course neither uses canned simulations to help students understand physics content (as in [1], [2]), nor is it structured around numerical methods, with physics content chosen incidentally to illustrate those methods (as in [3], [4]). Instead, we have developed a computational laboratory that functions analogously to conventional laboratories: students learn computational methods as they apply them to the physical systems that they are learning in their “conventional” courses—although the junior-year physics curriculum at Oregon State is far from conventional [5].

The approach of integrating computation into the curriculum has seen an increasing trend. There is currently considerable work being done to integrate student-performed computation into instruction the teaching of physics content at the lower-division and high-school levels [6], [7], [8]. There has also been an encouraging trend in textbooks for upper-division and graduate-level physics that incorporate computational concepts into the presentation of physics content [9], [10].

In this paper, we will introduce the pedagogical approach we have developed in this course. We will begin by discussing the pedagogical philosophy of the course, and give one example of a classroom activity, including typical student output. We will end with a discussion of our preliminary assessment results.

II. PEDAGOGICAL PHILOSOPHY

Our pedagogical philosophy is grounded in the belief that all physicists (and likely all university graduates) need to be able to program a computer effectively. This is borne out by recent surveys of physics graduates by the American Institute of Physics, which show that over 85% of new physics PhDs use programming skills regularly in their work, as do 75% of the bachelors recipients for whom data was available. Thus computation is not the realm of Computational Physics students, but should instead be a skill learned by all physics majors. The desire to teach *all* of our physics majors was a significant consideration in the design of this course. In particular, we aim to ensure that even students entering our Physics major with no programming experience are able to exit the major confident in their ability to program a computer to solve common problems numerically.

In this section, we will outline the approach we developed to address the difficulty of teaching students who are already under a heavy course load to program effectively.

A. Course structure and prerequisites

This new computational laboratory course is designed to be taken by students who are taking our junior-year Paradigms in Physics courses [5]. This is an intensive sequence of courses that meet seven hours per week, and makes heavy use active engagement pedagogy. The pedagogy and content ordering of the Paradigms are novel, but the content taught during this junior-year sequence is a subset of the content taught in a standard upper-division physics curriculum. Therefore, we anticipate that this course can be adapted to work at other colleges and universities.

The course has as a prerequisite an existing lower-division Computational Physics course that is required of our physics majors. This course is taught using Visual Python [11], and covers typical topics in Newtonian mechanics. Students leave this course with an ability to write simple python programs, and with some understanding of methods for solving for

the motion of a particle acted upon by forces that they can compute. In practice, only about half of our students have taken this prerequisite, while the remaining students either had prior programming experience or a similar lower-division computational physics course at a local community college.

A primary design principle for the course was to have students do all programming in class. This was motivated by our experiences teaching Computational Physics in the lower division. We have found that the students who struggle most with programming are the least able to learn effectively through completing homework assignments outside of class. Given that these are the students who most need a computational course, it seems counter-productive to have the majority of time spent on the class happen outside of class, when those who need the course the most are least productive. So we developed this course as a one-credit laboratory that meets three hours per week, either one or two days a week, with no expectations of student work outside of class.

B. Pair programming

In order for this course to work for all upper-division physics students—even those who are hesitant to use computers—we use the *pair programming* approach, in which students work together to write programs [12], in a laboratory setting in which students work on their assignments with an instructor present to help with debugging [13]. Previous research has reported that this pedagogy eliminated gender differences in reported confidence in programming [14].

One student in a pair is the *driver* and the other is the *navigator*. The driver uses the keyboard and mouse to enter in the program, while the navigator looks for bugs, gives advice, and tries to plan ahead. Every half hour or so, the instructor tells the students to swap roles [15]. We assign students to pairs, and we usually change up the pairings each week, even when students are in the middle of a project, which results in one student in each pair working with an unfamiliar code. Although some previous work has changed pairings in a similar manner [16], we are not familiar with previous work that changes pairings in the middle of a project. This changing of partners serves several goals. One is to help students to learn to write code that is comprehensible and editable by others, by giving them the experience of struggling to read and modify other students' code. A second is to encourage the each member of a pair to ensure that they understand how their program works, since either student may need to finish the program the following week without the assistance of their original partner. Finally, the practice of regularly changing partners limits the damage due to the situation where a particular pair fails to work together well, and helps to prevent the situation in which one student habitually defers to his or her partner.

Our experience with pair programming has been overwhelmingly positive. We have observed that students who are working in pairs are far more resistant to the frustration of tracking down bugs in their code than students working individually. This gives students the valuable experience of going through the lengthy process of tracking down bugs. At the same time, pair programming allows an instructor to effectively manage a larger class size, since students working in pairs are less dependent on the instructor to make progress.

The course proceeds as a sequence of projects, in which the students are asked to solve some task, which usually involve computing and visualizing a result. Typical projects take between one and three weeks, and end with a “show and tell” time, in which several students in the class present their code to the class, and show their results. We have found this show-and-tell to be both popular and instructive. Students gain experience in speaking in front of a group, which is always valuable. Show-and-tell also enables the entire class to benefit from a trick that one pair figures out, and gives students feedback on their programs.

C. Python + Numpy + Matplotlib

We have chosen to use python, with the numpy and matplotlib libraries. Python is a very easy language both to teach and to learn, and skills learned in python transfer well into other languages [17], [18]. Our experience using python in our lower-division computational physics course as well as the experiences of others [19], [20], [6] indicate that it is an excellent language for introducing programming to young physicists who have never before programmed. Python is also sufficiently powerful that students need not move on to a different language for their research needs. Python is widely used in the scientific community [21], [22]. The numpy and matplotlib packages allow python to be used for quick interactive matrix analysis and visualization [23], [24]. This combination of a general-purpose language that is easy to learn, and which is popular with research physicists makes python an excellent choice for a course such as this one, which aims to provide even novice programmers with the skills needed to use programming effectively.

D. Google it!

We provide our students very little in the way of teaching materials for python itself. There are abundant resources online for learning to program in python, and we encourage students to search for and use these resources. We believe that in this day and age, the skills needed to find online resources for programming are if anything more vital than the content that can be made available in a book on programming. Searching for help in programming is a skill that is *learned*, and as with most skills, learning requires practice.

We give students essentially no example code (47 lines of code for the one-year sequence). Our experience has been that when given example code, students approach tasks by copying the example code and modifying it. While copying and modifying sample code *is* expert-like behavior, there are several reasons why instructor-provided sample code can be problematic. When example code is provided by the instructor, students are not required to engage in several high-level activities. They can usually assume that the code is suitable for their use, relatively bug-free, and written in a programming language suitable for their coursework. Each of these determinations is challenging for novice programmers. By *not* giving students example code (apart from aforementioned 47 lines of code), but encouraging them to use online resources, we enable students to learn to program in a way that much more closely reflects the context in which they will actually use programming. The 47 lines of code we *do* give students is mostly examples for creating animations, since we ourselves

Fig. 1. Student code from day 1 and its output. The students have computed and plotted the electrostatic potential due to four point charges. The import statements and a redundant (but harmless) line of code are not shown.

have found that task challenging to figure out from resources on the web.

III. EXAMPLE PROJECT

On the first day of class, we ask students to write a function computing the electrostatic potential due to four point charges in a square, and to plot this function. The students have recently sketched a contour plot of the potential of this charge configuration in their electrostatics course. We encourage students to be creative in their visualization of the potential. Figure 1 shows one example of a student program and its output, generated in about two hours on the first day of class. Other pairs generated color plots or three-dimensional plots.

IV. PRELIMINARY ASSESSMENT

We collected considerable data regarding what actually happened in class. The instructor and teaching assistant wrote a half-page journal entry after each class period, noting what we did, and often recording either things that we wish we had done differently, or events during class that we found surprising. At the end of each class period, we collected survey results from each student answering the questions, “What did you do today?”, “What did you learn today?”, and “What was one thing that didn’t work well today?”, along with the name of their partner. These surveys were used to record class attendance, which resulted in a high response rate, although often brief and sloppy answers. We also saved a copy of the students’ code after each class period. Together, this data gives us a good picture of the amount of time spent on various activities, and what the students were struggling with.

After each quarter, an external evaluator conducted a focus-group interview with a majority of the students in the class over the past two years. We chose this format in order to identify consensus opinions, and distinguish these from

unique perspectives of individual students, as well as to assure students of anonymity.

Finally, we have performed several exam-style assessments, in which we asked students individually to perform some programming task in a given time period. We did not permit students to use any of their own source code, but did allow them to use any online resources. We used screen-recording software to record their progress, saved a copy of their source code, and noted whether they finished early. These assessments enabled us to identify specific learning goals that were not being achieved by the entire class.

In the following sections, we will summarize our conclusions from these assessments.

A. Format of the course

Students consistently expressed very positive attitudes about the course content and format. Even though they took the class while also enrolled in very work-intensive junior level paradigms classes, all students reported that they wished they had more time to work on the class.

Students expressed that they valued the pacing of the class. Most of them didn’t finish every project and a few didn’t finish one. Students’ didn’t see this as a problem, since their learning, both in terms of the physics and the communication skills, were always intensive and productive during class. Prior to the class, some faculty had been concerned that faster students would be bored by the slower pacing. No student reported anything that hinted the class had gone too slowly for them.

B. Pair programming

The overwhelming majority of students in the focus group interviews appreciated the group nature of the class format and the requirement that students must learn to communicate effectively with others while working. They saw this as both a worthwhile goal and for the most part an enjoyable process. Any frustrations associated with “wasting” time learning to communicate with new people were seen as necessary and in valuable in themselves. Even the one student who didn’t “like” the pair programming still said it was a good idea. After one particularly challenging class, one student reported that “troubleshooting with [my partner] was great.”

C. Physics content

Evaluating student learning of physics content material through the computational lab presents a significant challenge. A few students used python and matplotlib in their other coursework—particularly the analysis of experimental data.

In the focus group interviews, the group strongly agreed that they understood the paradigms class material more easily and in depth because of their experience in this class. Many said that they performed better on paradigms exams thanks to the class and those who did not still reported that they were better able to “visualize” the topics learnt in class.

D. Computational skills

In the focus group interviews, students widely recognized that numerical thinking was important for a physicist and that computational skills were very valuable. Students felt that the course satisfied both these learning goals well.

Your task: Write a program to numerically perform the integral

$$I = \int_0^1 e^{-x^2} dx$$

Fig. 2. Integral pretest task. Of the 8 incoming students who were assigned this task in Fall 2014, 5 were able to successfully write a program to compute the integral.

We are in the process of developing assessment methods suitable for this class. In particular, we have found it challenging to create tasks which are achievable by some, but not all, of our students. In addition, a pre-post comparison of results is problematic because a significant minority of our students enter the course with little programming experience. We will report here on pre-post results from the Fall of 2014. In addition to the source code generated, we collect screen recordings of these assessments in order to help us to understand student errors.

For the pretest, we gave students 30 minutes to complete a programming task. The students were randomly divided into two groups, and students in each group were assigned a different question. Prior to this assessment, we allowed students to familiarize themselves with our laboratory computers by writing a “hello world” program in python in pairs. Students worked on the assessment individually, and were allowed and encouraged to search the internet for help. We chose simple numerical tasks that did not require significant knowledge of python libraries to complete. For brevity, we will report on one problem in the pretest and a matching problem in the posttest. The task we omit showed qualitatively similar results, but several students failed to understand the mathematical nature of the problem in both pre- and post-tests.

In this following summary, we omit one student from both the pre- and post-test, who had previously taken the winter and spring terms of the course, and was thus not representative of a student beginning the sequence. In addition, we omit from the summary one student who is not a physics major, but is a professional programmer.

The first task (shown in Fig. 2) asked students to solve for the solution to a simple definite integral. An expert programmer would perform this integral in two or three lines of code plus an import. This task was given to 8 incoming students, of whom 5 were able to successfully complete the task in a half hour. Of the 3 remaining students, one produced a working program that integrated the wrong integrand. These results illustrate that we had a number of strong incoming students, with a few weaker students.

At the end of the term, we gave a two-hour final assessment. This assessment took the place of the final exam, but students were informed that their grade on the final exam would be based purely on participation. Again, the students were split into two groups, each of which were given a different task. These tasks were chosen to be analogous to those given in the pretest, but more challenging. We report here on a quadrature task analogous to the task described in Fig. 2.

Your task: Write a function $f(z)$ defined by:

$$f(z) = \int_0^z e^{-x^2} dx$$

and plot this function.

Fig. 3. Integral posttest task. Of the 7 students who attempted this task, all were able to write a working quadrature function, albeit in one case with a missing factor of Δx , and in other cases with incorrect behavior when $z < 0$. Of these 7 students, 4 were able to plot their function correctly.

As in the pretest, we asked students to compute a definite integral, but with several complicating factors. Firstly, the upper bound of the integral is a variable, and the students were required to write a function in terms of this bound. Secondly, we asked students to plot this function versus the variable upper limit (see Fig. 3). Students spend much of the fall term performing numeric integration in three dimensions, so this task directly tests material covered in the course. This problem was unusual in that the limits of the integral depend on the independent variable of the plot. In most cases seen in class students were able to pass an array to a function written for scalars to create the plot, relying on the elementwise arithmetic operators and functions implemented in numpy to transparently handle the arrays, as is seen in Fig. 1. In this task however, such an approach will fail, and explicit looping over the coordinate is required. An unanticipated challenge for this task was to write a function that works for values of $z < 0$, which corresponds to “integrating backwards.” While we did not prompt students to plot the function over any particular range, two did plot their results for negative values of z . We chose to interpret as correct solutions that gave correct answers for positive input.

All 7 students assigned this task were able to create a function integrated correctly, although several gave wrong answers for negative inputs. Of these 7 students, 4 were able to plot their results successfully. This demonstrates a considerable learning gain, as all of our students were able to tackle this more challenging integral with a variable bound.

V. CONCLUSION

We have developed a combination of three factors that enables an effective computational physics laboratory course, which fits into students’ heavy course schedules and provides students with valuable programming skills while simultaneously reinforcing physics concepts taught in their traditional courses. This combination consists of pair programming in a computer lab setting, requiring students to search for programming resources on the web, and the choice of python as a programming language. We anticipate that this combination can be effectively applied as a computational laboratory course suitable for any discipline that employs mathematics at a level that students find challenging.

ACKNOWLEDGMENT

The funding for this project was provided, in part, by the National Science Foundation under Grant No. DUE-1141330.

Interest-driven and innovation-oriented practice for programming course

Lingling Zhao, Xiaohong Su, Tiantian Wang, Yongfeng Yuan

School of Computer Science and Technology

Harbin Institute of Technology

Harbin, China

zhaoll@hit.edu.cn

Abstract—In order to maximize the motivation of students in the programming practice, this paper offers an analysis on the core factors of practice case motivating students put in effort in programming practice, namely, "interest", "usability", and "hierarchy". Furthermore, we present typical practice cases which are carefully designed according to the motivating factors and give a description on the implementation and experience of our programming practice course at Harbin Institute of Technology. The designed programming practice can not only train the students' practical programming skills but also enhance their self-regulated learning skills, creativity and self-efficacy.

Keywords—programming practice; interest-driven; usability; programming course

I. INTRODUCTION

For the introductory programming course, a large amount of practice is typically required for students to develop good programming skills such as design, coding, debugging skills and so on. But it's commonly hard to sustain unless students are strong self-control or sufficiently motivated. To overcome the natural and inherent learning difficulties created by programming characteristics, an important issue should be put emphasis on: **how do we improve the level of motivation of students to devote themselves to programming practice?**

It is reported by numerous studies that the motivation has a remarkable effect on learning [1, 2]. However, how to prompt students to programming practice poses challenges. Research from many different perspectives has been devoted to the topic, but there is still no consensus on what is the most effective way to raise students' interest and effort in programming practice.

Assignments, labs and projects are typical exercise patterns to train students' practical programming skills. There is no doubt that a series of well-designed labs or projects would be benefit of attracting more attention of students and help them maintain effort longer, which can explicitly and strongly enhance student's practical skills. Different approaches of teaching programming to overcome these problems emerged: pair programming[3,4], game programming[5-8], apprenticeship method[9], test-first approach[10] etc.

In this paper we exact and try to answer the following questions which we believe have significant influence on the quality of practice.

- What kind of labs and projects can maximize the motivation of novice students?
- What format of labs or projects should be exploited?
- How should we evaluate the quality of students' submissions?

The main contributions of the paper include: the core features that "good" practice cases should own are proposed, namely, "interest", "usability", and "hierarchy". We also provide some recommendations on how to design effective programming practice activities and two typical practice cases. Finally, we report the experiences from its application at Harbin Institute of Technology, especially the experience in assigning student new role in project evaluation.

II. MOTIVATION FACTORS IN PRACTICE TASK SELECTION

In order to motivate students to put in effort in programming practice, practice cases should be of some critical properties, including "interest", "usability", and "hierarchy". In this section we will provide detailed explanation on these features.

A. Interest

Interest is an essential factor affecting students learning. Compared with those vapid and dull problems, an interesting and novel project will automatically prompt students to actively put in effort, determination, and focus to work on their goal.

B. Usability

We consider usability as one of the most important characteristics when designing a specific project for students to implement, that means, the programs students submit are not only ones just as assignments but also useful tools they can utilize in real life, that is, it is of value for application or academic research. This point is usually ignored in traditional pedagogical programming course. But the usability enables students to feel real sense of achievement, which improves their self-efficacy and keeps them continuously attracted in the programming practice.

C. Hierarchy

If a project or a lab is considered hierarchical, it means the requirement to solve the problem in the project or lab can be divided into several levels. Foundational knowledge and programming skills are needed for the

basic requirement; while to meet the higher requirement, students have to rouse the facilities they have owned to act. A hierarchical problem makes the problem-solving easier and step by step as climbing a mountain with steps.

In addition, a hierarchical problem should also be open, which guarantees students more freedom and creativity so that they can improve their program according to their own ideas, making it more functional, friendly, or of other good properties.

III. FORMAT OF PROGRAMMING PRACTICE

A. Strategy for programming practice

The aim of programming practice is to develop students' ability in coding, problem solving, self-regulated learning skills and computational thinking. In the design and organization of practice activities, the following strategies should be followed.

1) The programming practice should proceed in an orderly way and step by step. The critical skills are repeatedly exercised until they are fully grasped by students.

2) The programming practice should concentrate on training students' problem-solving ability. The labs and the projects should be attractive for the students, full of interest or practicality.

3) The constraints on the practice should be relaxed as much as possible, which will inspire the creativity of students. For example, students are allowed to choose any format, implement method, tools or functions to perform, design their own process and implement by themselves so that they can independently and actively practice to achieve the self-regulated learning ability.

4) Students should be given enough freedom during the project, which includes several aspects. First, the teacher can provide the selective tasks for practice, and it's free for students to choose one from them or just initiate a new subject only if it is permitted by teachers. Second, students are encouraged to freely choose the implementation path to reach the mile stones with the direction and the inspiration of the teacher. Once the basic requirement is met, student achievement will encourage them to challenge other objectives. Third, students also have the right to freely choose cooperators to achieve a challenging project. Finally, the criterion is changed from the teacher decision to the demonstration and presentation mutually evaluated among the students.

B. Organizations of labs and projects

We divide labs (one 150-minute lab per week) into junior labs and senior labs. For junior labs, we put emphasis on the training of students' fundamental programming skills, such as debugging, common algorithms and problem-solving strategies. For senior labs, higher requirements are brought in so that students need to flexibly apply their knowledge to solve some complex problems. Additionally, they will face some new methods in software development such as incremental testing, which enhances their programming skills as well as computational thinking [11]. For projects, students

need to perform a project in two weeks and they are evaluated by a specific assessment method.

C. Student Requirements

Students are required to be familiar with some types of integrated development environment (IDE) as well as the common algorithms when solving problems by computers. Furthermore, it is necessary for students to utilize constructional and object-oriented programming methods to solve some practical problems, which cultivates their program analysis, design, coding and debugging abilities and helps them to get into a habit of good programming style.

IV. TYPICAL PRACTICE CASES

We present several typical practice cases carefully designed according to the motivating factors: Game of life and the upgraded Gluttonous Snake.

A. Case 1: Lab- Game of Life

Game of life is a cellular automaton proposed by John Horton Conway in 1970. Cells are initialized in an array space and continue to evolve according to a series of specific rules until they maintain steady or all die. Due to its fantasy and rigorous evolution, the game is popular in all over the world and has been exploited as the practical task in programming courses in some universities[12]. Here we provide our revised version of Game of life as a lab task.

● Lab objectives:

After performing this lab, the students should be able to master the syntax of array declaration, array assignments and array initialization, write programs to model repetitive data using arrays, and manipulate the array data structure.

● Background:

Cells live in a world composing of an infinite two-dimensional grid, each of which is in one of two possible states, alive or dead. Every cell interacts with its eight neighbors from 8 directions, horizontally, vertically, or diagonally adjacent. At each time step, the following transitions occur:

1) Any alive cell with too few or too many alive neighbors will die;

2) Any dead cell with a suitable number of neighbors will resurrect;

The system is initialized by the given first generation of cells. Then by applying the aforementioned rules simultaneously to every cell, further generations are created continuously at each discrete moment.

● Task

Subtask 1:

Build up your own cell world and then initialize the positions and numbers of ancestor cells randomly or by user input.

Subtask 2:

Let cell population evolves according to the evolution rules and depict the transition process

Subtask 3:

Judge whether the cell population stops evolution, here if one of the following conditions are satisfied we consider the cell population are steady:

- 1) No changes happen in the cell world;
- 2) Cycle changes happen in the cell world(suppose the length of a cycle is no more than 4)
- 3) Some cells maintain invariant, meanwhile others are in periodic variation.

Subtask 4:

If the cells live in a three-dimensional grid world, can you design an upgraded game of life?

Analysis:

This lab is designed according to the aforementioned design principles. First, the lab topic inherits the natural interest from game of life due to its miracle; Then, the task in the lab is also well divided into several difficulty level to gradually train students to complete more and more complex task. Furthermore, there are sufficient space left for the students preparing to challenge themselves.

B. Case 2:Project- Gluttonous Snake

● Lab objectives:

After performing this project, students can learn the knowledge on object-oriented programming and master the methods of object-oriented programming, and strength their abilities of system analysis, design, coding and debugging.

● Background:

Realize an upgraded gluttonous snake game which could help users to learn English and recite words.

● Task:

Subtask 1:

User's account management: the system can keep a record of user's information, point and rank; meanwhile has the capability to handle the CRUD(create/read/update/delete) management of some personal information.

Subtask 2:

Implement the following game rules:

- 1)foods shown in the window may appear randomly everywhere and the snake updates its location and length timely;
- 2) the player can control the motion of the gluttonous snake by the keyboard, or if the player leaves it alone, the snake will move along;
- 3) when the head of snake reaches a food, the snake "eats" it, at this time, the food disappears, the length of snake grows up, and the player's point increases;
- 4) if the snake's head reaches the boundary of the window or enters into any part of its body, the game is over.
- 5) when the point is above the given value, the player passes the level;

Subtask 3:

Implement the game management function: the player can set various levels of difficulty based on the food-appearing frequency and the velocity of gluttonous snake;

Subtask 4:

Implement the word-reciting function:

- 1) At the beginning of the game, a word is shown to the player;
- 2) Letters randomly appear in the window as the foods of the gluttonous snake, so the player must manipulate the snake to eat the letters in sequence to form the word shown to him/her.
- 3) Once the snake successfully eats off the word, the player's point will increase.

Subtask 5:

Implement the extra word-reciting function:

- 1) The word list is randomly extracted from a word file in disk.
- 2) Only if user's snake eat off all the words in the word list, the player passes the current level.
- 3) With the game ranking increasing, the level difficulty of words increases.

Analysis:

The highlights of the project exist in two aspects: it is originated from the classic computer game "snake", most of students are very familiar with the game but never try implementing it, which easily raises students' interest; Further, the tasks are also divided into several levels of different difficult degrees. For those students with weaker programming skills, subtask1, subtask2 and subtask3 are suitable for them to strengthen their fundamental coding and debugging skills; for students preferring to challenging themselves, they will face with more complex and difficult tasks in subtask4 or higher. Finally, the idea behind the updated Snake with English learning is to combine the preliminary game develop with English words recitation, which is especially suitable for non-English undergraduates. The project enables students to make use of their own small software to learn English words as well as relax themselves.

V. PEDAGOGICAL RESULTS IN HARBIN INSTITUTE OF TECHNOLOGY

In this section we will give a description on the implementation and experience of our programming practice course in Harbin Institute of Technology.

A. Practical teaching syllbus

Considering the characteristic of our local institution and undergraduates, we present an updated teaching curriculum and lab curriculum for C Programming Language course in relation to CS2013 recommendations[13,14], highlighting the development of the students' abilities on programming, problem-solving, self-regulated learning, and computational thinking. The practical course syllabus and corresponding knowledge coverage based on CS2013 is listed in table 1.

B. Student works

Here we provide several typical students' submissions from different tasks, which are shown in figure 1, 2, and 3.

TABLE I. KNOWLEDGE COVERAGE

Lab/Project	task	Knowledge unit and topics covered in CS2013	Features
Lab	Number-guessing game	SDF/ Fundamental Programming Concepts/ Basic syntax and semantics of a higher-level language; Variables and primitive data types; Expressions and assignments; Conditional and iterative control structures;	Interest; Hierarchy
Lab	Game of life	SDF/ Fundamental Programming Concepts/Arrays; Pointers; Functions and parameter passing; The concept of recursion.	Interest; Hierarchy
Lab	Strong password generator	SDF/ Fundamental Programming Concepts/Strings and string processing; SDF/ Algorithms and Design/ The role of algorithms in the problem-solving process;	Interest; Usability; Hierarchy
Lab	Class attendance test tool	SDF/ Fundamental Programming Concepts/ Functions and parameter passing; The concept of recursion. SDF / Development Methods/Defensive programming.	Usability; Hierarchy
Lab	Upgraded game of life or class attendance test tool	SDF / Development Methods/Debugging strategies. Object-oriented programming PL /Object-Oriented Programming / Object-oriented design; Definition of classes: fields, methods, and constructors.	Interest; Usability; Hierarchy
Lab	Personal financial management software	SDF / Fundamental Data Structures/ Records, structs; Strategies for choosing the appropriate data structure; file I/O. SDF / Development Methods/ Unit testing.	Usability; Hierarchy
Project	Intelligent schedule	SDF / Fundamental Data Structures/ Records, structs; Strategies for choosing the appropriate data structure; file I/O. SDF/ Development Methods/ Unit testing; Debugging strategies;	Usability; Hierarchy
Project	Encryption machine	SDF/ Algorithms and Design/ The role of algorithms in the problem-solving process; Problem-solving strategies; Fundamental design concepts and principles; SDF/ Development Methods/ Program correctness; Debugging strategies; Documentation and program style	Interest; Hierarchy
Project	Gluttonous snake game	PL /Object-Oriented Programming / Object-oriented design; Definition of classes: fields, methods, and constructors. SDF/ Development Methods/ Unit testing; Debugging strategies; Modern programming environments.	Interest; Usability; Hierarchy
Project	File Compression	SDF/ Algorithms and Design/ The role of algorithms in the problem-solving process; Problem-solving strategies; Fundamental design concepts and principles; SDF/ Development Methods/ Program correctness; Debugging strategies; Documentation and program style SDF/ Development Methods/ Program correctness; Debugging strategies; Documentation and program style	Usability; Hierarchy

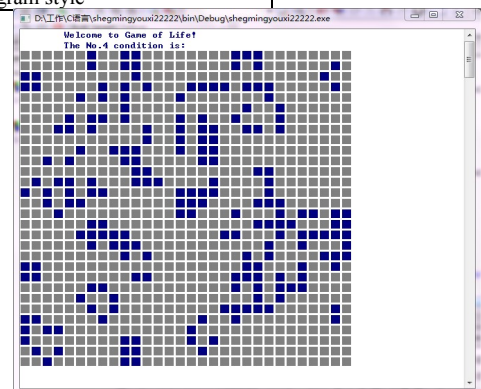

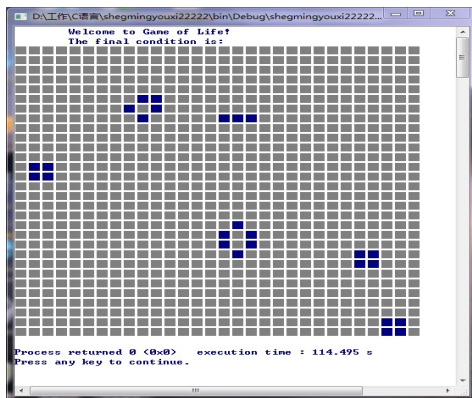

Fig. 1. Game of Life implemented in C.

The submission for Game of life is capable of the following extra functions: 1) users can change the evolution rules by input; 2) the system can automatically judge whether the evolution has stopped and once it is confirmed, the calculation will be terminated.

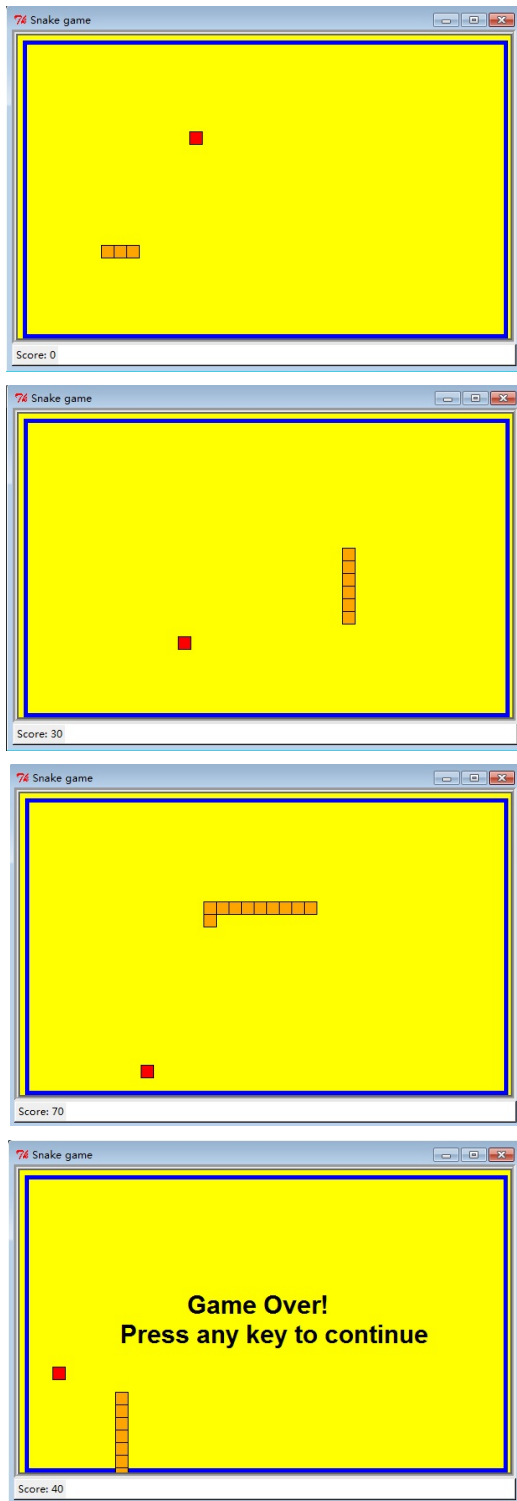

Fig. 2. Snake implemented in Python.

Figure 2 shows the work of a student who had faced with difficulty in programming. Through his great effort he performed 2 subtasks in 3 all in the given 2 weeks.

C. Student's new role in project evaluation

To motivate students to actively take part in the programming practice, we exploit a novel project assessment method by creating a new role for each student, a judge. When a team is making a presentation and defending for their own project, all other students take responsibility for assessing the project and giving scores from different aspects (shown as table 2). The weighted average scores are considered as the final score of a team. Besides, to avoid the possible injustice such as overestimating or underestimating because of emotional reasons, we eliminate those singular scores before calculating the final scores. Figure 3 depicts a score distribution to a submitted work "Encryption machine". 44 students and a teacher and a teacher assistant took part in the scoring activity. The final score calculated according to the following equation.

$$s = \left(\frac{w_1}{N} \sum_{i=1}^N s_i + w_2 s_T + w_3 s_{TA} \right) \quad (1)$$

Where w_1, w_2, w_3 are weight of student judge, teacher and teacher assistant respectively, N is the number of those effective scores s_i from student judges (without singularities), s_T denotes the score provided by the teacher, s_{TA} by the teacher assistant. In our application, we set $w_1 = 0.6, w_2 = 0.25$ and $w_3 = 0.15$.

TABLE II. SCORING ITEMS FOR PROJECT

item	technical difficulty	innovation	function	presentation	collaboration
score	10	10	10	10	10

TABLE III. SCORE DISTRIBUTION FOR WORK "ENCRYPTION MACHINE"

item	score
average score and variance from student judges	34.86(5.05)
score from teacher	32
score from teacher assistant	34
final score	34

Fig. 3. Score distribution for a submitted project. Points in rectangle are singular.

D. Student response

The failure rate of the students in this course is listed in table 4. Compared with the failure rate of 2014, it can be found that the failure rate decreases significantly.

TABLE IV. STURENT FAILURE RATES IN PROGRAMMING LANGUAGE COURSE

term	student number	failure rate
2014-Spring	131	16.03%
2015-Spring	123	9.75%

Students prefer the improved labs and projects to the traditional ones. Many of them indicated that on course evaluations:

“I feel it’s no longer difficult for me to implement a lab, although sometimes I can’t finish all tasks, I still solved most of them.”

“I like those interesting subjects, they are awesome!”

“I really like the project style, especially we can do what we like to do. We chose a challenging problem and made a lot of improvement by ourselves and also learned something new during the project performance. It is really important for me.”

VI. CONCLUSION

Based on the analysis of the features of good practice pattern and content, we provide some recommendations and descriptions on our experience during the building of students’ programming capability. Considering the characteristic of our local institution and undergraduates, we reorganized and redesigned the labs and projects for programming course, which highlights the development of the students’ abilities on programming, problem-solving, and computational thinking. The designed programming practice can not only train the students’ coding skills but also enhance their learning skills, creativity and self-efficacy as well as boosting their confidence in challenges in the field of computer science and software development in future.

Abstract — In the traditional form of teaching and classroom organization, lectures are given in class, and tests and examinations are given in class. The major drawback of this approach has been the difficulty of getting the students engaged in a traditional lecture. A computer science course in programming seems to be a natural class to implement a flipped classroom approach: individualized pacing for theory with cohort based skill acquisition. A flipped classroom is a form of blended instruction where students learn course content outside of the classroom and either homework or other forms of active learning activities occurs in the classroom. Herein is a summary of our observations based on several semesters of implementing a flipped classroom and report on observations made. There are numerous advantages to flipping a class such as allowing for more interaction during the face-to-face class meetings; it also allows for deeper learning to take place as students get their hands-on practice. We explore these practices and more, and compare and contrast what worked and what didn't work from our experiences. We also identify procedures critical to success and what procedures we view as less important.

Keywords—*flipped classroom; programming course*

I. INTRODUCTION

The first programming course discussed herein is a four-credit class which has traditionally been a three-hour lecture and a one-hour laboratory course. The course starts the student from the basic concepts behind programming such as the use of constants and variables all the way to the use of arrays, one-dimensional and multi-dimensional. It is a first course of a two-semester introductory sequence that covers the fundamentals of algorithmic problem solving. The typical audience for the course is first- and second-year students mostly in computer science and engineering. The course emphasizes general programming methodology and concepts common to object-oriented and procedural programming languages: algorithms, top-down structured program design, modularity, efficiency, testing and debugging, and user-friendliness. Java is used and the object-oriented paradigm is covered, including classes, objects, access control, abstraction, and encapsulation. Other topics include organization and hardware, input and output, subprogram units (methods), fundamental data types, reference types, control structures including conditions and iteration, and arrays.

II. THE FLIPPED METHODOLOGY

In the traditional form of teaching and classroom organization, lectures are given in class, and tests and examinations are taken in class [1]. Students are given homework which are completed outside of class. In a flipped classroom, some or all of this traditional methodology is reversed. A flipped classroom is a form of blended instruction where students learn course content outside of the classroom and either homework or other forms of active learning [2] [3] activities occurs in the classroom. The course content may be delivered by assigning readings from textbooks, watching and listening to videos prepared by either the instructor or a third party, or any combination of the two. In the classroom, students apply the knowledge they have read or watched by doing hands-on, practical work. The instructor is in class to guide students while they implement what they have learned outside of class. The continuous assessments (quizzes) of the students [4] [5] given outside of class are useful to spot trends which can be addressed in class as a “mini-lecture” or outside of class in a directed quiz-lecture (“quecture”). The quecture is a sequence of questions which guide the student in the review of a video or paper.

III. MOTIVATIONS FOR FLIPPING

Several motivations have driven us to flip our classes:

- Flipping liberates class time which can be used to address specific concerns and establish a “learning cohort”
- Students’ desire to be “doing” rather than “listening”
- The proliferation of technical tools such as recording videos, course management systems, and video hosting sites.

One of the main forces that has driven us to flip our computer science course is to procure more contact hours with the students doing actual programming. We all know that the more practice students have, the better they get at forming algorithmic solutions and implementing those solutions. Freeing up the class from lectures gives us this freedom to use our time dedicated to active learning. The time in class may

be one of the few times the students are able to interact and create a group to discuss concepts. The best students establish these cohorts early in the course, but it is hard for some students to create this network independently. Also, small corrections to bad programming practices, when caught early, can help develop good habits.

At the same time, students prefer to be “doing” rather than passively listening to a lecture given by the instructor. It is a lot easier to motivate the student when they are working on writing code than lecturing and perhaps quizzing them orally on the concepts in between lecture topics.

Another driving force towards this pedagogical approach is the proliferation of tools to help us create videos and manage course content such as Blackboard. As of recent, it has become easier to create your own videos whether it is simply narrating over prepared slides or recording a screen capture. Course management systems (Learning Management Systems) are also hosted at most universities allowing us to easily upload videos, create on-line quizzes and tests, and disseminate other electronic course materials to students.

All of these factors have been the impetus for making this flipped methodology both desirable and a possibility.

IV. THE FLIPPING APPROACH

Certain activities are delegated and required to be accomplished before class, some activities reserved for class time, and others for after the class. Candidates for pre-class activities are those in which one would be simply “broadcasting” to the class.

A. Before Class

Lecture videos are created by the instructor the content of which mimics the textbook content. Each chapter is broken into either 2 or 3 segments. Students are asked to either read the textbook or listen to provided videos. Original content can be supplemented with numerous online sources which provide rich interactive lectures with self-assessments. Care must be taken not to overwhelm the students with numerous sources.

To make sure students read or watch the material, quizzes are given before and outside of each class. The main purpose of these assessments is to make sure that students actually read or watch the course materials prior to class. From our experience, a simple randomization of fill-in-the blank questions is sufficient to curtail rampant cheating if the quizzes are given outside of class.

We have found a very high correlation of pre-class assignment completion and class attendance and use these assessments to take attendance.

B. During Class

During class time, laboratory work that correspond to the material assigned are given to the students. For example, if the lesson assigned for the class is on writing conditional statements using if-else, a laboratory that has the students write the code to find the roots of a quadratic equation (stating whether or not there is one root, two unique roots, or no roots)

might be assigned. Most of these labs are assigned to student pairs where a couple of students are grouped and the two student cohorts are expected to work together. These labs are assessed as well after they are submitted.

Tests and examinations are also given in class to ensure that students are assessed on the knowledge they have gained. These generally count for a larger percentage of their final grade.

C. After Class

After the lesson(s), a more challenging assignment is given on the topic and students are expected to work on these on their own.

A summary of the flipping approach and task distribution:

Before Class	<ul style="list-style-type: none"> • Read textbooks and/or watch video lectures • Take a short quiz after reading/watching
During Class	<ul style="list-style-type: none"> • Laboratory activity reinforcing material read/watched • Take examinations
After Class	<ul style="list-style-type: none"> • Complete assignment to reinforce topics learned

V. FLIPPING EXPERIENCES

We have implemented the flipped approach for several semester now and, over time, have honed some of the procedures around this technique. Here we present our observations and we group them based on the student’s and the instructor’s perspective. We also classify our observations based on benefits (good), harsh reality (bad), and the unpleasant (ugly). The results shown below are gathered through observations and direct feedback from students via conversations and questionnaires.

A. The Good

From the students’ perspective, the flipped approach gives them a chance to actively learn in class as opposed to passively listening to a professor lecture. This is a great incentive for those who truly want to learn. It is a chance to practice what they’ve read/watched. For those students who watch the video lectures, they have the option of pausing and replaying material that are more difficult. On the contrary, if an advance student picks up the material easily, they can fast forward or skip certain content material. Using pair programming as a cohort system, students have a chance to learn from each other as they collaborate on the same design, algorithm, and code.

As was mentioned earlier, this approach buys the instructor that precious time in class. It frees the instructor from lecturing passively, talking to the class rather than interacting and checking out students’ progress. This is possible because learning the syntax and definition of terms (shallow learning) has been delegated to before-class activity. Class time is now

spent creating a deep and active learning environment for the students.

B. The Bad

All this means that the student has to be proactive with their class, knowing what the material to be covered is ahead of class. As students watch videos or read the book, any difficulties are not addressed immediately but they typically wait until class meets to resolve them rather than reaching out for help earlier.

As quizzes are given outside of class, there is no supervision so there is no guarantee that the student is not getting external help in answering assessment questions. Another hurdle is that in order for the active learning to occur in a programming classroom, the room need to be equipped with enough computers for students.

A pathway for the more advanced students to bypass work or assessments designed to keep less motivated students in pace with the course must be provided, otherwise these students may underperform.

C. The Ugly

Since students do their reading/watching before class, this implies that students spend more time dedicated to the course than usual since there is also homework to complete after class. Another big difficulty is that students need to be self-motivated to complete all the pre-class work in order to succeed. This has proven to be the biggest challenge in our flipped classroom, as it is in a traditional classroom.

For the instructor, there is lot more preparation required. In addition to creating laboratories, assignments, quizzes, tests, there are lecture videos. Creating videos, as an activity, may not necessarily be a quick task; similarly, looking for appropriate, third party video material is also time-consuming. There is more grading involved since all the contact time generates student work; assessing these have proven to be time-consuming as well.

A summary of the good, the bad, the ugly:

	<i>Student's Perspective</i>	<i>Instructor's Perspective</i>
Good	<ul style="list-style-type: none"> Students write programs, instead of listen to lectures Student may pause video lectures or repeat sections Advance students may "fast forward" Peer and collaborative 	<ul style="list-style-type: none"> More personal contact between instructor and students Shallow learning occurs outside of classroom (syntax, terminology, etc.), Deep and active learning in class

	learning possible	
Bad	<ul style="list-style-type: none"> Students need to actively get ready for class Lecture questions have to wait 	<ul style="list-style-type: none"> Quizzes outside class, no supervision Need a classroom in a laboratory setting
Ugly	<ul style="list-style-type: none"> More work (videos + assignments) Need to be self-motivated to learn material 	<ul style="list-style-type: none"> Prepare lecture material (videos) Prepare classroom activity (lab work) More grading

VI. CONCLUSION

While a few educators still resist the change from the traditional pedagogical approach, many of us are embracing this new trend. Not every course or classroom is suitable for flipping. Our experience tells us that a course in programming is one course that is ideal for implementing a flipped approach. This is especially true when students have personal computers staring right at them throughout an entire class period; resisting the temptation to wander on the Internet rather than listening to a lecture is quite challenging. Turning this around by making the students actually use the computers and having a "lab day" every day dovetails with students' yearning for being hands-on. Learning definition and syntax are delegated to activities before class, while active and deeper learning takes place in the classroom for a rewarding experience, both for the students and the instructor.

Abstract— While Object-Oriented programming in Java has been widely adopted as an introductory programming course in Computer Science, it is considered difficult to teach and learn. Studies have identified that the difficulty is from the underlying Object-Oriented concepts and principles. To help student programmers better understand the structure of a program and the concepts of Object-Oriented design, visualizations in various formats have been applied to programming environments.

This paper presents a web-based interactive educational programming environment, Javlinacode, and its unique design principles. Javlinacode is designed for teaching object-oriented programming in Java. It aims to enhance student programmers' programming skill and to help them understand object-oriented design concepts. It provides integrated static and dynamic visualizations: the static state of a Java program in an UML class diagram and the dynamic run-time state of the program execution. With the synchronized multi-view real time visualization along with source code, Javlinacode is highly expected to reduce student programmers' cognitive workload in Java programming and to enhance comprehension of the object-oriented programming and design concepts.

Index Terms—object-oriented programming, programming education, static visualization, dynamic visualization

I. INTRODUCTION

Brian Kernighan stated, "No matter what, the way to learn to program is to write code, and rewrite it, and see it used, and rewrite again. Reading other people's code is invaluable as well" [1].

In the process of learning Object-Oriented Programming (OOP) in Java, difficulties including programming language syntax, programming environment, and problem solving skills, have been commonly mentioned. Although Java is one of the most popular programming languages taught at universities and colleges, studies have discovered that it is difficult for students to learn due to the underlying OO concepts and principles such as encapsulation, abstraction, inheritance, and polymorphism. With inheritance, polymorphism, and dynamic binding features, objects in OOP typically interact with each other asynchronously and method calls are difficult to track. Comprehension of the functionality, structure, and behavior of a program is a crucial component of the programming learning

process. OO programs are known for being complex to visualize and their control flow difficult to follow making the learning process challenging.

A student's development environment is another factor that influences learning OOP because it requires students to manage issues such as platform dependencies and conceptual understanding of classes, objects, and Object-Oriented Design (OOD). It also appears that software visualization tools are seldom employed in the OOP development environment. This is because current tools visualize a single aspect (i.e. structure or behavior) of the software. As a result, visualizations from these tools are not enough to support the understanding of OOP.

In order to address the limitations of current visualization techniques, an approach is proposed to integrate abstraction along with structure and behavioral aspects. Many programming environments that provide graphical visualization have been developed to help students enhance OOP learning. While those are used in conjunction with source code, code writing is still a programmer's responsibility. Studies have pointed out students encountering difficulties in installing an IDE and JDK, and modifying system environment variables on their own machines. Somehow make clearer that this is not an issue with Javlinacode since it is web-based.

The aim of this research is to enhance OOP education by improving the effectiveness of OOP development environments with static and dynamic visualization. The motivation for this work is the lack of an interactive OOP environment integrated with both static and dynamic visualization. A static class diagram is generated from the static information which is derived from source code. Dynamic tracing visualization is generated from the dynamic information of the program execution. When polymorphism is taught using class diagrams, sequence diagrams, and source code, students need to simulate running the program in their minds to understand how it works. As the combined visualization of both static and dynamic aspects suggests [2], visualizing the dynamic run-time state in corresponding to the source code and static diagrams will reduce the burden of a complex simulation in students' minds.

JavelinaCode provides integrated static and dynamic visualization of Java programs at line level and a full overview of a project under development. This interactive hybrid visualization approach is expected to help students to better understand current code and to choose the right design alternatives. The research hypothesis explored in this paper is whether an interactive static and dynamic visualization that incorporates structural and behavioral views supports OOP comprehension in an OOP development environment.

II. COMPARING VISUALIZATION SYSTEMS

This section compares some programming environmental tools based upon how the OO features are highlighted in the visualization. Unlike JavelinaCode, these tools must be downloaded and installed as a stand-alone program, or plugged into Eclipse (AguiaJ) or NetBeans (CoffeeDregs).

A. BlueJ

BlueJ is an integrated software development environment targeted on novice programmers [3]. It allows programmers to interact with objects by inspecting their values, calling methods, and passing them as parameters. The strengths of using BlueJ include the ability to help students link source code and visualizations and the ability to support learning in the cognitive domain. Evaluation studies revealed that BlueJ is good for students in the first year object-oriented programming course due to its simplicity and pedagogy [3, 4] and it helped students to understand the object-oriented paradigm [5].

Hagan et al. report that students who participated in the experimental study had difficulties with installing and running the BlueJ system [6]. BlueJ does not place emphasis on communication between objects or illustrate the association or aggregation of classes [17]. Linking Java source code and its UML class diagram visualization is done in separate windows which makes it hard to find the correspondence among them.

B. CoffeeDregs

CoffeeDregs is an educational visualization tool of executing Java programs aiming to teach OOP and to build a conceptual semantic model through the visualization of the connections between static source code and dynamic execution in objects [7]. CoffeeDregs claims that visualizing the state of program execution helps programmers better understand certain behaviors of the code. From the qualitative experiments to assess its educational effectiveness, CoffeeDregs was found to be beneficial for students learning OOP [8]. However, the study also shows that the correspondence between source code and run-time execution visualization is not directly recognizable, in particular to trace instance variables and method arguments when fixing a problem.

C. Jeliot 3

Jeliot 3 is a program visualization tool designed to help novice students learn both procedural and OOP with the basic production of algorithm animation for the data flow of variables and the supporting visualization of control flow and expression evaluation [9]. Jeliot 3 helps students and teachers in sharing graphical and verbal vocabularies with animation

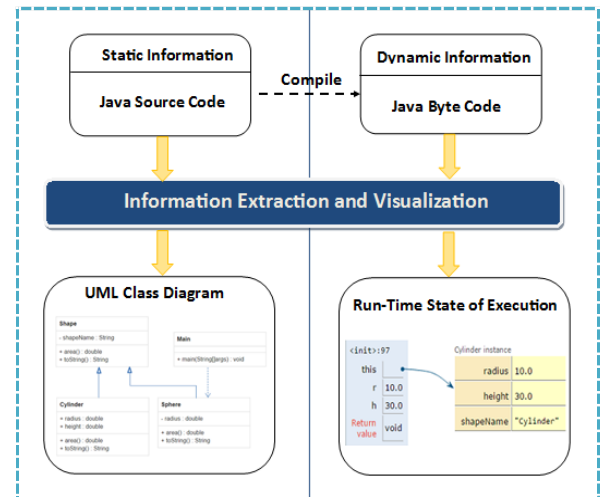

Fig. 1 JavelinaCode system overview

visualization that makes it easier to discuss programming concepts [8]. A qualitative investigation found that the animation of Jeliot 3 is easy to use and useful for students to debug programs [9]. However, other experimental studies report that the use of Jeliot 3 does not show any significant difference on students' attitudes toward OOP [10], and Jeliot 3 animation is difficult for novice student programmers to understand. It is suggested to add verbal explanations to the visual animation which might optimize students' understanding with the combination of graphics and audio or textual captions [11]. As the length of code and its complexity increase, visualization becomes difficult to understand and objects are sometimes overlapped which makes it more challenging to follow the program execution.

D. AguiAJ

AguiAJ is a pedagogical tool for interactive experimentation and visualization of OOP in Java [12]. AguiAJ greatly illustrates OOP concepts (encapsulation, interface, polymorphism, and inheritance) by showing and hiding private instance variables, indicating inherited members and overridden operations, and the usage of image domains [13]. Evaluation of AguiAJ reveals positive impacts on training in terms of suitability and visualization of the images used. It was concluded that AguiAJ is usable for interactive lecturing [13].

While AguiAJ supports an instant change between source code and object illustration, it is hard to map them together because the editor window and the visualization window are not visible simultaneously. The user must switch between windows.

III. JAVLINACODE

JavelinaCode is a web-based interactive and educational programming environment for enhancing program comprehension in OOP. It aims to enhance student programmers' programming skills and logical thinking, and to help them understand OOD concepts. This section describes

JavelinaCode by featuring its system overview, user interface, design principles, and implementation.

A. System Overview

Fig. 1 gives the system overview of JavelinaCode. A student accesses JavelinaCode through a front end web browser. Java source code created by student is sent to a back end server. From the source code, static structural information such as instance/class variables and their types, methods and parameters, and the relationships among classes is extracted and visualized in a UML class diagram. From the Java bytecode translated by the Java compiler on the server, dynamic functional information such as the values of the instance/class variables is extracted and the dynamic run-time state of the program is visualized.

B. User Interface

The user interface of JavelinaCode is presented in Fig. 2. The user interface consists of four main components: a static UML diagram area (a), an editor area (b), a dynamic run-time state visualization area (c), and an input/output console area (d). The editor area displays the active Java code a student user is currently working on, and, by selecting a tab, the user will be able to create multiple Java or text files and to add them into a project. When a new class is added, the default code representing the basic structure of a class is generated for the user to start immediately making changes to the existing code. For each line of code, its corresponding structural information will be highlighted in the class diagram and the functional information of data is synchronized in the run-time state visualization. Two sets of UML diagrams are also generated in (a): one for the active Java program in the editor and the other for the whole project. When an enlarge icon in area (a) is clicked, a detailed UML diagram for the project will be displayed as illustrated in (e).

C. Implementation

JavelinaCode is being developed on the AWS (Amazon Web Services) cloud computing platform on the back end virtual server running the Ubuntu 14.04 LTS operating system, Apache 2 HTTP server, and MySQL database server with php5 and Java 8 installed. Also, PhpMyAdmin is used to handle the administration of the MySQL and to interact with its databases for managing users and project files.

JavelinaCode is being implemented with a front end written in HTML5, CSS3, and jQuery and a back end written in PHP. Ace, an embedded open-source code editor, is fully integrated into the environment [14]. For the run-time state visualization of program execution, the Java Visualizer by David Pritchard and Will Gwozdz [15] based on the Online Python Tutor [16] by Philip Guo is fully integrated into the interface. The Java Visualizer reads Java source code as input, traces the Java bytecode data (objects, methods, and variables) translated by the compiler using Java debugger, and outputs the trace in JSON format for the front end visualization. Information of the abstract design of the Java source code is extracted to draw the UML class diagram.

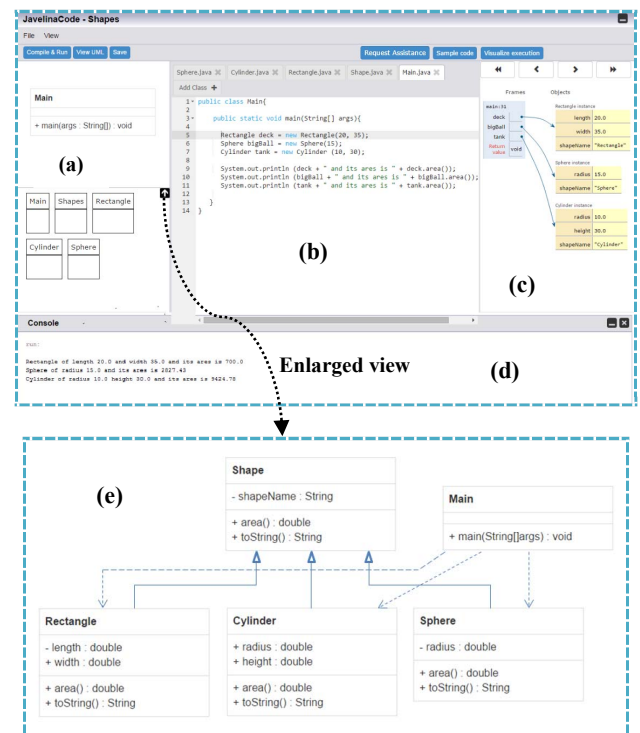

Fig. 2 Screenshot of JavelinaCode and UML class diagram

D. Design Principles

For the best practice of OOP and OOD, JavelinaCode is designed with the following principles: 1) *Easy to Access*, 2) *Easy to Use*, 3) *Easy to Understand*, 3) *Source Code and User Centered*, 4) *Static Visualization of Structural Information of a Program*, 5) *Dynamic Visualization of Functional Information of Data*, 6) *Static and Dynamic Visualization together*, 7) *Synchronized Multi-View along with Source Code*, and 8) *Structural and Functional Feedback in real Time*.

JavelinaCode is platform-independent. Students use a web browser to develop and run a Java program without any required software or plug-in installation. They are able to program anywhere and anytime using their laptops, desktops, tablets, and mobile phones. The project files created by a student are saved on the cloud storage. The student does not need any kind of memory systems to keep and manage the data. The student is free of concern with continuous version changes and evolutions to the Java language, IDEs, plug-ins, and operating systems. This provides a great deal of accessibility and usability to the program development environment. JavelinaCode will be further developed as mobile applications that run on both iOS and Android.

JavelinaCode is both source code and user centered. When a student writes a line of code, the corresponding structural information of the program is dynamically linked with the two sets of UML class diagrams and the functional information of data is synchronized in the run-time state visualization. Real time feedback of the current line of the code will be immediately given to the student. The links will be highlighted when the user hits the 'Enter' key after completing the line,

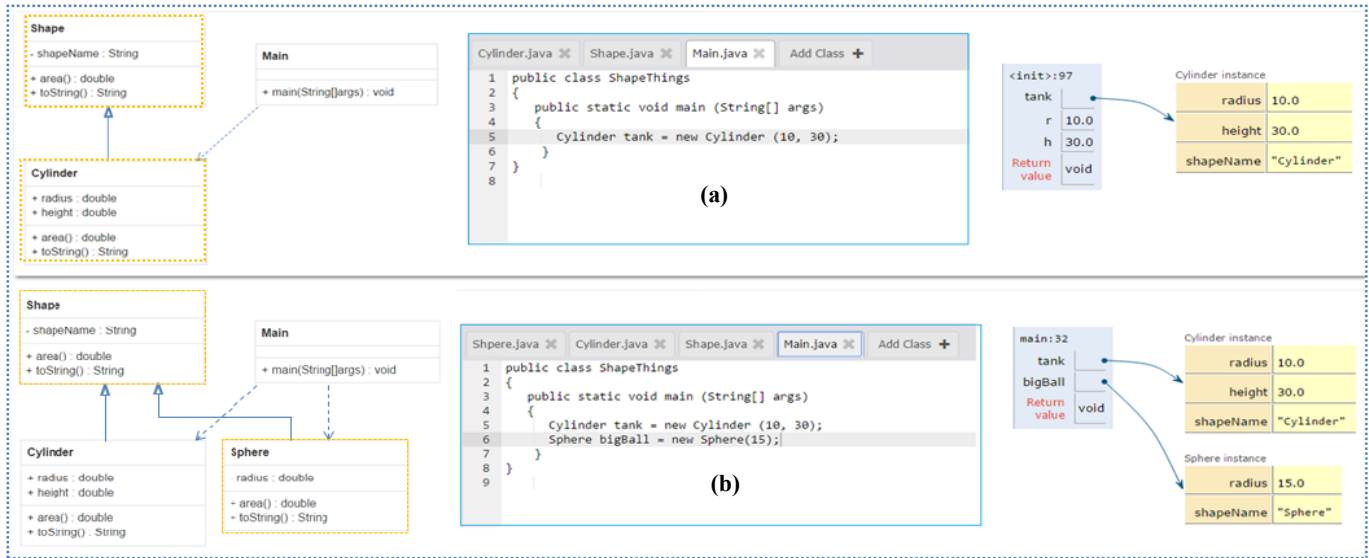

Fig. 3 Modeling example linking source code with static and dynamic visualization

such as variable declaration and/or initialization, method declaration, or expression. This will greatly help the student establish the mental model of program execution [17]. Fig. 3 illustrates the modeling example of linking and highlighting a line of code with its static and dynamic changes in visualization.

IV. MODELING EXAMPLE

The modeling example of JavelinaCode is presented in Fig. 3. In the example, the UML notation and the run-time state are instantly changed when a line of code changes. Upon the complete implementation, JavelinaCode will fully support all functionalities described here.

The running example involves three classes having inheritance and polymorphism relationships: Shape as a parent (super) class and Cylinder and Sphere as children (sub) classes. As illustrated in (a) of Fig. 3, after the Shape and Cylinder classes are defined with inheritance and an object of Cylinder is created in the testing Main class, its corresponding UML class diagram on the left indicates the inheritance relationship between Shape and Cylinder and association between Main and Cylinder.

The values of the Cylinder object are assigned to the instance variables, which are also visualized as the run-time state on the right. As shown in (b) of Fig. 3, when a new Sphere class is added and an object is created in center editor, the UML diagram also instantly changes showing the new inheritance relationship between Shape and Sphere and the association between Main and Sphere. The values of the instance variables of the Sphere object are also illustrated in the dynamic visualization.

V. CONCLUSION AND EVALUATION PLAN

This paper has demonstrated JavelinaCode, a web-based interactive educational programming environment, which proposes an approach to support programming in Java

providing both static and dynamic visualizations in a real time multi-view model. The main contributions of JavelinaCode are: a) Students use a web browser to run a Java program without any required software and plugin installation or configuration on a local computer. They are able to program anywhere and anytime using their laptops, desktops, tablets, or mobile phones. b) Students do not need any kind of memory systems to keep and manage project files. They are free of concern with continuous version changes and evolutions of the Java language, IDEs, plug-ins, and operating systems. c) JavelinaCode will help students establish the mental model of program execution along with the source code of a program. d) With the synchronized multi-view real time visualization along with source code, JavelinaCode is highly expected to reduce students' cognitive workload in Java programming and to enhance comprehension of the OO concepts such as inheritance, polymorphism, and OO design.

To evaluate its educational effectiveness, both qualitative and quantitative experiments will be conducted. The experimental studies will be designed to correlate student users' usage and performance in OOP and OOD by comparing the results of the data from a group of users using JavelinaCode and a group of users using a standard IDE. Accordingly, the following two null hypotheses are formulated:

- H1: Having JavelinaCode available does not impact the time of problem solving.
- H2: Having JavelinaCode available does not impact the correctness of the program comprehension.

While the experimental group uses JavelinaCode featuring the synchronized static and dynamic visualization, the other controlled group uses a standard IDE such as Eclipse or NetBeans in order to answer the questions. We may claim that the availability of JavelinaCode will reduce the amount of time taken to solve and answer the comprehension questions and increase the correctness of the solutions.

ACKNOWLEDGMENT

Partial support for this work was provided by the National Science Foundation's Robert Noyce Teacher Scholarship Program under Award No. DUE-1439861 entitled "Phase I Robert Noyce Teacher Scholarship Program: Future STEM Teachers in South Texas F(ST)²".

We would like to thank Swetha Murthy and Sai Kiran who are graduate students in the Department of Electrical Engineering and Computer Science at Texas A&M University-Kingsville for making a great contribution to the implementation of JavelinaCode on the front end and back end systems respectively.

Wireless Cybersecurity Education via a Software Defined Radio Laboratory

Cem Sahin*, Danh Nguyen*, James Chacko*, and Kapil R. Dandekar*

*Drexel Wireless Systems Lab, ECE Department, Drexel University

Emails: {cs486, dhn24, jjc652, dandekar}@drexel.edu

Abstract—Cybersecurity is one of the fastest growing concerns in the world today. Recent global events show the need for more strict measures to protect the public from cyber attacks, which has triggered an increased demand for cybersecurity professionals. Many academic institutions began offering courses covering current cybersecurity concepts to satisfy this need. Although these courses educate students with proper skills, they lack the connection to current advancements in academic research. A more encompassing curriculum is needed in this rapidly growing field. For the most up-to-date education, we developed a course that takes a student-centric hands-on approach supported with Software Defined Radios to study current cybersecurity research projects in wireless networks. Our course consists of short lectures followed by lab sessions, where students implement security algorithms described by standards or by recent peer-reviewed research articles. Our results indicate that students appreciate the mixture of textbook and research topics being covered in the course and they feel more prepared for any future task in the cybersecurity field. While deviating from the textbook applies additional strain to educators, our paper shows that including current research practices in curriculum development efforts is a good investment towards a better educational outcome.

Keywords—*engineering education; curriculum development; data security*

I. INTRODUCTION

The amount of data that is being transmitted over the Internet is growing rapidly every day. The modern lifestyle is shifting users towards having multiple devices connected to each other and the Internet, which comes with the natural tendency to complete daily tasks online and share more information on social media sites. According to Youtube, one of the most popular video streaming services, “300 hours of video are uploaded every minute” into their servers [1]. As more of our daily lives shift from being face-to-face transactions to online encounters, the vulnerabilities of the Internet are being

realized. Global news shows that the information put into the Internet is not as secure as it should be.

With the increased need for Cybersecurity, the demand for professionals in this field is increasing. Many academic institutions started offering courses, certificates, and now even majors in Cybersecurity [2]. We have also started seeing initiatives from government agencies and private companies to raise awareness and attract more interest in Cybersecurity [3]–[5]. PBS NOVA Labs is offering an educational digital game, which introduces Cybersecurity basics, that can be played from any computer with an Internet connection [6].

In addition to offering students more hands-on modules, educators continued to look for additional tools that will support these labs and projects. There has been a growing interest in integrating Software Defined Radios (SDR) with hands-on course modules because of their flexibility. Initially, signal processing courses started taking advantage of them [7] for running labs covering topics such as modulation, encoding, and filtering. As their popularity increased, platforms such as GNURadio Companion [8], and OSSIE [9] emerged to offer visual development tools. These tools allowed students to create a signal, process it, and send it via the SDR. However, they lack key details pertaining to the hardware implementation aspects of SDRs. On the other hand, Computer Engineering and Software Engineering courses focus more on the hardware implementation portion and do not emphasize the signal processing capabilities of SDRs [10]. In this paper, we merge the gap between the SDR hardware implementation, signal processing and radio capabilities, and discuss a multi-disciplinary course that leverages SDRs to introduce wireless cybersecurity to students.

In order to provide up-to-date materials to our students, we developed a student-centric, SDR based wireless security course, where we support traditional textbooks with current research practices. Some of the

topics covered in our course are packet detection [11], eavesdropping and man-in-the-middle attacks [12], and encryption techniques including Physical-layer security [13]. During the labs, students are encouraged to implement various attack mitigation techniques on SDRs, which requires them to use hardware design techniques, along with signal processing concepts, and to comment on their findings. Grading is done by checking the validity and strength of their solution.

In [14]–[16], the authors discuss the benefits of offering a student-centric learning experience, which is especially preferred when the course is related to technology. In the recent years, this approach has been augmented by several others to include competition between students [17]–[19]. Our course tries to combine the benefits of both student-centric and game-based learning styles. We developed our labs to give our students as much experience as possible with the current SDR and security topics. We also created a wireless *hacking* competition as their final project.

In this paper, we discuss the use of SDRs in teaching wireless cybersecurity and the effectiveness of bringing research into the classroom in terms of student acceptance and success. We organize this paper as follows: In the next section, our course logistics and methodology is discussed. Section III then goes into details of the specific course modules we developed. In Section IV, we present a case study and investigate the specifics of one of the lab modules. Section V provides a summary of the course outcomes. Our end of term student evaluation results are summarized in Section VI. Then, we conclude this paper in Section VII.

II. COURSE DESIGN AND METHODOLOGY

A. Student Demographics

Since our SDR security course was being offered for the first time, a small pilot section was created, where 9 graduate students were enrolled. The decision to limit enrollment to this number was based on available computer resources and classroom space. All students were enrolled in a Masters of Science program within the Electrical and Computer Engineering Department at Drexel University. Out of the 9 students, there was only one female student. One of the students was pursuing his education while also working full-time at a company. No country of origin or race information was collected for the purposes of this paper.

B. Course Logistics and Flow

Our SDR based security course is developed and offered weekly at the graduate-level. We were assigned a 3 hour meeting period. Our classroom was a Digital Signal Processing (DSP) laboratory with built-in equipment racks and available computers for student use. Each work area was designed to accommodate 2 students. There were 4 work areas in total. Desktop computers were pre-installed with the Ubuntu operating system before the beginning of the course. Students were then guided to install any additional programs and/or packages as the course progressed. We ran the course by splitting the students into 3 groups of 2 and a group of 3. Although students had the freedom to choose who to be partners with, we encouraged them to form groups to include at least one person knowledgeable in Linux programming.

Drexel University offers a term based system, where each term consists of 10 weeks of in-class sessions followed by a week of final examinations. Table I shows a breakdown of the 10-week term by labs. A similar table was also given to the students as a part of the course syllabus. The table also reminds students of important dates, such as the course drop deadline. Each lab was originally designed to last for two weeks. Small adjustments were made as the term progressed.

TABLE I: Breakdown of the term by lectures and labs

Week	Lectures	Labs	Homework
1	Lecture 1	Lab 1	-
2	Lecture 2	Lab 1	-
-	Course drop deadline	-	-
3	Lecture 3	Lab 2	HW 1
4	Lecture 4	Lab 2	-
5	Lecture 5	Lab 3	HW 2
6	Lecture 6	Lab 4	HW 3
-	Course withdraw deadline	-	-
7	Lecture 7	Lab 4	-
8	Lecture 8	Lab 5	HW 4
9	Lecture 9	Lab 5 / Project	-
10	Lecture 10	Final Project	HW 5
11	Final Project due	Final Competition	-

The course was run as a series of short (usually 30-40 minutes), theory-based lectures followed by the student-centric lab assignment. The lab assignments were designed to leverage the concepts covered in the lecture portion but also to invite the students to indulge into research papers to complete their lab and the homework assignment at the end of the lab directions. The lab assignments were expected to be completed in-class.

Additional homework assignments were given at the end of each lab. Each homework was due before the beginning of the next lab. Students were provided with USRP N210 SDR platforms to work on their lab and homework assignments. They were also given remote desktop access to lab computers for when they would want to have access to the experiment setup with SDRs. Students were not allowed to remove the SDR nodes from the classroom. Throughout the term, two unannounced quizzes were given. These quizzes were mainly focusing on the theory covered in the lecture component of the course. Although a textbook was listed in the syllabus, most of the course material was custom prepared and distributed via the Blackboard Learn course management system. Blackboard Learn was also used to post grades, collect assignments, and make announcements.

The course was assigned 3 teaching assistants (TAs), who were knowledgeable in wireless communications, security, and SDRs. All assistants were present in the classroom during the labs.

C. Student Work Evaluation

Student work was graded regularly. Each week, specific lab checkpoints were communicated to students. In order to ensure students were not falling behind, these checkpoints were strictly enforced. When students reached a checkpoint, they called one of the TAs over to their table and demonstrated the functionality of their setup. They were also asked to clearly explain what they did and how they did it. A successful demonstration yielded full points for that checkpoint. In case something was wrong, the TA tried to help them by leading them towards the correct output without actually giving them the answer. If a checkpoint was not met at the end of the meeting time, partial credit was given. A general grading breakdown is presented in Table II.

TABLE II: Final grade breakdown

Labs & Homework	60%
Quizzes	10%
Final Project	30%

The final project, which will be described later, was a competition based setup, where students were *fighting* against the instructor and the TAs. The grading was performed based on how successful their security implementations were. Further discussion of the final project is discussed below.

Fig. 1: USRP N210 SDR [20]

III. CYBERSECURITY LAB MODULES

Our course was designed to introduce students to security vulnerabilities present in wireless networks. It took a Software-Defined Radio (SDR) implementation approach to demonstrate selected wireless network security challenges. With the use of open-source tools and commercial off-the-shelf SDRs, students gained hands-on experience to analyze wireless security problems and prototype their solutions.

This course met 3 hours a week for 11 weeks and covered five separate laboratory assignments spanning various topics in wireless security. The labs were organized as follows:

A. Lab 1: Introduction to GNU Radio and USRP

This lab introduced students to the concept of software radios and gave specific examples of an SDR design flow. Students were introduced to the course's main hardware platform, the Universal Software Radio Peripheral (USRP) seen in Fig. 1, and its accompanying software design tool, GNU Radio. The lab also included a run-through for setting up the development environment on an Ubuntu 12.04 installation and executing the included example designs. Most importantly, the lab showed a tutorial on implementing a single carrier wireless communication link between two USRP nodes. Students were then asked to extend this tutorial to come up with their own implementations.

B. Lab 2: Digital Communications Hardware Design

This second lab familiarized students with the tools and concepts required for hardware design in the context of digital communication. The USRP platform is extremely customizable and allows for user-defined operations on the hardware side. This lab merges several

different topics from Computer Engineering, Telecommunications, and Software Engineering to create an interdisciplinary bridge, which continues throughout the rest of the labs. Students were instructed to implement the modulation and coding components for a wireless link on the FPGA available on the USRP, rather than processing them on the host side. Some of the concepts introduced in this lab were adopted from current research described in [21] and [22]. The design environment was conducted in Xilinx System Generator, an industry-standard hardware design suite for FPGAs. Through this lab, students gained essential hardware design skills required for prototyping fast (in the order of nanoseconds) turn-around wireless systems with real-time attack and defense capabilities.

C. Lab 3: Basics of Eavesdropping and Encryption

This lab covered signal detection, classification, and encryption techniques. Students were introduced to the basics of passive wireless attacks, including raw signal capture and off-line processing to identify the frame structures of common over-the-air (OTA) wireless protocols including WiFi and 4G WiMAX. Provided with an always-on transmitted signal from the instructors (realized using the USRP), students were asked to sniff the OTA packets and identify their key signatures, such as the source IP address, port number, packet length, etc. The lab mainly illustrated the role of an eavesdropper on an unencrypted wireless network. However, state-of-the-art encryption techniques were also introduced along with the history of cryptography. This discussion was also complemented with current research practices in Physical-layer security schemes [13]. Students were asked to take additional measures to secure the wireless link using any of the discussed encryption techniques.

D. Lab 4: Real-Time Signal Detection

We continue to follow the multi-disciplinary approach in this lab by introducing students to real-time, hardware-based techniques for signal detection. It covered important signal processing techniques such as cross-correlators, energy detectors, frame filtering, and identification of signal components with low entropy. Students were asked to design, validate, and demonstrate a series of signal detectors. For extra credit, students should allow certain customization capabilities for their detectors, including the ability to search for signals from different standards such as WiFi and WiMAX signals. The lab required FPGA hardware logic design and embedded programming techniques to capture and analyze

packets in real time. This lab prepared students towards developing eavesdropping-resilient signal transmissions.

E. Lab 5: Introduction to Jamming

This lab covered the basics of signal jamming, a series of active attacks to render the wireless network unusable. Students were introduced to the different types of jammers and asked to improve upon their design from Lab 4 to realize a reactive jammer [23]. Reactive jamming is a sophisticated form of jamming attack, wherein the attacker listens on the wireless channel and triggers jamming waveforms on positive signal detection. Due to legal considerations concerning the operating of real-time over-the-air jammers, this lab was conducted primarily in simulation. The jamming performance was analyzed and evaluated under variable signal-to-interference (SIR) ratio and different modulation parameters. This lab also provided theoretical background on jamming mitigation techniques, such as frequency hopping and spread spectrum communication [24].

F. Final Competition: Multi-team Melee

By the end of the five labs, students had gained understanding of SDR programming basics and important wireless security principles. The final project consisted of an aggregation and extension of the labs covered. Students were asked to implement an over-the-air eavesdropper using the GNU Radio / USRP framework. The instructors provided a working WiFi 802.11g link using either commercial hardware or SDRs with a fixed bit rate. The students' goals were to listen in on this wireless communication and extract any useful information they could find. In the first phase of the project, transmitted messages were encrypted with a given restricted set of keys, which were provided to students. In the second phase of the project, the keys used in message encryption were drawn from an unrestricted set of keys, and students had to conduct brute-force attacks to guess the correct keys while eavesdropping on the wireless medium. The student team that could extract the most useful information from the provided wireless link would win the competition.

IV. LABORATORY CASE STUDY: REAL-TIME SIGNAL DETECTION (LAB 4)

In this section, we provide as an example the detailed description of one of the labs covered in our SDR security course. The materials presented here are representative of the scope and outcome expectations of every

other laboratory assignment. We focus our description on Lab 4: Real-time signal detection.

A. Lab Introduction

This lab introduces the concept of real-time signal detection in wireless communications. Signal detection is an important procedure to achieve synchronization between the transmitter and receiver, as well as to gain awareness of an active transmission in the channel. We will focus on two primary methods to detect the presence of a signal: cross-correlation and energy detection.

Wireless communications rely on successfully transmitting signals and correctly detecting them on the receiver end. A thorough understanding of packet detection principles is necessary to study cybersecurity principles. Many of the cyber attacks originate from an eavesdropper, who is trying to snoop on the packets in a wireless network. In this lab, we expect students to gain knowledge on packet detection principles and urge them to think of possible ways to develop algorithms to protect their data against an eavesdropper.

Cross-correlation: A cross-correlator performs template-based matching between the incoming wireless signal and a standardized template to identify the template presence in the signal. The template is usually designed with a very high auto-correlation property, yielding a high coefficient when correlating with itself. This enables us to pinpoint precisely the start of an active transmission frame in fine-grain synchronization.

The cross-correlator can be implemented as a matched filter, which is simply an FIR filter with tap coefficients set to the time-inverse of the template values. Recall that an N -th order FIR filter is implemented with an N -tap convolution:

$$y[n] = \sum_{i=0}^{N-1} h_i x[n-i]$$

In hardware, an FIR filter can be implemented as either a parallel or serial filter. Figures 2 and 3 show the block diagrams of example hardware implementations for both filter types. The serial version of the filter runs at $3x$ sample rate in order to produce outputs at the same rate as the input samples.

Energy Detection: an energy detector computes the short-term energy of incoming signal and tries to detect a rise or fall in the energy levels. Energy detectors are effective in detecting an active transmission without the

Fig. 2: Parallel 3-Tap FIR Filter Example

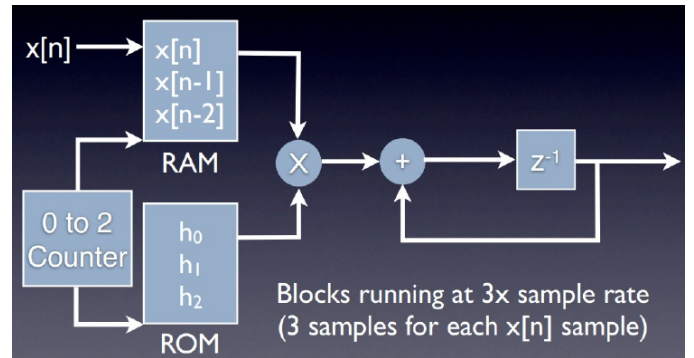

Fig. 3: Serial 3-Tap FIR Filter Example

need to understand the underlying modulation methods and data content.

In hardware, the energy detector can be implemented as an energy sum calculator, which continuously compares the energy level of incoming samples against the recent past to detect an energy rise or fall. Figure 4 shows an example structure of an energy detector. In essence, this hardware block keeps a running sum of N recent energy readings, where N is the desired length of the detector (specified here as 32 samples). At the n th instant, an energy reading $x[n]$ is computed from the incoming pair of I and Q values. The energy sum $y[n]$ is then updated according to the relationship:

$$y[n] = y[n-1] + x[n] - x[n-N]$$

The output of the energy sum calculator is compared to its own previous values after scaling by a user-defined threshold for either energy high or low detection. The thresholds are selected based on the desired probability of detection and false alarm rate.

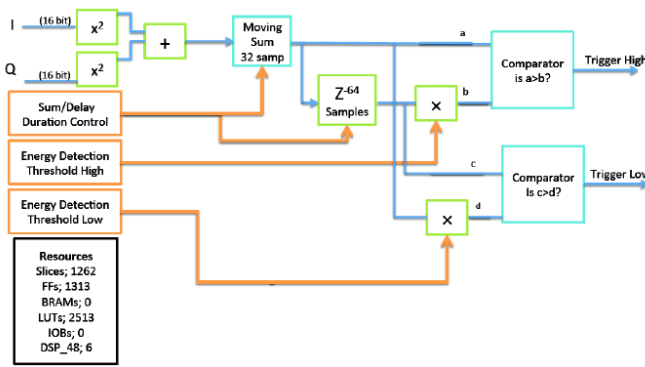

Fig. 4: Example Implementation of an Energy Detector

B. Lab Deliverables

The deliverables for this lab include two hardware implementation components: a single-rate, fully parallel FIR filter with $N = 8$ tap coefficients, and a single-rate, fully serial FIR filter with $N = 13$ coefficients. The serial design may include only one multiplier and one adder, so students are expected to use RAM memory for managing samples. Students may use either a blocked RAM or an addressable shift register (ASR) to implement the sample RAM buffer.

In addition, students need to deliver a hardware implementation of a *cross-correlator* with the 13-value Barker sequence $[1, 1, 1, 1, 1, -1, -1, 1, 1, -1, 1, -1, 1]$ as the template. Detailed simulation results in the System Generator are expected in the deliverables.

Students are also encouraged to identify and discuss any possible scheme that would prevent an eavesdropper to be able to employ the basic packet detection principles described above to gain access to the network. Some of the possible ideas include designing a different cross-correlator and/or leveraging the interference in the network.

V. COURSE DISCUSSION

Based on students' assignment completion and their grades against the rubrics, an overall final grade was calculated for all enrolled students. The grade distribution was shown in Table II. Once the numeric grades were calculated a standard letter mapping was used to identify a student's final letter grade. At the end of the term, 5 students received grades in the A range, 3 students received grades in the B range, and one student in the C range. This distribution yielded an average of 90.8% with a standard deviation of 10.0%. This high average could

be attributed to the extremely high educator (instructor and TAs)-to-student ratio.

VI. END-OF-TERM STUDENT EVALUATION RESULTS

After having developed and conducted the Software Defined Radio security course, a brief feedback survey was given focused on the course's reception. In this survey, students were asked to anonymously elaborate on their experience throughout the term. They were allowed to write as little or as much as they needed. Student participation for this survey was voluntary and students were allowed to see their final grades before the submission of the survey. The received testimonials were all positive. The word map seen in Fig. 5 was created to get a general idea of the student feedback, where the most frequently used words appear the biggest. As the frequency of a specific word gets smaller, its font size follows the same trend.

While most classes rely completely on teaching the theory, our class offered students guidelines to help develop and realize current research techniques in a student-centric approach. One of the students mentioned the following in his/her feedback: *"I feel like the class is the glue which combines different pieces of knowledge together. The class is both a challenge and a great opportunity for anyone who wishes to learn more security issues in SDR."* Another student adds to the submitted evaluations by focusing on the course's hands-on approach. He/she says, *"The course involved a lot of hands on learning using [...] hardware interfacing with student-created software in a lab setting. I enjoyed this course very much due to the fact that students were able to prototype designs on the computer and then realize them in live transmissions, comparing actual results, and demonstrating the security concepts."*

Simulations are much more effective in being flexible enough to teach over a range of concepts but true learning comes from seeing the end goal. We realized this need to concentrate the concepts being taught by guiding students to physical implementations. Not only simulations and implementations were important part of the student-centric learning goal; however, we also introduced the latest achievements in the research field during our labs. Our course was described as *"an excellent balance between background theory and hardware implementation"*, where we covered *"[m]odern topics related to wireless security and communication systems [...], which highlighted examples of current technologies using the techniques discussed."*

One of the students concluded his/her review by saying he/she “*would highly recommend this course and similar courses for anyone interested in pursuing a degree in wireless communications, cryptography, or signals intelligence related fields.*”

In this paper, we presented our graduate-level Software Defined Radio based Cybersecurity course. Our course balanced theory and implementation by offering students short descriptions of their upcoming labs and then following a student-centric learning approach during the labs. The five lab modules we designed not only introduced students to wireless security concepts but also leveraged the latest findings in related research fields. Students used SDRs throughout the term to implement their algorithms via hardware implementations, embedded programming, and wireless signal processing techniques. By going outside the boundaries of textbooks, and integrating current research into the classroom, we were able to offer a more up-to-date learning experience to our students. Although, our job as course developers was made more challenging by not being bound to a textbook and by following and integrating the latest research achievements into our course, testimonials we received show that the end product was appreciated by students.

This material is based upon work supported by the National Science Foundation under Grant No. DUE-1241631. The authors would like to also thank Doug Pfeil for his valuable comments throughout the design stage of the course.

Student-centered Learning in Cybersecurity in Summer Semester

Xiaojun Wu, Shuzhen Tian

Department of Computer Science and Technology
Tsinghua University
Beijing, China
[xjwu, tiansz]@tsinghua.edu.cn

Abstract—Work in Progress: University-level cybersecurity education is encouraged by both the US government and academic organizations. A new practical course in cybersecurity in the summer semester is introduced, in which junior students made teams to learn in a student-centered and competitive style. Students were provided with course materials in five topics. An online judge system was developed with problems of levels from the beginner to the advanced to encourage competitive learning. A contest was held, in which teams designed their own problems and tried to solve the others'. A scoring method was used to avoid the students' problems being too easy or too difficult. Considerable engagement of the students was observed during the course. Almost all problems in the online judge system had been solved at the end of the semester, and the problems designed by the students involved a considerable breadth and depth of cybersecurity related knowledge and technologies. Feedbacks from the students greatly appreciated the online judge system and the contest. They also gave suggestion on the contest and suggested more presentation and discussion in the course.

Keywords—cybersecurity; student-centered learning; online judge system

I. INTRODUCTION

Cybersecurity attracts more and more attentions in politics, economics, military, culture, and our everyday lives. IT related employees are expected to have basic cybersecurity mindset and skills, and cybersecurity professionals are in a great demand. The US government has recognized the importance of cybersecurity and has made efforts to promote cybersecurity programs and education, including the National Initiative for Cybersecurity Education (NICE) led by The National Institute of Standards and Technology (NIST) and the Centers of Academic Excellence (CAE) program led by the National Security Agency (NSA) and the Department of Homeland Security (DHS) [1, 2]. ACM's Education Board organized a workshop to give guidance to university-level cybersecurity education. In the workshop report, there is advice for all undergraduates and computing majors. The workshop participants considered that the practical activities are vital for students and that experiences in both offensive and defensive activity are desirable [3, 4].

However, learning cybersecurity requires knowledge in various foundation courses as well as some advanced ones. It is

very difficult for freshmen or sophomores to have a deep understanding without practical applications, although they can learn some security knowledge points and have some ideas about failure modes in a specific context [5].

With the above considerations, we constructed a new practical course in cybersecurity for junior students majored in computer science and technology in the summer semester in Tsinghua University. Through this course, students are expected to form a fundamental and comprehensive idea of cybersecurity with basic awareness and skills in cybersecurity through lots of problem-solving experience. It is even more important to arouse students' professional interests for further study and research in cybersecurity.

Most teaching and learning experiences in cybersecurity were in regular semesters [5-9]. It is more critical to provide a good learning environment to the students for us to achieve the teaching objectives in a 5-week summer semester. In [6], it is demonstrated that young people like competitions and challenges, and challenge-based exercises are well-suited for training in cybersecurity. So we decided to bring competitive elements into this course with a student-centered learning approach.

We grouped the cybersecurity related technologies into 5 categories. We prepared teaching materials, lecture notes and expansion reading materials for beginners, together with matched problems and solution hints for each category. A competitive online judge system was developed and deployed with plenty of problems in different levels of difficulties. The course was divided into 2 stages. Students made teams to solve assigned problems in the first stage, and designed their own problems for other teams to solve as a contest in the second stage. A scoring method was proposed to prevent too easy or too hard problems in the contest. The detailed description of this course is in the next section. In the third section, we presents our observations of student engagement and the course outcomes, especially the statistics of the contest among the teams. Feedbacks from the students and the future work is introduced in the last section.

II. COURSE DESCRIPTION

A. Background

“Computer Professional Practice” has been a practical course for junior students in computer science in the summer semesters in Tsinghua University since 2004, aiming to increase the students’ grasp of professional knowledge, practice ability, innovative mind, research skills, and team spirit. Students can choose one subject from several alternatives, each of which requests design and development of a big comprehensive system in 5 weeks [10].

Cybersecurity is a supplementary subject added in 2014. There were 19 students selecting this new subject, who had learned basic courses about computer architectures, compiler theories, operating systems, principles of network, and databases, as well as programming languages including C/C++, Java, assembly language and Python. However, only a few of them had learned a cybersecurity related course about contemporary cryptology.

In this course, students were required to go to a designated lab both in the morning and in the afternoon from Monday to Friday for 5 weeks. There were 5 lectures, each about 3 hours, given in the first two weeks in the lab. Students had about 125 class hours of lab time in total to learn by themselves under the teacher’s guidance. Additional 30 class hours were reserved for students to write reports and give presentations.

B. Course topics and materials

Cybersecurity involves a considerable number of technologies, which we roughly grouped into 5 categories as course topics: recon and forensic analysis, crypto, web penetration, reverse engineering, and exploit.

We compiled teaching materials for the first two topics and chose [11-13] for the other topics respectively. Lecture notes were also prepared, in which we introduced an overview of cybersecurity in the real world and discussed about some legal problems. Two more books about codes and cryptology were recommended for expansion reading. All these materials are really for beginners so that they can easily understand the topics.

To help students to better understand the materials, we provided appropriate beginner problems for each topic. For each problem, we gave hints or a step-by-step solution.

C. The online judge system

The course materials were very basic, and we wanted to encourage the students to learn advanced knowledge and technologies by their own choice. So we developed an online judge system to enable competitive learning in students.

The system was similar to the jeopardy-style in Capture the Flag (CTF) contests in cybersecurity. The correct answer to a problem is hidden somewhere. A registered user can submit the answer to an unsolved problem to earn the problem’s difficulty point which is then added to his/her problem solving score if the answer is successfully revealed. We not only deployed the beginner problems of each topic in the system, but many real CTF problems as well. The CTF problems need a variety of

basic or advanced knowledge and technologies beyond the course materials. More difficult problems have higher problem points. The answers, or the flags, of the CTF problems were changed to avoid solving simply by a Google search. We used virtual machines for web penetration and interactive problems. When a virtual machine makes no response, the system administrator will restart it. Fig.1 is the screenshot of a problem whose difficulty point is 50, and the translation in English is shown in Fig. 2.

There are several measures to promote student initiatives. Every user can look up the problem solving score rankings at any time. The number of users who have solved the problem will be shown to the upright of the problem description and the fastest three will be listed below the description (as in Fig. 1), which is also helpful for the students to find and learn from the solvers.

D. Assignments and the contest

During the course, students were asked to make teams of 2 or 3 persons and all assignments were for teams. In the summer semester in 2014, we got 7 teams in total.

The course was divided into 2 stages. The first stage was 2-week long, and we designed a series of 5 problems in the context of a student love story as the team assignment of this stage. The problems covered all the course topics. For example, in the first problem, students should collect information from a Twitter-like social network site, a blog site, and a free mail service site to find clues leading to the answer. A team could probably solve these problems, if they learned the course materials seriously and completed the beginner problems. A problem solving report was required to submit by every team

Fig. 1. The screenshot of a problem.

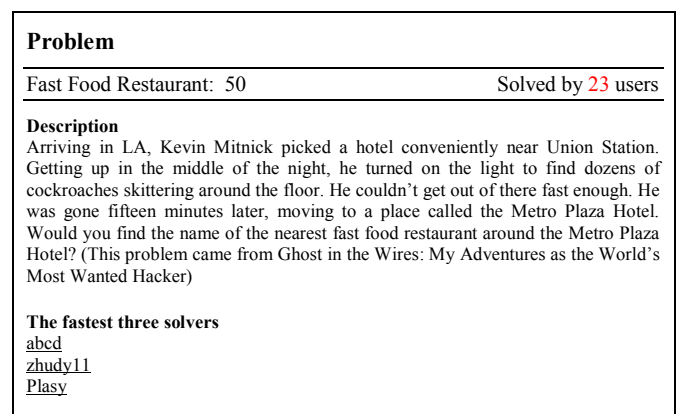

Fig. 2. Translation in English

for assessment.

The second stage was a contest stage. Each team were required to design 3 problems of their own and then help the TA to deploy them in the online judge system for other teams to solve. After the contest, each team should submit a report and make a final presentation illustrating how their problems were designed and deployed, and how their problems could be solved.

E. Contest scoring method

When deploying a student problem for the contest, the TA evaluated the problem's difficulty to assign a corresponding difficulty point. The TA might give minor suggestion to make the problem more solvable, such as embedding more hints and adding affirmative words in an intermediate result.

In order to make the contest challenging at an appropriate level, no teams should design unsolvable problems, neither beginner problems. We proposed a scoring method to avoid the inappropriate problems: A team's final score is calculated as the sum of their scores for all contest problems. Both the designer team and the other teams will be scored for every problem. For a problem with a difficulty point P , suppose there are x teams that have solved it and y teams that have not solved it. The designer team will be scored $2*S$ for this problem, and each successful team will be scored S , while the unsuccessful teams will be scored zero, where S can be calculated as (1).

$$S = P * (x + 2) / [(x + 2)^2 + y^2] \quad (1)$$

The value of the denominator in (1) is high when $x + 2$ and y make big difference, since the sum of x and y is a constant (equaling to the total number of teams minus 1). So the designer team will be scored low if the problem is too easy to get a small P and a large denominator. On the contrary, if the problem is too difficult, the designer team will not be highly scored because of a large denominator. The best situation for the designer is that approximately half teams have solved the problem.

The contest was finally composed of 21 problems from the students. The TA estimated the difficulties and assigned the problem difficulty points in 4 levels: 100, 200, 250, and 300 when deploying. TABLE I gives the number of problems of each difficulty level and the average number of teams that successfully solved for a problem in this level. It seemed that our scoring method was effective and the assignment of difficulty levels was rational.

F. Miscellaneous

We invited a member of the blue-lotus team from Tsinghua University, who had participated in the Defcon CTF contest, to give a talk about CTF contests during the course. We encouraged the students to watch a real online CTF contest held in the semester and to take part in GeekPwn, a security geek contest for smart devices. These activities presented the students a more real world of cybersecurity.

TABLE I. CONTEST PROBLEMS AND SOLVING RESULT

Points	100	200	250	300
Count	1	11	6	3
Avg. Solving	6	5.55	5.5	2

The assessment was summative according to the attendance rate, the team reports in both stages, the contest ranking result and the final presentation.

Students were asked to give some comments on this course as a feedback to help us to improve the pedagogy in the future.

III. OBSERVATION AND COURSE OUTCOMES

It was observed that the students were greatly engaged in learning. Besides 6 hours a day as the course time in the lab, they spent hours after class. Submissions in the deep of night or before dawn were often seen in the logs of the online judge system.

We were glad that all teams had solved the assigned problems in the first stage, which demonstrated that the students had understood the basic ideas and had the basic skills to deal with cybersecurity problems in the course topics.

The students found the advanced problems interesting and challenging. They usually had no ideas how to start with a problem in the beginning because of few experiences in cybersecurity. They discussed a lot in the team and among teams. They searched the Internet to find the original CTF problem and the corresponding write-ups to follow the solving steps. At the end of the course, nearly all problems in the online judge systems were solved, which was a big surprise to us.

We referred to several useful crypto tools in the course materials, which were free for download from the Internet. However, some students developed their own tools. This was really a good practice to help master the knowledge and skills.

Another surprise came from the contest problems designed by the students. These problems employed a considerable breadth and depth of technologies. In the process of problem designing, the students learned where and why there were vulnerabilities. Some students gave possible ways of inspection and prevention in the report.

All the facts implied that the students were able to explore and research in cybersecurity in depth.

IV. STUDENTS FEEDBACKS AND FUTURE WORK

We collected comments from 14 students. Most students said the course topics were really new to them and they learned more and deeper than expected before the class. They gave high credit for the online judge system with so many interesting problems and for the student contest. They had a full, challenging, and happy learning experience in this course. By learning cybersecurity, they began to look at the computers and the network in a new point of view, which led to a better understanding of what had been learned before. Meanwhile their programming skills had been improved.

Some students suggested we arrange team presentations to demonstrate how they solved the CTF problems in the online judge system, and organize group discussion on the most difficult ones. Some students wanted to know more about real websites, products, and services with cybersecurity defects, and to know more about means of protection and defense. These suggestions were useful.

Several students pointed out there were some contest problems that had too few clues to find the breach. We also noticed this phenomenon. Although the TA was experienced in cybersecurity and worked carefully, it was impossible to ensure the quality of all student designed problems for a limited time. The solution might be more TAs and earlier involvement in the design phase with the teams.

There have been more than 100 problems in the online judge system including the students designed problems for the contest. We will add additional problems. The method in [6] will be useful to find and remove the problems not so effective for learning. More features can be implemented to enhance the online judge system. For example, the answers of a few problems can be enumerated. This will be practically impossible if the system limits the submission frequency. The automated management of virtual machines is also desirable, in case there are too many virtual machines to run with the limited computing resources.

One more important thing to do in the future is to assess students' security awareness before and after learning. It is concerned as well whether they like to devote to research on cybersecurity or take on cybersecurity related jobs.

ACKNOWLEDGMENT

We would like to recognize the great help from Dr. Jianwei Zhuge and the blue-lotus team from Tsinghua University. They gave good advice on many aspects of the course. They assisted to prepare the course materials and to maintain the online judge system.

Using a Case Study to Teach Students about Finding and Fixing Logic Flaws in Software

Lindsay Simpkins, Xiaohong Yuan, Huiming Yu, Kenneth Williams

Computer Science Department
North Carolina A&T State University
Greensboro, NC, USA

lsimpkin@aggies.ncat.edu, xhyuan | cshmyu | williams@ncat.edu

Abstract—An application logic flaw is a type of software vulnerability related to privilege manipulation or transaction control manipulation. They are often difficult to identify using automated scanners. A case study on the eCommerce merchant software Bigcommerce, integrated with PayPal Express as a third party payment collector, was created to teach students about this topic. Case studies provide students with a real-world context, and help them understand complex topics better than traditional teaching methods. However, the computer science field, especially computer security, does not have many case studies available. The case study on logic flaws in software was taught in Spring 2015, and the teaching experience is discussed.

Keywords—software security; computing education; case study; application logic flaws; manual code review method

I. INTRODUCTION

With codebases reaching millions of lines, software vulnerabilities exist even in thoroughly tested code. Security expert McGraw separates these into two categories: bugs, and flaws [1-2]. Bugs are defined as implementation problems in software, such as off-by-one errors or buffer overflows [1-2]. They only exist at the code level and can typically be fixed on one line or in a localized area. Flaws, on the other hand, exist at both the code level and the design and software architecture levels. They are typically related to the architectural design, or application logic. Examples include bad error handling (fail-open), lack of encryption, and poor access control [2-5]. The vulnerability may be due to the design itself, or with how the code was implemented. To fix flaws, the logic or software architecture may need to be redesigned, and it could affect multiple areas of code. An estimated 50% of software security vulnerabilities are flaws [1-2].

Source code analysis tools are effective at identifying bugs, because bugs typically follow defined patterns. However, application logic is inconsistent and thus a poor candidate for automated testing tools. While several prototype scanners have been developed to identify application logic flaws, they are still in the research phase, so logic flaws must be found through manual testing [2, 6-7]. Therefore, it is important for computer science students to learn how to reduce logic flaws during software development, and how to test for them manually.

The topic of application logic flaws seems to be omitted or poorly addressed in both software engineering courses and textbooks. A case study was developed to teach students about

this topic. Case-based teaching methods can help students better apply learned skills to real world industrial settings. This helps bridge the gap between theoretical concepts and industry-related skills that exists in current software engineering education [8]. There is a need to develop case studies due to the lack of case studies available for software engineering curriculum. [9].

Existing resources on logic flaws provide very specific categories of vulnerabilities to test for, but do not cover how to handle logic that is custom to an application. For example, one web application may perform authentication on the client side, while another does this on the server side. An introduction to logic flaws was developed to address this shortcoming by explaining where logic flaws come from, and how to reduce flaws during development using industry standard best practices. It also describes the manual code review method used to discover an exploitable logic flaw in the case being studied.

A case study was developed to illustrate how a logic flaw could cause security vulnerabilities. The case is based on the research article *How to Shop for Free Online: Security Analysis of Cashier-as-a-Service Based Web Stores* [10]. It is about the eCommerce merchant software Bigcommerce, previously known as Interspire, using PayPal Express as a third-party payment collector. A logic flaw allowed attackers to complete an expensive order using the payment intended for a cheaper order. A PowerPoint animation was created to trace the API calls and back-end code representing the steps of the exploit from this case, and explain the manual testing method used to discover the exploit. A set of discussion questions has students apply this method to similar code in order to find potential vulnerabilities and then fix them.

This case study is meant to be easily integrated into existing upper-level undergraduate or graduate level computer science courses. It can be taught in-class or given as an online assignment, and should have 2 lecture hours and 1 hour for student discussion, or an equivalent of one week of instruction. At the undergraduate level, it fits under the Software Engineering or Information Assurance and Security Knowledge Areas in [11], and the topics of Secure Software Architecture and Design or Secure Coding and Testing for Software Security Engineering courses, or the topic of Testing Methods for Software Quality Assurance courses in [12]. At the graduate level, it could fit under the core body of

knowledge areas 6.2.1 Development Methods and 6.3.5 Testing For Assurance in [13]. Software engineering or security testing courses that use [2] as a textbook can use this case study after the Architectural Risk Analysis chapter.

The rest of the paper is organized as follows: Section II provides a literature review of using case studies in computer science education. Section III describes the materials developed for the case study on application logic flaws. Section IV describes the results and teaching experience. Section V concludes the paper and discusses future work.

II. CASE STUDY TEACHING METHOD

Research has shown that case studies are an effective teaching method. They actively engage students, increase students' motivation to learn since the topic is more enjoyable, and help students develop skills such as problem solving and working as part of a team [8, 14-17]. Using case studies in university education provides several benefits: case studies provide a real-world context to the topic being taught, help students synthesize the course content, and require students to apply critical thinking and analysis [18]. In [19] it was noted that "Even theoretical disciplines are beginning to adopt more experience-oriented instruction as opposed to passive, lecture-oriented instruction."

Engineering fields, including Mechanical Engineering, Civil Engineering, and Chemical Engineering, have used case studies as a teaching method with successful results [26-29]. It was found that students generally had better discussions and felt they improved their critical thinking skills when compared to similar courses taught with traditional methods [27, 29]. The use of case studies in university level Computer Science education is more recent. For example, the ACM/IEEE Computer Science Curricula 2013 [11] mentioned case studies for teaching ethics in computing, the effects of computing on a variety of populations, causes of computer failures, parallel programming, and distributed systems. However, only one case study was mentioned in the 2008 interim revision [30], which was on object recognition and tracking for graphic and visual computing. Case studies in the computer science field are lacking in both breadth and depth [9]. Commercial Harvard-style case studies are available; however, most of them are focused on business or management, and necessary technical details are still lacking in cases designed for Information Systems or Information Technology [9]. Within the computer science field, security is a relatively new topic. Therefore, we need more software security focused case studies.

There is also a gap in the computer science field between academic theory and industry skills and best practices [19-21]. Students may understand examples used in the classroom, but have little knowledge of practical aspects and challenges faced by industry [19, 22]. Reference [23] found that students needed additional instruction before they could successfully apply skills learned in university courses to industry settings. A multi-year study [19] showed that a graduate-level requirements engineering course taught with industry-based case studies resulted in higher quality student discussions, increased in-class participation, improved exam grades, and had higher self-reported levels of positive learning experience,

compared to when the course was taught with more traditional approaches in previous years. When compared to other courses in the same department, students also reported higher levels of problem solving skills, ability to work independently, and interest in the course [19]. At the undergraduate and graduate level several case studies on information security topics have been taught with successful results [12, 14-15, 24-25]. Students reported they were confident about applying what they learned to future jobs [24].

III. THE CASE FOR TEACHING LOGIC FLAWS

This section describes the learning objectives for the case study, the case that was used, and the materials developed to teach students about application logic flaws [31].

A. Learning Objectives

Logic flaws are regularly listed as primary causes of commonly exploited software vulnerabilities [2, 32-34]. Seven vulnerabilities out OWASPs' 2013 Top 10 list [33] and 16 vulnerabilities out of CWQ/SANS Top 25 list [34] are logic flaws. Since they are difficult to identify with automated testing tools, student should learn a manual testing method to identify application logic flaws.

The goal of this case study is to help computer science students understand the concept of application logic flaws, and why manual testing methods must be used instead of automated testing tools. As part of the accompanying discussion questions, students should be able to identify logic flaws in provided code using the following manual testing method:

- Manipulate the data
- Manipulate the workflow
- Manipulate both the data and the workflow.
- After each manipulation, trace through the entire checkout process and track how each argument affects the internal state of the transaction, and the end result.

To guide the development of this case study, a set of learning objectives was created. These are listed in Table 1.

TABLE I. LIST OF LEARNING OBJECTIVES FOR THE CASE STUDY

ID	Learning Objectives
1	Explain what an application logic flaw is.
2	Explain why it is difficult for an automated tool to find logic flaws.
3	Identify potential areas for logic flaws in HTTP interactions.
4	Critique back-end code for a set of HTTP interactions, which has logic flaws.
5	Fix logic flaws in a set of HTTP interactions to secure it.

B. Bigcommerce and PayPal Express Case

Reference [10] covered two popular eCommerce merchant softwares: NopCommerce and Bigcommerce, in combination with four 3rd-party cashier services: PayPal Standard, PayPal

Express, Google Checkout, and Amazon Payments. Using the manual code review method covered in III.A, serious logic flaws were discovered that allowed an attacker to complete orders for free or at reduced prices. The flaws were in Amazon Payments itself, or with how NopCommerce and Bigcommerce integrated with the remaining three cashier services to collect payment.

The case chosen was Bigcommerce and PayPal Express. An exploitable logic flaw involved the use of two sessions, and replacing a digitally signed argument from one session with the same argument from a second session. An attacker could pay for a cheap order, but prevent the final step of the checkout process from completing. In a second session, expensive items are placed in the order, but the attacker skips the payment step. Despite failed payment, Bigcommerce still generated a digitally signed argument containing information about this expensive order. This argument is then copied to the first session, and the final step of the checkout process resumed. The end result is that an expensive order is completed after paying for a small order.

C. Case Study Materials

This section lists the materials developed for the case study.

1) *Introduction*: The introduction to Logic Flaws includes material from Section I in more detail. It directly addresses Learning Objectives 1 and 2 from Table 1, defining what application logic flaws are, where logic flaws come from, and limitations of using automated testing tools to identify logic flaws. Specific recommendations for manual testing are listed [3, 7], including the manual testing method used by [10]. Recommended industry best practices [2, 35-36] are provided, organized by category of logic flaw. The case study is described in detail. It is also recommended to have students read [10].

2) *Case Study Animation*: To teach about the Bigcommerce and PayPal Express case, a PowerPoint animation was created. Before starting the animation the manual code review method from [10] is summarized, and notations used in the case study are explained. A sequence diagram is provided an overall view of the HTTP interactions between the user, merchant using Bigcommerce, and PayPal Express during a typical checkout transaction.

The two sessions used to exploit the flaw in this case are presented during the animation. Each step in the checkout process has two stages during the animation:

a) *Sequence Diagram*: The HTTP interactions for this step are animated in a sequence diagram. Parameters are color-coded based on the last party who could modify them. Fig. 1 shows an example slide.

b) *Back-End Code*: The back-end code is traced line-by-line, and a table maintaining the current variable state is updated. This table is also color coded to show which variables are used by which party. This code is based on [37] and modified for clarity. Fig. 2 shows an example slide. After the animation is complete, several slides explain steps taken

by Bigcommerce and PayPal Express to ensure the transaction was done securely and correctly, such as verifying that payment was attempted and did not fail. The exploitable logic flaw is then described in detail, including which steps let to the exploit.

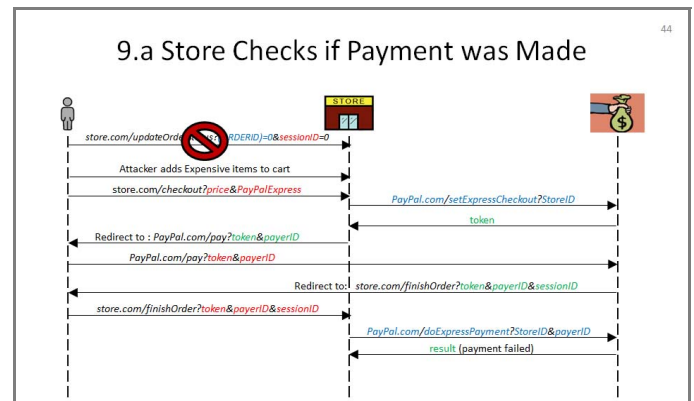

Fig. 1. Sequence Diagram with HTTP interactions.

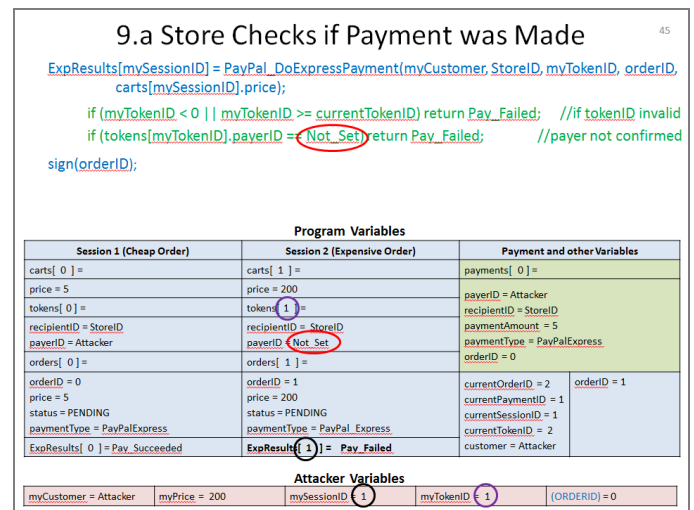

Fig. 2. Back-end code accompanying sequence diagram in Figure 1.

3) *Discussion Questions*: Eight discussion questions were developed based on the learning objectives and Blooms Taxonomy [38] to have students apply knowledge learned from the case study to similar code. Two additional cases from [10] were used for this. These questions were designed to be difficult, and should be given to students in groups of 2-3. Not all of the questions need to be given along with the case study; a subset can be chosen. Table 2 shows the mapping between the discussion questions, Blooms Taxonomy cognitive levels, and the Learning Objectives from Table 1.

Questions 1 and 2 ask students about application logic flaws and about the case study. Questions 3-5 are part of a set and should be given together. They use back-end code from the Bigcommerce and Google Checkout case [10], and are related to the primary learning objectives of identifying and fixing logic flaws. Question 6 asks students to brainstorm for testing methods to identify logic flaws. Questions 7 and 8 use

the back-end code from the Bigcommerce and PayPal Standard case, but only one question should be chosen. Question 7 asks students to trace through the code and complete a table maintaining the current variable state. Question 8 provides the same code with the table already completed, however the steps in the transaction are given out of order, and the correct order of API calls must be found. A grading rubric is available for instructors.

TABLE II. MAPPING OF DISCUSSION QUESTIONS TO LEARNING OBJECTIVES (LO) AND BLOOMS TAXONOMY

LO ID	Question ID	Learning Objectives	Blooms Taxonomy Cognitive Level
1, 2	1	What is a logic flaw, and why are they difficult to identify?	Level 1 - Knowledge Level 2 - Comprehension
	2	Why is it NOT a security vulnerability that the token, payerID, sessionID, and PayPalExpress URL parameters from the Bigcommerce and PayPal Express case are unsigned?	Level 4 - Analysis
3	3	Read through the following URLs representing HTTP interactions between three parties. Suggest potential security flaws for each of the arguments.	Level 4 - Analysis
4	4	Read through the following code and critique it.	Level 6 - Evaluation
5	5	Fix the following code to better secure it.	Level 5 - Synthesis
	6	Propose methods to test for logic flaws (does not have to be automated)	Level 5 - Synthesis
	7	Given the following code and variable table, trace through the variables at each stage.	Level 3 - Application
	8	The following URLs/code sequence is out of order. What is the correct sequence?	Level 3 - Application

4) *Prototype Automated Testing Tool*: To provide students with first-hand experience of the benefits and limitations of using automated testing tools to identify application logic flaws, a Virtual Machine was created. VMware was used to set up the Virtual Machine running Windows 7, and a tool called Corral [39] and its' prerequisites were installed. Corral was developed by the Microsoft Research Team, and can be used to scan for application logic flaws in C, .NET, or Java code when given a proper driver program to make the API calls.

IV. TEACHING EXPERIENCE

This case study was taught in the Spring 2015 semester in COMP 727 Secure Software Engineering [31]. This was an online course, and 21 students were registered. Students were given three weeks to complete the case study and discussion questions, which included Spring Break.

To help evaluate the effectiveness of the case study, students were given a voluntary pre-survey prior to starting the assignment, which asked them to rate their level of knowledge or skills for the learning objectives on a 5-point Likert scale. A post-survey with the same questions was given upon completion of the case study. It also asked students several questions evaluating the case study on a 5-point Likert scale, and open ended questions on what they learned or problems that were encountered. These surveys were approved by the Institutional Review Board (IRB) at North Carolina A&T State University.

The discussion questions were assigned in groups of three, for a total of seven groups. As this case study was taught in an online course, each group was provided with a Blackboard forum in which to record their groups' discussion. These forum posts were then reviewed to evaluate if students had active and lively discussions. Each group submitted a final report with their answers to the discussion questions, and these were graded using a rubric.

A. Survey Results

Participants in the survey were graduate-level computer science students. More detailed demographics were not collected. Three pre-surveys were submitted blank or partially blank out of 21 submitted surveys. Three post-surveys were also submitted blank out of 17 submitted surveys. Since an unequal number of usable surveys were completed, and several students declined to provide the information being used to pair responses, a paired statistical analysis could not be performed. Instead, a Mann-Whitney U test was more appropriate, with the before and after data treated as independent samples. It is a nonparametric test of the null hypothesis that two populations are equal.

The null hypothesis H_0 is that the two populations are equal, and the research hypothesis H_1 is that the two populations are not equal. With $N_1 = 18$, $N_2 = 14$, and $\alpha = 0.05$, the calculated critical value for this test is 74 [40]. Thus, H_0 is rejected if $U \leq 74$. The results of the Mann-Whitney U test are shown in Table 3. All of the p -values indicate these results are statistically significant, and H_0 is rejected for each Learning Objective. This indicates that students felt their knowledge improved for each of the Learning Objectives in Table 1. However, this was calculated using a relatively small sample size; therefore the results of this test may not be representative of the population of university-level computer science students. It is also not an evaluation of students' knowledge or skill level, and merely how they perceived their knowledge or skill level.

TABLE III. MANN-WHITNEY U TEST RESULTS OF STUDENTS' RANKING OF THEIR KNOWLEDGE/SKILLS ON LOGIC FLAWS ON A 5-POINT LIKERT SCALE

Learning Objective	1	2	3	4	5
U	49.5	72.5	41	57	67
Asymptotic 2-tailed p-value	.002	.032	.001	.004	.013

Additional questions on the post-survey included rating students' interest in the topic of logic flaws, and to review the case study. Overall, the results in Table 4 show students enjoyed the case study and felt it was useful. Most importantly, 78% of students felt the learning objectives were met and 63% of the students felt they improved their problem solving and critical thinking skills.

TABLE IV. RESULTS OF HOW MUCH THE STUDENTS AGREE OR DISAGREE WITH THE STATEMENTS ON THE POST-SURVEY

Question	Response
The case study was useful to help you understand the material	29% Strongly Agree 50% Agree
You were motivated to learn about application logic flaws	29% Strongly Agree 36% Agree
You enjoyed the case study	29% Strongly Agree 36% Agree
The learning objectives were met	7% Strongly Agree 71% Agree
The case study helped you to develop problem solving and critical thinking skills, and ability to think independently	21% Strongly Agree 43% Agree

From the open ended questions, the most important things students said they learned were:

- Never trust input from the client side of a web application
- How seemingly simple vulnerabilities can lead to serious logic flaws
- The process of tracing an applications' workflow

A few comments reiterated that students enjoyed the analytical thinking involved in this case study.

In addition to learning a manual testing method for identifying logic flaws, students also learned several key concepts about software security. First, that input validation is extremely important since input can be malicious and processes can be manipulated. Second, that a vulnerability in one part of an application may not cause immediate security issues, but can still detrimentally affect the end result of a process. Finally, students improved their skills of tracing through the steps of a process. Having learned these concepts, students are more knowledgeable about how software can be attacked, and may be more mindful about designing security into software and performing software security testing in the future.

During the case study, problems were encountered with:

- Running Corral on the Virtual Machine
- Understanding [10]

- Tracing the state of the variables when using the manual code review method

These were caused by a lack of information, and will be addressed in future work. The instructions for running Corral can be clarified, and a more detailed explanation of the scan results can be provided. The case study instructions can mention that [10] should only be read after the introduction discussed in III.C.1, and the introduction can be expanded to include a glossary of new terms covered in [10]. A blank trace similar to the table n Fig 2 can be provided with the discussion questions.

Notable comments were: "The case study was really good. It helped me a lot in enriching knowledge of application logic flaws," and "This is an interesting topic and something I think we need to do with all programs and applications that are released to the public and considered safe." This confirms that students enjoyed the case study and found it useful.

B. Discussion Questions

Out of the eight questions in Table 2, five were chosen: questions 2-5, and 8. Students were also asked to run Corral on provided code, and describe their experience with the tool. Later in the semester, question 1 from Table 2 was given on a mid-term exam.

Students' grades for the case study were based on their individual participation and quality of forum posts, the quality of the group discussion as a whole, and the final group report with answers to the discussion questions.

1) *Quality of Discussion*: Overall, the students' discussions in the online Blackboarded forums was high-quality and indicated that most of the groups had very active discussions. The posts show that students were in fact able to perform the high level of analysis, synthesis, and evaluation that was asked of them. The following is an excerpt from the student online discussion of one group:

"I think you are right. We may have been overthinking this stage of the order processing. If the cashier sends over the price information for verification then that would be sufficient as long as the merchant can always verify the origin of the message as coming from a cashier and not from an attacker." This shows that students were able to trace through the transaction process, and identify what input validation was necessary to verify that the price of the order matched payment amount received by the cashier.

2) *Graded Discussion Questions*: The rubric mentioned in Section 2.C.3 was used to grade each of the discussion questions in the group reports, and the question on the mid-term exam. Grades ranged from 75 to 100 percent, with an average of 90.7 percent.

Question 3 from Table 2 was the question most students struggled to answer correctly. Instead of providing their own responses based on the provided HTTP arguments, students referenced [10]. However, the question was asking for general responses and not about the back-end code behind those HTTP requests. Based on the comments in the post-survey, question 4 from Table 2 was the question students found most

difficult. Some groups relied on [10] instead of performing their own analysis and those responses were lacking the existing security measures in addition to listing the vulnerabilities they discovered. A correct method for fixing the discovered logic flaws was attempted by most groups in question 5 from Table 2; however it was not always implemented properly. Question 1 from Table 2 was given on a mid-term exam, and students were able to correctly define logic flaws and provide examples. They also understood why logic flaws are difficult to identify, for both manual and automated testing methods.

V. CONCLUSION

Based on the overall results, this case study was successful at teaching about application logic flaws to graduate-level computer science students. It adds to the number of case studies available for computer science education, specifically supporting secure software engineering or software security testing courses. It should help bridge the gap that exists between academia and industry best practices for software engineering.

The evaluations of this case study are limited, as it has only been taught once. The results were promising, but they are from a relatively small sample size. A quiz or simple exercise could be given along with the pre- and post-surveys to quantitatively evaluate and changes to students' knowledge or skill level of the Learning Objectives. The quiz could ask students several questions related to defining logic flaws and how they are identified through annual testing. An exercise involving a short segment of code could ask students to identify potentially vulnerable arguments, explain why they are vulnerable, and identify a logic flaw.

Another limitation is that students also may have difficulty applying this manual testing method to software that does not follow a client-server model, or to software unrelated to eCommerce, as the code structures and process workflows may be different.

Future work can be done to improve the case study as a whole, and more case studies on logic flaws can be developed to supplement the existing case. The animation can be re-done in a platform-independent format, to help prevent display formatting issues. The grading rubric for the discussion questions can be updated to include new possible answers, as the discussion questions are fairly open-ended. Incorrect answers can be added as well. In the animation, students recommended that a slide be added to each step of the transaction that summarizes the step before showing the sequence diagram and back-end code, to help explain what is actually happening.

Future work also includes teaching this case study again at North Carolina A&T State University, or in other universities. Several professors from other universities have already expressed their interest in using this case study as part of their curriculum.

Healthcare Security : A course engaging females in cybersecurity education

Krishnendu Ghosh

Department of Computer and Information Technology

Miami University

Hamilton, Ohio 45011

Email: ghoshk@miamioh.edu

Abstract—The paper describes experience in teaching a sophomore-level healthcare security course. The course introduced security in context. The context was healthcare. The structure of the course is outlined. The pedagogy and research questions are described. Surveys conducted provide insights that security in context of healthcare is effective in engaging students in security topics.

I. INTRODUCTION

Women are seriously underrepresented in cybersecurity workforce [1]. We address this challenge by a healthcare based course to engage females in cybersecurity. Healthcare is a discipline that has attracted more females [2] than computing because of social and cultural reasons [3]. Healthcare informatics is a rapidly growing field and it is critical to address security in healthcare informatics [4]. We create a course that introduces and engages females in cybersecurity concepts, leveraging upon a large pool of female students interested in pursuing healthcare related professions. The anxiety to learn programming and the stigma attached to cybersecurity professionals as being male dominated ([5], [3]), are bypassed by creating a healthcare based curriculum to teach cybersecurity concepts. Healthcare based topics provide a context for engagement for students, interested to become healthcare professionals. We created a special topics sophomore level undergraduate course, Healthcare security (HS) to investigate the following questions.

- 1) What are the pedagogical practices that engage undergraduate females in cybersecurity education?
- 2) How does participation in the healthcare security course impact students' perception of themselves as future cybersecurity professionals?

Studies addressing student engagement in cybersecurity topics in healthcare were conducted in the HS course. More than 50% of the students in the course were female. The topics covered in the healthcare security course were: healthcare forensics, security analysis and audits in information technology (IT) systems, interoperability of medical devices, usability security of medical devices and malware breaches in healthcare devices. Given the wide variety of topics covered in the course, we were interested to know the engagement level of the students in topics in cybersecurity. The knowledge gained by the students in the course was evaluated using pre-post surveys on the learning outcomes of the course. The instructional delivery of the topics in the course was critical in student engagement. Periodic surveys were conducted on

students during the semester. The surveys were informative in evaluating the level of the student engagement on topics in cybersecurity. The high enrollment of female students in the HS course was possibly due to the following recruitment practices:

- 1) The advertisement flyer for the course stated no prior programming experience is required to register.
- 2) The healthcare provided the context for teaching topics in cybersecurity to undergraduate females ([6], [7]). The advertisement flyer for the course emphasized on security vulnerabilities in healthcare-related software and healthcare devices.

II. COURSE DETAILS

The course, *Healthcare Security* was a three credit sophomore level course and offered as a special topics course in the fall of 2014. The course was offered as an elective for bachelors degree in health informatics technology majors and associates degree in IT. The prerequisite for the course was foundational courses in IT or permission of the instructor. The topics in the course were digital forensics in healthcare, security analysis of IT devices, interoperability of medical devices, usable security of medical devices and malware in medical applications. In the course, there were no programming assignments and assumed the students had no prior programming experience. Some of topics in operating system were covered to support concepts in forensics.

The course was taught in a traditional lecture-class activity format. The instructional delivery emphasized on active learning with problem based approaches. There were two tests, a midterm and a final. The midterm was based on digital forensics concepts and healthcare forensics. The finals was based on the topics that were covered after the first midterm, namely security analysis of IT devices, interoperability of medical devices, usable security of medical devices and malware in medical applications.

III. STRUCTURE OF THE ASSIGNMENTS

The structure of assignments were problem based in the HS course. There were no programming assignments. The arguments put forward by Guzdial [8] to "understand computing before programming" and computational thinking [9], were motivational for not including programming. The emphasis of the assignments was problem solving [10] to address a diverse group of students, with different background and motivation to

pursue IT courses. The following are samples of assignments on the topics that were covered in the HS course.

- **Healthcare forensics:** The assignment focussed on the file retrieval from Linux.
You are hired by a hospital to recover data in the form of files. The files were stored in a server that had linux operating system. Write the steps that you will be performing in order to recover the files from the system. The steps should be based on the material "LinuxFileSystem" and the power point slides that has been uploaded. Write two pages (double space) for your description for retrieve the files.
- **Interoperability:** The emphasis of this assignment is understanding the concepts involved in the interoperability of devices.
A device runs on a software based on computer language Y on operating system Z Another device , runs on a software based on computer language,V on operating system W. State how will you construct a system so that the two devices can communicate with each other. Explain the key concepts and illustrate with an example.
- **Usability Security:** The assignment tested the understanding of modeling using graphs for user interfaces.
 - 1) *Choose an interface that you and your colleagues are excited about.*
 - 2) *State your assumptions when you model precisely.*
 - 3) *Model the interface with at least 6 different button using graph*
 - 4) *Draw the graph of your model*
 - 5) *State why you think the user model is a star or a complete graph.*
- **Malware in Healthcare Devices:** The assignment tested the security risks in healthcare devices.
Describe any security risks that may exist with implantable devices? List 3 ways to secure implantable devices.

IV. METHODOLOGY

Data was collected from the surveys for a qualitative study. The reasoning was that the small class size would not produce data on which statistical analysis can be performed. The responses from the survey provided the student perception on the topics as the course progressed. There were two sets of surveys administered.

- 1) *Pre-Post* Course surveys were conducted to evaluate the knowledge gained by the students after taking the course.
- 2) *Periodic* surveys were administered in the second week (first periodic survey), seventh week (second periodic survey) and in the fourteenth week (third periodic survey) of the semester. The surveys focussed on the impact of topics on healthcare security on student perception of computer and information security.

All the surveys were paper-based, anonymous and voluntary. There were total fourteen students who had enrolled in the

course. Out of 14 students enrolled at the beginning of the semester, 12 students completed the course at the end of the semester.

A. Evaluation of Learning Outcomes of the Course

The learning outcomes of the course were:

- 1) Become familiar with the healthcare laws, HIPAA and HITECH
- 2) Provide a working understanding of threats to data and IT systems
- 3) Describe the formulation incident response in an IT system
- 4) Explain the security analysis steps and audits for an IT systems
- 5) Provide a working understanding of fundamental concepts in interoperability of devices
- 6) Provide a working understanding of usability security of medical devices.
- 7) Describe different kinds of malware
- 8) Analyze malware breaches in medical systems and propose solution

Voluntary and anonymous surveys were conducted to evaluate the knowledge gained during the course in the semester. The Pre-Course and Post-Course survey were administered on the first day of the class and the last day of classes, respectively. Table I shows the responses to the queries directly mapped to the learning outcomes. For example, the question mapped to the first learning objective is *I am able to Become familiar with the healthcare laws, HIPAA and HITECH*. The likert scale options to the questions were strongly agree, agree, indifferent, disagree and strongly disagree.

Twelve students responded to the survey questions mapped to the learning outcomes. There were twelve responses to the question mapped to the first learning outcome. Several students in the class were familiar with HIPAA and HITECH from other that had health informatics as part of the curriculum. All of the female students in the Post Course survey either strongly agreed or agreed to have learnt the concepts. All the students agreed or strongly agreed to have a working understanding of threats to data and systems. The third question in the Post-Course survey reported four responses that were "Indifferent". The possible reason could be there was only one short assignment that addressed the topic. There were eleven responses to third learning objective and one female did not respond in the Pre-Course survey. The first three learning outcomes focussed on the basic concepts in health forensics. For the fourth learning outcome which focussed on the security analysis and audits, one female responded in different and only, one male strongly agreed in the understanding the outcome. One male student did not respond in the Post-Course survey for the fourth learning outcome. The security analysis could have been made more hands-on than lectures only for a better understanding of the concepts. The concepts on interoperability stated in the fifth learning objective was well received by all students. The data from Post-Course survey shows the learning was effective for concepts of usability security, when compared with Pre-Course survey. All of the responses were "Agree" or "Strongly Agree" to understanding different malware and the processes how they affect the systems. Students responded favourably learning to

Surveys	Pre-Course										Post-Course									
Likert Scale	A		B		C		D		E		A		B		C		D		E	
Outcome	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F	M	F
1.	0	1	1	1	2	2	2	1	0	2	2	2	3	5	0	0	0	0	0	0
2.	0	2	0	2	2	1	1	2	0	2	1	1	4	6	0	0	0	0	0	0
3.	1	0	1	1	0	2	2	1	2	1	3	0	2	3	0	4	0	0	0	0
4.	0	0	1	2	0	0	4	2	0	3	1	0	3	6	0	1	0	0	0	0
5.	0	0	1	2	1	0	3	2	0	3	3	2	2	5	0	0	0	0	0	0
6.	1	1	0	1	2	0	2	2	0	3	2	2	3	5	0	0	0	0	0	0
7.	0	1	3	4	0	1	1	0	0	2	2	3	3	4	0	0	0	0	0	0
8.	1	0	0	1	0	2	3	1	1	3	2	0	2	7	0	1	0	0	0	0

TABLE I. STUDENT RESPONSES FROM PRE-POST COURSE SURVEYS ; LIKERT SCALE OPTIONS, A= STRONGLY AGREE, B =AGREE, C=INDIFFERENT, D=DISAGREE, E=STRONGLY DISAGREE; M =MALE, F = FEMALE

analyze malware breaches in medical systems and propose solution. Hands-on activities using software tools could have been led to better understanding of malware breaches. Female students surveyed to have learnt the concepts well in almost all the learning objectives. There were "Indifferent" responses by females in the third and eighth learning objectives.

B. Student Perception in Security Topics

The evaluation of student perception in security topics was using periodic surveys. The first periodic survey was administered in the second week of classes. The topic, healthcare forensics was taught during the first two weeks. All of the 14 (7 females and 7 males) students did the first survey shown in Table II. For the first question in Table II, one male student selected all the options and one female student selected (a) and (b). In the first periodic survey, the questions (1)-(2), the responses from female students indicated to learn about topics of security in healthcare. Question (3) indicates the females and males are inclined to be in healthcare IT field. Questions (4)-(5) clearly shows the interests of males slightly higher when compared to females in taking security related courses and careers in IT security.

The second periodic survey (shown in Table III) was administered in the seventh week of the semester, after the midterm. The midterm consisted of topics healthcare forensics , concepts of digital forensics and healthcare laws. The midterm included foundational concepts of operating system, incident response in an IT systems and threats to data and IT systems. One male student dropped the class after the first midterm. The responses of question (1) suggest that female students responded that their performance was good or extremely good. The female students felt comfortable in learning the material. All the students found the topics in the midterm intriguing. The number of students who wanted to take more computer and IT security courses was almost the same when compared to the first periodic survey. One female student did not want to take the any computer or IT courses in security which was not the case in the first survey. All the female students were interested in careers in IT security. Two male student were unsure of careers in IT when compared with first periodic survey.

The third periodic survey was administered in the fourteenth week of the semester and the responses are shown in Table IV. Twelve students completed the third periodic survey. The majority of the responses for the first question

Questions	M	F
1. Why are you taking this course? ¹		
(a) The topics are interesting and worth exploring.	2	1
(b) Wanted to learn about security in healthcare.	3	4
(c) Had to fill the credits as an elective for my degree.	4	3
2. If there was another course that was exclusively on "healthcare security", would you have registered for that course?		
(a) Yes	3	2
(b) No	1	3
(c) Unsure	3	2
3. Do you envision yourself in working in healthcare IT field ?		
(a) Yes	4	5
(b) No	1	1
(c) Unsure	2	1
4. Do you plan to take more computer/IT security courses in future?		
(a) Yes	6	4
(b) No	0	0
(c) Unsure	1	3
5. Would you seek careers that require skills sets in computer/IT security?		
(a) Yes	7	5
(b) No	0	0
(c) Unsure	0	2

TABLE II. QUESTIONNAIRE IN THE FIRST PERIODIC SURVEY; M = MALE AND F = FEMALE

whether the students had gained adequate knowledge in healthcare security were "No". The foundational concepts of the topics were introduced. The students were exposed to different security problems that may occur in healthcare systems. The students were expected to take higher level security courses. All students enjoyed the topics in the course. Two of the female students responded the negative opinion about programming led to positive opinion after taking the course. This is important because the course was taught without any programming assignments and in a "problem solving" approach. Five female students were interested in taking more computer/IT security courses in future, an increase from the first and second surveys. Ten out of twelve students expressed interest that they would seek careers in computer/IT security. One female student responded "unsure" to the fifth question in the third periodic survey when compared to the second periodic survey.

Based on the periodic surveys, the student perception of

Questions	M	F
1. How is your performance in the class so far?		
(a) Extremely Good.	1	2
(b) Good.	3	5
(c) Poor.	0	0
(d) Unsure	2	0
2. Does this course so far fulfill the reasons that made you take this course?		
(a) Yes	6	7
(b) No	0	0
3. Are you intrigued with the topics so far?		
(a) Yes	6	7
(b) No	0	0
4. Do you plan to take more computer/IT security courses in future?		
(a) Yes	5	4
(b) No	0	1
(c) Unsure	1	2
5. Would you seek careers that require skills sets in computer/IT security?		
(a) Yes	4	7
(b) No	0	0
(c) Unsure	2	0

TABLE III. QUESTIONNAIRE IN THE SECOND PERIODIC SURVEY; M = MALE AND F = FEMALE

the learning of topics security was positive. All the students, male and female enjoyed taking the course. Majority of female students were interested in take security courses in future and envision IT security as an career option. The retention of the course among female students in the course was hundred percentage.

V. CONCLUSION AND FUTURE WORK

In this paper, we described a special topics course, healthcare security. The topics in this course addressed concepts in security. The first set of surveys, Pre-Post course surveys provided insights knowledge gained in the course. Female students gained knowledge in the topics of security, based on the comparison of the responses in the Pre-Post course surveys. The second set of surveys, periodic surveys, focussed on the impact of the security topics on student engagement and student perception. The surveys showed that females are interested in healthcare and are intrigued in security of healthcare systems. The context based introduction of security in healthcare is a way to expose female undergraduates to topics related to computer and security. The "problem based" approach employed in the course seems to be positively received by female students. The retention among the females was hundred percent. In future, hands-in assignments based on software tools such as interactive disassembler (IDA) could be introduced to understand the concepts. The engagement of the students in the topics of security in the HS course provides insights to use mobile health and bioinformatics as contexts to teach cybersecurity concepts. The courses with different contexts would interweave cybersecurity concepts and hence, appeal to a diverse student population.

Questions	M	F
1. Do you feel that you have gained knowledge in healthcare security from this course?		
(a) Yes	5	7
(b) No.	0	0
(c) Unsure	0	0
2. Did you enjoy learning the topics in this course? as this course "healthcare security", would you you have for that course?		
(a) Yes	5	7
(b) No	0	0
3. If you had any negative opinion about learning security topics in IT such as "it requires too much programming", or "it is not interesting to me" then after taking this course, did any of those negative opinions change to positive opinion?		
(a) Yes	0	1
(b) No	0	1
(c) Neutral	5	5
4. Do you plan to take more computer/IT security courses in future?		
(a) Yes	3	5
(b) No	1	0
(c) Unsure	1	2
5. Would you seek careers that require skills sets in computer/IT security?		
(a) Yes	4	6
(b) No	0	0
(c) Unsure	1	1

Abstract— Joint ACM/IEEE Computer Society undergraduate computer engineering curriculum guidelines are slated for release in 2016. These update the 2004 guidelines commonly known as CE2004. The presenters are part of the task group leading the revisions and will give an overview of the latest draft. Participants will engage in discussions on potential improvements to the guidelines to ensure that they are useful to programs as they work to ensure their curricula reflect the state-of-the-art in computer engineering education and practice and are relevant for the coming decade.

Keywords—Computer engineering; curriculum guidelines; CE2004; CE2016; ACM; IEEE Computer Society

I. BACKGROUND

This is the seventh conference presentation [1–6] supporting a process began by the ACM and the IEEE Computer Society in 2011 to update the CE2004 document, formally known as “Curriculum Guidelines for Undergraduate Degree Programs in Computer Engineering” [6]. Using nearly 300 survey responses plus input at conferences and working meetings, the authors are leading a significant update of the

document with a goal of a 2016 release. The document will be known as “CE2016”.

In various subject areas the authors are also consulting the related document “Computer Science Curricula 2013” (CS2013) and the draft produced by the parallel effort to update the software engineering guidelines (SE2004).

II. SPECIAL SESSION FORMAT

This special session will engage computer engineering educators in evaluating the current draft as it approaches completion.

The authors will give an overview of the structure of the CE2016 document followed by key areas receiving initial or substantially enhanced coverage. They will also discuss how computer engineering educators can contribute to the process. Small group discussions will focus on how the document can best provide value to both new and existing computer engineering undergraduate programs.

Specifically, the presenters will summarize topics added, expanded, and removed from the guidelines in response to feedback from academia and industry. They will show how the new document also aims for greater clarity by succinctly documenting the scope and purpose of each major “knowledge area” for computer engineering undergraduates. Drilling down, they will show how “knowledge units” give clarity to programs by specifying “learning outcomes” that define what successful students will be able to do. The document also incorporates details of the required mathematical background and includes many important, “discretionary” areas and outcomes that not all programs will wish to cover.

The agenda will be as follows.

0:00–0:15	Overview of the CE2016 guidelines document
0:15–0:25	Summary of key areas receiving initial or significantly updated coverage: embedded systems, digital systems design, multicore, security, mobile and power aware, software engineering, and verification and validation of computing systems
0:25–0:35	Plans for completion and ways individuals can contribute to the process
0:35–1:05	Small group discussions among the audience participants: How should the document change to provide a valued resource to both new and existing undergraduate computer engineering programs?
1:05–1:15	Report feedback to all attendees
1:15–1:30	Questions and comments from audience participants

Abstract— Numerous avenues exist for faculty to learn about new pedagogical techniques, but these techniques rarely make it into practice, even by experienced and motivated engineering educators. They often suffer from the perception of “that won’t work because my classroom is different.” The focus of this session is to help faculty explore this perception and to identify new techniques for potentially overcoming this limitation. Using the Diffusion of Innovation framework, faculty will be guided through several activities to explore ways of adapt known evidence-based instructional practices to a variety of classroom setups and course styles. They will then have the opportunity to confront the limitations they hold about implementing them in their own courses.

Keywords—*Diffusion, Pedagogical Adaptation, Evidence-based Instructional Practices*

I. GOALS OF THE SESSION

The purpose of this session is to capitalize on the benefit of peer interaction to support the diffusion of Evidence-Based Instructional Practices (EBIPs). Faculty will explore differences in their context and content, establish high empathy, and create an environment for more effective communication around EBIP adoption. Faculty will also build on each other’s ideas and conceptions of EBIPs in order to identify alternative implementations for their context.

II. DESCRIPTION OF SESSION CONTENT

As each faculty member decides to use an Evidence-Based Instructional Practice (EBIP) in their classroom, Diffusion of Innovation [1] tells us they will go through the five stages of the innovation-decision process: knowledge, persuasion, decision, implementation, and confirmation (p. 163). Physics [2] and Engineering [3] faculty member’s progression through the innovation-decision process has been investigated and it was found that many faculty members have moved beyond the knowledge stage of this process. Henderson [2] also found that a number of faculty tried using innovative practices in their classroom, but then stopped.

A key element within dissemination is the concept of “re-invention, defined as the degree to which an innovation is changed or modified by a user in the process of adoption and implementation” [1] (p.174); this concept is also

referred to as adaptation [4]. One of the benefits to re-invention is that it “encourage[s] customization of the innovation to fit it more appropriately to local situations or changing conditions” (p. 177). This allows adopters to adapt the innovation into their personal context [4]. When adopters are able to re-invent or adapt the innovation, they are also less likely to discontinue the use of the innovation [1]. However, when exploring the re-invention of innovation, adopters should be conscious of the fidelity of implementation [5] when discussing the innovation. Fidelity of implementation broadly means how well the implemented innovation follows the original [6]. Where faculty should be allowed to adapt EBIPs into the context of their specific classroom, they should maintain a level of awareness of the overall innovation and the critical elements that make the practice effective. This special session will apply the principle of diffusion of innovation and fidelity of implementation to support attendees’ adaptation and implementation of evidence-based instructional practices.

III. SESSION AGENDA

The session is planned to run on the following timeline:

(00 - 05 min) *What the heck is that?* In order to situate the attendees in the context of the special session, the presenters will play a video clip from a Saturday Night Live skit where Bill Murray and Steve Martin point to an unseen object and question “What the [heck] is that?” in a variety of tones. (<http://youtu.be/RV7Qz640OeM>). At one point, they think they have figured it out, only to realize that they still don’t know “what the [heck] is that.” At the back of the room, facilitators will place a poster with a list of evidence-based instructional practices.

The SNL skit can be seen as analogous to learning about a specific EBIP or seeing a colleague implement it, thinking “oh I know what it is”, then walking away confused when thinking about how to implement the innovation in their own course.

(05 - 10 min) *Overview of evidence-based instructional practices.* Drs. Cutler and Pembridge will provide a brief review of common EBIPs and their characteristics.

(10 - 20 min) *Spot the difference*. A common barrier to diffusion involves the adaptation of an implementation into a different context, leaving many faculty to proclaim “But my course is different”. Dr. Verleger will highlight the variety in the room by having participants identify a variety of contextual and subject matter differences across attendees.

(20 - 25) *Overview of Diffusion of Innovation and Adaptation with respect to Fidelity of Implementation*. Dr. Cutler will then explain the theoretical grounds for the following activities by providing an overview of diffusion of innovation, placing emphasis on adaptation, followed by implications of the adaptation while maintaining the fidelity of the evidence-based instructional practice.

(25 - 45 min) *Group Story Telling*. Using the method of group storytelling, participants, in groups of 3, will be given a mock context (size, setting, course content) and a randomly assigned EBIP. Together they will develop an implementation of that EBIP. To support this, the group will be supplied a small poster that will outline the necessary details that need to be explained. Following the activity, the groups will report out their implementation.

(45 - 80 min) *6-1-5 Method*. Adapting the 6-3-5 method from design methodology for brainstorming, participants will be seated 6 per table. Each participant will receive a different EBIP on a handout. They will be required to describe their context and how they would implement the EBIP. After 5 minutes the handout will be rotated to the next person, allowing them to build on the idea and share how they would implement the EBIP. This will continue until the handout you began with is returned to you. While the 5 minutes is a short time to provide details, it will require the participants to focus on the key components of the implementation, thus ignoring first instinct barriers.

(80-90 min) *Summary and Recap*

IV. DESCRIPTION OF ANTICIPATED AUDIENCE

This session should primarily be of interest to faculty at all levels interested in better understanding evidence-based instructional practices and mechanisms for integrating those practices into their courses. The session will also be of interest to faculty members struggling with identifying ways they can adapt any evidence-based instructional practices that they are already aware of because “their course is different”. There is also some potential benefit for graduate students who are interested in academic positions that include teaching, though this is not anticipated to be the target audience.

V. EXPECTED OUTCOMES AND FUTURE WORK

Participants will gain a better understanding of a variety of evidence-based instructional practices and reflect on their

experiences trying to incorporate them into their own courses. They will share their perceptions and ideas of how others may be able to integrate these practices. In turn, they will receive guidance from other attendees on integrating evidence-based instructional practices into their courses.

The research team will continue to investigate the barriers and constructive experiences that help faculty become more effective teacher-facilitators. Work currently being conducted by the team continues to address the faculty development research-to-practice gap.

VI. DISSEMINATION OF OUTCOMES

Following the session, all worksheets will be summarized and emailed to participants so that they may further explore alternative implementations of evidence-based instructional practices. These worksheets will include the course subject matter and context so that faculty may continue to use them for a variety of courses.

Prior to the session, the presenters will receive IRB to collect data. The primary data will include a survey that participants will complete upon entering the session, and the completed session artifacts. The findings of this session will then be disseminated at FIE the following year.

VII. JUSTIFICATION FOR SPECIAL SESSION

Rogers reminds us that “Mass media channels are relatively more important at the knowledge stage and interpersonal channels are relatively more important at the persuasion stage in the innovation–decision process” [1] (p.195). However, with many faculty who attend FIE have advanced past the knowledge stage [2, 3], and more personal channels should be explored to aid faculty in moving into the decision and implementation stages. This session will be highly active; engaging participants with each other to develop implementations in a variety of contexts, especially their own.

VIII. AUTHOR INFORMATION

James Pembridge graduated from Virginia Tech with a PhD in Engineering Education. His recent work has focused on the diffusion of evidence-based instructional practices through peer-review (NSF-TUES, DUE #1244852) and the application of a cyclical change model to explore stages of pedagogical change with respect driving and restricting factors (NSF-WIDER, DUE #1347790) [7-10].

Stephanie Cutler graduated from Virginia Tech in May 2013 with her PhD in Engineering Education. Her dissertation research focused on faculty adoption of research-based instructional strategies [5, 11, 12]. She currently works for the Rothwell Center for Teaching and Learning Excellence at Embry-Riddle Aeronautical University’s Worldwide campus where she aids faculty in bringing innovative instructional strategies into the classroom, specifically inquiry-based learning [14].

Matthew Verleger graduated from Purdue University with a PhD in Engineering Education. In his current role as a faculty member in the Engineering Fundamentals program at Embry-Riddle Aeronautical University, he is involved in department-wide work on the adoption of evidence-based instructional practices and conducts his own research on using peer review of artifacts in the classroom [15]. He also conducts research on hybrid and online learning models [16].

ACKNOWLEDGMENT

The authors would like to gratefully acknowledge the National Science Foundation for their support of this work under the WIDER program (NSF # 1347790). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not reflect the views of the National Science Foundation.

Abstract— This paper describes two mobile learning journeys in the zoo using either smartphones or tablets, and a mobile learning application SamEx, all designed and implemented as part of a research study in a Singapore primary school. Out-of-school semi-formal learning activities such as zoo trips present standard curricular topics where students go out of their schools in order to explore topics of interest in a semi-controlled designed environment. Typically, students observe and connect their observations with prior knowledge or further extend their knowledge on the go or later with their teacher in the classroom. The initial study in 2013 included the whole Primary 3 (P3) level of students, 305 of them, while the subsequent study in 2015 included 321 students. Between the years technology shift was inevitable – the participating school switched from smartphone devices to tablet computers, where each child has a tablet with the option to connect to both a WiFi network and to a mobile broadband network. Furthermore, the changes in the design of the mobile learning SamEx application were carried out in collaboration with the teachers, through a design-based research process. SamEx allows for the collection, organization and storage of media collected by students typically as responses to questions and prompts set up by their teachers. The initial design was oriented towards individual students, to support their individual in-class and homework learning tasks and assignments. The main features added to the application incorporated additional teachers' needs in carrying out curricular topics including inquiry learning and collaborative learning. The paper explores the evolution of both technology and the implementation of the application in the period, and problematizes the notion of inevitable technology change, constant software maintenance and enhancement and the effect of these changes on learning activities and outcomes.

Keywords—mobile learning; e-learning; tablet computers in education; software design

I. INTRODUCTION

Mobile learning technologies stimulate student engagement while enabling authentic learning scenarios used as part of diverse educational programs around the globe [1]. With the goal of providing a more sustained learning experience for their students, teachers in a Singapore primary school collaborated with a research team in 2012 in a Seamless Learning project in which the goal was the incorporation of mobile learning technologies into the science curriculum. An application named SamEx was developed and has been used as a part of the curriculum since then. The application is constantly improved through a process of iterative design with both teacher and student usage experiences in mind.

SamEx is an educational application for Android platform designed to allow students to post, store and share educational content with their colleagues and teachers either as responses to contextual prompts set up by their teachers or as student-initiated contributions. As a result of the two-year usage, the data on student involvement in form of media contributions, text answers, likes and comments is available for research analysis.

This paper focuses on the comparison of two mobile learning journeys using the data provided by SamEx application. The comparison is characterized by unavoidable technology improvement and insights provided by constant collaboration with the teachers. Analysis is conducted on the data collected from the Primary (Grade) 3 level students in the year 2013 and 2015. In 2013 the students had been using the smartphone SamEx application, while in 2015 the students were equipped with tablet computers running a redesigned and improved SamEx application. Analysis is based on the comparison of two student trips to the Singapore zoo, and characterized by a number of questions specifically designed

by teachers for the students to answer on the spot by providing textual, picture, video or audio responses via the application.

Section II provides an overview of the state of the art mobile learning and pedagogical approaches to it. Section III follows with a detailed description of SamEx design. Sections IV and V describe the methodology used and present the results of the data analysis, while Section VI discusses interaction specifics.

II. STATE-OF-THE-ART

The rapid development of mobile technologies has in recent years encouraged the emergence of a number of novel software applications, and also opened the possibility of transferring many existing applications from desktop PCs to mobile phones and tablets. Moreover, the ease of use, device portability, different connectivity options, built-in camera and various sensors made mobile platforms an ideal environment for many software applications. Used in the mobile educational applications, many of these features have potential of greatly improving user (learner) experience and motivation [2], which could in the end, lead to better learning results. Similarly to Web learning platforms in the late '90s, mobile learning applications are "the hot educational topic" throughout the last ten years [2].

Although handheld devices, smartphones and tablet computers exist for a number of years now, the real revolution in the field happened in 2007 and 2008, when Apple iPhone and the first Google Android based phones were unveiled. These two, along with Microsoft Windows Phone, are the prevalent mobile and tablet computer platforms today. As soon as the technology stopped being a limiting factor, and tablet or smartphone devices started coming with enough processing power and memory for demanding applications, many studies started actively researching appropriate pedagogical approaches to mobile learning [3].

Until recent years lectures were mainly designed so that teachers deliver knowledge to the students, who are mostly passive participants in the whole process [4]. Developments in e-learning, and especially m-learning, which is characterized by using mobile phones and unlike e-learning is available on any location, resulted in a more active involvement of students in the educational process.

There is a number of review papers on mobile learning written in the recent years, like [3], [5], [6], [7] and [8]. Sharples [3] gives an overview of the mobile learning field, accompanied with critical review of existing studies and general guidelines for development of future mobile learning applications, without information about specific technologies. Wu et al. [5] give a very comprehensive analysis of the field and existing mobile systems. Their study includes papers published until 2011, so a number of new trends and technologies are not included. Jacob and Issac [6] made an analysis of learning practices and the accompanying exploitation of mobile devices. They state the advantages and

disadvantages of a particular mobile device type in mobile education, as well as the usage of these devices amongst their students, with also no technology-specific information given. Parsons & Ryu [7] describe generic software architectures for mobile educational applications and conclude that the best (the "richest") platform for mobile learning seems to be the client-server architecture. Martin et al. [8] analyze the existing frameworks and middleware applications for mobile learning applications and focus only on these two aspects of mobile application programming, without a deep focus on available technologies.

III. SAMEX

A. System Design

SamEx was designed to support self-directed and collaborative learning activities and provides a participatory platform for students to contribute, share, and give feedback. Students can use it to take a picture to collect data or post information they found to be useful for their learning. These postings are shared with other students who can review, give comments and evaluate by giving "Likes" to the contribution.

SamEx was developed for the Android [9], Windows 8.1 [10] and Windows Phone 7 and 8 [11] mobile operating systems in the Seamless Learning Curricular Innovation project in a Singapore primary school. SamEx system architecture consists of the following components (Fig. 1): server-side components, web application for system administrators and mobile clients (Android, Windows 8.1, Windows Phone applications for smartphone and tablet devices). The system is based on a centralized data model where clients are not responsible for data processing, and thus focus on the interactions with users. SamEx server-side components are: relational database, web application and web services for communication with mobile clients. All three components allow for seamless data storage and administration for both users and administrators. The key issue in SamEx system design is maintaining a consistent state of the data between the server and client applications.

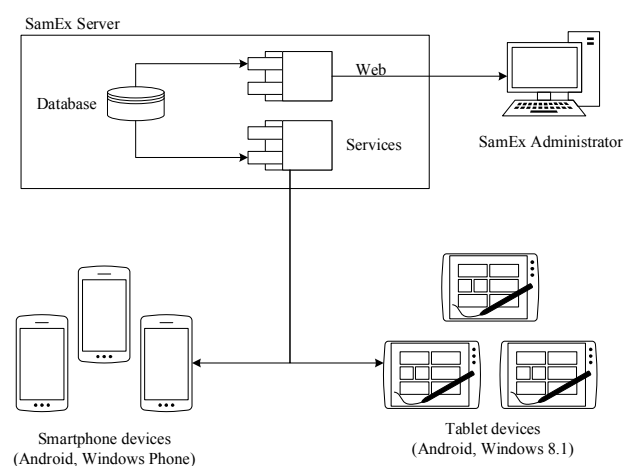

Fig. 1. SamEx system architecture

The generic SamEx mobile client application is built of several layers: a server communication service, a data access layer, and modules for user interaction (GUI). Data is periodically fetched from the server side and stored locally via a background service. A data access layer is implemented over the storage data structures, allowing developers to make easy structural changes without affecting the application logic for the communication with users.

SamEx can be installed on Android or Windows Phone smartphone or tablet devices. Students are given a mobile device with SamEx application preinstalled and preconfigured to immediately act as an active system component. SamEx web application provides an administrative user interface. Teachers and administrators are able to search, filter and sort data, and administer student groups or set up location-based prompts (so called “triggered questions”).

Activities in SamEx were designed for primary school students who used SamEx in their school activities. In addition to collecting, storing and accessing multimedia artifacts, SamEx can store contextual users’ information for potential educational use. Depending on the current time and users’ location, the system allows question prompts to be displayed on students’ smartphones potentially facilitating or scaffolding learning tasks. Students can therefore be guided in outdoor mobile learning trails or just prompted periodically in connection with their homework observations or other work they are recommended or required to pursue outside of school. Students can also subscribe to their peers’ contributions.

To reward students’ activity, SamEx leverages on its own badge system, an extrinsic motivational tool. By collecting media, answering location-aware questions, providing comments to other students’ questions and “liking” other students’ work, students take part in a game to accumulate points leading to the earning of badges in five categories with four levels in each category. The badges were designed as recognition to motivate student to participate and share in the inquiry process. The content of uploads is not automatically checked for quality, so it is possible for students to upload content just in order to get high badge scores. This is solved by closely examining contributions of students with suspiciously high counts of content.

B. Technology Shift From Smartphones to Tablet Computers

Between the years of SamEx usage a technology shift was inevitable. The participating school decided to switch from smartphone devices to tablet computers, which pushed the evolution of SamEx system. The changes in the design of the mobile learning applications were carried out in collaboration with the teachers and researchers, as part of the design-based research methodology.

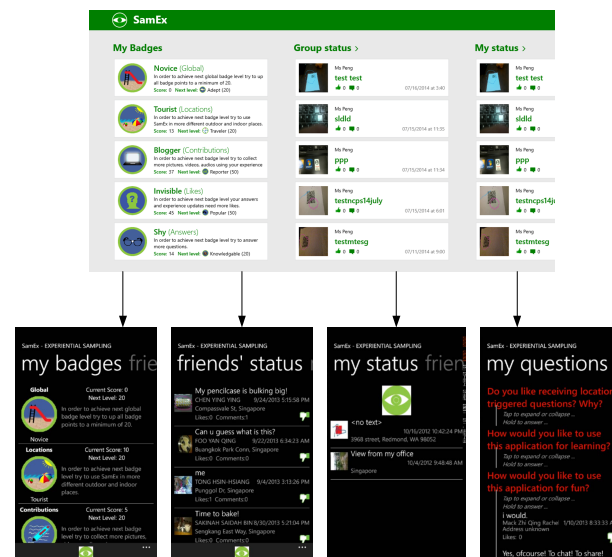

Fig. 2. Badges, my status, group status and questions in tablet (above) and smartphone (below) applications

The foundation of the new application design was the restructured home page for tablets (Fig. 2). In order to improve the application user experience, the new landing page exposes all important features on only one screen: recent statuses, questions and most importantly badge status for the current user. This design reduced the amount of time a user has to spend in the application by laying out the crucial information in a dashboard-like structure. With the new organization of the features, users rarely need to venture deeper into the application because the summary of the most important details is shown right after its launch.

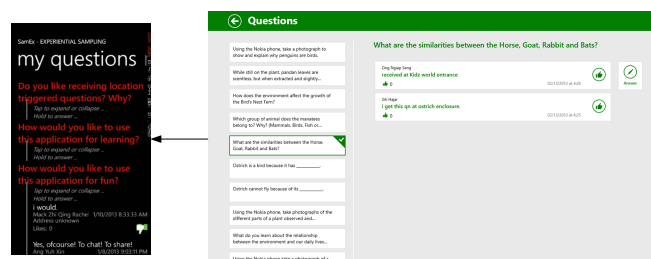

Fig. 3. Questions page in tablet (right) and smartphone applications (left)

Another improvement coming with the SamEx application on tablet devices is the enhanced interaction with media elements. Due to the larger screen, the preview of multimedia artifacts posted by the other students is now much more suitable from the visual perspective. Furthermore, the module for posting a new status now allows previewing, posting or discarding media on the same screen with a clean and user-friendly design (Fig. 4).

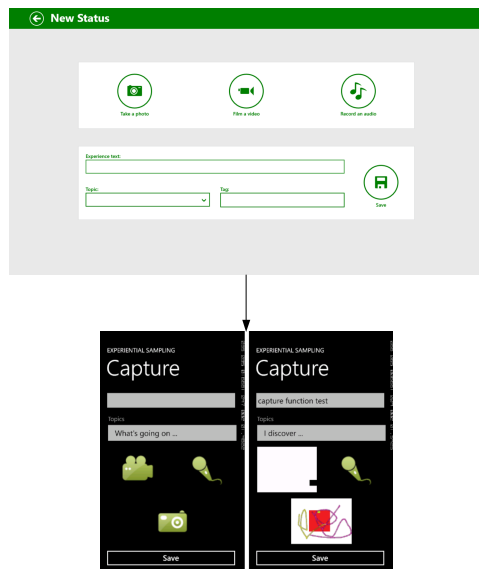

Fig. 4. New status page in tablet (above) and smartphone (below) applications

The SamEx module which gained the most from higher screen resolution on tablet devices is the Group Drawing module (Fig. 5). Students are presented with a canvas where they can draw, re-arrange the multimedia artifacts, add captions and collaborate in creating interactive dashboards. Interactive canvas functionality is much harder to utilize on smaller smartphone screens, which is why this module was not included in smartphone versions of SamEx mobile application.

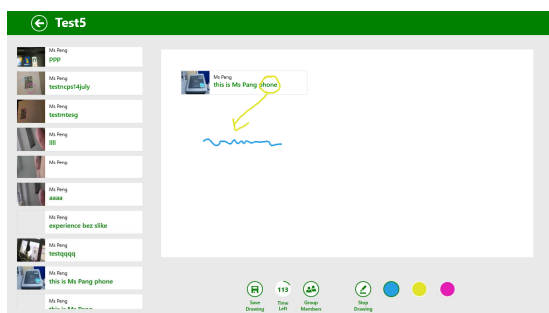

Fig. 5. Group drawing module in SamEx for tablet devices

On the other hand, tablet devices are larger and more robust which makes them difficult to use during highly mobile activities, whereas smartphone devices can easily be carried around in one hand or in students' pockets.

IV. METHODOLOGY

The students taken into analysis are primary three class students, divided into eight level classes: A, B, C, D, E, F, G, H, both in 2013 and 2015. During both 2013 and 2015 each group had a one day visit to the Singapore zoo. During that visit, students are encouraged to answer predefined questions involving specific zoo exhibits and spots. Some of those

questions are triggered via the application as a consequence of the user location change. Students can post their own text or media contributions, read their colleagues' observations and comment and like them. All the data provided by student contributions is collected and stored in the application database for further analysis. The result of SamEx application usage is a rich data set mostly composed of student contributions produced and stored in the period of two years.

Observations in this paper are based on the comparison of the data collected as a result of these two zoo trips. This was decided due to the conclusions of the preceding study where the application usage was the highest during the trips and thus richest in terms of content provided [12]. Even though both trips are characterized by almost the same locations visited and almost the same visit duration, the following differences were observed:

- Number of question prompts decreased from 23 in 2013 to 12 in 2015 in order to focus on student involvement in trip activities
- Questions in 2013 require a multiple choice, textual or experience based answer, while questions in 2015 are only experience-based
- Tablets used in 2015 had constant WiFi connectivity and GPS signal, which was not the case with smartphones used in 2013
- Eight group visits were spread throughout two weeks in 2013, while in 2015 the zoo visits were conducted in one week time
- Number of enrolled P3 students in 2013 was 305, while in 2015 a total of 321 primary three students were involved in the study

Taking these differences into account, the methodology of this study is aligned in order to respect and properly analyze these two approaches to the zoo visit. Student contributions taken into the analysis are exclusively the ones corresponding to the dates of the visit of the student's group in order to avoid at home or classroom usage and to only focus on the trip data. Student experiences are filtered in order to avoid repetitive duplicate experiences, due to errors in the system operation mainly due to the lack of WiFi connectivity.

Experience updates submitted by the students are grouped by text, user, and the quantity of audio records, videos, pictures and time. In case more than one experience with the same text and media files have been uploaded in a short time span, they are declared as repetitions, and only one is taken into consideration for the data analysis. Experience updates which contain no text and no media files are disregarded. Audio experiences are disregarded in analysis due to the considerable lack of this type of experiences. Furthermore, data analysis is based on contribution efficiency and frequencies, and not solely on the number of contributions in order to respect differences caused by the different number of question prompts, which will be described in more detail in further text.

V. DATA ANALYSIS AND INTERPRETATION

The first step in data analysis is the comparison of means of student contribution quantities from the two given years. The results of this step are presented in Table 1. Group 1 represents the cohort of 2013 students, while Group 2 represents 2015 cohort of students.

The variable named *Experiences* presents the total number of any type of student contribution (textual, media or mixed). *Experiences* can be uploaded either as answers to question prompts or as standalone. *Pictures* and *Videos* represent the number of contributions which include media files. *BaseUsageTime* is a variable which gives the information on total usage time of the application in seconds in the given time frame (during the trip). *QuestionAnswers* represents the number of uploaded answers to teachers question prompts. Question answers can be either textual answers, multiple choice answers or answers in form of experiences. Comments can be added to experiences, while likes can be added to either question answers or experiences. All the variable values are grouped by users.

Table 1 shows raw means are greater in group 1 compared to group 2. As previously mentioned, the number of questions was greater in the year 2013 (23 questions) than in 2015 (12 questions). This difference explains the decrease trend of variable values. However, an unexpected increase in number of question answers is present. Since the number of question answers is lower in 2013 than in 2015, but the total number of experiences is greater, it can be concluded that 2013 students uploaded their own contents more often than directly answering the predefined questions. A substantial difference between groups is present in *BaseUsageTime*. This is partially due to less content upload in general in 2015, and partially due to overall simplicity of tablet usage.

Next step in the analysis is the computation of efficiencies and frequencies based on the previously defined variables. Equations used to calculate these values are following:

$$\text{Experience Efficiency} = \text{Experiences} / \text{BaseUsageTime} \quad (1)$$

$$\text{Picture Efficiency} = \text{Pictures} / \text{BaseUsageTime} \quad (2)$$

$$\text{Video Efficiency} = \text{Videos} / \text{BaseUsageTime} \quad (3)$$

$$\text{Answer Efficiency} = \text{QuestionAnswers} / (\text{TotalQuestions} / 10) \quad (4)$$

$$\text{Comment Frequency} = \text{Comments} / (\text{TotalExperiences} / 1000) \quad (5)$$

$$\text{ExperienceLike Frequency} = \text{ExperienceLikes} / (\text{TotalExperiences} / 1000) \quad (6)$$

$$\text{AnswerLike Frequency} = \text{QuestionAnswerLikes} / (\text{TotalQuestionAnswers} / 1000) \quad (7)$$

TABLE I. MEANS OF CONTRIBUTIONS FOR GROUPS OF 2013 AND 2015

Measured variable / Group Id	N	Mean
Experiences	1	277
	2	192
Videos	1	277
	2	192
Pictures	1	277
	2	192
BaseUsageTime	1	294
	2	247
Comments	1	68
	2	51
QuestionAnswers	1	287
	2	182
ExperienceLikes	1	83
	2	92
QuestionAnswerLikes	1	32
	2	137

BaseUsageTime in (1), (2) and (3) is transformed into hours in order to make the results easier to interpret. The same principle is followed by introducing the factors 10 in (4) and 1000 in (5), (6) and (7).

Table 2. shows the means of these transformed variables. It can be seen that after these transformations the means are in fact greater in Group 2 in contrast to the initial results. Exceptions are variables *Video Efficiency* and *Picture Efficiency*. This can be explained by the fact that none of the questions in 2015 strictly required students to upload their collected pictures or videos. To query the significance of this difference among groups, an independent samples t-test has been conducted. Equal variances were not assumed for any of the variables except for *Comment Frequency*.

The results show that students demonstrated greater efficiency in the second group, by uploading more content in less time and providing a greater frequency of comments, likes and question answers.

TABLE II. T TEST RESULTS FOR CONTRIBUTION MEAN DIFFERENCES BETWEEN COHORTS OF 2013 AND 2015 STUDENTS

Group	Mean	MeanDiff	Sig (2-tailed)
Experience Efficiency	1 10.5459	-17.74	0.000***

	2 8.6527		

***p<0.001, **p<0.05

VI. INTERACTION SPECIFICS

An important feature of SamEx is question prompts, designed by the teachers in order to motivate and encourage students to participate in SamEx activities. The system allows for three types of question prompts to be created: open-ended (type 1), multiple-choice (type 2) and media (type 3) questions. Media questions encourage students to document their learning process with a photo, video or audio.

The reaction of students to various questions with different content, level of detail and type was analyzed. The questions set for the zoo trip in 2013 were of all three types of questions. The results are unexpected - there was a large number of incomplete or very brief textual answers, while the attached media was of high quality and to the point. Students seemed to gain a lot by making observations based on media questions and produced high quality media content, but failed to give the proper textual explanations along with the photographed artefacts. For example, the question "Using your phone, take a photograph to show and explain why penguins are birds" produced a lot of quality photos and videos, but the majority of students failed to answer the second part of the question. Giving the students too extensive tasks resulted in a lower contribution quality than expected.

Using the observations from 2013, the questions for the zoo trip in 2015 were designed differently. Teachers stopped actively encouraging students to provide media content and focused on shorter, simpler questions. Despite not being explicitly prompted to take pictures, the students continued to provide media contributions along with the textual answers, but with one big difference: the textual answers were now of much higher quality and more focused on the actual question when compared to the previous zoo activities. By giving the students more freedom and more open-ended questions, along with some hints about what to focus on, their answers became more creative while still in line with the learning objectives.

TABLE III. COMPARISON OF QUESTIONS FORMATS IN 2013 AND 2015

2013.	2015.
Using your phone, take a photograph to show and explain why penguins are birds.	How do you think the Stingray breathes in water? Hint: Is it similar to other fish?
Observe the fish and describe at least 5 characteristics that you can see.	Why is the bat a mammal? Hint: Which characteristic(s) of a mammal does the bat have?
Take a video of an insect to show that it is a living thing.	Which group of animals would you classify the hissing cockroach as? Give 2 reasons why.

VII. CONCLUSIONS

Results of the two groups of students laid out in this paper are challenging when it comes to comparison since the differences between them and the concept of their zoo visits are characterized by a number of differentiating factors. Through the analysis the authors came to a conclusion that the factors which carry the most differences are the number of questions, the type of questions and the use of tablets opposed to the use smartphones.

The number of questions is greater in the year 2013 in comparison to 2015, but students gave better answers in 2015, both in terms of quality and quantity. Teachers decided to decrease the number of questions in 2015 in order to allow students to focus more on the zoo artefacts and exhibits and verbal communication. This proved to be a successful approach, since students react well to a small number of well-defined questions, giving answers which are in most cases correct, concise and often accompanied by media even though not instructed. The better quality answers given by the students prompted their peers to view and respond to the contributions causing the comment and like frequency to rise.

The second factor is the type of questions used. In 2013 students provided adequate answers to multiple type questions and textual questions but the quality was lower in the case of experience-based questions. In contrast, in 2015 students gave high quality experience-based answers. The question type disparity, can be explained by the fact that the questions in 2013 contained more subquestions and strict rules, while questions in 2015 were more concise and provided optional possibilities of uploading media content which caused a favorable reaction from students.

Informal observations also offer an explanation of a more efficient user interface provided by tablets. As previously described, tablet devices offer the possibility of simpler and more accessible application usage. The smaller number of answers in 2013 can thus be explained with an issue of connectivity and location acquisition which was present in the smartphone version of the SamEx application and caused inconsistent prompts, so the students had to use experiences instead. What is more, graphic interface in the tablet application version offered easier and faster question answering and media attachment which explains the decrease of application usage time. The improved graphic interface on the larger tablet screen also promoted better social interaction between the students as they are able to easily view the answers and experiences contributed by their peers.

An obvious progress can be noticed in the gathered data, mainly in terms of efficiency and quality of the contributions provided by students. Technology shift, application improvement and graphical user interface redesign as well as the change in terms of class organization have proven beneficial for students. Cooperation between the technology and educational expertise through constant iterative redesign gives the expected affirmative results which are expected to further excel in the following years.

The experiences of setting up, developing and implementing a mobile learning project in Croatia

The SCOLLAm project

Abstract — This paper problematizes the challenges of setting up a new mobile learning project in a Croatia, a country where technology-enhanced tools in classrooms are not often used due to a number of reasons, two of which are the lack of infrastructure and no teacher professional development. There are three focal points of this paper: designing scalable and durable mobile learning solution, working with teachers in order to ensure an adequate teacher development and creating appropriate digital contents to match primary school level 2, 3 and 4 curriculum. Scalable and durable mobile learning solutions in the context of this project include two main platforms: (1) a mobile learning tablet application for primary school students and (2) a designer application mainly aimed at digital contents designers and producers, to also be easily used by the teachers. On the other side, it describes the processes of strengthening digital competences of the participating school teachers, including technology competence, leadership capacity and technology supported curricular innovation processes. Thirdly, the issues of design and implementation of digital lessons are explored with a special focus on digitalization of the existing non-digital lessons together with the teachers, wherever appropriate and feasible. As a result, conceptual prototypes of digital lessons are produced to be analyzed and discussed amongst teachers and researchers, after which the selected ones get integrated into digital lessons for tablet computer. In addition to describing the threefold process and the accompanying issues, the paper presents preliminary experiences and results in this novel research initiative, sets up mid-term goals and proposes and adequate methodology in achieving the project goals.

Keywords — *mobile learning; educational technology; tablet computers; informal learning; mobile applications*

I. INTRODUCTION

Introduction of innovations and new technology in a system that operates in more or less similar way for many decades is not an easy task. With other difficulties, such as lack of adequate infrastructure, scarce financial resources and insufficient professional development of teachers, there is a number of challenges to overcome in order to successfully implement a desired system improvement. Croatia is a country that still feels the consequences of war, economic transition and the recent global economic crisis. Many schools are poorly equipped, without sufficient number of computers and fast internet connection, which is one of the reasons why

Informatics is still only elective course in all primary, and in many secondary schools in Croatia [1].

In September 2014, in such circumstances, a project to explore the potential of using mobile technology for seamless and mobile learning in Croatia was launched. Named SCOLLAm (“Opening up education through Seamless and COLLABorative Mobile learning on tablet computers”), this three-year project is one of the first scientific research projects closely related to mobile learning that is implemented in Croatian schools. SCOLLAm is building up on the experience of team members and in similar projects from Sweden, USA, and especially the Seamless learning project conducted by the National Institute of Education in Singapore [2]. The main goals of the project are: proposal and design of a technologically innovative, scalable and durable mobile learning platform, cooperation with teachers in order to ensure an adequate teacher development and their competences in the ICT and mobile technologies fields, and creation of digital content tailored for usage in the first years of primary school.

SCOLLAm research team is multidisciplinary, comprised of scientists from both, ICT and fields of teaching methodology and pedagogy. Together with school teachers and international e-learning and m-learning experts as a team consultants, SCOLLAm created a small mobile learning community, which, in addition to their work on the project, encourage and participate in the discussions on the modernization of teaching, and carry out various studies on the use of technology in everyday teaching.

In the first stage of the project focus was on the analysis of teaching methods and tools the teachers are using in their everyday work with students, estimation of digital and ICT-related competences and education level of teachers, and analysis of the current state of computerization in a typical Croatian classroom. In the second stage a prototype digital lessons will be created and tested. For this purpose two software applications are being developed: a mobile learning platform named SCOLLAm [in]Form, and a designer and player of digital lessons – [in]Form Author. Other parts of the system include collaborative learning, augmented reality, analytics and adaptivity modules, which will be, when finished, integrated into the [in]Form platform.

The rest of this paper is organized as follows: in section II the experimental school and project participants, together with some details about Croatian schooling system, are described. The research methodology is described in section III. Current status of the project, findings, issues and design decisions that had to be made are discussed in Section IV. Section V describes the work of the team members in improving the digital competences of teachers. Finally, Section VI concludes the paper.

II. PARTICIPANTS: FROM AN EXPERIMENTAL SCHOOL TO A NATIONAL LEVEL PARTICIPATION

The project is implemented in cooperation with elementary school Trnjanska from Zagreb. It is a small school with around 25 mix-gender pupils per generation. The research focus is on the first four grades, with students aged 7 to 10 years. Elementary school education in Croatia is split into two four-year parts, with lower four grades, having one dedicated teacher for most of the subjects as per curriculum (Croatian language, mathematics, nature and science, music and visual arts and physical education) [1]. Members of the research team regularly attend lectures in all four classes, participate in field lessons, and organize meetings and consultations with teachers. Team members are monitoring and analyzing activities in the classroom, and suggest the possibilities of their “digitalization” or enrichment with additional digital content. Often teachers themselves propose their own ideas how to improve the existing lessons with simple mobile games or questionnaires.

In the autumn of 2015, a national-wide project named e-Schools starts in Croatia. The project that will last for next three years aims to computerize and equip about 150 Croatian schools with modern technologies, tools and teaching materials. E-Schools is a preparation for an even larger national informatization project that starts in 2019. The SCOLLAm team is actively involved into preparation of both of these projects, in fact SCOLLAm serves as a pilot to both. Results

and experience from SCOLLAm will be used in planning these and other Croatian educational system computerization projects in the future.

III. RESEARCH METHODOLOGY

The research methodology of the project is based on the Design-Based Research (DBR) [3][4][5] approach. It is an approach that combines theoretical and empirical research in education, giving better insight why and when a certain intervention in educational process gives a positive outcome. The whole DBR process is iterative, starting with predefined learning goals, through a series of iterative “design – develop – implement - test – analyze - redesign” cycles, resulting in a design principles and theories closely linked to the context in which they are applied [5].

Through a series of stages the researchers of the SCOLLAm project are iteratively collecting information and gaining a better understanding of the seamless mobile learning system implementation. Fig. 1 gives a deeper insight of stages in the project research and development process. On the basis of observed lessons the conceptual model and lesson description documents are created. These materials are input into the next stage, the identification of digitalization opportunities. Together with teachers, the researchers from both pedagogical and ICT field suggest and design prototypes of new “digitalized” lessons. Lessons are then iteratively evaluated and modified, and finally integrated into the SCOLLAm [in]Form platform (Fig. 2).

The platform itself is client-server based. According to Parsons & Hokyoung [6] this seems as the most flexible and popular solution for mobile educational applications.

IV. DESIGNING MULTIPLATFORM MOBILE LEARNING SOLUTIONS

SCOLLAm builds upon a number of educational projects

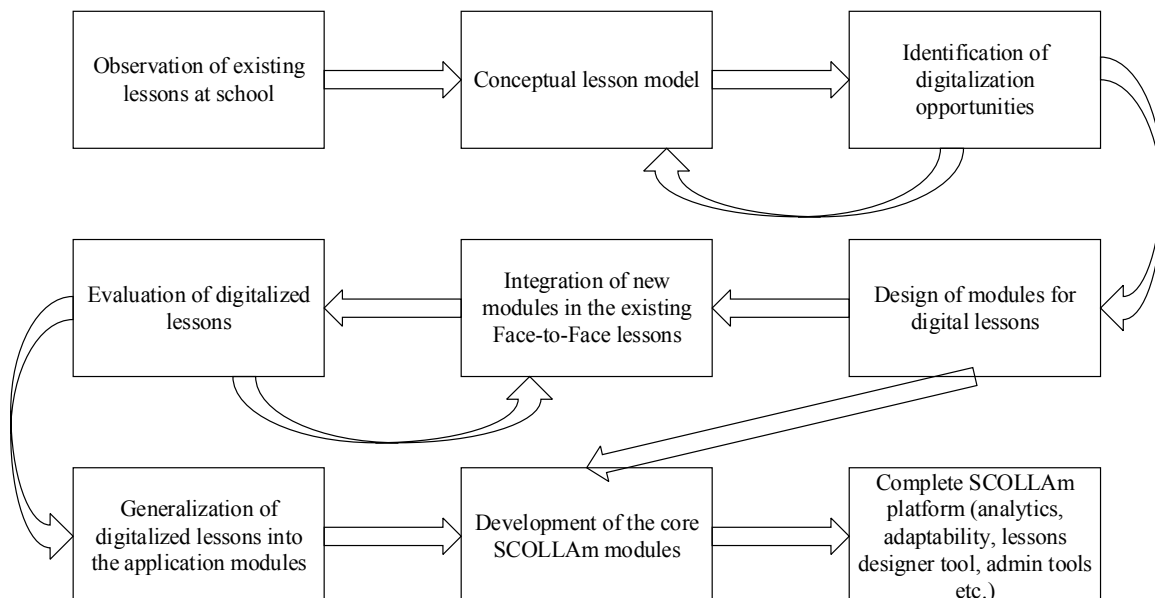

Fig. 1 The SCOLLAm research methodology flowchart

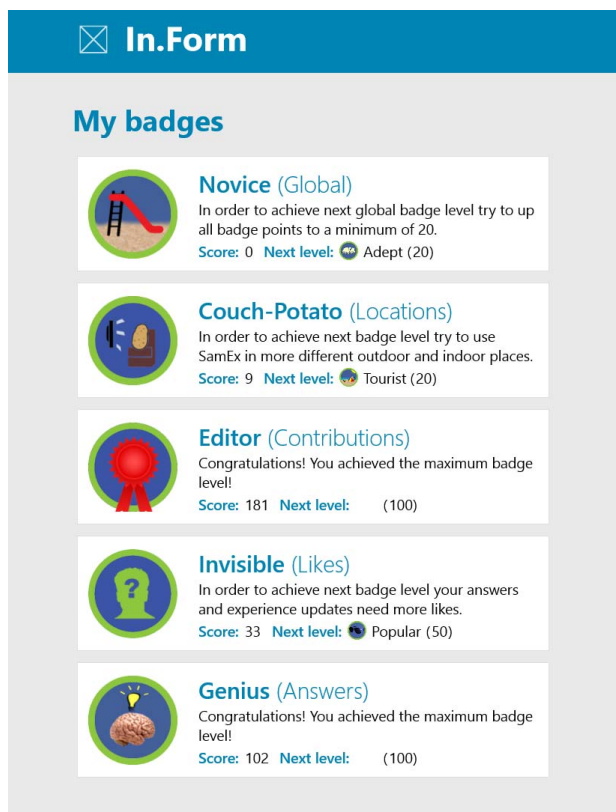

Fig. 2 [in]Form platform

carried out by team members in the past, that included work with primary and secondary school children [7], university students [8], as well as people with specific communication needs. For most of these projects custom mobile applications were developed, but the solutions were generally platform-specific. For instance, the mobile social learning platform SamEx [7] was developed only for Windows Phone, preventing it to reach a large number of Android and iOS users.

In the early stages of the SCOLLAm project, various single platform tools to extend SamEx's functionalities were developed for Windows Phone and Android operating systems. The code was also platform-specific, often duplicated and thus hard to maintain and further developed, especially when additional operating systems are concerned. With that in mind, in this project the goal was set to develop a single - integrated mobile learning platform. The platform is intended for two categories of users: primary school students and their teachers - who are also content designers. For the content generation part, a single web application named "[in]Form Author" (Fig. 3) is developed. It is used from the desktop computer, via internet browser, to design and generate lessons. Lessons are saved in JSON format (with additional media files), packaged, and subsequently deployed to the students' mobile devices where they are executed via mobile application module named "Player" (Fig. 4). Apart from Player, the existing SamEx code-base is used to include the support for collaborative learning, badges, experiences etc. in our mobile learning platform. Unfortunately, SamEx code, written in C# was available only for the Windows Phone platform, and the project objective is to support all three major mobile platforms.

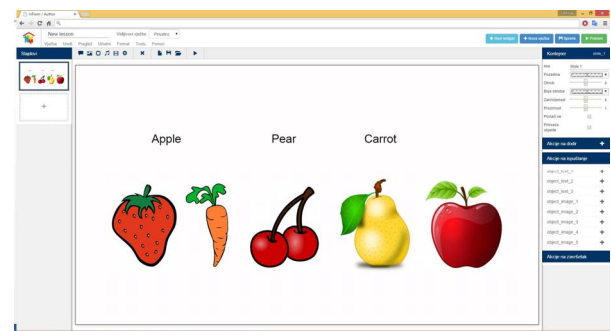

Fig. 3 [in]Form Author - digital lessons authoring tool

In terms of user experience and speed, the best approach would be to develop separate parallel applications for all targeted platforms [9] [10], but that yields duplicate code in different programming languages, intertwined with platform-specific API calls. Such approach requires significantly more resources for development and, equally important, long-term maintenance and development of our application and was assessed as not appropriate in our case. The alternative is to abstract the mobile platform differences, that is to use cross-platform mobile development approach, where a single code base would be maintained. Though it is apparent that 100% write-once-run-anywhere code base cannot be achieved in this project because certain advanced mobile device's capabilities (augmented reality, shared canvas drawing, etc.) are required, the goal is to maximize the common code base and provide the platform specific code only when it is necessary.

There are three main types of approaches to cross-platform development [11] [12]:

Pure web applications – application is written in HTML and related technologies (CSS, JavaScript, etc.) resides on the server, and is accessed via internet browsers on the respective devices. Applications are typically CSS-styled (e.g. jQuery Mobile) to mimic the look-and-feel of the native applications

Hybrid applications – also written in HTML but are embedded inside a thin native container (e.g. WebView in Android, UIWebView in iOS). They are also executed by a browser, though it may not be apparent, being that the browser is integrated in the native application.

Compiled or interpreted applications – applications written in a single programming language and then converted and compiled into native applications for each targeted platform. Unlike the previous two approaches, the resulting applications are true native applications. However, frameworks in this category vary in the level of support of generic UI, that is – sometimes it is necessary to define separate UIs for different platforms.

Pure web applications were not an option since they lack the hardware and data access on the mobile devices, and therefore only leading hybrid and generated (compiled and interpreted) frameworks were considered: Titanium¹, open-

¹ <http://www.appcelerator.com/product/>

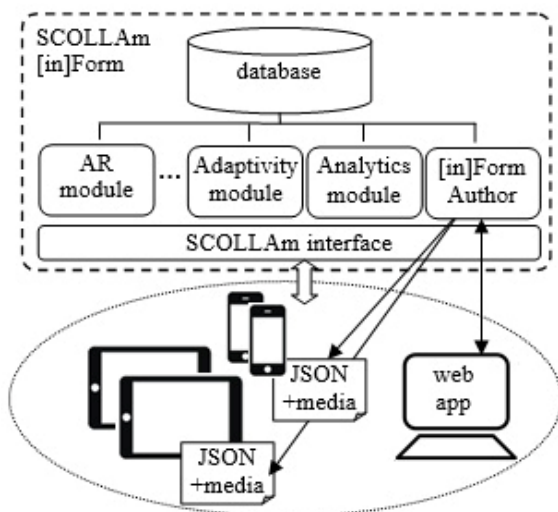

Fig. 4 The SCOLLAm architecture

source Cordova (ex PhoneGap)² and commercial Xamarin frameworks³.

Titanium, though being a high-quality mature development framework, was discarded because of the limited Windows 8 support, and only Cordova and Xamarin frameworks were evaluated in further detail.

Both Cordova and Xamarin seem as an acceptable solutions, with Cordova having the advantage of being free, while Xamarin has a better technical support and a state-of-the-art development environment (Xamarin leverages Microsoft's Visual Studio). Cordova also uses more widespread and open technologies (HTML5+JavaScript) when compared to Xamarin's C#. What tipped the scale in our particular case, is the ability to leverage the existing legacy C# codebase and the excellent Xamarin's IDE and more integrated environment. Also, Xamarin enables us to nicely structure the project and separate the generic views (through Xamarin Forms technology) from the OS-specific views (through Xamarin iOS and Android projects), as it enables to mix-and-match those approaches⁴.

The Player part of our learning mobile solution, which is a packaged web page and data, will be executed through native web view container, as hybrid approach is employed in that part. At the time being, the complete legacy code with additional features is ported to Xamarin framework and most functionalities are covered with single code-base generic forms which greatly facilitates maintenance and further development. Xamarin has proven to be a right choice for our particular project.

V. STRENGTHENING DIGITAL COMPETENCES OF TEACHERS

The teacher development and strengthening of IT competences among teachers is, besides mobile learning platform development, one of the most important parts of the

project. For that reason, the team members constantly cooperate with teachers, discussing lessons design, the development of the educational tools, but also discussing privacy, security and safety issues and concerns some teachers and parents have. Team members and teachers who are a part of the project participate in various events related to the development and planning of the future Croatian education system, attending different informal and formal educational meetings and conferences. In addition to discussions about the possibilities of using tablets and other technological tools in everyday teaching and as a part of ongoing efforts to improve their IT competences, the teachers attended The Carnet Users Conference⁵, a leading Croatian IT and education conference, which took place in Zagreb from 19th to 21th November 2014. A BoF (birds of a feather) session on the topic "What should we do with the tablets in the classroom?" was organized by team members as part of the same event.

Additionally, course on internet safety and cyber bullying by Kidscape⁶ was organized for team members and the principal of Trnjanska elementary school. Similar lectures and discussions for parents are also planned.

VI. CONCLUSION AND FUTURE WORK

In this WIP study the current state of one of the first mobile and seamless learning implementation projects in Croatia was presented. Based on the previous experience in similar domestic and international projects, the SCOLLAm project aims to go few steps further, offering the complete mobile learning platform, digital lesson authoring tool, collaborative and augmented reality modules, adaptation and analytics.

The project is entering the second phase where the mobile learning platform and a range of additional application modules will be developed, and tested in the pilot school.

In the end, the research aims to propose technologically innovative mobile learning solution, together with system architecture, a number of digitalized lessons, experimental modules, different insights and good practices that were identified during the project.

Abstract—Open education offers higher education opportunities for underprivileged communities and solves the problem of deficit in learning resources, such as human and material resources, throughout developing countries. Open education, however, has certain challenges in terms of dependency on the Internet. The use of mobile devices is expected to aid in meeting these challenges. Mobile learning (m-learning), which is learning through mobile devices using various modes of communications like a phone line and contiguous communications, can potentially provide learning services anytime and anywhere without using the Internet. Our Creative Higher Education with Learning Object (CHiLO) project aims to provide an adaptable learning environment corresponding to diversification and uncertainty in large-scale online courses such as MOOCs using device-agnostic m-learning centered on e-textbooks with media rich content. It also aims at a comprehensive open network learning system through the use of various existing technologies and various learning resources, including OER on open network communities, such as SNS. Our set of experimental outcomes demonstrates the efficacy of m-learning using CHiLO, particularly with an e-textbook, including media-rich content, nano lectures, and digital badges.

Keywords—*m-learning; MOOCs; e-textbook; micro-credential; Social networking service*

I. INTRODUCTION

The Education for All (EFA) movement by the UNESCO is a global commitment to provide quality basic education for all children, youth, and adults [1]. Open education (OE) movements such as Massive Open Online Courses (MOOCs) radically contribute in enhancing opportunities for higher education around the world as well as creating a new learning artifact or ecosystem while sharing personal knowledge [2]. OE movements offer higher education opportunities particularly for underprivileged communities and also alleviate the challenge of learning resources' deficit, such as

human and material resources, for developing countries [3]. However, since the majority of online education available today utilizes video streaming, which requires substantial and sustainable connections and relatively high bandwidth, it does not offer equal opportunities to different populations. About 60% of individuals do not have access to the Internet globally [4]. Further, 80% of people in the world do not have a personal computer [5]. Therefore, people in remote locations and developing countries have difficulty accessing online learning environments [6].

Mobile communication devices are so ubiquitously used in the world that "Globally, mobile-broadband penetration will reach 32% by the end of 2014—almost double the penetration rate just three years earlier (2011) and four times as high as five years earlier (2009)" [4]. Mobile communication devices that provide satellite communication and a personal area network (PAN) such as Bluetooth, a traditional telephone infrastructure, as well as Internet access, proliferate in the world. It implies that these mobile communication devices do not depend on only the Internet.

Therefore, the use of the mobile devices may potentially provide a solution to these challenges. Mobile learning, or "m-learning" based on the mobile devices, comprises learning services that can be used anytime and anywhere without the Internet connection. Moreover, the m-learning also should be device agnostic mobile learning or ad-hoc m-learning.

Our Creative Higher Education with Learning Object (CHiLO) project aims to develop a radically new learning system for introducing changes to higher education based on large-scale online courses such as MOOC that differs from a traditional classroom. It uses a CHiLO learning system that provides a flexible and diversified learning environment based on learners' abilities and living situations using m-learning technology. The CHiLO system possesses a capacity of

effectively high portability in electronic publication 3.0 (EPUB3) format as well as a comprehensive open network learning system through the use of various existing technologies and learning resources, including open educational resources (OER) on open-network communities, such as social networking services (SNS).

The CHiLO system comprises the following four components developed with a novel design: (a) CHiLO Lectures based on one-minute nano lectures; (b) CHiLO Badge providing authentication and certification; (c) CHiLO Book with a packaging of learning resources, such as CHiLO Lecture and CHiLO Badge using an e-textbook with an EPUB3 format; and (d) CHiLO Community, such as SNS, bulletin boards, and chat rooms.

In this study, we report m-learning's possibilities for CHiLO through our experiment on one of the massive open online courses in Japan, Japan Massive Open Online Courses (JMOOC). Our experiment demonstrates evidence of m-learning's effectiveness through the use of e-textbooks.

II. AD-HOC M-LEARNING

A. Online education and Digital divide

Online education is characterized by cost-effectiveness with transparency, scalability, flexibility, and accessibility consistency. Online education also improved student performance by enabling to influence many different students [7, 8, 9]. Nevertheless, in developing countries, open education has not become popular [7, 9, 10].

Online education has two barriers [11]. The barriers are categorized as external and internal. The internal barriers include lack of equipment, unreliability of equipment, lack of technical support, and other resource-related issues. The external barriers include both school-level factors such as organizational culture and teacher-level factors such as beliefs about teaching and technology and openness to change.

These two barriers have also been observed in developing countries [12]. In particular, the internal barriers including lack of equipment, unreliability of equipment has indicated as having a serious effect in the developing countries. In the external barriers, the people face digital divide issues including a lack of necessary skills-set, knowledge, and concepts that are needed for effective consumption-access, locate, operate, manage, and understand [13].

B. Mobile Learning

Mobile learning (m-learning) is defined as the combination product of mobile technology and e-Learning technology [14], or learning that occurs with the help of mobile devices [15]. M-learning is expected to bridge the digital divide that provides the opportunity to learn from anywhere at any time in developing countries using mobile devices that has the following features [16].

- **Affordability of Demand-Side:** The many pricing models offer affordability and choice, even for very low-income customers (cheap handsets, micro prepayments, top-up cards). [17]

- **Reduce of electricity problems:** Mobile devices do not necessarily require a stable power supply [16]
- **Several communication:** Mobile devices can be utilized through several communication technologies such as global system for mobile communications (GSM), wireless application protocol (WAP), and Bluetooth, without permanent physical connection to cable networks [16].
- **Ease of use:** Mobile devices are easy to use without the need for computer skills [17, 18].
- **Pervasive and ubiquitous:** Mobile devices are pervasive and ubiquitous and are increasingly changing the nature of knowledge in modern societies [17, 19].

C. M-learning based on ad-hoc network

Mobile ad-hoc network (MANET) is a network of mobile devices that are interconnected in an ad-hoc manner to share data. Data are shared in a multi-hop manner by being passed between devices, with each device having the potential of routing data to another device in a mesh network [20]. MANET is an effective approach to make up the digital divide in developing countries that do not possess reliable network connection such as the Internet [20].

M-learning using MANET improves learning in a poor network environment [21, 22, 23]. MANET uses grid technologies and creates a rapidly changing learning environment for mobile learners, who can dynamically join and leave these communities. [24].

III. COMPONENT TECHNOLOGY

CHiLO comprises different technologies such as e-textbooks, micro-credentials, and SNS, is a combined advantage of m-learning.

A. E-textbook

A learning method using e-textbooks provides a new way of learning adapted to the network-learning model.

The e-textbook, which is not only device-independent but also available offline or online, has adopted m-learning. Furthermore, e-books have the interoperability of EPUB and major e-book formats, namely Kindle's K8 format, iBook's .iBooks format, and others [25]. EPUB3 is a distribution and interchange format standard for e-books developed by the International Digital Publishing Forum (IDPF) [26].

With the advent of the EPUB3 format, e-books now include media-rich and interactive contents. The International Digital Publishing Forum [27] stated that "the EPUB specification is a distribution and interchange format standard for digital publications and documents. EPUB defines a means of representing, packaging and encoding structured and semantically enhanced Web content—including HTML5, CSS, SVG, images, and other resources—for distribution in a single-file format." Thus, the EPUB3 format has greater sourcing flexibility. In the education field, learning materials in EPUB3 format are easily repurposed by tutors, adapted to

improve learning outcomes, and also offer a way of avoiding vendor-lock-in [28].

IDPF has proposed the EDUPUB format to meet the requirements of next-generation learning content based on the e-book EPUB3 format [27]. EDUPUB implemented a system for cooperation with the Learning Management Systems (LMS), the Analytics System, the Student Information Systems (SIS), and the assessment system on EPUB3 using JavaScript and JavaScript Object Notation (JSON) (see Fig. 1).

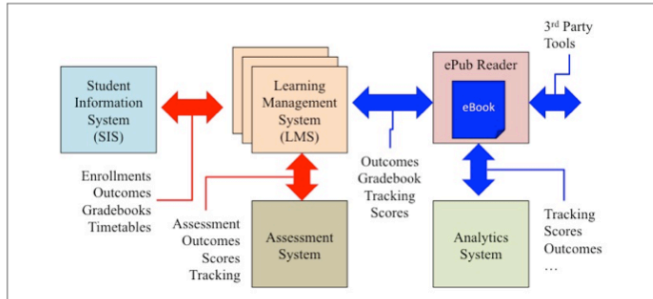

Fig. 1. Overarching EDUPUB Architectural Model [14].

New generation e-textbooks like EDUPUB and EPUB3 show equal to or greater educational effect than traditional LMS. Smith and Kukulska-Hulme [29] reported the following on the results of an 18-month project (2010-12) led by the Institute of Educational Technology (IET) at the Open University, UK.

- 1) E-books on portable devices are apt for the lifestyle needs of distance-education students.
- 2) Internet access allows for timely downloading and use, when it is available. "situational reading" occurs when one or more books with desired content are accessible to learners when needed, thus matching readers' requirements in relation to the situation they are in.
- 3) An e-book can contain all the resources needed by a student in one package.

B. Micro-credentials

The challenge in a traditional online course like course-centric learning is that learners of diverse backgrounds and levels receive the same service, such as studying uniform material with fixed lecture time [30, 31, 32]. A micro-credential system of competency-based education (CBE) connecting with learning paths in current efforts to demonstrate their mastery of those competencies [33] solves the challenge. CBE focuses on effective learning for adult learners, for instance, working and self-supporting students in a brief period. The CBE uses a digital framework, such as digital badges whose conventional system has been successful in motivating participants by showcasing challenges that have been overcome, displaying pathways, and improving social connections using SNS such as Stack Overflow and Foursquare [34].

Mobile devices are effective for micro-credentials because m-learning students use bite-sized contents within a fragment

of time without wasting a minute [18, 35]. Brandman University is offering a completely online competency-based bachelor's degree since 2014 [36].

C. Social networking services

Many studies strongly suggest that cooperative learning is more effective than individualistic learning with respect to contributing to motivation, raising achievement, and producing positive social outcomes [37]. Interactive learning using SNS such as Twitter, Facebook, LinkedIn, and others has drastically developed cooperative learning [38, 39, 40].

Furthermore, mobile devices improve communication among members of a social network within a country as well as internationally [41].

Online classrooms using social networking services through mobile devices solve the challenge of resource deficit, such as teachers and educational materials; this is very effective in the brick-and-mortar classrooms of developing countries or impoverished areas.

IV. ARCHITECTURE OF CHiLO

A. Overview

CHiLO, based on e-textbooks, aims to develop an affordable and scalable design for using m-learning with regard to large-scale online courses. It consists of the following four components (see Fig. 2):

- The CHiLO Book using e-textbooks in EPUB3 format;
- The CHiLO Lecture based on one-minute nano lectures embedded in CHiLO Books;
- The CHiLO Badge in CHiLO books that provides authentication and certification using Mozilla Open Badges (see <http://openbadges.org>); and
- The CHiLO Community such as SNS, bulletin boards, and chat rooms.

Fig. 2. Four components of CHiLOs

A. CHiLO's Architecture

1) CHiLO Book

The core component of CHiLO created through an e-textbook with an EPUB3 format contains media-rich contents, including graphics, animation, audio, and embedded video. The CHiLO book based on micro credential method consists of learning materials for a classroom hour. Those who complete a CHiLO book receive a CHiLO Badge as a certificate of completion.

Another idea of online education involves the use of e-textbooks by EDUPUB. However, most e-book readers do not

currently support the media-rich functions of the EDUPUB format, such as embedded videos, JavaScript compliance, and JSON. One reader that does support JSON is Radium, which is an open source EPUB reader developed by the IDPF. One of Radium's disadvantages is that it currently does not support mobile devices, such as smartphones and tablets. The CHiLO book offers a realistic solution by combining an e-book reader and a web browser. The EPUB3-based CHiLO book ensures access to a learning environment anytime and anywhere even without connecting to the Internet, thus avoiding the difficulties of most e-books. The CHiLO book as an e-book is also available in e-book stores such as the iTunes Store and Google Play Books. Another potential disadvantage of an e-book is that it requires a special application like an e-book reader and even downloads the e-book in the e-book reader. Learners without this access will need to use the web-based CHiLO book.

2) The CHiLO Lecture

The CHiLO Lecture comprises videos with scripts, quizzes, and other learning materials. Videos are one-minute nano lectures. This concept emerged from an experiment that revealed that most online learners' viewing time is approximately one minute [42].

A CHiLO lecture is equivalent to one section in a traditional textbook. A CHiLO book comprises approximately 10 CHiLO lectures. A standard CHiLO course, which is comparable to a traditional university course with one academic credit, consists of 10 CHiLO books.

3) The CHiLO Badge

It is difficult to perform indirect assessments, e.g., of learning time and academic workload, in large-scale online courses. Although CHiLO adopts a direct-assessment approach for learning outcomes, completion of a CHiLO course is measured in standard course hours, which correspond to academic credits.

Whenever a learner completes a CHiLO book, he or she receives a CHiLO badge, which is a simple mechanism for successful outcome assessment in CHiLO. When a tutor wishes to check a learner's progress, he or she asks the learner to present his or her CHiLO badges, thus removing the need to confirm using indirect assessment tools, such as grade books or tracking past results or test scores.

4) The CHiLO Community

The CHiLO Community provides both a social network function. Learners may share the downloaded CHiLO Book and have discussions on open SNS on the Web, such as Facebook and Twitter.

A CHiLO Community comprises many learners and a few tutors, known as "connoisseurs." These tutors act as substitutes for teachers. A learner who has studied and completed CHiLO books in a specific field can become a connoisseur. The connoisseur and learner are on equal footing, so a connoisseur often exchanges information with learners in their community.

In the CHiLO Community, a learner does not learn from a tutor but rather learns independently using CHiLO books as a

learning resource. In this way, learners are constantly required to find suitable CHiLO books within the community. The CHiLO Community provides methods for discovering, sharing, aggregating, and repurposing CHiLO books for learners.

V. RESULTS OF DEMONSTRATION EXPERIMENT

A. Experimental Methodology

In collaboration with the Open University of Japan (OUJ) and the Japan Foundation, we produced 10 CHiLO books named "Nihongo Starter A1 (NSA1)," which were composed of 10 successive lessons for those who would learn Japanese for the first time.

The NSA1 series was distributed in two different EPUB3-based and Web-based formats in accordance with the CHiLO architecture, and functions of assignment tests and issuing badges were implemented by linking Moodle modules of quizzes and badges. Both of the formats included hyperlinks to Facebook groups, which were created as the "CHiLO community" and were opened for the learners and teachers.

As a demonstration experiment, we distributed CHiLO books of the NSA1 series in about one year (from April 2014 to March 2015) at no charge through three different distribution channels shown in Table I. Among these distribution channels, the OUJ-MOOC site is one of the platforms supported by JMOOC, which is a MOOC provider in Japan (see <http://www.jmooc.jp/en/about/>).

Table II shows the start/end dates and terms in which each class (Class1–Class5) was held as a CHiLO community. In each community/class and term, our staff members of the support team for NSA1 facilitated discussions and question-and-answer sessions among the community.

TABLE I. DISTRIBUTION CHANNEL

Distribution channel	EPUB3-based	Web-based
<i>OUJ-MOOC site</i>	✓	✓
<i>iBooks Store</i>	✓	N/A
<i>Google Play books</i>	✓	N/A

TABLE II. LEARNING COMMUNITIES AS CHiLO COMMUNITIES

	Start	End	Term
<i>Class 1</i>	4/14/2014	5/1/2014	35 days
<i>Class 2</i>	6/2/2014	7/6/2014	35 days
<i>Class 3</i>	8/4/2014	10/15/2014	73 days
<i>Class 4</i>	11/3/2014	12/21/2014	49 days
<i>Class 5</i>	1/12/2015	3/22/2015	70 days

We evaluated the demonstration experiment by analyzing these data sources below:

- 1) Downloaded data of the CHiLO books provided by iBooks Store and Google Play books.
- 2) Site access logs on OUJ-MOOC server and aggregate data by Google Analytics.
- 3) Access logs to Moodle quiz module that linked the CHiLO Books with both EPUB3-based and Web-based formats.

- 4) Questionnaire results from learners (n = 105) who had earned all 10 badges of the CHiLO books in NSA1.

B. General Data

We found the results of the demonstration experiment held from April 2014 to March 2015 as shown below:

- The total number of download-volumes on three distribution channels together is 17,590 for the EPUB3-based CHiLO Books and 5260 for the Web-based CHiLO books.
- Comparing the number of lesson 1 downloads (6774 books) to that of lesson 10 downloads (1304 books), lesson 10 was only 19% of the lesson 1 total.
- 3156 learners took assessment examinations at least once.
- Despite the number of download-volumes being greatly reduced from lesson 1 to lesson 10, the percentage of those who earned a badge in each lesson held a range of 11% to 17%.
- 145 learners earned all badges of the 10 CHiLO books on NSA1.
- 3181 learners participated in the CHiLO communities (Class 1–Class 5) on Facebook.
- The total number of posts in the CHiLO communities (Class 1–Class 5) on Facebook is 1219, with 4046 comments to the posts and 5808 “likes”.

Fig. 3. Total number of CHiLO books downloads and percentage of those who earned a badge on each lesson

C. Data Analysis

Table III shows the number of downloaded NSA1 CHiLO books by country. Although there were legal restrictions in some countries and regions to download EPUB3-based CHiLO books in iBooks Store and Google Play books, in this demonstration experiment, we found that CHiLO books had been downloaded in different countries and regions: Google Play books in 45 countries, iBooks Store in 34 countries, and OUJ-MOOC in 109 countries.

Particularly, CHiLO books was downloaded frequently in developing countries such as Indonesia (2,022), Thailand (1,833), Philippines (1,201), Mexico (710), Malaysia (690), Colombia (678), Venezuela (532) and Brazil (499). This result shows that CHiLO book and its format appeal to people from developing countries.

TABLE III. THE NUMBER OF DOWNLOADS OF NSA1 CHiLO BOOKS BY COUNTRIES

	Total	Google	iBooks Store	OUJ-MOOC
United States	3,625	1,214	1,844	567
Indonesia	2,022	1,578	0	444
Japan	1,833	488	701	644
Thailand	1,384	1,308	0	76
Philippines	1,201	826	0	375
Mexico	710	88	164	458
Malaysia	690	541	0	149
Colombia	678	14	31	633
Venezuela	532	16	11	505
Brazil	499	183	69	247
Other	8,954	2,114	895	5,945
Total	22,128	8,370	3,715	10,043

In terms of the population on these results (see Fig. 4), we found some interesting features. That is, there is no significant difference in gender (male = 54%, female = 46%), and the ratio of age groups 18 to 44 years old accounts for 89% of the total population. It may be presumed that these features indicate that the CHiLO books and their formats are suitable for higher education because the main target population for higher education, in general, fits the age group of 18 to 44 years for both the genders.

Fig. 4. Ratio of people who downloaded CHiLO books by age (left) and gender (right)

Questionnaire results from those who have earned badges on this demonstration experiment (n = 105) are the following.

- 91.4% (96) of the respondents learned with the CHiLO books at home.
- 79.0% (83) of the respondents primarily used PCs.
- 50.5% (53) of the respondents used the EPUB3-based CHiLO books in some way (see Table IV).

TABLE IV. QUESTIONNAIRE RESULTS: WHICH CHiLO BOOK DID YOU USE, EPUB3-BASED OR WEB-BASED CHiLO BOOK? (N = 105)

Mostly used the eBook version.	17	50.5%
Mainly eBook version, sometimes Web version.	13	

Used both eBook version and Web version at the same rate.	6	
Mainly Web version, sometimes eBook version.	17	
Mostly used Web version.	52	49.5%

Concerning the analysis of device-specific access to the Moodle quiz module, 56.1% (1,771) accessed from PCs, 18.1% (572) from tablet PCs, and 25.8% (831) from smartphones (see Fig. 5).

Furthermore, we divided the access logs into EPUB3-based and web-based CHiLO books; in the case of web-based ones, about 69% of the accesses were from PCs, while in the case of EPUB3-based ones, approximately 73% accessed from mobile devices such as smartphones and tablet PCs (see Fig. 6).

Fig. 5. Ratio of traffic of quizzes in each CHiLO Book by device

Fig. 6. Ratio of people who responded to the questionnaire by CHiLO book format and devices

While we did not appeal to learners to choose either the web-based or EPUB3-based CHiLO book on this demonstration experiment, some learners responded to our questionnaire noting that they used PCs primarily at home, but that they also downloaded and used EPUB3-based CHiLO books in case they did not have access to the Internet.

To consider the above results, it may be presumed that learners on this demonstration experiment tend to switch the devices effectively depending on their Internet connection; they would learn through web-based CHiLO Books on PCs when they could get access to the Internet at home or at school. On the other hand, they would download EPUB3-based CHiLO books and learn the contents on their own mobile devices such as smartphones or tablet PCs when they did not have Internet access.

VI. EVALUATION AND FUTURE DEVELOPMENT

A. Evaluation

From the results of the demonstration experiment, we consider that the CHiLO system has two advantages.

First, CHiLO can offer flexible formats wherein we can provide learning content to people in different countries. Although CHiLO books were unfamiliar to most of the people

who participated in the experiment, we obtained the result that we successfully delivered our books to a large number of people including those in developing countries.

Second, CHiLO can potentially provide a device-agnostic and ubiquitous learning environment in which learners select web-based or EPUB3-based CHiLO books according to their preferences.

The badge-earning rate in this experiment was not very high. According to the report by [43], a survey for people who registered for HarvardX/MITx courses showed that 57% of responding participants expressed an intention to earn a certificate. That indicates that not all of the participants in MOOCs have an intention to earn a certificate by completing a course. It also suggests that participants who pay to “ID-verify” certify at a substantially higher rate, 59% for verified students compared to 5% for non-verified students, on average, across 12 courses. This is an interesting result, but we need further investigation to take a cue for improving the completion rate because the direct cause is not clear.

B. Issues

An issue in the demonstration experiment is that the learners did not completely enjoy the merits of EPUB3-based CHiLO books. The learners reported that EPUB3-based CHiLO books were not successfully downloaded, videos could not be played, and assessment examinations could not be connected. The possible cause for the reported problems is that some EPUB3 reader apps cannot play videos, and learners must connect to Moodle for assessment examinations.

Another issue is that we offered only one successive series of CHiLO books in the demonstration experiment. There are still things about the learners’ behavior traits, such as motivation, ability, and skill that are unclear.

C. Future Development

To solve these issues, we are now starting to develop the CHiLO Reader and the CHiLO Analytics (see Fig. 7).

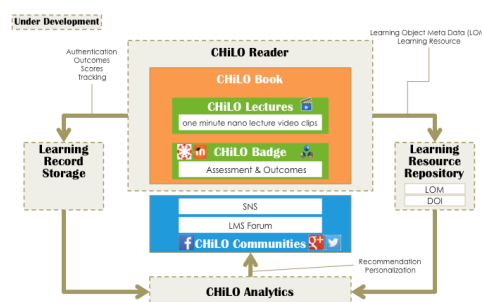

Fig. 7. Context-awareness and ad-hoc learning

The CHiLO Reader: To solve problems of EPUB3 reader apps, an e-book reader app optimized for using CHiLO books. Its purpose is to enhance the usability of CHiLO books. The CHiLO Reader is compliant to EPUB3 with embedded JavaScript and JSON data. This enables us to develop embedded-type CHiLO books (see Fig. 8) that contain assessment examinations and a digital badge-issuing feature. With embedded-type CHiLO books downloaded in each user’s devices, it is possible to enjoy learning activities

without an Internet connection, beginning with viewing a video lecture and resulting in winning a badge. The CHiLO Reader also has the feature of recording learning history (outcomes, scores, tracking, etc.) when it is offline, and sending it to a Learning Record Storage when it gets online.

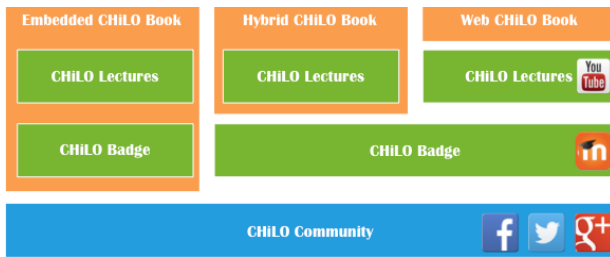

Fig. 8. CHiLO Book Architecture

CHiLO Analytics: To figure out the learners' behavior trait. Recommendations of learning content, learning methods, and the learning community that fit the learner's purposes and preferences are made possible by analyzing the learner's activity logs, which are stored in the learning record storage (LRS). This collects and stores learning events such as outcomes, scores, and tracking acquired from the CHiLO Reader, and the learning resource Repository, which stores Learning Object Metadata (LOM) for CHiLO books.

VII. CONCLUSION

A learning system based on an e-book is now being introduced into the field of education and their improvement is being widely studied. At IDPF, the EDUPUB standard is being discussed and implemented (see <http://epubzone.org/news/edupub-phoenix-2015-report>). To solve the issues of web-based online courses, we developed the CHiLO, an m-learning system based on e-books and conducted a demonstration experiment. Our results and findings are meaningful for future research on a learning environment based on the m-learning system.

The learning environment can be packaged into one e-book. When such e-books are delivered as an OER, flexible and diverse learning environments are possible any time, any place, and on any device, both in online and offline situations.

Bell [44] stated "since the scope of the change exceeds personal and interpersonal learning activities to include larger scale organizational and societal change, additional theories are needed to explain change, to plan interventions and to develop policies" (pp. 100-101). A traditional online course using the existing educational approach such as standardized education can neither respond to the various needs of diverse learners nor create possibilities of online education. CHiLO available for ad-hoc learning, which has a flexible and diversified service for the m-learning creates an ideal online environment.

Abstract— This paper builds on the authors' previous work with Augmented Reality (AR) technology, where interactive three-dimensional (3D) content was developed and combined with traditional printed materials to enhance the visualization and understanding of technical information. In this study, we describe a method to rapidly create custom marker-based AR content using 3D data from real objects and an authoring tool developed in-house. We present a two step process, where 3D geometry is generated automatically by capturing and processing a series of photographs of a real object and subsequently converted to an AR element that can be linked to a unique marker and used with a marker-based AR system. This system provides an opportunity for instructors to quickly and effortlessly create their own AR content to support their innovative teaching practices.

Keywords— *augmented reality; image-based modeling; 3D content creation*

I. INTRODUCTION

Although many instructors still rely primarily on lectures and traditional teaching practices and laboratory sessions, the growing body of empirical research shows that didactic lectures do not necessarily succeed in eliciting comprehension of complex concepts [1] and that learning can be improved when instructors incorporate teaching strategies that are interactive, student-centered, and take advantage of the existing technology [2, 3]. As stated by Millar [4], good teaching demands ongoing creative effort. In this regard, Augmented Reality (AR) technology provides an attractive and engaging resource to complement and enhance traditional teaching materials, usually based on pen and paper exercises, while promoting the development of visualization, self-assessment, and self-directed learning skills [5, 6].

The term “augmented reality” refers to the live direct or indirect view of a physical environment whose elements are augmented by computer-generated content (text, images, videos, 3D models, animations, etc.) [7]. Augmented worlds are generated in real-time and typically experienced via computer screens, projectors, or head mounted displays (HMD). The technology has been listed by the Horizon Report

[8] as a key visualization tool that will be widespread in higher education in the near future. According to this report, the ability of AR to respond to user input confers significant potential for learning and assessment, as students build new knowledge based on visualizations and interactions with virtual models that bring underlying data to life [8].

AR systems have been used effectively as educational tools in various fields such as visualization and engineering graphics [9-11], architecture [12], and medicine [13, 14]. However, most educational applications focus on very specific subjects, the content is usually predefined by developers, and it is difficult for instructors to create or update existing content. This situation was described by Kerawalla et al. [15] who reported that teachers recognize the educational potential of AR, but demand more control and availability of the resources, so they can adapt them to the specific needs of their students.

In this regard, the development of AR content (a fundamental component of the system to ensure a truly engaging educational user experience) requires the creation of 3D computer models, which is a time consuming task and often involves a high level of proficiency in the use of 3D modeling packages such as Maya, SolidWorks, or SketchUp. While traditional geometry-based approaches such as polygonal and surface modeling enable the construction of highly realistic and sophisticated 3D shapes, they have a steep learning curve and require a significant amount of training and skill, which can make them unsuitable for non-expert users [16]. Such limitations can easily discourage educators from creating custom materials. Therefore, there is a need for efficient, cost effective, intuitive, and simple tools that allow instructors (who cannot be expected to be 3D experts) to author custom 3D models for augmented reality environments and applications.

In this paper, we present a rapid approach to AR content development that requires no 3D modeling skills and no expertise with CAD packages. Our approach comprises the use of a simple image-based modeling tool and a custom AR authoring application, which allows content designers to set up AR experiences in just a few minutes. All content is created

Fig. 1. Image-based modeling sequence: (a) image capturing, (b) point cloud, (c) 3D mesh

automatically from real objects through a series of photographs that are processed as 3D geometry by the image-based modeling tool. The conversion of the 3D model to an interactive AR element is performed by a separate authoring application developed in-house that links the 3D model to a two dimensional marker which can be physically manipulated by the user and works in conjunction with a software viewer that displays the content.

II. IMAGE-BASED MODELING

The process of developing a three dimensional computer representation of an object using graphics software is known as 3D modeling. Requirements and strategies for the generation of 3D models depend on a variety of factors such as the desired level of detail, completeness, reliability, accuracy, data volume, costs, and operational aspects, among others [17].

Different techniques exist (both manual and automatic) for creating 3D models, depending on the application and purpose. In general, manual methods allow more control over the geometry during the modeling process, but require more knowledge and expertise of the tool. Popular methods to rapidly generate 3D models from existing data, such as 3D scanning or photogrammetry, often involve geometry reconstruction techniques. These methods have been used successfully in many specialty areas, including ancient architecture and cultural heritage reconstruction [18-20], dentistry [21], and large-scale scenes such as urban structures [22].

Recent advancements in specialized hardware such as laser scanners and structured lighting systems have made 3D reconstruction possible for non-experts. However, these tools are often costly, not portable or scalable, and constrained in terms of material properties (scanners cannot scan certain materials) and environmental conditions [16]. In recent years, personal digital cameras (and their seamless integration with smart phones) are providing real alternatives to more expensive systems. Compared with conventional geometry-based modeling and hardware-heavy approaches, these cameras, when combined with the appropriate software, provide an intuitive and increasingly attractive proposition for affordable 3D reconstruction [17].

The term “photogrammetry” refers to a wide range of techniques and algorithms by which 3D properties of an object are derived from a set of 2D images. Using triangulation, any feature seen in at least two photographs taken from known locations can be localized in 3D space. Furthermore, it is mathematically possible to solve for unknown camera positions when a sufficient number of corresponding points are available [23].

Digital close-range photogrammetry has been an active area of research for years and is used in many different fields and industries, such as architecture, engineering, mining, quality control, geology, and archeology [24, 25]. Recent technical developments include automatic orientation and measurement procedures, generation of 3D vector data, and digital surface models [26].

Digital photogrammetry techniques require the user to provide a group of images of an object acquired from different viewpoints (typically, at small increments around the object). The way in which photographs are acquired is a critical aspect of the process, as it greatly determines the quality of the final reconstruction [27].

The second step is computationally intensive, as it involves the generation of point cloud data from the source images. In this step, specialized algorithms identify points of interest in the image set and calculate the 3D coordinates of the surface of the object using the collinearity equation that defines the relationship between object and image coordinates [28].

Finally, a 3D mesh model is generated from this point cloud. Depending on the quality, the resulting mesh may contain gaps, so additional cleanup is sometimes necessary. The complete sequence is illustrated in Fig. 1.

Digital photogrammetry techniques have matured considerably to a point where a number of stable software tools have become widely available both as commercial products and as free and open source tools. Examples include programs and services such as Photoscan, Acute3D, or Autodesk’s 123D Catch and Memento, which was the tool used to create the examples shown in this paper.

III. MARKER-BASED AUGMENTED REALITY

Augmented Reality is a visualization technology where virtual content is rendered in real time and seamlessly overlaid onto real live footage providing an enhanced or “augmented” view of reality [29].

In terms of hardware, augmented reality can be experienced through a regular desktop PC equipped with a Webcam (Desktop AR). The camera captures the real world view and specialized software generates the augmented content, which is positioned, oriented, and displayed on the computer screen as an augmented mirror. Early work of the authors with augmented reality books involves desktop AR experiences for teaching engineering design graphics [10], as shown in Fig. 2.

Handheld devices such as tablets and smart phones can work as see-through tools or “magic-lenses” to visualize AR content [30]. Previous work of the authors with augmented reality books includes AR experiences using this “magic lens” metaphor [9], as shown in Fig. 2.

Finally, special displays and eyeglasses, such as the popular Google Glass, can also be used to experience AR. These devices integrate a series of cameras that capture real world images and combine it with the virtual content, which is displayed directly on the transparent lenses. Other visualization technology includes virtual retinal displays [31] and special head-worn displays (HWDs) [32].

There are many tools to develop augmented reality content, some of which require technical and programming skills. A common technology is based on markers. In this technology, fiducial 2D images are used to recognize the three dimensional space seen by the camera and correctly position and orient the virtual content on the screen. Because of their simplicity, markers can be easily integrated in printed lecture notes and assignments, allowing instructors to enhance educational materials, and students to visualize the contents being described on paper in full 3D [9].

Two different elements can be used: black and white patterns and regular images. Black and white markers are the most recognizable, reliable, and widely used type of augmented reality. They are typically square shapes with unique black and white patterns inside. This unique pattern allows the AR software to select the correct AR content that is linked to the marker.

Alternatively, regular images provide a “markerless” interaction, which is a more ubiquitous and user friendly approach [33]. Any image can be used to trigger AR content but a high level of contrast and detail in the image, as well as more processing power, are required. Examples of both black and white markers and image-based markers are shown in Fig. 3. A comparison of both approaches is described in Table 1.

In this paper, we use a custom authoring tool called *Aumentaty Author* (available at <http://author.aumentaty.com>) to develop AR content from 3D models generated through image-based modeling techniques. The tool was designed with simplicity in mind and no prior programming experience is required to use it.

Fig. 2. Desktop AR (top) and "Magic lens" (bottom)

Fig. 3. Sample AR elements: black and white markers (top) and regular images (bottom)

TABLE I. MARKER (BLACK AND WHITE) VS. MARKERLESS (IMAGES) AUGMENTED REALITY

Marker	Advantages	Disadvantages
Black and white markers	Common and easy to find and create. Relatively low computer requirements. Efficient tracking.	Intrusive and Invasive. Marker similarity. All markers are combinations of black and white patterns, which can be confusing for the user. If part of the marker is covered the virtual model is lost.
Markerless (Images)	Any image with sufficient level of detail can be used as a marker. Ubiquitous. There are no intrusive markers which are not part of the environment. They allow occlusion and virtual buttons.	The image must have significant details and proper contrast. More complex image tracking. More hardware demanding.

IV. METHODOLOGY

We present a simple and intuitive approach to AR content creation that comprises two steps: creation of 3D models from real objects using an image-based modeling tool (*Autodesk Memento*, in our case), and conversion of the 3D model into an interactive AR element using an AR authoring tool (*Aumentaty Author*, in our study). The proposed methodology is illustrated in Fig. 4.

Although many AR tools, libraries, and services such as *ARToolkit* [34], *Hyperspaces* [35], *EonReality* [36], and *Augment* [37] are available (and could certainly have been used for our purposes), we selected *Aumentaty Author* for affordability reasons and to ensure proper integration of AR content with future custom applications and materials. Using our own software also gives us full control over different marker types and sizes, templates-based markers, adaptive thresholds to manage illumination variations in the scene, and a graphical interface for camera calibration and pattern creation.

A. Creation of 3D Models

The first step requires the acquisition of 3D information of the object that needs to be modeled. Because of the nature of image-based modeling software, objects with plain, transparent, glossy, or reflective surfaces will not work correctly. Similar problems occur when underexposed or overexposed photographs are used.

Multiple pictures will be taken by shooting at least a loop of sequential photographs about the subject (two loops at different heights are usually recommended). For better results, the same lighting conditions must be used for all photographs, and the object being photographed must not move. Additionally, to facilitate the 3D reconstruction, it is also recommended that the object being photographed occupies at least 70% or more of the pixels in the images and that the sequence of pictures has some overlap.

The set of photographs can now be processed by an image-based modeling tool. In this paper, we used *Autodesk Memento Beta*, a solution for converting captured reality input into high definition meshes that can be fixed and optimized.

Depending on the quality of the resulting 3D model, additional cleanup may be required to eliminate unnecessary noise or busy surroundings. Basic fixing/cleanup can be performed by smart selection and clean up tools available in *Autodesk Memento*.

Finally, the textured 3D model reconstructed by *Autodesk Memento* can be exported to several formats: OBJ, STL, PLY, and FBX. Because of the formats supported by our AR authoring tool and based on *Aumentaty* recommendations, models are exported to FBX so they can be processed successfully.

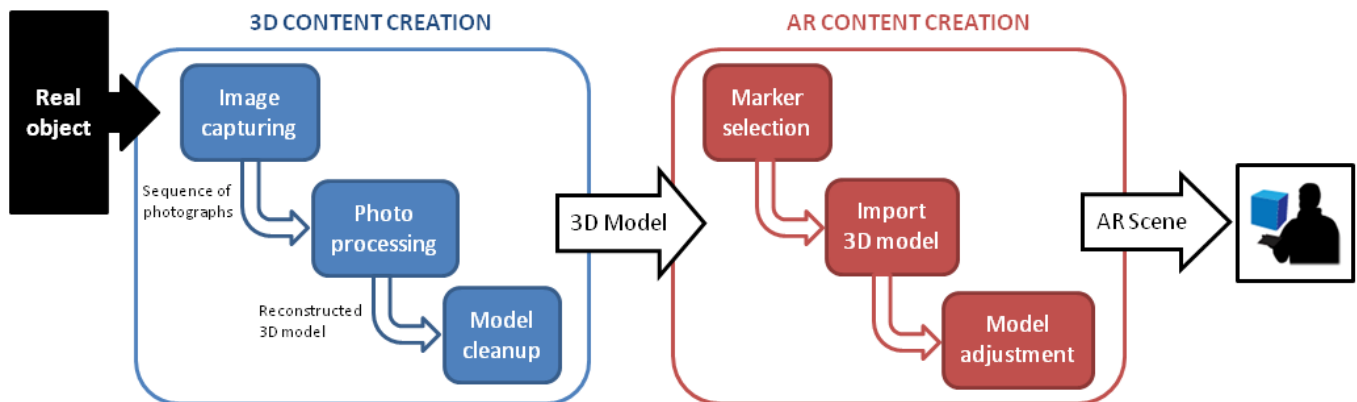

Fig. 4. Proposed methodology for creating Augmented Reality (AR) content

Fig. 5. AR creation process: (a) real object, (b) reconstructed mesh (low quality), (c) cleaned textured model, (d) augmented reality content

B. Creation of AR Content

Aumentaty Author uses computer vision algorithms to calculate the relative viewpoint of the camera with respect to a real world marker. The software integrates computer-generated three-dimensional objects with the real footage captured by the camera. When the marker enters the area that is visible for the camera, the position and orientation of virtual object is calculated based on the marker's orientation and shown on the screen.

In terms of scene definition, creating an interactive AR element with *Aumentaty Author* is a visual and intuitive process. First, a marker is selected from the marker ID menu and printed, so the scene can be visualized interactively as it is being created.

Next, the camera that will be used for AR needs to be activated (in case there are multiple cameras installed) and pointed to the printed marker. In the application screen, the marker will turn orange, indicating that the AR software is recognizing the marker. At this point, the user can browse for the model that was created in the previous step, select it, and drag and drop it from the models' library area of the interface to the icon that corresponds with the marker that was printed in the first step. The 3D model will be placed over the marker in the software interface to provide a visual cue of the link that was created. The tool can import 3D models in the following formats: FBX, DAE, and OBJ. If textures are used, they must be included as part of the 3D file, and not at separate files. If animations are included in the model, they will be played repeatedly when the scene is exported and visualized with *Aumentaty Viewer*.

The controllers located on the main panel can be used to move, scale, and rotate the 3D with respect to the marker. This allows for basic adjustments in the scene, which are useful in many situations such as when the model has a different vertical orientation from the marker's scene or the 3D model is too large with respect to the marker. This basic process will be repeated as many times as models and markers are used in the application. A maximum of 12 models can be included in a single scene.

Finally, the AR scene with all markers and models will be exported to *Aumentaty Viewer*, so it can be visualized on any device (desktop or mobile) equipped with a camera. *Aumentaty*

Viewer is a 3D content viewer that can open AR scenes created with *Aumentaty Author*. Content can also be exported to portable devices and shared via email and various social networks. An example of the process is illustrated in Fig. 5.

V. CONCLUSIONS AND FUTURE WORK

Augmented reality has the potential to become an effective tool to enhance traditional teaching materials and deliver instruction. In previous research, we studied the educational value of both mobile and desktop-based AR in the area of engineering design graphics. However, the creation of content for these applications remains a time consuming task that requires a significant level of technical expertise.

The methodology we discussed in this paper was designed to be simple and easy to implement, as no 3D modeling experience is required to develop content. Unless there are problems with the photographs, the image-based modeling part is mostly an automated process. The 3D reconstruction is live, which means that results can be refined by taking more pictures of the object in the region where it failed.

We noticed that not all meshes come out of the reconstruction process perfectly. Although many require additional cleanup work, specialized tools in Memento, such as "slice and fill" or "smart selection" are usually sufficient in most situations.

In terms of AR authoring, we propose a tool that is easy to use by teachers. *Aumentaty Author* provides a graphical environment that does not require any scripting or programming skills and content is created by experiencing the augmented reality content as it is being created. Users learn to work with the authoring tool almost immediately and the interaction with the markers becomes natural very rapidly.

Despite its simplicity, the proposed methodology still relies on users having access to the real object that needs to be modeled (so photographs can be taken), which may not be easy depending on the content. In addition, the computational resources involved in reconstructing the 3D mesh are significant, which makes time an important factor in the process. We are preparing a usability study with a group of teachers to validate both the proposed methodology and the tools used.

Long term plans include collaborations with K-12 educators in the creation and integration of custom AR materials in the classrooms. We plan to perform a study at different levels, examining both the use and limitations of the proposed methodology in terms of content development and usability, and also the impact of such contents in the students' understanding of the material. As a technical challenge, we are interested in building special hardware for mounting multiple cameras so we can speed up the image capturing step.

Abstract

A report published in 2014 by the World Economic Forum ranked the quality of South Africa's mathematics and science education in the last place out of 148 countries. Educational experts believe that learners can benefit from educational mathematical applications. Senior post-graduate students at the Central University of Technology in South Africa, therefore, embarked on a socio-constructivist project to develop appropriate educational mathematics applications for primary school learners in their community. This paper focuses on the first stage of this project where the aim was to investigate the use of mobile mathematics applications by primary school learners within the South African context. Quantitative and qualitative data was collected by using a survey targeting mathematics teachers and parents of children in grade 1 to 3 in the Free State province of South Africa. The results indicate that 64% of grade 1 to 3 learners have access to mobile devices and that both teachers and parents have a very positive perception towards the use of mathematics applications by their learners and children. In addition 30% of parents have downloaded mobile mathematics applications for learners to use at home. The most important reason why parents are not downloading mobile mathematics applications is because they do not know where to find them, or they do not have time to search for appropriate applications. High costs associated with Internet connectivity and the fact that not all learners have access to mobile devices were two key obstacles mentioned by teachers involved with the use of mobile mathematics applications in primary school education.

Keywords— *Mobile learning, mathematics applications (apps), mathematics education, primary school*

I. INTRODUCTION

"Do not worry about your difficulties in mathematics. I can assure you mine are still greater" [1]. World famous scientist Albert Einstein originally directed these words at young learners, in an attempt to encourage them to persevere despite their perceived difficulties. Unfortunately, these words offer little consolation to learners in South Africa (SA), whose performance in mathematics (math) is the worst of all middle-income countries in the world, and even worse than many low-income African countries according to international studies [2]. In addition, according to a report published by The World Economic Forum in 2014, SA also has the worst quality of math and science education of all 148 countries surveyed [3].

Consequently, the poor performance of learners in math greatly decreases the national pool of learners who are able to

gain admission into engineering degree and diploma programs after completing grade 12 [4]. Higher Educational Institutions (HEIs), therefore, stress the importance of investigating and implementing innovative methods that may help to improve math performance of school learners in their community. The Information Technology (IT) department at the Central University of Technology (CUT) in SA initiated a project at the start of 2015 where senior post-graduate students were involved in a socio-constructivist project to design and develop appropriate mobile math applications (apps) for grade 1 to 3 learners in their immediate community. The goal of the project was two-fold. The first goal was to create a platform where post-graduate students and math teachers in the community could collaborate in an effort to improve the current low math performance of SA learners in the Free State Province. The second goal was to immerse post-graduate IT students in a socio-constructivist environment where they could work in groups, applying their existing knowledge of mobile programming to a real-world problem. A diagnostic assessment of grade 1 to 3 learners in their community was firstly undertaken to determine the access to mobile devices and the extent of exposure to current educational math apps. Perceptions of parents and teachers towards the use of mobile math apps were also sought. Therefore, the first phase of the project involved an investigation into the current usage patterns of mobile math apps by grade 1 to 3 learners in the Free State province of SA. Each group of post-graduate students were expected to gather data from the parents of the learners and the teacher they collaborated with. The aim of this paper is to report on the findings of the first phase of this project.

To the authors' best knowledge, only a few papers have been published pertaining to the use of mobile math apps by school learners in SA. The aim of this paper is to fill this gap and to provide a report regarding the current state of mobile math apps usage by grade 1 to 3 learners. The contribution of this study is that it lays the foundation for future research by HEIs and other stakeholders in the development of appropriate mobile math apps. The paper is structured to firstly provide the context for the study. Secondly, the research methodology is discussed followed by the results and discussions. The paper concludes with the implications of the study.

II. CONCEPTUAL FRAMEWORK

This section provides the study's context within SA in the following way: 1) pedagogical theory 2) shortage of engineers; 3) low graduation rates of engineering students; 4) bad

performance of learners in math; 5) using Information and Communication Technology (ICT) solutions in math education; and 6) smartphone penetration. This section concludes with the research questions of the study.

Firstly, this section will focus on the pedagogical theory that underpins the project that post-graduate students from the IT department of CUT were involved with during the first semester of 2015. These theories include constructivism and socio-constructivism.

Constructivism is a learning theory that offers an explanation of the nature of knowledge and of how human beings learn. It maintains that individuals create or construct their own knowledge or new understandings through the interaction of what they already know and believe and the events, ideas, and activities with which they come in contact [5]. In addition, knowledge is acquired through involvement with content, instead of by repetition or imitation [6]. Constructivism and socio-constructivism share similarities. However, socio-constructivism requires groups of students to drive individual learning where the emphasis is on the collaborative nature of learning [7]. Collaborative learning activities encourage students to explore their course material in groups, thereby helping them to form connections between their newly acquired and existing skills and knowledge, allowing them to actively respond to the ever-changing needs of society [8]. The discussion will now turn to the current shortage of engineers in SA.

SA is suffering from a chronic shortage of engineers in various disciplines [9][10]. For example, according to CEO Sandra Burmeister of the executive search firm Landelahn Business Leaders Amrop SA, 74% of local construction companies are struggling to fill engineering positions [11]. In addition, the SA mining industry faces a skills shortage in many of the technical disciplines, a situation which is exacerbated by large numbers of SA mining professionals immigrating to Australia [10]. Moreover, a survey of nearly 800 SA engineers in 2012 found that the confidence level of respondents to whether the current skills shortage in their profession will be adequately addressed by government in the short to medium term was just 40%. Furthermore, the confidence level of respondents on whether the current education system is providing the necessary skills for the creation of potential engineers was only 41% [12].

Despite efforts of the SA government and the Engineering Council of SA (ECSA) to address these engineering shortages, initiatives are severely hampered by two factors, namely the low graduation rate of engineering students in higher education and the poor performance of grade 12 learners in math and science for their final school examinations [9]. Graduation rates in engineering disciplines from 1998 to 2010 were a mere 13.8%, as compared to the international average of 25% [9]. The second factor that has an impact on the shortage of engineers in SA is the poor performance of school learners in math and science, which is demonstrated by the results of the 2014 National Senior Certificate (NSC). It indicates that of the 225 458 candidates who wrote math, only 35.1% obtained a mark of 40% and above. In addition, of the 167 997 candidates

who wrote science, only 36.9% obtained a mark of 40% and above [13].

Regarding the performance of school learners in the NSC for math and science, the Department of Basic Education in SA (DBE) only releases the number of candidates that achieve a mark of 30% or higher. However, the DBE does release the distribution of results of the Annual National Assessment (internationally benchmarked national test), for Grade 9 math performance. According to the 2014 assessment, only 1.5 % of grade 9 learners obtained a mark of 50-59%, 0.8% a mark of 60-69% and 0.4% a mark of 70-79% [14]. This situation subsequently places tremendous pressure on math teachers at grades 10 through 12 who are expected to make up for large deficiencies in the run-up to the NSC. These figures indicate that the national pool of learners that would be able to obtain admission to an engineering degree or diploma qualification after grade 12 is very low [11] given that one of the key entry requirements to engineering related programs in SA requires a minimum math and science mark of 50%.

When the results of the Annual National Assessments (2013 to 2014) are further analyzed, it is evident that learner's poor math performance is already noticeable in lower grades with the average mark for grade 4 learners in 2014 being only 37% [14]. This low average mark at an early stage of the school career of a large number of learners indicate that corrective measures are warranted at the primary school level to improve math performance in SA.

The preceding observation is supported by several international studies that indicate that the problem with math has its roots in primary school, where many learners fail to gain basic math skills [15]. Additionally, McCarthy and Olifant [2] state that there is significant evidence demonstrating that the best way to improve math performance is to focus on primary school learners. They furthermore emphasize that the learning deficiencies which exist at the start of learner's primary school education hinder their ability to improve in later years. Therefore, as time progresses, these learners tend to fall further and further behind, until it is nearly impossible to attain the required math performance [2]. Emanating from the preceding discussion, it is reasonable to deduce that the low performance of grade 12 learners in math is caused by inadequate teaching and learning of foundational math principles in early primary school years. Consequently, in an effort to enlarge the pool of students that will be eligible for engineering related programs in the future, it is crucial for HEIs to investigate the use of innovative methods, specifically in early primary school years, to try and improve the current poor math performance. The authors agree with educational experts who believe that learners can benefit from educational math apps, and that the focus should be on supporting learners using ICT solutions [4].

As far as the use of ICT solutions in math education is concerned, several researchers are in agreement regarding the benefits that it offers. Baya'a and Daher [16] state that ICT integration into math education provides math teachers with integrative teaching methods that support learners' independent learning. Appropriate math apps seem to have great motivational appeal [17] and encourage active participation [18] in the discovery of math topics and concepts causing a

deeper understanding of math principles [16]. In addition, one of the most recent and comprehensive studies conducted, involving 800 teachers of learners aged 3 to 8, revealed that 71% of these teachers who use digital educational games reported improved math performance amongst their learners [19].

Mobile math apps can assist learners in various ways to master math skills. Prensky [20] argues that mobile educational apps include some of the most useful learning tools that have ever been available and are preferable to books and laptops as learning tools. More specifically, Subramanya and Farahani [21] have identified several key benefits of mobile apps for learning concepts in math including: self-paced learning; reinforcement of abstract concepts; supplemental learning aids; anytime/anywhere use; enhanced retention; being entertaining and engaging; encourage the use of multiple (rich) media; immersion in interaction; self-assessment; provisions for exploration and experimentation; providing positive feedback; cost-effective; customizable; and time-effective. Another very important potential learning benefit of mobile apps, as identified by Bos & Lee [22], is the repetitious use of content that will enable weaker learners to use an app repeatedly to learn or practice difficult concepts.

In addition to the various benefits that mobile math apps have for learning, several studies now confirm that their use has led to improved academic performance. For example, a study centered on a mobile math app, Motion Math, has revealed that fifth graders who regularly played the game for 20 minutes per day over a five-day period increased their math test scores by 15% on average [23]. Likewise, a Stanford College study revealed that an experimental group that regularly played the mobile math app, Wuzzit Trouble, showed a 20.5% increase in numeracy between the pre- and post-assessment, compared to the control group who did not play Wuzzit Trouble [24].

Despite the advantages of ICT solutions for math education, it is not always possible for young learners in SA to access math apps due to low computer and Internet penetration, especially in rural parts of SA. For example, only 10% of SA schools have access to one or more computers [25], while only 3.95% of SA households own a computer [26]. However, newly developed math apps and games are available on less expensive mobile devices that now offer access to many who previously or currently do not own personal computers. Consequently, a dramatic increase in the percentage of the population that can access math apps is now possible [25].

This leads to a brief discussion on smartphone penetration in SA. According to World Wide Worx, SA's leading independent technology research organization, smartphone sales in SA already outnumber ordinary phone sales, and they estimate that by 2017 more than half of the population using phones will be using smartphones [26]. More specifically, the 2014 study conducted by the SA Audience Research Foundation revealed that 36% of the SA population owns a smartphone, while 5% are tablet owners [27]. In contrast, the overall smartphone penetration in Africa is estimated to only be between 6% and 15% [28].

The research questions that arise from the preceding discussions and that were included in the first phase of the project of the development of math apps by post-graduate IT students at CUT include the following: 1) To what extent do grade 1 to 3 learners have access to smartphones or mobile devices? 2) To what extent do parents and teachers of grade 1 to 3 learners download educational math apps for their children? 3) What are the obstacles for the use of mobile educational math apps from a parent and teacher perspective? 4) What are the perceptions of teachers and parents towards the use of mobile educational math apps?

III. RESEARCH METHODOLOGY

A cross-sectional design was used where both quantitative and qualitative data was collected using survey questionnaires as the data collection instrument. Cross-sectional designs are used when a cross section of a population is sampled and studied at a single point in time using one questionnaire, one survey, or one observation. The reason for using a cross-sectional design was due to the fact that it is a relatively inexpensive method enabling the researchers to gather similar data from a large number of respondents [29]. A cluster sampling strategy was followed where a cluster or group of population elements constitutes the sampling unit [30]. The reason why this research strategy was followed is due to the fact that learners in schools are already grouped together in classes, and only one teacher can be contacted to distribute the surveys to all the learners in the class. The advantage of cluster sampling is that the generation of the sampling frame for clusters is economical, and the sampling frame is often readily available at cluster level. A disadvantage of cluster sampling is that the sample may not reflect the diversity of the community [31].

Senior post-graduate students of the IT department at CUT, located in the Free State province of SA, were divided into 12 groups with a maximum of four students per group. The groups were required to find a math teacher of grade 1 to 3 learners in their immediate community to collaborate with. The 12 student groups selected 12 teachers from 8 schools in their community for this collaboration. The teachers were thus selected by the post-graduate students themselves and became the target population along with the parents of these grade 1 to 3 learners. The sample of class groups that were selected by students closely represents the overall population of SA. According to the 2012 census of SA, 9.6% of the population is not previously disadvantaged (PD), while the percentages of PD members include 79.2% for black, 8.9% for colored and 2.49% for Indian or Asian descent. The sample included one class group from a non PD school and 11 class groups from PD schools, resulting in the sample containing 8.8% of non PD learners and 91.2% of PD learners from eight primary schools in the Free State province of SA. Of the eight primary schools that were selected only one school was a private school situated in the township, while all the other schools were public schools. Two questionnaires were distributed: one for parents of learners and one for the teachers of the learners. The first survey questionnaire was based on various studies that investigated the usage of mobile devices and apps by young learners [32], [33], [34] and featured mainly quantitative data. A total of 534 questionnaires were distributed and 452 were

received back resulting in a response rate of 85%. From the 452 questionnaires that were received, only 437 could be used for analysis due to the fact that 15 questionnaires had some information that was missing (therefore $n = 437$). A second survey questionnaire was distributed to the teachers of these primary school learners and featured mainly qualitative data. The quantitative data was analyzed with the help of Statistical Package for the Social Sciences (SPSS) and the qualitative data was analyzed by making use of content analysis.

IV. RESULTS

The first objective of the study was to determine to what extent grade 1 to 3 learners have access to mobile devices. A total of 437 parents responded to the question and the results are summarized in Tables I through III. As depicted in Table I, a total of 37% of learners have no access to a mobile device per week (27% are not allowed to access the parent's device and 10% of the households do not own a smart mobile device). This is comparable with 29% of pre-school to grade 2 learners, and 16% of grade 3-5 learners in America that do not use any family-owned mobile devices [33]. As can be seen from Table I, some learners have access to only one mobile device (36%), while others have access to two (25%) or more mobile devices (2%).

TABLE I. ACCESS OF LEARNERS TO MOBILE DEVICES (SMARTPHONES AND TABLETS)

Mobile Device Access	n	%
Learner not allowed access to mobile devices	120	27
No smart mobile device in home	42	10
Access to one mobile device	159	36
Access to two mobile devices	109	25
Access to three mobile devices or more	7	2
Total	437	100

If these percentages are combined, it results in a total of 64% of all learners that have access to at least one mobile device (smartphones and tablets). These results were not expected by the researchers due to the fact that it is much higher than the penetration rates of the general population (with only 36% of the SA population owning a smartphone, and 5% owning a tablet [27]). These results align with international results reported by Common Sense Media in 2013 that 72% of learners under the age of eight in America have used a smart mobile device, which included smartphones and a tablets [35].

Table II indicates the type of smartphones learners have access to, with Android smartphones (38%) leading the pack followed by Blackberry devices (27%), iPhones (21%) and Windows phones (13%). In addition, a total of 62% of learners (271 out of 437) have access to smartphones that can be compared to 65% of primary school learners between six and ten years of age in Germany that have access to a smartphone [36]. Furthermore, Grunwald Associates LLC reported in 2013 that 43% of pre-school to grade 12 learners in America use a smartphone [33].

TABLE II. TYPE OF SMARTPHONE LEARNERS HAVE ACCESS TO

Type of smartphone	n	%
Android	104	38
Blackberry	74	27
iPhone	58	21
Windows	35	13

Table III depicts the type of tablets learners have accessed; with Android tablets (55%) again leading the pack, followed by iPads (37%) and finally Windows tablets (8%). In addition, a total number of 145 learners out of 437 (33%) have access to an electronic tablet, which is six times the national tablet ownership of 5% [27]. Furthermore, it is almost equal to the 34% of pre-school to grade 12 learners in America that use tablets (according to a study that was conducted by Grunwald Associates LLC in 2013 [33]). However, research conducted by Pearson in 2013 estimated the usage of tablets by grade 4 to 12 learners in America to be 41% [34].

TABLE III. TYPE OF TABLET LEARNERS HAVE ACCESS TO

Type of Tablet	n	%
Android Tablet	80	55
iPad	53	37
Windows	12	8

In addition to the results presented in Tables I through III, further data analysis of the 437 questionnaires revealed that only 36 out of 437 (8%) learners owned their own mobile devices compared to 25% of German learners (between 6 and 10 years) [37] and 19% of American learners [34]. Fig. 1 displays the amount of time per week that learners have access to a mobile device.

Fig. 1. Amount of time per week learners have access to a mobile device.

A total of 58% of the parents indicated that their children spend less than two hours per week (17 minutes per day) on their mobile devices. The remaining 42% of learners are allowed to use their mobile device for more than two hours per

week. This can be compared to access levels of 15 minutes per day for children 8 years and younger in America [35].

The second objective of the study was to determine to what extent parents of grade 1 to 3 learners download educational math apps for their children. Table IV indicates that 44% of all parents have downloaded educational apps for their children on a mobile device, while 30% of parents have downloaded math educational apps for their children. This can be compared to 58% of parents in America that downloaded educational apps for their children in 2013 [26], and 40% of parents of pre-school to grade 3 children in America that have done so in 2012 [37].

TABLE IV. APPS DOWNLOADED BY PARENTS

Downloaded Apps	Yes	No
Educational apps	44%	56%
Math educational Apps	30%	70%

Parents were also asked if their children used any of the apps that they have downloaded on a regular basis. Table V shows that parents indicated that 68% of children regularly use their downloaded educational apps and 55% of children used their downloaded math educational apps on a regular basis. This can be compared to a study that was commissioned by Joan Ganz Cooney Center at Sesame Workshop regarding young learners who used mobile devices for learning, which reported that most learners reused an educational app several times and only 1% reported abandoning apps after just one attempt [32].

TABLE V. REGULAR USE OF DOWNLOADED APPS

Regular Use	Yes	No
Educational apps	68%	32%
Math educational Apps	55%	45%

In order to determine whether teachers have downloaded any educational math apps they had to answer yes or no to the following question: "Have you downloaded any educational math apps or games for children on your mobile device in order to be able to inform parents on the availability of math apps/games that can assist their children with the learning of math skills?" The question results are summarized in Table VI.

TABLE VI. MATH EDUCATIONAL APPS DOWNLOADED BY TEACHERS

Math apps downloaded	n	%
Yes	5	45
No	6	55
Total	11	100

As can be seen from Table VI 45% of teachers have downloaded math apps. Teachers were also requested to list the

most important skills that should be incorporated in educational math apps/games for grade 1 to 3 learners. Content analysis was performed on the feedback that was received from teachers and the results are summarized in Table VII. These results reveal that teachers view addition, subtraction and multiplication skills to be the most important skills that need to be incorporated into math apps, followed by shapes, place value, counting skills and number bonds and concepts.

TABLE VII. MATH SKILLS TO BE INCORPORATED IN MATH APPS

Type of math skill recommended	%
Addition and subtraction	21
Multiplication tables	17
Shapes	13
Place value	13
Counting skills	8
Number bonds and concepts	8
Money problems	4
Patterns	4
Expanded Notation	4
Long division/ multiplication	4
Fractions	4

The third objective of the study was to determine what obstacles existed in using mobile educational math apps from a parent's and teacher's perspective. Feedback obtained from parents is firstly presented, followed by the feedback received from teachers. The reasons why parents have not downloaded math apps for their children is summarized in Table VIII, with 34% of parents reporting that they are not aware of appropriate math apps, while 16% reported that they do not have time to search for appropriate apps. This suggests that 50% of the polled parents would benefit from information that would assist them to select suitable math apps for their children. In comparison, 43% of American parents reported that they needed help finding educational apps [33]. A quarter of the parents that were approached indicated that data costs to download and use educational apps are very high, while 13% of parents stated that their mobile devices do not support educational apps. The least important reason mentioned by parents for not downloading math apps relates to the belief that children cannot learn any skills from apps (12%).

TABLE VIII. REASONS WHY PARENTS HAVE NOT DOWNLOADED MATH APPS

Reasons	n	%
Don't know about appropriate educational apps	110	34
Data costs too high to download or use apps	80	25
Don't have time to search for appropriate educational apps	52	16
Mobile device does not support apps	43	13
Do not believe child can learn skills from apps	40	12

Table IX presents the results of feedback received from teachers regarding why they are not downloading educational math apps. The most important reason relates to the fact that teachers have never considered the possibility that mobile math apps or games can assist their learners with learning math skills. Another reason is that they do not think parents will be interested in downloading math apps to assist their children with the learning of math skills.

TABLE IX. REASONS WHY TEACHERS HAVE NOT DOWNLOADED MATH APPS

Reasons	N	%
I have never considered the possibility that mobile math apps or games can assist my learners with learning math skills	3	23
I do not think parents will be interested in downloading math apps to assist their children with the learning of math skills	3	23
I do not know where to search for appropriate educational math apps or games	2	15
Data costs too high to download or use apps	2	15
Do not have time to search for appropriate educational math apps or games	2	15
Mobile device does not support the downloading of apps or games	1	8

Teachers were also asked the following open-ended question: "What in your opinion is currently the biggest obstacle for the use of mobile math apps in South Africa?" The content analyses of the results of this question revealed two key aspects. First, almost all teachers reported that the data costs associated with downloading these educational apps are high. Secondly, many reported that not all learners have access to mobile device technology. Teachers also mentioned that parents are not aware of suitable math apps which may be downloaded for their children's use.

The fourth objective of the study was to determine what the perceptions of teachers and parents are towards the use of mobile educational math apps. In order to investigate this objective, parents and teachers were presented with the following three questions:

- I believe that mobile educational math apps can increase the math skill level of my child/learners.
- I am in favor of the use of mobile educational math apps to teach children math skills at home.
- I am in favor of the use of mobile educational math apps to teach children math skills at school.

A summary of the responses (Likert-scale used) to the three questions is shown in tables X through XII.

Table X reveals that the total percentage of parents that believe that mobile educational math apps can increase the math skill level of their children is 76% (the sum of 42% that agreed and 32% that strongly agreed). In comparison, 75% of American parents with children in grade R-2, and 72% of American parents with children in grade 3-5 reported that

mobile apps help teach children math content and skills [33]. In addition, the APM Marketplace report revealed that parents think that mobile technology can be especially effective for subjects like math and science, with 62% of parents reporting that mobile technology has increased the math skill level of their children [38]. Table X further revealed that the total percentage of teachers that believe that mobile apps can increase the math skill level of their learners is 81% (45% plus 36%). This figure can be compared to 71% of American teachers of learners aged 3 to 8 that indicated that educational games improved the math skill level amongst their learners [19].

TABLE X. I BELIEVE THAT MOBILE EDUCATIONAL MATH APPS CAN INCREASE THE MATH SKILL LEVEL OF CHILD/LEARNERS

Option	Parents		Teachers	
	N	%	n	%
Strongly Disagree	13	3	1	9
Disagree	12	3	0	0
Neutral	94	21	1	9
Agree	187	42	5	45
Strongly agree	144	32	4	36
Total	450	100	11	100

Table XI indicates the total percentage of parents that are in favor of the use of mobile educational math apps at school (total of 74% by adding 40% and 34%). It also indicates that the total percentage of teachers that are in favor of the use of mobile educational math apps at school is 91% (55% plus 36%).

TABLE XI. PARENTS AND TEACHERS IN FAVOUR OF THE USE OF MOBILE EDUCATIONAL MATH APPS AT SCHOOL

Option	Parents		Teachers	
	n	%	N	%
Strongly Disagree	11	2	0	0
Disagree	19	4	0	0
Neutral	88	20	1	9
Agree	179	40	6	55
Strongly agree	152	34	4	36
Total	450	100	11	100

Table XII indicates the total percentage of parents that are in favor of the use of mobile educational math apps at home (total is 72% by adding 38% and 34%). It also indicates that the total percentage of teachers who are in favor of the use of mobile educational math apps at home is 72% (36% plus 36%). Comparing the results from Table XI and Table XII reveals a noteworthy aspect in that teachers are far more positive regarding the use of mobile educational math apps at school (55% + 36% = 91% in favor) compared to their use at home (36% + 36% = 72% in favor).

V. DISCUSSION

The main contribution of this study is that it sheds light on the usage of educational technologies of grade 1 to 3 learners in the Free State province of SA, focusing on mobile math apps. There is a general tendency to include only secondary learners in initiatives aimed at the improvement of math skills, while several research studies indicate that the best way to improve math performance is to focus on primary school learners [2]. It is therefore, important for HEIs, in particular faculties offering engineering, science and technology programs, to conduct research on methods that can be used to improve the math skills of primary school learners. Consequently, post-graduate students in the IT department of CUT collaborated with primary school math teachers in their communities to design and develop appropriate math apps for grade 1 to 3 learners. The aim of the first stage of this project was for post-graduate student groups to investigate the use of mobile math apps among these learners in their immediate communities. This focused on the following four objectives: 1) determining the level of access of learners to smartphones and tablets; 2) establishing whether parents are downloading educational math apps for their children; 3) identifying obstacles to the use of mobile educational math apps by learners; and 4) determining what the perceptions of teachers and parents are towards the use of mobile educational math apps.

In terms of the first objective of the study, the results indicated that 64% of all learners in the target population have access to a smartphone or a tablet and that 8% of learners own a mobile device. Learners have the highest level of access to Android smartphones and tablets. These results tend to suggest that SA is not far behind first world countries where 72% of learners in America [35] and 65% of learners in Germany have access to a smart mobile device [36].

In relation to the second objective, the results indicated that 44% of all parents have downloaded educational apps for their children on a mobile device, while 30% of parents have downloaded math apps for their children's usage. More than half of these learners are using the math apps on a regular basis. This compares favorably with 58% of parents in America that have downloaded educational apps for their children in 2013 [35].

Pertaining to the third objective, the results showed that 50% of parents are experiencing trouble searching for educational apps, either not knowing where to search or not

having time to search for them. SA parents are not the only ones struggling with this problem, as 43% of American parents admitted that they needed help in finding educational apps [33]. This implies that the number of parents that download and use mobile math apps may drastically increase if parents were assisted in selecting the appropriate math apps for their children. Providing appropriate math apps developed specifically to improve the math skills of their children would also prove beneficial. The majority of teachers and a quarter of parents reported on the high costs associated with mobile data, which poses a real obstacle to its future usage. Another obstacle relating to the usage of mobile math apps is the fact that not all households have access to mobile device technology, but predictions indicate significant increases in smart device usage [26] which should remove (or reduce) this as a hurdle in the near future.

In terms of the fourth objective, the results showed that the majority of parents and teachers believe that mobile educational math apps can increase the math skill level of their children/learners. The results also indicated that the majority of parents and teachers were in favor of the use of mobile educational math apps at school and at home.

These results have various implications for the development of math educational apps for grade 1 to 3 learners in SA. The study has established that more than 60% of grade 1 to 3 learners do have access to a mobile device, but that more than half of the parents do not know where to find appropriate apps and need assistance with the downloading of apps. In addition, it has established that both parents and teachers are very positive towards the use of math apps at home and at school. Furthermore, teachers recommended that addition, subtraction and multiplications skills are the most important skills that post-graduate IT students should incorporate into their apps. These findings indicate that teachers and parents have a positive attitude toward the design and development of appropriate math apps for their grade 1 to 3 learners. These developed apps can be made available to parents and teachers through the current collaboration, thereby overcoming the problem of high downloading costs as well as the problem of parents and teachers not knowing where to find applicable apps. The collaboration between students and teachers could also potentially ensure that the apps that are developed target the specific needs of the specified learners.

The second phase of this project will include the testing of the developed math apps in order to determine if these apps do assist learners to master the necessary foundational math skills. In addition, this research could lay the foundation for additional research to understand the usage patterns and habits of learners pertaining to mobile math apps in order to promote learning efficacy, fun learning and learner engagement. Collaboration from various stakeholders, including parents, game developers, basic education teachers, government, the DBE and the private sector should be strongly recommended to achieve this goal.

A limitation of this study is the fact that the sample size was limited to school learners in one province of SA, thereby negating inferential statistics. Furthermore, the only variable

that was used to select clusters was whether the group represented the PD population of SA or not.

VI. CONCLUSIONS

The purpose of this study was to investigate the usage of mobile math apps by grade 1 to 3 learners in the Free State province of SA. Literature indicated that mobile math apps have a tremendous potential to improve the math performance of primary school learners. The collaboration between senior post-graduate IT students at CUT with primary math teachers from their communities could play an instrumental role in the development of appropriate math apps that could alleviate the great demand for innovative and educational math apps.

However, an enormous collaborative effort is strongly recommended between various stakeholders to overcome two key obstacles, namely high data costs associated with mobile devices and the lack of awareness of where to find appropriate math apps. This is especially important to ensure the successful integration of mobile technology to assist many learners in improving their math skills. Perseverance in adopting and spreading the use of mobile educational math apps must continue to be advocated, despite the perceived difficulties and obstacles which may be encountered.

Computer Security Literacy via Game-Based Learning

Jin-Ning Tioh, Dr. Mani Mina
Department of Electrical and Computer Engineering
Iowa State University
Ames, IA, USA
jinning@iastate.edu, mmina@iastate.edu

Abstract— Within the field of computer and information security, there has been a relatively recent surge of interest on a multitude of topics. However, this body of research typically focuses on the implementation or theory of security controls and mechanisms at the application, operating system, network, and physical layers. The user layer, long recognized as the weakest link in the security chain, has had little to no attention paid to it by comparison, especially from a sociotechnical perspective which is fairly new to engineering. With the introduction of new technologies putting modern society in an almost constant state of flux, familiarity with technology is no longer simply a luxury, but almost a necessity. To that end, we propose the development of an educational game to help instill vital engineering skills as well as practical and relevant computer security practices to users who might not necessarily have a technical background. This approach would take advantage of the relatively recent explosion in the popularity of video games and digital distribution platforms such as Steam to reach a wider potential audience base. In addition, we would assess the effectiveness of this approach utilizing the evaluation of training programs as proposed by Kirkpatrick.

Keywords—educational game; game-based learning; education; computer security literacy.

I. INTRODUCTION

Although recent years have seen a steady decline in violent crimes including murder, forcible rape and armed robbery within the United States, there has been a phenomenal increase in the commission of cybercrimes such as extortion, financial scams and sabotage. This corresponds to the growth in popularity of what are now arguably indispensable technologies to everyday life, prime examples being the internet, as well as home and even corporate computer networks. As with most new technologies however, one of the most crucial challenges to their broad application is with regards to issues of personal, national and even international data security. Several news stories from all over the globe within recent years shines a glaring light on this critical issue, including the theft of approximately a million dollars from several ATMs [1], the collection of credit card information that affected millions of consumers when a Target was compromised starting with a relatively simple phishing attack [2], and even the acquisition of the private email

correspondence of President Obama by a Russian hacking group [3].

Within the field of computer and information security, there has been a relatively recent surge of interest on a multitude of topics, ranging from secure programming practices, protocols and algorithm design to cryptography and ethics. However, this body of research typically focuses on the implementation or theory of security controls and mechanisms at the application, operating system, network, and physical layers. The user layer, long recognized as the weakest link in the security chain, has had little to no attention paid to it by comparison, especially from a sociotechnical perspective which is fairly new to engineering [4].

To quote the old adage, knowledge is power. With the introduction of new technologies putting modern society in an almost constant state of flux, familiarity with technology is no longer simply a luxury, but almost a necessity. While engineering students are able to keep abreast of these changes with relative ease, non-engineering students may oftentimes find themselves lost. Thus instilling in them the basic vital skills of an engineering education, such as general problem solving skills, and the ability to question a process or procedure, is an important step towards relieving their fears of using new technologies, and to allow them to adapt in an increasingly technological society.

This paper is structured as follows. We will first further clarify and elaborate on the problem of computer security literacy as well as our stated goals in section 2. We then delve into the motivation behind utilizing game-based learning over more traditional methods in section 3. A rough design is then offered in section 4, followed by a description of the proposed criteria for its assessment in section 5. Finally, we present our conclusions as well as future challenges that need to be tackled to produce a viable prototype.

II. PROBLEM STATEMENT

As we noted earlier, there has been a phenomenal rise in the number of cybercrimes committed in recent years. Besides the use of a computer in the commission of a crime however, many of these crimes shares another common thread - the hackers often take advantage of the user layer. The vast majority of these users more likely than not do not possess any engineering

or technical training, and are thus oftentimes more susceptible to attacks which exploit this, including phishing, computer virus hoaxes, and so on. The obvious goal then, is to raise awareness on such attacks and bestow knowledge on sound security practices. Computer security professionals most commonly accomplish this through awareness campaigns and the creation of websites that contain security tips and advice [4]. In addition, conventions and competitions such as DEFCON, and the National Collegiate Cyber Defense Competition are held annually. Recently, a limited-release massively multiplayer game was even created in which players have to actively hack and exploit the game code in order to win by design [5].

Unfortunately, such measures don't do enough to overcome the common perception that computer security is a topic of concern only for the technological elite. Our goal then, is to devise a solution which will reach a larger audience, specifically those who might not be as technically inclined to begin with.

III. GAME-BASED LEARNING

As has been known for some time, one of the key ingredients of successful learning is motivation - a motivated learner will tend to find a way to overcome any obstacles or difficulties over their less-motivated kin. Unfortunately, traditional pedagogical strategies tend to come across as 'dry' and 'technical' to current students, which leads to a natural erosion in their motivation to learn more about a subject. Several authors such as Presnky [6] explain this phenomenon by arguing that current students are what are termed as 'digital natives', people used to interacting on a daily basis with rich interactive digital media devices such as computers, mobile devices and video game consoles [6, 7].

Yet there is an industry which specializes in motivation - the computer and video games industry. Game designers have long been experts in the art of player engagement - the ability to keep people in their seats hour after hour, day after day, at rapt attention, actively trying to reach new goals, elated by each success and determined to overcome each failure, all the while begging for more. Since its inception in 1974 with Pong, there is now an estimated 170 million people who play games at least casually in the US as of a study done in 2009 [8], which constitutes more than half of the US population. In addition, the growing popularity of major digital distribution platforms such as Steam and GOG.com makes it easier than ever to reach them, compared to traditional retail distribution methods with cumbersome CD and DVD boxes. As of February 2015, Steam alone has 125 million active users, boasting as many as 9 million concurrent users as of March 2015 [9].

To quote another old adage then, one might as well fight fire with fire. Instead of competing against the video games industry, it makes a great deal of sense to attempt merging the content of learning with the motivation of games [7]. Educational games have the potential to enhance the learning process in several respects. One of the most discussed and pointed out of course involves player engagement. The ability to capture and hold a person's attention while keeping them engaged and immersed is a quality which can be easily

exploited to motivated a student to keep at a particular subject matter for hours at a time - which as almost any educator can safely tell you, is a trying task at the best of times [10, 11]. Another interesting trait is the ability to provide deep, immersive in-game worlds which students can freely explore at their leisure, promoting self-directed learning [12]. Additionally, games oftentimes have a short feedback cycle - an almost immediate and steady stream of rewards and punishments for each action taken by a student, which in turn gives them the perception of relatively rapid progress [13]. Last but not least, in comparison to traditional training methods, game-based learning allows students to make mistakes and learn from them in a risk-free environment [14]. The following table shows a comparison between traditional training methods which include lectures and online tutorials, hands-on training methods such as apprenticeship programs, and game-based learning.

TABLE I. COMPARISON OF TRADITIONAL TRAINING, HANDS-ON AND GAME-BASED LEARNING [14]

	Traditional Training	Hands-On Training	Game-Based Learning
Cost-effective	X		X
Low physical risk / liability	X		X
Standardized assessments allowing student-to-student comparisons	X		X
Highly engaging		X	X
Learning pace tailored to individual student		X	X
Immediate feedback in response to student mistakes		X	X
Student can easily transfer learning to real-world environment		X	X
Learner is actively engaged		X	X

The effectiveness of hands-on training approaches such as apprenticeship programs can't be disputed - it has a rich history which traces all the way from ancient times to the present day. However, well-designed game-based learning could potentially retain the advantages of both traditional training and hands-on training, being both relatively cost-effective and low-risk (safety training utilizing a virtual representation of machinery as compared to using live machinery). In addition, as we noted earlier, learners are free to re-enact a precise set of circumstances multiple times, exploring the consequences of different actions which could have disastrous consequences in real life. For example, learners could deliberately cause a virtual explosion to understand why gas line disasters happen, which would not be a viable nor desirable option during hands-

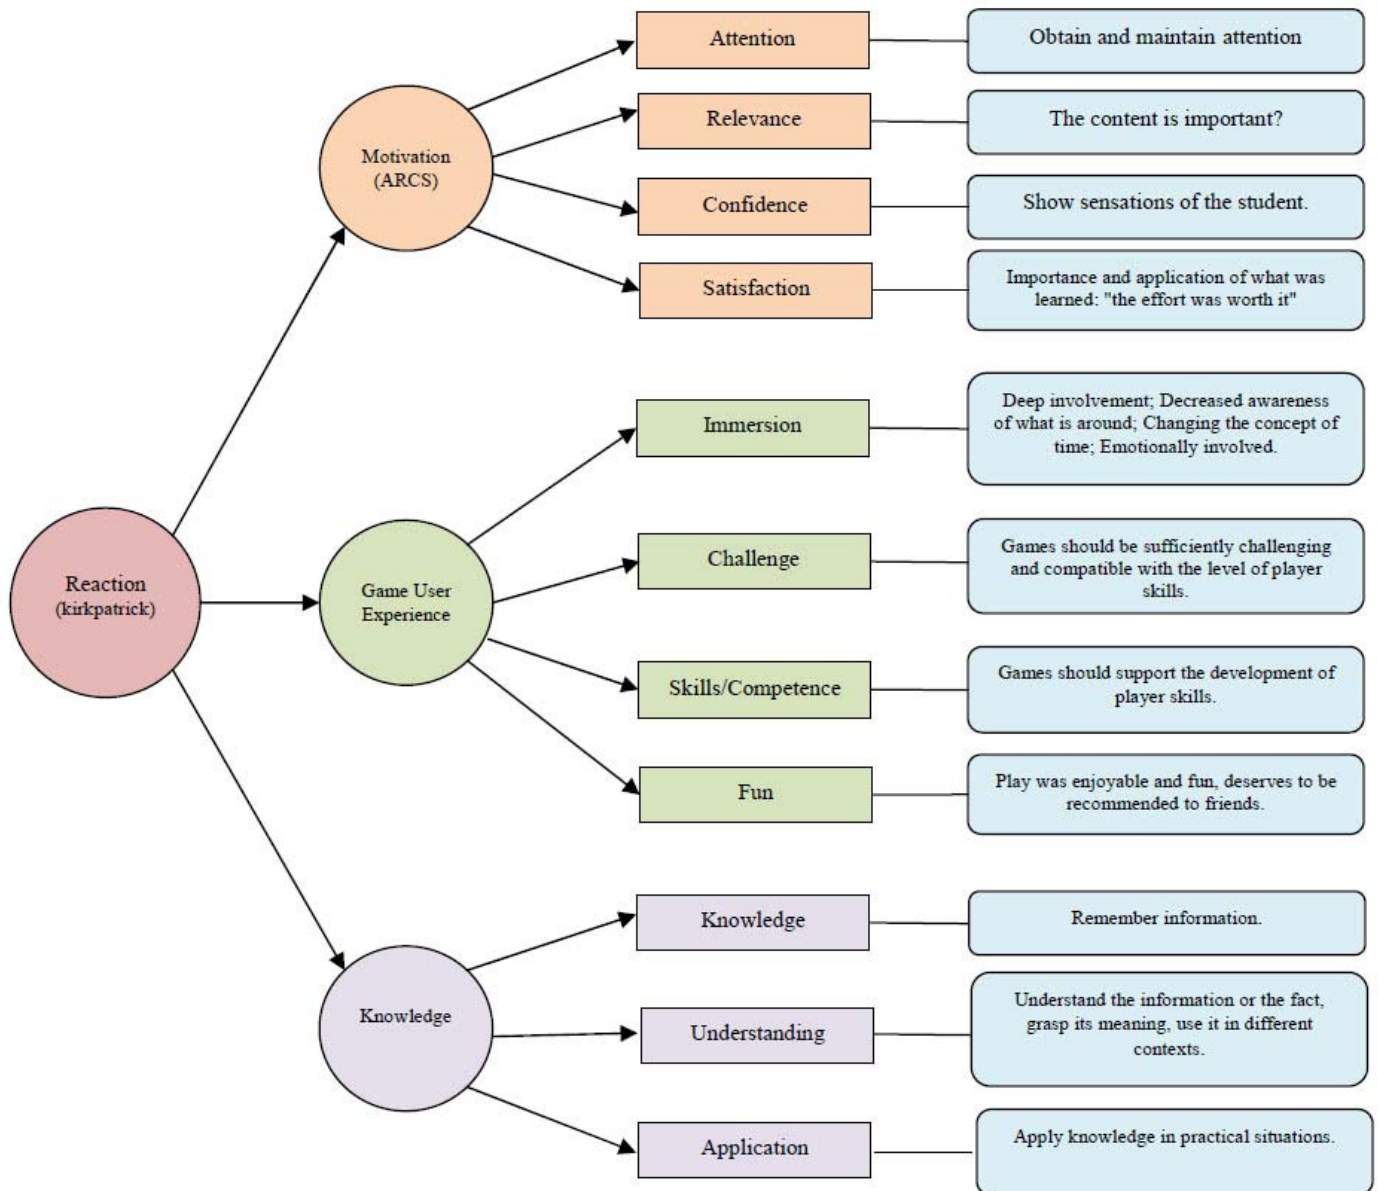

Fig 1. Proposed assessment criteria [15].

on training. Finally, with virtual reality head-mounted displays such as the Oculus Rift making virtual reality relatively affordable in the near future for consumers, game-based learning could potentially become even closer to the real thing, engaging learners even further.

IV. PROPOSED SOLUTION

As one might deduce, our solution then for tackling the perception that computer security is a topic of concern only for the technological elite is to package this information in the far less intimidating guise of an educational game, while at the same time taking advantage of the many benefits associated with game-based learning as we illustrated earlier. Our goals

with this approach, in addition to overcoming the perception barrier mentioned, would be to provide context to everyday computing tasks to better understand how security relates to these actions [4], and to reach a broader audience than most traditional means of education.

Placing players in the role of a penetration tester, the aim of our proposed game would be to infiltrate the corporate headquarters of a fictional major corporation and steal as much sensitive corporate and technical information as possible. Much like how actual social engineers and penetration testers operate, preparation will be key before a player ever sets foot in this fictional major corporation. They would have to case the establishment, going through the company website, perhaps researching key employees through spoof versions of popular

websites such as Facebook and LinkedIn, and so on. Utilizing the information obtained during this phase of the game, players would then attempt to gain physical entry to the office complex, which depending on how well they did, might be accomplished by impersonating a company employee, a janitor, or even a third party such as a pest exterminator. From there, players would attempt to obtain confidential information such as company secrets, or technical information such as the version number of an operating system or anti-virus software while moving through the office in a turn-based manner. They would have to avoid security personnel while doing so, unless they managed to obtain or manufacture fake credentials in the preparation phase. At the end of a week, players would then be scored based on how much information they managed to obtain.

As mentioned above, time is a factor in doing well in the game. Players are given only an in-game week to plan and infiltrate the office complex, with every action taking a set amount of time. In addition, players would only have a limited amount of funds to spend, which can be used to purchase uniforms, create fake credentials, and so on. This adds a sense of challenge to the game, which might otherwise seem boring to the player. In addition, while some security concepts might have to be understandably simplified to avoid overwhelming players with complications, an in-game encyclopedia with more in-depth and accurate explanations of these concepts would be included in the game for players, complete with links to online resources to allow them to research more into them should they choose.

We intend to utilize the Unity game engine for the development of this educational game, owing to the lack of fees for its usage, its ability to easily target games to multiple platforms and its relative ease of use compared to most other engines.

V. ASSESSMENT CRITERIA

One of the most essential evaluation models of training programs still in use today, is based on the work of Kirkpatrick, which is based on four hierarchical levels:

- **Reaction:** What participants thought and felt about the training. This includes how the training motivated and awoke interest in learning the content.
- **Learning:** The resulting increase in knowledge and/or skills, and changes in attitudes. This occurs during the training program.
- **Behavior:** Transfer of knowledge, skills, and/or attitudes from classroom to the job (change in job behavior due to training program).
- **Results:** The final results that occurred because of attendance and participation in a training program.

The evaluation metrics we chose was developed by Mesquita et al. [15] for educational games, and is based on Kirkpatrick's first level, as our interest lies specifically in determining the degree of motivation of students, as well as the value they attribute to the experience they had in the educational game. The proposed assessment criteria are

presented more clearly in Fig. 1. Based on this assessment model, a basic questionnaire will be set, which students would be invited to answer after playing.

VI. CONCLUSIONS AND FUTURE WORKS

In this paper, we explored and laid out a case for the creation of an educational game aimed at turning users into assets instead of liabilities in issues of cyber security, especially those lacking a technical background. We explained the advantages of our choice of using an educational game instead of more traditional means such as awareness campaigns and websites. In addition, we described a rough design for the educational game, as well as described the proposed criteria for its assessment.

Despite their inherent potential however, several challenges and issues will need to be overcome in the development and evaluation of an educational game. During the design stage, one of the major challenges will be to maintain a careful balance between its educational and entertainment value. If the player finds the game itself boring, they will inevitably quit the game, and nothing will be achieved. If too much effort is directed towards just its fun factor however, there will be little impact achieved as well. Thus this leads to the difficult task of achieving a measure of educational value to the already challenging task of developing game elements that are fun and engaging. Another consideration would be the cost involved in its development. While a large part of the traditional costs associated with the development of a video game can be defrayed with the use of relatively recent professional game engines such as Unity with affordable costs and no licensing fees, care will still need to be taken to limit the scope of the game to a manageable level for a small team. Finally, human-computer interaction experiments will need to be conducted to evaluate the effectiveness of our educational software, taking into account Kirkpatrick's four levels of learning.

Abstract

This paper, overview a study performed in two 10th grade chemistry classes at a girls High School in Philadelphia, PA. . Discussion with the teacher of the two classes, led to the realization that students are finding a hard time understanding the structure of an atom. Comprehension of the atom is a foundational skill in Chemistry, without the understanding of the atom, many topics in chemistry will be very difficult to understand. To tackle this problem, students in these two classes worked in groups of four, and each group was assigned a periodic element. They used iPads provided by the university to first design the structure of the atom in an app called AutoDesk 123Design. Students then provided their design to a NSF funded GK-12 graduate student fellow, and the 3D models were printed via a 3D printer at Drexel University. Once all atoms were completely printed, the students were able to paint and put together the different components using various household materials. A short PowerPoint presentation was also done by each group to discuss the various elements assigned, their structure and how electrons move in the orbitals of their specific atom. To assess their knowledge a pre and post-test was given to each student, and as a benchmark. Two additional classes that did not participate in this activity were also given a pre and post-test to be used as a control. Results of this study showed that the experimental group had a stronger understanding of the subject matter as opposed to the control group, thus, indicating that technology and arts may had a positive correlation to students' learning experience.

INTRODUCTION

The NSF GK-12 Fellowship program pairs graduate students with teachers of STEM in K-12 classrooms in the Philadelphia Greater area in an effort to expose K-12 students' to the grand challenges engineers are facing and simultaneously piquing their interest in the STEM fields. Using the 14 Grand Challenges established by the National Academy of Engineering, the graduate students and teachers develop hands-on modules and activities that enhance the students'

personalized learning and also upsurge the visibility and significance of engineering and science in society.

Education has been an essential part of society for thousands of years. Currently, however, technology has slowly entered the classroom and has changed many things especially the way information is now digested¹. Digital tools, such as computers, audio and visual tools, are slowly replacing standard traditional teaching methods. Studies have shown that an increase of technology in the classrooms has led to increase in test scores, problem solving skills and improve students' self-concept and motivation^{2,3}. The result of these studies has pushed an initiative in the United States to integrate technology in the classroom. Programs like E-rate program and various state formula programs controlled by the US Department of Education have been put into place to allocate money to different districts and manage the distribution of the funds⁴. However, there are many internal and external barriers typically faced by K-12 schools both in the United States and other countries when integrating technology into the curriculum for instructional purposes. Inadequate technological support, scarcity of time to insert technology in the curriculum, and leadership who aren't supportive of technology are just some of the many barriers that K-12 educators encounter⁵.

These barriers were evident in the two 10th grade chemistry classes at Philadelphia High School for Girls that the fellow was placed in during the academic year of 2013-2014. The computers they received were slow with many of them unable to properly function. They were being taught via

traditional teaching methods such as lectures, discussions, seat work and direct instructions. However, their interests were not piqued from the very first day, thus making basic theories difficult to teach and to comprehend. Upon discussion with the teacher of these classes, she expressed her dismay in the students' inability to remember what an atom is and the structure of the atom, specifically the Bohr model. An atom is the basic unit of a chemical element and thus is the fundamental concept in which many topics are built on in chemistry. As an alternative to her traditional method of teaching this lesson, the fellow decided to integrate an emerging form of technology to teach the structure and properties of an atom. Utilizing 3D printing is a fun and innovative way to integrate technology and the arts into the curriculum in hopes of making a difficult topic more manageable.

Research Question & Hypothesis

The Fellow sought out to investigate whether technology in the classroom have a positive effect on student's ability to retain information and also find the topic at hand more interesting. The fellow hypothesized that the students who use technology to learn atoms will have a better grasp on the structure, and shape of the atom as oppose to those who were taught the traditional way.

METHODS

Research & Tutorial

Students were placed in groups of four and were assigned an element from the periodic table. They worked for two days in the school's library to research their specific element, paying attention to how their element form bonds, how electrons move in their orbitals, and their isotopes. Using iPads borrowed from the Excite Center at Drexel University, students were given a tutorial by the fellow on how to use the application *AutoDesk 123Design*. Their tutorial consisted of learning the different settings and features of the application through various activities that included them building various shapes and items.

Design & Printing

Two days were allocated to the students to design their atom. They were responsible for designing the nucleus of the atom with the proper number of

electrons and neutrons. They were also told to design the electrons in a way that facilitate building the atom once all parts are printed. The fellow saved all the files, and printed them using a 3D printer at the Excite Center at Drexel University. Students then painted and used wires and pliers to assemble their atom together, as examples can be seen in Figure 1. Graded presentations were also done, where each group had to explain their atom and various characteristics of their element.

Evaluation

To evaluate the effectiveness of this activity, a pre and post- test was given to the two 10th grade chemistry classes that the fellow was assigned to. As a control, two 10th grade classes who did not participate in this activity were also given a pre and post- test. The Pre & Post test were exactly the same and consisted of 10 questions with the last question consisting of drawing an image of an atom. Figure 2 depicts the results of the pre and post test for the control and experimental group. Pre-test average for control and experimental groups are 42.3 +/- 3.2 and 39.6 +/- 3.7 respectively. The Post-test average for control and experimental groups are 64.1 +/-11.3 and 86.7 +/-12.5 respectively, where, n=63 for experimental and 54 for control. avg+/-SEM)

RESULTS

Figure 1: Above are two examples of two different groups final 3D model of an atom. To the left is Carbon and to the right is Boron

DISCUSSION:

Our findings show that the students who participated in the activity (experimental group), scored significantly higher on the post-test than those who did not (Figure 1, $p < 0.05$). A breakdown per question dives further into the pre-test and post-test to analyze how the students answered each question (Table 1). The last question on the pre and post test, question 11, asks students to draw and label a diagram of what they believe an atom looks like. (See Appendix for all the questions of the pre and post test). The experimental group that developed i). a model the atom, ii) 3D print of it and iii) put the different parts of the atom together were able to more accurately draw the structure of the atom as opposed to the control group who were taught the structure of the atom the traditional manner. Students in the experimental group showed a greater understanding of how ions are formed by losing and gaining electrons as oppose to those in the control group (questions 8 & 9). Both groups however, were not able to properly explain an atom in words (question 1).

These findings have shown positive correlation between integrating technology in the classroom and students' performance in the classroom. Although there are still many barriers that need to be conquered in the classroom, especially in urban areas, technology in the classroom has shown positive impact on the students performance and understanding. Studies have shown that technology in the classroom keeps students engaged, brings excitement into the curriculum, allows students to learn at their own pace and also prepares them for the future that they will later be working in⁶. Technology also allows teachers to teach sections in their curriculum that were once difficult to understand in a new way that will capture the

Figure 2: Results of the pre and post test for the control and experimental group.

	Pre-Test		Post Test	
	Contr ol	Experiment al	Contr ol	Experimenta l
Q1	22%	19%	52%	64%
Q2	31%	37%	44%	81%
Q 3	42%	39%	61%	83%
Q4	38%	36%	67%	94%
Q5	27%	24%	59%	87%
Q6	42%	44%	66%	85%
Q7	39%	39%	60%	88%
Q8	21%	19%	55%	81%
Q9	23%	21%	57%	84%
Q10	52%	49%	64%	91%
Q11	11%	13%	49%	92%

Table 1: Depicts the breakdown of the pre & post test by question.

The value in the table is the percentage of students in each group that answer the question correctly

attention of the students. Technology however, is not perfect, and we certainly shouldn't diminish the roles of traditional learning processes – such as handwriting, and lectures – but when used correctly, technology can help both teachers and students soar to success.

FUTURE WORK

This study was done on a small population of chemistry students in one high school. Future work will include and is not limited to: i) using 3D printing to teach atoms in all the chemistry class at this specific high school ii) speaking to other fellows at other high schools in the district in hopes that they will integrate 3D printing into their atoms curriculum and iii) finding other forms of technology to integrate into science and math courses throughout the district in hopes of making subject matter that was once deem difficult more manageable.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under Grant No. DGE-0947936. We would also like to thank the Drexel University Department of Electrical and Computer Engineering and College of Engineering as well as the School District of Philadelphia. Many thanks to all Drexel GK-12 partnership schools, Teachers, Fellows and project co-investigators for your efforts.

APPENDIX

Pre& Post Test Questions

1. How would you describe an atom?
2. The nucleus of an atom is made up of what?
3. The electron has what kind of charge?
4. What subatomic particle has a neutral charge?

5. How many electrons are in the first energy level?
6. Which subatomic particle has a positive charge?
7. How many electrons can fit in the 2nd valence shell?
8. When an atom loses an electron, what is the overall charge of the atom?
9. When an atom gains an electron, what is the overall charge of the atom?
10. Which subatomic particle is the smallest?
11. Draw and label a diagram of what you think an atom looks like

Introducing Gaming Tools for Computing Education in STEM Related Curricula

Amalia Rusu

School of Engineering
Fairfield University
Fairfield, USA
arusu@fairfield.edu

Abstract — In this paper, we provide an overview of two Computer Science for High School teacher training workshops, offered at Fairfield University in 2012 and 2013. These professional development programs offered the skills necessary to integrate Google Apps education and interactive, metaphor-based computer games tools into middle and high school curricula, to help students learn computer science and engineering concepts. The first year workshop was primarily focused on the implementation of computer science and gaming concepts within STEM curriculum. The focus of the second year workshop was two-fold, first to continue the implementation of computer science and engineering concepts through STEM education, and second, to create connections and extensions for high school teachers who have already been introduced to STEM curricula and teaching models. Multiple urban and suburban school districts were included in a collaborative program with our university, designed to teach educators how to use computer science as a mean to make connections between different curriculum areas and teach higher order problem-solving skills. Various learning activities during the workshops are presented, and outcomes and teachers' feedback after attending these workshops are discussed.

Keywords—CS4HS; teacher training; Computer Science; STEM; gaming

I. INTRODUCTION

Research and data from several professional journals have indicated the absolute promise of STEM education to improve documented students' performance and knowledge in science, technology, engineering and mathematics, especially when early intervention occurs [1]-[2]. This will exceed the lack of performance that currently exists. The application of these integrated skill sets will make the difference in terms of future student achievement. Various explanations have been cited to prove this. One factor consistently mentioned has indicated a general lack of understanding relative to the structure of the disciplines involved in STEM education. Mathematics, as taught at the middle school level, involves different assumptions and conceptual understanding than science. This fact does not seem to be readily understood by curriculum planners and teachers. According to the Common Core State Standards, middle school mathematics, for instance, involves the concepts of ratios and proportionality, equilibrium and balance. Conversely, middle level science, as stated in the

currently released science standards and emphasized in the philosophy of the Next Generation Science Standards, focuses on experimental design, gathering data, pattern recognition used to predict future outcomes. "If...then" statements used in formalized hypothesis indicate that a set of assumptions are used to predict future results. Coincidentally they are also used in higher mathematics and by Microsoft Excel in the development of relational databases. These skills are key to language arts learning as we consider the Common Core State Standard's call for conceptual understanding of cause and effect and the emphasis on nonfiction reading skills for all students.

Another area of concern is the selection of STEM themes in the curriculum development process with little or no regard to the structure of the disciplines, or their habits of mind, or the true technology integration. For instance, an unit on cell biology may be identified for development into a STEM unit. Often curriculum planners will examine the unit and identify areas where mathematics, technology and engineering may be correlated into the expanded unit. This forced trans-curriculum relationship tends to result in segregated units of study where students have a difficult time making conceptual associations among the various disciplines. It also makes developing of effective assessments difficult, with each discipline creating various assessment models unique to the area of study. Therefore selecting a broad topic that easily and fluently encompasses each of the STEM domains with seamless technology integration is essential for the future success of the unit. True STEM education speaks to the total immersion of inquiry and integration as strategies throughout all disciplines. These strategies lead to greater student achievement for all. The "T" in STEM, that of technology, if employed correctly, is the glue to bring together the disciplines and to ensure the highest achievements for all students.

However, at the same time, computer science in K-12 education in the United States is also in crisis, according to the Association for Computing Machinery (ACM) and the Computer Science Teachers Association [3]-[8]. Middle school students use computers in their daily lives, but unfortunately they never quite understand what computer science is and how it relates to problem solving and computational thinking [9]. Their exposure to computers in school is most likely with spreadsheets, word processing, and presentation tools. Few

high schools offer a computer science course, and even fewer middle schools offer one, which is usually the time when students are beginning to formulate their ideas about careers. The lack of exposure to computer science at the K-12 level leads to few students choosing computer science as a career in college [10]-[11]. The U.S. Bureau of Labor Statistics predicts that the United States will only be able to fill about one-third of technology jobs in 2018 with U.S. citizens.

In this paper, we address these issues by offering professional development workshops to middle and high school teachers in school districts throughout the state of Connecticut. Through grant opportunities from Google, we have run two CS4HS workshops at Fairfield University in the summer of 2012 and 2013. The CS4HS program promotes computer science education worldwide by connecting educators to the skills and resources they need to teach computer science and computational thinking concepts in fun and relevant ways. The seamless infusion of technology presented to teachers at our CS4HS workshops, and ultimately provided to students, helps reduce the educational needs of our schools since it acts as the glue necessary to ensure a higher level of achievement for students. Our approach used the concept of gaming to assist secondary education by increasing student engagement. Increasing student engagement occurs when students become more interested in their schoolwork. This continues to be one of the most difficult tasks that teachers face. It is important that teachers ensure that students have a good balance of fun and learning while engaged in classroom activities [12]-[14]. Educational games aim to do just that. Gaming emphasizes entertainment, which can have its benefits among young audiences, but could be far more powerful if used as an educational tool. Learning how to develop, integrate, and teach educational games, and use them to effectively instruct middle and high school students STEM-related concepts with focus on computational thinking, was the focus of our workshops.

Our training also emphasized Google Apps, such as Google Drive and Google App Script, as both of these apps help support collaboration among their users. Educators and their students are able to create, share, and present materials more efficiently through these tools. They allow students and educators to work collaboratively while in the classroom but also outside the classroom to extend the learning opportunities through the use of technology. By focusing on Google Apps, the professional development activities were centered on creating and presenting collaboratively. Thus all disciplines can be aided by this process. The collaboration model is also used in many of today's popular video games. Lee Sheldon in his book "The Multiplayer Classroom" explains the benefits of having students build challenging game strategies [15]. This experience used as part of a class creates a new environment where students are challenged to be an engaged and active decision maker within the class. The gaming industry designs games as entertainment for their users, so classrooms should be able to work on that same principle creating entertainment for students while engaging them in higher order problem solving and cause and effect principles. All of these actions are based on the idea that the skills of the collective parts are greater than the skills of an individual. The objectives include generating

interest and enthusiasm for teaching and learning STEM and Computer Science related fields of study.

II. OUR APPROACH

There is preponderance of research and data published through many professional journals that states the advantages of using STEM based curricula for improving students' performance in mathematics, science and technology [16]-[19]. This data is causing a growing shift within schools to move towards a STEM based curricula. This change can be seen in Fairfield and New Haven County in Connecticut with the implementation of STEM curricula in the schools in towns such as Bethel, Bridgeport, Fairfield, Madison, Monroe, Naugatuck, and others. Though the specific content taught in the math and science curricula is different, there are connections between the two disciplines, as both the Common Core State Standards and the Next Generation Science Standards put a strong emphasis on higher order problem-solving skills and causal relationships. Causal relationships such as "If...Then" or "While...Do" are the data flow concepts presented in high school computer science classes. These relationships can also be seen in the Common Core State Standard's conception understanding of cause and effect within non-fiction reading skills. These causal relationships are introduced in all subject areas and should improve student understanding of balance vs. imbalance, pattern recognition, data gathering and the ability to predict future events and form hypothesis.

Computer science curricula and the course offering within Fairfield and New Haven County schools vary significantly, from a basic introduction to Computer Science to AP Computer Science courses. Some schools are now offering courses in video game design, some have developed multiple course offering, and others are just starting to investigate courses they would like to offer. It is through these opportunities that teachers can include the implementation of educational games and gaming tools to create further connections between all subject areas not by a forced use of technology but rather an immersion into technology by allowing multiple teachers to demonstrate the advantages of working among disciplines. This collaborative effort will show students that disciplines are not islands of independent knowledge but networks that must be connected in order for knowledge of all subject areas to grow.

A. Workshops Goals

The main goals for the two workshops were as follows:

- To recruit and provide training to middle and high school teachers from local area towns (including, but not limited to, Ansonia, Bethel, Bridgeport, Madison, Monroe, Naugatuck, Ridgefield, Shelton, and Trumbull Public and Parochial School Districts)
- To make teachers aware of computational thinking resources and educational tools as they specifically relate to Computer Science and technology curricula based upon the State of Connecticut framework

- To have educators gain knowledge of the structure of Computer Science and STEM disciplines and become familiar with methods of computational thinking unique to them
- To have educators gain knowledge of Google Apps to foster collaborative learning
- To educate teachers in making connections between disciplines through the use of metaphors-based games and technology, leading to higher achievement for students
- To design and implement a set of CS learning activities to be utilized in regular classroom models and/or in after school clubs for middle and high school students
- To increase teacher awareness and enthusiasm for Computer Science and STEM related activities, leading to increasing student self selection into CS and STEM classes and career fields

In the ten school districts of interest, middle school Computer Science curricula is currently near inexistent. The involvement and enrolment in Computer Science and technology courses at high-school level is not encouraging either. Unfortunately, middle and high school students do not realize that other fields with educational nature can be used in the Computer Science and STEM disciplines. The overall goal for our program is to provide ways for educators to teach middle and high school students how to solve problems creatively and uniquely, in relationship to other disciplines. A particularly useful technique for teaching these skills is using simulated activities to reinforce problem-solving concepts. When learning, it is important for students to learn about how to approach a given problem space. It is well known that students have different learning styles. For students to effectively retain the information, the lessons must include elements of all senses, visual, auditory, tactile and kinesthetic. There are many studies about multiple intelligence and learning styles and all of them show that students retain more of what they learn when the information is presented through multiple media and subliminate real world situations [20]-[23]. Students remember less of what they read than when they hear or see visuals related to what they are hearing; or if they watch someone do something while explaining it. Moreover, students retain much more of the information they learn in a simulation. These simulations' educational value is increased even more when the simulations reflect real world situations. Lastly, it is important that teachers allow students to have some feeling of accomplishment at the end of their work. This feeling of accomplishment compels students to continue to learn and work harder. Along these ideas, our workshops give teachers the opportunity to experience educational tools through a set of Computer Science resources and learn how to engage students in problem solving and computational thinking.

B. Target Audience, Recruiting Strategy, and Benefits

Each year, twenty middle and high school teachers were recruited for the workshop in several ways. Teachers were contacted by email from lists provided by the participating

school districts and at large. Recommended candidates also received follow up information from the program director and the teacher coordinator. Teachers and administrators were invited to attend an informational meeting regarding the summer workshop. Both workshops have reached their full capacity within a month of advertisement and were running with a waiting list of over twenty teachers.

The population of students in the participating districts who will be impacted by this program was very diverse. Approximately 40% of the students are male and 60% are female. The diversity of ethnic groups varies from a mix in the Diocese of Bridgeport (68% African American, 14% Caucasian, 3% Asian 1% Hispanic and 1% Other) to a slight demographic mix in the Naugatuck school system (8% African American, 77% Caucasian, 3% Asian, 11% Hispanic, and 1% Other) to little diversity in Monroe Public Schools (2% African American, 89% Caucasian, 3% Asian, 5% Hispanic and 1% Other). The author of this paper, as the program director, and the teacher coordinators in collaboration with the district curriculum coordinators were in close collaboration for the content of the workshop, in order to address the diversity of the participating districts. Moreover, Fairfield University, as a Jesuit institution, has a further obligation to the wider community it belongs to, to share with its neighbors its resources and special expertise for the betterment of the community as a whole.

Besides the obvious benefits of participating in the workshop, teachers entered into a network of professionals to continue fostering the relationships built at these workshops and extended to other school districts around the nation. A Google group for CS4HS participants is available so that sharing resources and expertise, and communication can continue amongst participants after the end of these workshops.

In addition, teachers attending these workshops can apply for continuing education units to be utilized for certification purposes through their school districts.

C. Workshops Format

1) First Year Workshop

The first CS4HS workshop was held Wednesday to Friday, on June 27-29, 2012, from 8:30 a.m. to 3 p.m. in the School of Engineering at Fairfield University in Fairfield, CT. Morning presentations were held in an auditorium while afternoon hands-on activities were held in a computer lab.

During the 3 days workshop, various learning activities alternated between presentations and hands on activities (Fig 1). Teachers were introduced to several popular game development platforms used for computing education including Scratch, Alice, and Game Maker. They were exposed to educational resources and Computer Science learning activities, such as CS Unplugged, and provided examples of collaboration among computing, STEM, and other fields [24].

Presentations included a speaker from Google on Google technologies, also topics such as Computing Basics: Algorithms and Abstractions, Educational Computer Games, CS Unplugged, Computing in Lesson Plans: Some Ideas, Merging Musical Arts and Technology, Pattern Recognition

and Clustering, Resources for Graphics and Animation, Careers in Computer Science, and Software Engineering Serious Computer Games.

Typical hands-on sessions evolved around the following tasks:

- Identify the concept to educate students about
- Develop the proper metaphors for the concept
- Identify the proper tools, such as modeling software and platform
- Determine how educators can develop and use the game to educate their students

Fig. 1. Participants’ games demo on the last day of the workshop.

The issue of how these topics could be addressed, as most middle and high school students do not take Computer Science classes, was also discussed. Several strategies for incorporating these games into middle and high school curriculum were brainstormed during the workshop with teachers sharing their STEM curriculum and in particular, any computer science related modules, courses, or clubs. The workshop included a pre- and post-attitudinal survey to help gauge teacher attitudes towards educational gaming in the classroom, in addition to the standard Google CS4HS participant survey (Fig. 3). For the latter, a Likert scale was adopted for the quantitative questions, with 1 (strongly disagree) to 5 (strongly agree) as the choice of answers.

Fig. 2. Participants in the computer lab for hands on activities.

What grade/grades do you teach?	If you are a teacher, what subject(s) do you teach?	Overall, I found this workshop to be worthwhile.	I felt a sense of community among participants of this workshop.	What did you like about the program?	What didn't you like about the program?	Is there anything you wish you had learned during the workshop, but didn't?	Would you recommend this workshop to other colleagues?	If you are a teacher, how likely is it that you will incorporate knowledge you've learned into your curriculum?	What would enable you to incorporate what you've learned into your classroom?	Is there anything else that you would like us to know about your experience?
---------------------------------	---	--	--	--------------------------------------	---	---	--	---	---	--

Fig. 3. Google CS4HS participant survey.

The breakdown of the teachers participating in the first year workshop was as follows:

- 3 teachers were grade 9-12, 14 teachers grade 6-8, with a very high percentage of 8th grade teachers; we thought it is important that teachers of students about to start high school need to get the students excited about Computer Science in preparation for the high school more technology-oriented curriculum
- 2 male, 15 female
- 4 from private schools, 13 from public schools
- The range of teaching disciplines included: science, technology, math, computer science, and media, with the majority in science

2) Second Year Workshop

The second CS4HS workshop followed the same 3 days structure in June 2013, with various learning activities

alternating between speakers/presentations, panel discussions, and hands on activities (Fig 2). However, based on lessons learned from the prior workshop, some of the topics and presentations were altered to better assist the teachers with information and programs/games that can be brought back to the classroom and incorporated into lesson plans to enhance STEM based student learning. Thus, some more theoretical presentations have been replaced by customized resources, networking time, and programming assignments. In addition to exposing the teachers to game development platforms used for computing education, such as Scratch and Game Maker, they were introduced to Google Apps through examples, as a better way of collaborative learning in K-12 education. The hands on activities helped them determine how to develop and use games and Google Apps to educate students and make connections with other disciplines.

A Google speaker has been invited to provide insight for using Google Apps in education, including Google Drive and Google Apps Script. Google Apps Script - a Cloud Based

JavaScript platform allows users to quickly write simple applications. The teachers were walked through many tips and tricks around Google Drive and other third party applications that provide value to education, as well as provided with many related educational resources [25]-[28]. Other presentations were focused on resources for teaching computational thinking, video game design, and gamification of the classroom. A panel of high school teachers who have been successful in teaching either programming, gaming classes, or STEM-related topics in a way that engages their students, was also included, as a great opportunity to share best practices and lessons learned. The workshop also included a pre- and post- attitudinal survey to capture teacher attitudes towards educational tools in the classroom, in addition to the standard Google CS4HS participant survey (Fig. 4) and the results are presented in section III.

The breakdown of the teachers participating in the second year workshop was as follows:

- 13 teachers grade 9-12, 7 teachers grade 6-8
- 8 male, 12 female
- The range of teaching disciplines included: computer science, technology, science, math, and special education

All teachers, in both workshops, received a stipend for attending the workshop. Most of the budget was supported through the Google CS4HS grant. Additionally, there were advertising materials, as well as media packages for each participant, generously donated by the School of Engineering which also provided computer hardware/software, facility use, and network administration for the duration of the workshops.

Google Apps and Gaming Tools for CS Education 2013 Pre –Attitudinal Survey	Google Apps and Gaming Tools for CS Education 2013 Post –Attitudinal Survey
Your Name: _____ Grade: _____	Your Name: _____ Grade: _____
School: _____ School District: _____	School: _____ School District: _____
How often do you utilize technology in your classroom? (Frequency and with what subjects)	This workshop has contributed to my enjoyment of technology in the following ways:
I enjoy using technology because	After completing this workshop the use of technology in my classroom will: Circle one, Increase/ Decrease/ Stay the same
The thing I like most about integrating technology for students is.....	Why?
The thing I like least about using and developing technological resources in my classroom is.....	What technologies/concepts will you introduce to your classes/school in the Fall 2013?
I think the best approach to the teaching of technology within the curriculum is	How will these technologies/concepts be integrated in your classroom and into your instruction of students?
The biggest obstacle for me to utilize technology effectively is	What obstacles may prevent you from utilize the technology/concepts introduced at this workshop?
What Google tools have you used?	How has your understanding of computational thinking changed? (I used to think, but now I think.....)
Do the staff and students at your school have Google accounts? (will they?)	How do you plan on using gameification and/or video games in your classroom/school?
What presentation/collaboration tools do you currently use with students and staff?	How will you share what you have learned with your colleagues and students?
What do you know about using gameification to aide learning?	What type of follow up professional development would interest to you?
How have you used gameification to date?	What would you change about this professional development?
How are gaming/simulations and/or modeling utilized in your classroom to further student understanding of different topics?	
What do you know about computational thinking?	
How have you used computational thinking to date?

III. SURVEY RESULTS AND EVALUATION

A. What Worked for Our Workshops

Based on the feedback received from the participants through the Google CS4HS survey at the end of the workshops, we were pleased by the variety of activities appealing to them, as follows:

- Hands-on activities that could easily be integrated in middle and high-school curricula
- Breakout sessions and discussing ideas in groups
- Presenting end of workshop results to the whole group
- Introducing several gaming platforms (including Scratch) and related gaming activities
- CS Unplugged ideas and resources
- Having Google speakers give presentations on various Google Apps for education
- Panel discussion on current Computer Science situation in high schools and sharing successful programs and implementation ideas for programming, gaming, and robotics classes
- Meal and refreshment time provided an excellent opportunity for them to network with each other and with the presenters

The participants liked the “immediate availability of materials” presented, that the topics were “timely and the information current”, “lots of different ideas for things to do in the classroom” were given, that “computer time to test out and utilize the information” was allocated during the workshop, and “sharing information and communicating ideas” with other teachers has been a priority.

Most of the post-attitudinal survey comments, when compared to the pre-attitudinal survey responses, have shown a great deal of change in how the participating teachers viewed Computer Science and its relationship to other fields. Comparing teachers’ understanding of computational thinking before and after the workshop indicates that the teachers left the workshop better prepared to infuse it in their classes. Some of their responses are summarized as follows:

- “I used to think it was too complex to teach it, now I know it can be broken down into smaller pieces.”
- “I used to think it was all Math but now I think it is more process and logic.”
- “Now I view it as more realistic problem solving.”
- “I used to think that algorithms were related only to Math.”
- “I do not think I knew what computational thinking meant, now I do.”
- “I have never heard about computational thinking before this so I now understand how important it is to push computational thinking in the classroom.”

- “I think about algorithms now...”
- “I had no idea that computational thinking involved sets of numbers and so many steps...”
- “I used to think it would be hard to integrate more technology but now gamification can attract more students”
- “I used to think it is important to teach the program language but now I feel it is also important to teach the thought process”
- “I used to think it was hard but now I know anyone can do it”

Examples of first year workshop games generated by the participants and presented during the last day of the workshop are provided in Fig. 5. Some teachers wished the workshop duration was extended a few more days to have more time to work on the programs and learn the software better, as they got excited about the topics.

B. After the Workshops

After the first year workshop, in the post-attitudinal survey, more than half of the participants highly expressed their interest in incorporating knowledge they learned into their curriculum in various ways such as:

- Using Scratch in their classes
- Incorporating games or game strategies into class exercises
- Using CS Unplugged when teaching computational thinking topics
- Promoting Computer Science as a discipline and professional career to their students

With curriculum refined, after the second year workshop, in the post-attitudinal survey, unanimously the participants expressed their interest in continuing learning about the topics they were introduced during the workshop and adding them into their curriculum in various ways by:

- Using Google Apps for education to facilitate collaboration and sharing
- Using gamification strategies in their classes to engage and motivate students
- Incorporating games or game exercises into lesson plans
- Using CS Unplugged and computational resources documents in the classroom with little additional preparation

Fig. 5. Examples of games created by teachers during the workshop for various STEM topics (i.e., in anatomy, math, and language art).

While the more fun and interactive activities were immediate success for teachers and probably fitting directly into their curricula, the more theoretical lectures and exercises did not sync well with the audience. In the surveys, most of the participants expressed their lack of time in classroom preparation which would make it harder to implement them due to both teachers' and students' inappropriate background skills.

Consequently, we made several changes in the content of the workshop between year one and two. As a result, the Google CS4HS survey for the second workshop was showing a great improvement, with all participants (100 percents) responding either 5 (strongly agree) or 4 (agree) to all quantitative questions in the survey as follows:

- "Overall, I found this workshop to be worthwhile"
- "If you are a teacher, how likely is it that you will incorporate knowledge you've learned into your curriculum?"
- "I felt a sense of community among participants of this workshop"

Moreover, all participants (100 percents) expressed their satisfaction with the workshop by answering "Yes" to the "Would you recommend this workshop to other colleagues?" question.

IV. CONCLUSION AND FUTURE WORK

In this paper, we present the framework and outcomes of two CS4HS Google-sponsored workshops that helped middle and high school teachers learn more about computational thinking, gaming, and Google Apps for education. The ability to solve problems with a given problem space but also recognizing relationship and similar problem types benefit students in all disciplines. For teaching these skills, using simulated activities to reinforce problem-solving concepts is a powerful technique.

For each workshop, a diverse group of middle and high school teachers in Computer Science and STEM disciplines from Connecticut school districts, was recruited and introduced to game development platforms, techniques for gamification of classroom, and Google Apps for a more collaborative way of learning in education. They were also exposed to educational resources and various computer science learning activities, with or without the use of computers, and provided examples of collaboration among computing, STEM, and other fields.

Based on surveys, the feedback received has been very enthusiastic and we are hopeful that ultimately it will reflect in raising student awareness of relevance of CS fields and future changes in enrolment. Many teachers mentioned that while they thought Computer Science is all about programming, after attending these workshops, they will dedicate more time to activities enforcing problem solving and computational thinking which are crucial in many fields.

Similar teacher training workshops have the potential to work as well at other universities due to an increased demand

to prepare a STEM-proficient workforce and future Computer Science experts. We plan to continue offering other workshops like these in the future and expand our efforts to new school districts as part of preparing K-12 education for a stronger foundation in CS and STEM. Currently, we are working with several teachers for similar proposals that would support professional development for in-service teachers in the state of Connecticut. We are also actively looking to adapt the program and join national efforts to create opportunities for the teachers to transform CS and STEM education into vibrant and inspiring learning environments.

ACKNOWLEDGMENT

Both summer workshops were funded by generous grants from Google, with additional support provided by private donors and the School of Engineering at Fairfield University. We thank all our sponsors, presenters who made the efforts to transfer their knowledge to middle and high school teachers, and the teachers participating in the program. Special thanks to Bonnie Maur and Bill McDonough, our teachers coordinators, for valuable school district partnerships.

Abstract—Because collaboration plays a key role in today’s society, it is beneficial to prepare people at a young age for collaborative work. However, there is no academic or professional consensus on the most effective approach. To remedy this shortcoming, our research will expand on one promising method: the incorporation of collaborative scaffolding into collaborative educational video games. Although there will be several challenges, we have already made progress through the development of a multilevel taxonomy of collaboration to aid our evaluation approach. Our findings will bring academics and educators one step closer to developing methodology for the seamless integration of 21st century skills, such as collaboration and technological proficiency, into today’s classroom curricula. In addition, researchers can utilize our taxonomy to more easily identify aspects of collaboration relevant to their interests, and educators can use the taxonomy to help identify collaborative skills that students lack.

Keywords—computer aided instruction, electronic learning, curriculum development, career development, collaboration

I. INTRODUCTION

21st Century Skills [1], such as collaboration and technological proficiency, are necessary in today’s ever connected world, yet there remains a lack of insight into best practices when it comes to teaching collaborative skills. One option is to embed collaboration into activities, either explicitly through team formation or implicitly by assigning a goal impossible to achieve alone. A major advantage to this methodology is its seamless integration into existing curricula; there is no need to take time away from teaching traditional topics because everything is imparted concurrently. However, without explicit guidance, there is no guarantee that group members encounter and ingrain the necessary collaborative skills. Another approach is to create activities aimed purely at teaching and encouraging collaboration. In this case, potential frustration from a lack of academic understanding will not interfere with the collaborative process, but classtime must be set aside.

Although the value of collaboration has been known for some time [2], [3], technology’s rapid evolution requires us to reexamine methodologies to collaboration education. An approach not yet explored is the incorporation of collaborative scaffolding into educational video games. Aside from educational benefits [4]–[6], such games have already been shown to have positive effects, such as an increase in motivation to learn [8] and improvement in self-efficacy and self-esteem [7]. Through collaborative play in particular, children have shown

an increase in collaborative behaviors [9], [10], such as sharing [11], and a decrease in aggression [9]. The addition of specialized scaffolding allows educators to leverage the inherent benefits of collaborative educational games and facilitates the parallel teaching of collaboration and traditional topics.

To examine the impact of collaborative scaffolding, we built a collaborative multiplayer game and developed a pre-post study design. Through the process of creation, we encountered and predicted several challenges associated with developing study-specific technology, working with children, and running on-sight trials. To identify a focus for our evaluation, we performed an analysis of over 25 existing studies and surveys to identify the components of collaboration. We chose two facets from the resulting multilevel taxonomy for our study: performing part of a task for a group member (direct helping) and providing guidance to a group member (indirect helping). Moving forward, we plan to iterate on our materials, finalize our study design, and flesh out our data analysis so that we can examine the impact collaborative scaffolding has on these behaviors both during and after play. Aside from aiding our own work, the taxonomy can help researchers pinpoint aspects of collaboration relevant to their interests, and it can help educators identify collaborative skills that students lack.

II. DEFINITIONS

A. Collaboration

The concept of *collaboration* is not well defined in literature, and is often referenced in conjunction with *cooperation* and *teamwork*. Some researchers make an effort to distinguish between these terms [12]–[22], while others use them interchangeably [9], [23], [24]. The popularity of each term depends largely on the area of study; computer science favors *collaboration*, most prominently in the areas of Computer Supported Collaborative Learning (CSCL) [14], [15], [21], [23] and Computer Supported Collaborative Work (CSCW) [13], while *cooperation* dominates the field of psychology [3], [9], [11], [25]–[28] and *teamwork* is featured in the industry [2], [12], [29], [30] and military [19], [31] sectors.

Some researchers define collaboration by its behaviors and skills, which in turn are often defined themselves [12], [18], [32], while others define collaboration as an activity [20], [28], [33] or a context [25], [27], [34]. We developed our own definition, taking most of our wording from Roschelle and Teasley [20] and Ryan and Wheeler [27]:

Collaboration is the mutual engagement of participants, whose goals are interdependent and positively correlated, in a coordinated effort to complete a task.

For the purposes of our work on collaborative scaffolding in educational video games, *participants* will be the children who establish a *mutual engagement* among themselves, and *coordinated effort* will refer to their self-organized approach. Because the goal of each player on a team is for the whole team to win, player goals will be *positively correlated*.

B. Helping Behaviors

The concept of a helping behavior is closely tied to backup behavior. According to Porter et al. [29], *backup behavior* is help that occurs when “it is apparent that [a] team member is failing to reach those goals [defined by his or her role],” while *helping behavior* occurs when help is not strictly necessary. Our helping behavior definition is based on Porter et al.’s backup behavior definition, sans dependence on need:

A helping behavior can be described as the provision of resources and task-related effort to a group member intended to help that member contribute to task completion.

In contrast to Porter et al., Marks et al. base their definition of backup behavior on Dickinson and McIntyre’s [35] work and define it as occurring when “(1) providing a teammate verbal feedback or coaching, (2) helping a teammate behaviorally in carrying out actions, or (3) assuming and completing a task for a teammate” [36]. Although Marks et al. call these backup behaviors, they also qualify as helping behaviors under Porter et al.’s definitions. We use two of Marks et al.’s backup behaviors as a focal point for our research on collaborative scaffolding: performing part of a task for someone (assuming and completing a task for a teammate) and providing guidance (providing a teammate verbal feedback or coaching).

C. Scaffolding

Wood et al. coined the term *scaffolding*, meaning a “process that enables a child or novice to solve a problem, carry out a task or achieve a goal which would be beyond his unassisted efforts.” [37] They went on to identify six scaffolding functions that we incorporated into our collaborative scaffolding design: recruitment, reduction in degrees of freedom, direct maintenance, marking critical features, frustration control, and demonstration. As a form of direct maintenance and frustration control, our collaborative scaffolding system mentions the benefits of collaboration to players when they are stumped. To mark critical features, the system directs student attention when collaboration becomes a necessity. Because the scaffolding system is limited by the game in which it resides, Wood et al.’s other functions are more relevant to the educational game itself, which has its own educational and game scaffolding. The game’s contents entice potential players (recruitment) and technology restrictions limit player input channels (reduction in degrees of freedom). In addition, mechanics are gradually introduced (direct maintenance), the difficulty level can be fine-tuned (frustration control), and in-game highlights and dialog guide the player (marking critical features).

III. RELATED WORK

A. Collaboration among children

Since our research focuses on middle school children, it is important to understand the relationship between kids and collaboration. Studies show that young girls perform better in a collaborative environment than in a competitive one, while boys perform equally well in both [38], [39]. In addition, a collaborative classroom goal structure, when compared to a competitive one, leads to higher achievement, greater acceptance among group members, and more positive attitudes towards tasks and teachers [40]. It is also better at promoting critical thinking competency, motivating further exploration into the educational subject, and encouraging positive expectations of future inter-student interactions [41]. Even at the undergraduate level, a collaborative structure leads to groups that show more subdivision of activity, attentiveness to fellow members, and friendliness during discussions [25]. Facilitating an effective collaborative environment requires child proficiency in collaborative skills, which we aim to teach and encourage through our collaborative scaffolding system.

Aside from environment, research has also been done on comparing collaborative and competitive tasks. Ryan and Wheeler [27] found that fifth and sixth grade students given collaborative, rather than competitive, lessons exhibited more collaborative tendencies during post-lesson game play. These tendencies came in four categories: seeking help for one another, positively responding to help sought, volunteering help for others, and establishing group strategies for sharing resources with individuals in need. In our exploration of collaborative scaffolding, we are also interested in the retention of helping skills, although we distinguish categories by the help itself instead of its initiation. Moreover, rather than compare the effects of a collaborative vs. a competitive task, we concentrate on collaborative vs. neutral scaffolding during in-game collaborative missions.

B. Scaffolding

Effective scaffolding systems often incorporate the concept of *fading*: “once the learner has a grasp of the target skill, the master reduces his participation (fades), providing only limited hints, refinements, and feedback to the learner, who practices by successively approximating smooth execution of the whole skill” [42]. To this end, our system tracks player input and in-game events to identify when collaboration is advantageous but overlooked. Ideally, as players progress they begin to identify collaboration opportunities on their own. In turn, our system limits its presence to avoid providing unnecessary information. In addition to fading, we incorporate all relevant scaffolding strategies from Quintana et al.’s [43] guidelines into our scaffolding design: (1c) Embed expert guidance to help learners use and apply science content, (2a) Make disciplinary strategies explicit in learners’ interactions with the tool, (5a) Embed expert guidance to clarify characteristics of scientific practices, and (5b) Embed expert guidance to indicate the rationales for scientific practices.

Traditional scaffolding systems tend to address educational topics like math and science. Research has also been done on collaborative scaffolding in general [44] and topics related to collaboration, such as exploratory talk [45], [46] and reaching

group consensus [47]. However, little of it addresses helping behaviors in particular, which is the focus of our work.

IV. STUDY DESIGN

A. Focus

To inform our exploration into the impact of collaborative scaffolding in educational video games, we developed a research question based on two dyads. The first dyad is setting. Our main interest is collaboration in a classroom context, but we also aim to explore the impact of collaborative scaffolding as it appears in real time during video game play. The second dyad is type of help. We chose to concentrate on direct and indirect helping to keep our scope broad but realistic. These focal points result in the following research topic:

Does collaborative scaffolding in an educational video game promote more instances of performing part of a task for a group member (direct helping) and providing guidance to a group member (indirect helping) than non-collaborative neutral scaffolding in the context of the game and a collaborative classroom activity?

B. Procedure

To explore collaborative scaffolding, we modified Singapore-MIT GAMBIT Game Lab's *Waker* (<http://gambit.mit.edu/loadgame/waker.php>), a 2009 action-puzzle Flash game that teaches displacement and velocity. We chose this game because of its light-weight nature, educational content, and potential for rapid modification. Since the game was originally single-player, we altered the code to allow simultaneous play, developed new corresponding levels, and implemented a collaborative scaffolding system.

Our mixed-factorial study design meant that we needed to create two versions of content for the scaffolding. For the treatment group, we will have collaborative scaffolding with statements such as "Remember each of your abilities, and use them to help each other." and "Sometimes things are easier to do together." We can think of these phrases as positive, in line with scaffolding's formal definition. Scaffolding can also be neutral or even negative. In the context of an educational video game, neutral collaborative scaffolding would include statements that neither help nor hinder players, including "It must have taken a long time to build this place." and "It sure is bright outside." We will use this type of scaffolding for our control group. Negative collaborative scaffolding hinders people with statements such as "You don't need anyone's help." and "Working with others is a waste of time." We chose not to use this type of scaffolding in our study.

During each trial, students will start by taking a short pretest that covers their collaborative experiences and attitudes towards collaboration, as well as their knowledge of the topics that the game will teach. They will then split into small groups and perform a simple collaborative classroom activity during which we will take note of any direct or indirect helping. To collect data during the activity, we will use audio recorders and several observers. After the activity, students will break into two groups: the control and the treatment. Students in each group will form pairs and play the appropriate

version of the game before filling out a short questionnaire on engagement and motivation. They will disperse into small groups to perform another group activity, after which students will fill out a post-test once again pertaining to collaboration and knowledge of the subject area.

V. CHALLENGES

Although our research on the effects of collaborative scaffolding in educational video games will contribute both to academics and educators, there were considerations and concerns that needed to be addressed as we developed our system and that still need to be addressed as we finalize our study design. For example, in determining an appropriate game, it was important to remember that just because an activity appears collaborative does not mean it lacks implicit incentives for competition. In the workplace, two employees with similar jobs may work on the same project but try to discredit each other because of an upcoming job opening in management. In the classroom, a teacher may try to encourage collaborative skills by randomly assigning groups for a project, but group members may compete to look better by requesting the least help or finishing their part first. Actively avoiding help and rushing to finish a task can easily lead to subpar results. The teacher may choose to have students always work in the same groups to avoid such a case, but they will not gain experience in dealing with different types of people.

Technological challenges existed beyond the collaborative nature of the game. When using school computers, reliable internet access and computer permissions for installing software are not guaranteed. We developed a stand-alone Flash game for our trials because it will not need to be installed, and we will be able to store all logging locally to avoid potential issues with the internet. We also had to carefully approach our design of the scaffolding content and levels. Because the game is collaborative, students of varying gaming experience and learning abilities will share challenges and scaffolding feedback. This imbalance will potentially prevent group members from maintaining a state of *flow*: "the state in which people are so involved in an activity that nothing else seems to matter; the experience itself is so enjoyable that people will do it even at great cost, for the sheer sake of doing it" [48]. If the levels are too easy, players will get bored, but if the scaffolding is not helpful enough, players will get frustrated and may give up. To help ensure that our system will maintain an adequate balance, we will perform preliminary testing and iterate on its design.

The logistics of running our trials will also pose challenges. Because we will be working with children, they will need additional privacy protection. To this end, we will limit our data collection to computer logging, audio recording, and direct observation to avoid storing video records. In addition, we will not refer to students by name, and all data will be anonymized before analysis.

Running trials on-site at local middle schools and after-school programs will also have implicit challenges. Recruitment opportunities will be limited by the number of schools in the surrounding area due to the logistical limitations of performing trials far away. Scheduling will also be a major concern; we will need to work around holidays, standardized

testing days, and exams, as well as periods of inactivity, such as the summer break between academic years. Another timing concern will be within the trial itself, as class length and meeting times vary among schools and programs. Often they are too short to run an extensive session, but splitting a trail into multiple days leads to lost data due to student absences. For our work in particular, curriculum timing will also have an impact. If students have just covered the academic topic our game teaches, then they will have little need for the scaffolding, as the game will be too easy.

Although we have addressed many of the challenges thus far, there remain several unanswered questions we must tackle in the near future, including:

- How should we word instructions to participants?
- How does raw in-game data correspond to helping behaviors?
- What contingencies must we implement to account for real-world imperfections during trials, such as computer errors?

VI. EVALUATION

Collaboration is a broad and vague notion, yet our focus on the impact of collaborative scaffolding requires a method of evaluation. To deconstruct the concept and determine a focal point, we analyzed over 25 existing studies and surveys from a wide range of disciplines and with diverse target demographics. The resulting multilevel taxonomy is split into four components, each consisting of additional subcomponents.

The first component in our taxonomy is *group quality*: group aspects indirectly related to task completion. Even if group members are highly intelligent and capable of performing necessary functions, if members feel isolated, lack motivation, or simply do not get along, then group performance suffers. For example, when a conflict arises, ineffective conflict resolution can lead to a prolonged period of time wasted on overcoming the dispute rather than completing the task.

The next component is *coordination*: the methods that groups use to organize group members and their actions. Without coordination, a team cannot effectively distribute subtasks to maximize group performance, nor is it trivial to respond to environmental changes.

Coordination is usually achieved through effective *communication*. While this component does not encompass task-specific content, such as strategies, it does include considerations before message sending, apt response to message reception, and the appropriateness of message content. Without adequate communication skills, group members cannot articulate thoughts and opinions, which inhibits the ability to form a shared mental model and prevents the creation of an optimal strategy based on the informed opinions of group members.

The final component of collaboration is *support*: group members helping each other complete a task, satisfy a role, take on a responsibility, or understand a concept. The quality of support is based on many factors, including an individual's willingness, time, resources, and ability to help, as well as a person's understanding of the tasks assigned to group-mates. Without support, group members cannot build off of

each other's experiences and knowledge, meaning time is wasted learning without a teacher or mentor and re-developing solutions for obstacles overcome in the past.

For our evaluation, we chose to focus on two subcomponents of support: direct and indirect help. *Direct help* involves explicit aid through the supply of instructions, an explanation of what to do next, or the partial or total completion of a task assigned to another group member. *Indirect help* occurs through resource sharing or by providing guidance, education, structure, suggestions, advice, or constructive feedback. Instead of keeping these subcomponents vague, we selected an example of each to use in our study: performing part of a task for a group member (direct helping) and providing guidance to a group member (indirect helping). In our trials, we will count instances and note interesting examples of these actions during group activities and video game play.

VII. IMPLICATIONS

Because collaboration plays a key role in today's society, it is beneficial to prepare people at a young age for collaborative work. However, there is no academic or professional consensus on the most effective methodology. Through our research, we will explore one promising option: collaborative scaffolding in educational video games. No matter the results, we will gain invaluable insight into how we can approach collaboration education, which we will encompass in future design guidelines. Our work will help shape the collaboration education design space through its application to future software products and research. In addition, it will contribute to the validation of video games as an area of study and as an educational tool.

ACKNOWLEDGMENT

We wish to thank the University of Rochester Computer Science Department for their support and Henry Kautz of the University of Rochester for his invaluable guidance and suggestions. We would also like to thank the MIT Game Lab (formerly the Singapore-MIT GAMBIT Game Lab) (<http://gamelab.mit.edu/>) for allowing us to modify their game and use it for our research.

Project Management Game 2D (PMG-2D):

A Serious Game to Assist Software Project Managers Training

José Eduardo Nunes Lino, Marco Antonio Paludo, Fábio Vinícius Binder, Sheila Reinehr, Andreia Malucelli

Abstract - In these times of great changes, managing software projects effectively is a big challenge and it is increasingly more difficult to find skilled professionals. This paper presents the Project Management Game 2D (PMG-2D), an educational serious game that aims to assist inexperienced software project managers to be trained, considering cost, time, risk and human resources management areas. The PMG-2D simulates a real software development environment where the player, acting as a project manager, goes through all basic phases of a software project lifecycle. There are many roles in the team that have to be managed, and the members have different personalities in order to challenge the player when dealing with people and their conflicts and performance, among other characteristics. The mechanism implemented to control the character's personalities is based on the theory of the Five Big Factors, described by the lexical method conceived in the Psychology area. The evaluation was conducted within the context of a software engineering continuing education course, and 25 participants have played the game and answered a questionnaire. When analyzing the results, it was possible to find evidence that the game, besides assisting the project management training, stimulates the player to learn more about it.

Keywords - Electronic Learning, Unsupervised Learning, Project Management, Management Training

I. INTRODUCTION

A project is an essential tool for any changes of product and service activities. It may involve only one or thousands of people, organized into teams and its duration can be from a few days to several years. As stated by the ISO 10006 technical standard, a project is "a unique process consisting of a set of coordinated and controlled activities with start and finish dates, undertaken to achieve an objective conforming to specific requirements, including constraints of time, cost and resources." [1]

When considering some growing scenarios of rising domestic market, as presented by [2], it is evident the need for qualifying project management professionals, considering that it is a real challenge to manage software projects effectively and it is hard to find available and qualified professionals with this expertise. Many reports point out the main cause for software project fails as the lack of project management activities and skills. It is also stated by [3] that large scale software projects are like puzzles that need to be solved, once the manager follows a well documented management processes, making all parts fit together and in the right place.

One question that this work aims to answer is if it is possible to manage projects, make decisions, take risks and

also make mistakes without compromising the real projects for the organizations, and at the end even learn with right and wrong decisions. The base for stressing these possibilities is the Project Management Game 2D (PMG-2D), a serious educational game, which intends to help inexperienced project managers to be trained, considering the management of costs, time, risk and human resources.

Educational games are excellent tools to improve the teaching-learning process because they stimulate and inspire the students, providing a more attractive and ludic way of learning. They are different from traditional approaches because they encourage participants to achieve goals due to lack of resistance and fear of failing [4]. However, it is not enough to use any kind of game within any activity. In order to effectively learn and better retain the practices, the students have to be more active and use instructional methods in which they participate in cognitive tasks of higher levels, as stated by [4]

Recently many educational games are being used to teach software engineering and project management, like SimSE [5], PM Master [6], SESAM [7], among others. When using a game, it is possible to simulate the behavior of some professional roles, as in PMG-2D in which the objective is to stress the actions and decisions that a project manager could take. The idea of using this game is to provide inexperienced project managers the opportunity to deal with many professional challenges, in a fun and motivating way, leading the participant to act and take his own decisions.

Within this context, this paper presents the project that planned, designed and implemented the Project Management Game 2D, aiming at teaching inexperienced project managers some of the most important concepts and approaches of project management, at the same time that it tries to be challenging, motivating and fun.

The rest of the paper is organized as follows. In section II, the background of the factors of personality used and concepts of serious games are presented. In section III the research method is explained and in section IV the project and the product features are presented. Section V discusses the evaluation results and, finally, in Section VI, the conclusions and future lines are given.

II. BACKGROUND AND RELATED WORKS

This section will provide the theoretical approach used to determine the NPCs (non-playable character) personality and

the way they work and interact within the game context. It also presents the concepts of serious games that form the basis of the game.

A. Five Big Factors

The Five Big Factors model was conceived in the 30s by the British Psychologist William McDougall [8], who had suggest analyzing the personality of people considering five factors, in order to define a profile for human personality.

However this model has just spread and gained attention from the 80s on, when researches had started to prove the existence of the five basic personalities traces. So, in the last decades many respectful psychologists had agreed with the Five Big Factors [9]. The personalities imposed to the characters of the PMG-2D game are those presented by William McDougall: neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness.

Considering that the goal is not just to ascertain the project employee's personality, but also to define its final state, some new attributes were introduced. Composing all the attributes and the factors, it was possible to conceive an "if-then" rules decision tree, thus classifying a state of personality. Following are presented the attributes that are also considered by every character of the game: stress, food, physical, health, relationship (with friends and family), motivation, adaptation, interest, experience, training, cooperation (with company employees).

When analyzing the Five Big Factors previous works it was possible to better understand the personality factors, which attributes are more relevant and to what other attributes these main five factors are mapped. Some questionnaires were created in order to better understand the factors and among them, the NEO-PI-R (Revised NEO Personality Inventory) conceived in 1992 by the researches Paul Costa and Robert McCrae is here emphasized. To answer the questionnaire, the authors have proposed a table dividing the factors into six facets, as presented in Table I.

These facets were largely used to conceive the algorithm that controls the state of each NPC that will play a role during the project, in the game.

B. Serious Games

A serious game is a software or hardware conceived following the principles of interactive game design, aiming at transferring concepts and knowledge to the user.

TABLE I. FACETS OF NEO-PI-R QUESTIONNAIRE

Neuroticism	Extra-version	Openness to experience	Agreeableness	Conscientiousness
Anxiety	Warmth	Fantasy	Trust	Competence
Angry Hostility	Gregariousness	Aesthetics	Straight-forwardness	Order
Depression	Assertiveness	Feelings	Altruism	Dutifulness
Self-Consciousness	Activity	Actions	Compliance	Achievement striving
Impulsiveness	Excitement seeking	Ideas	Modesty	Self-discipline
Vulnerability	Positive emotions	Values	Tender-mindedness	Deliberation

The origin of using games with the educational purpose precedes the current technological revolution and widespread use of computers. One of the first serious games was considered the Army Battlezone, a project developed by Atari in the early 80s that was created to train soldiers in a simulated battlefield [10]. Michael and Chen define a serious game as a game in which the education (in its many forms) is the main objective, other than the entertainment.

Some recent approaches consider more complex environments where the objective is to get the users to feel immersed in a presentation or situation as if they were inside a real environment. These environment are called Immersive Virtual Environments and demand a very complex set of hardware and software, as can be found in 3d head mounted displays and full-domes projection rooms, using 3d, surround sound, high realism, large field of view etc.

These technologies can provide the sensation of presence and immersion to the user, but the cost to have these facilities and the lack of tools and complexity to develop proper software make them a very expensive option. [11]

The concept of immersion is the intensity that the system presents information about the virtual world to the senses compared to the extent these senses if received from the real world [12]. The presence concept is the subjective sensation of feeling inside a real environment and the extent to which the user responds to the virtual environment as if it was the real environment [13]. The main difference between them is the fact of the user is included in the narrative in the presence.

Both immersion and presence, with special emphasis in the last, were considered during the development and evaluation of the game, but with very limited expectations due to the target environment: a regular personal computer and small screen, with no extra hardware or even special tool other than a two dimensional game framework. The evaluation questionnaire was partially built considering the presence evaluation tool, as proposed by [14]. Some of the dimensions considered during the evaluation of the game were control, concentration, feedback and balance between challenge and skill.

The evaluation of a simulation game is a complex matter, as stated by [15], and some of the dimensions proposed by the UGALCO frameworks, as challenge, competence, immersion and positive effects were also considered to conceive the evaluation questionnaire.

Some related works are SimSE [5], a software engineering simulation game where the student plays the role of a project manager experiencing all phases of the life cycle, dealing with the team and resources of the project. It is a digital game and can be played by just one person. Its main weaknesses are: the lack of a proper game; the lifeless art and the poor feedback both visual and auditory. It is more a simulation than a game, as it lacks some important game's features, like: aesthetics that are rich both visually and spatially and that immerse players in worlds that seem real [16].

Another work considered is the PM Master [6], which is a board game with questions about project management in some knowledge area, as scope, time, quality and others. The player that first answers the set of questions correctly wins the game.

It is necessary to have groups of 4 to 6 players for each round of the game. It is a very limited game based only on questions and answers about project management. It is not very engaging neither motivates students to play again. It also lacks more enticing features of games and has no meaningful mechanics of play. It does not provide a sandbox environment where the players can explore a project development cycle, elaborate plans and make interesting decisions.

The ProGames [17] is a serious game that teaches programming by playing games. This work adopted an evaluation approach of four dimensions considering usefulness, ease of use, ease of learning and satisfaction. From the 29 questions, some of them were considered in the evaluation questionnaire of this work, like "It is pleasant to use", "It is user friendly" and "I am satisfied with it" and some other similar.

Lost in Space [18] is a game that teaches XML where the player controls a ship by performing tasks assigned with instructions in XML. Some common characteristics with the PMG-2D game is that both tries to practice time pressure handling, establish clear and defined objectives and calculates the score of the player, in order to train and show the progress as the game advances.

In [19] the authors propose a game focused on teaching requirements collection and analysis at tertiary education level. Once requirements phase is known as the most challenging phase of the entire lifecycle, the focus of this game was to lead students to practice such activities in order to improve their knowledge and skill to deal with the difficulties of this phase.

III. RESEARCH APPROACH

The research method used follows the guidelines proposed by Jean-Marie Van Der Maren [20]. The author proposes three different approaches to conduct a research project: the Evaluation Research, the Intervention Research and the Development Research. The last approach was the selected due to the characteristic of the project that matches the subtype Object Development Approach, aiming to develop an object by analyzing the needs (requirements) and producing tools, techniques or strategies. In this case the deliverable is a serious game, altogether with the supporting documentation that is used to teach project management.

The Object Development Approach has four phases: Market Analysis, Object Analysis, Preparation and Development, as following described:

1) Market Analysis (Context Analysis)

This phase of the method aims to identify the research goals, needs, motivation and the main participants involved. When performing this phase, the correlated works were identified, mainly considering serious games for software engineering.

2) Object Analysis

Based on the Market Analysis, the Object Analysis phase defines the object in order to build a model, which is a consistent representation of the project's elements, still in a preliminary stage. This phase is divided into two parts: object's conceptualization and object's modeling.

During this phase it was identified a need to search for works about personality models and serious games. A plan was made based on such searches that included the main mechanics of the game, target audience and possible contributions.

3) Preparation

Once the research object has been conceived as a model and its representation is considered stable and coherent, the Preparation phase starts defining possible alternative strategies for the project, evaluating these strategies and after selecting and building the prototype, as the materialization of the object. In this phase the Game Design document was prepared based on the previous definitions and the game was implemented in C/C++ using the framework Chien2D 2. A set of preliminary tests was performed and improvements were made based on the feedback of the authors.

4) Development

The last phase of the research method can start when it is possible to have a prototype of the research object and its evaluation can be done. A cycle of tests, evaluation and change has to be conducted up to the point when the object is considered in compliance with the specifications and can be released to the market or for practical use. The work followed these steps of the method and after some cycles of tests, evaluation and changes, the game was considered ready to be evaluated. A structured questionnaire was conceived and the game was executed under a monitored and controlled environment with 35 professionals of information technology, who stressed the game and answered the questionnaire. The results of this phase are presented in the evaluation section of this paper.

IV. PMG-2D DEVELOPMENT PROJECT

During the Object Analysis and Development phases of the research method, the software development process used the incremental approach and the following modeling assets were developed: project charter and project plan, requirements specification, use case diagram, class diagram, activities diagram, sequence diagram and state diagram, use case specifications, test plan and test cases. The concepts that the game intended to teach were discussed during its development in order to evidence their importance to all members of the research team.

A partial and adapted version of the use case diagram of the PMG-2D project is presented in Figure 1, and shows part of the activities the player, within the role of a project manager, has to perform. This can be considered the iterative part of the game. The other functionalities are internal and respond according to the stage of the project during the game and the algorithms that treat all relationships of the project stage, team and employees' status and intervention of the player as the project manager.

An employee can perform the following activities: develop solution, test, deploy, send message, resign, be late, have difficulties, refuse overtime, leave earlier, argue with others, give feedback, attend meetings, ask for rest, get sick, among others.

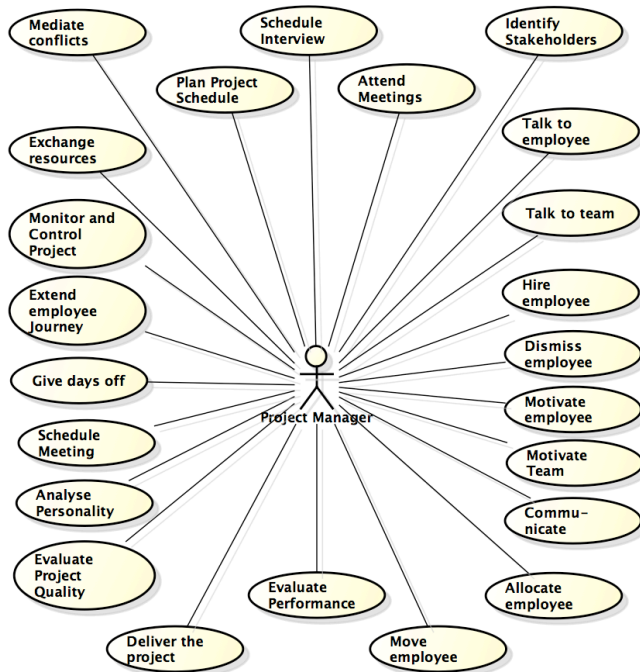

Fig. 1. Partial use case diagram with Project Manager actor.

The employee class has 38 main attributes, besides the Five Big Factor previously presented, and among the most important are: capability, experience, interest, adaptation, motivation, relationship, health, physical conditions, stress, responsibility, union, performance, training, work schedule, salary, position, feedback, problems and others.

Each of these attributes have scales that vary as time passes during the game play, according to if-then rules based on a decision tree, and also considering random situations, in order to bring more reality to the game. Most of the attributes also vary taking into account the relationship with other attributes, for instance, it is very likely that an employer will argue with others if his/her stress level is high and the relationship and salary attributes are low.

To illustrate the inner workings of the algorithm, let's consider one of the rules: performance of the employee. First, it is necessary to compute the Activity and Personal attributes and then get the Performance attribute, which will determine the amount of work the employee will be able to perform in a fraction of time, as following:

Performance = (Activity * 0.35) + (Personal * 0.35) + ((100 - Neuroticism) * 0.05) + (cordiality * 0.05) + (Responsibility * 0.20)

Activity = (Capability * 0.30) + (Experience * 0.3) + (Interest * 0.2) + (Adaptation * 0.2)

Personal = (Relationship * 0.2) + (Motivation * 0.25) + (Union * 0.2) + ((100 - Stress) * 0.25) + (Salary * 0.1)

Most of the attributes are related to other attributes and the final state of the character personality results from the composition of them all, considering 38 different aspects that have direct influence to his/her performance, relationship, health, stress, motivation among others.

A. PMG-2D Execution Life Cycle And Features

The game PMG-2D was structured in five groups representing the life cycle of the project management process according to PMBOK [21]: initiation, planning, execution, monitoring / control and finishing.

The game starts in the initiation phase where the project manager must identify the project stakeholders. The game presents the project charter so the player can understand the overview of the project. The next phase is the planning phase that will point to the player the need for a requirements analysis. To guide the player in this process the game presents the work breakdown structure (WBS) for the project. The main goal of the player is to create a roadmap for the project.

Next phases are execution and monitoring/control. The player will be trained in the abilities of cost management, time constraints, risk and human resources. To make the game more interesting, the manager has its own basic needs that must be fulfilled and if they are not, the project may not be complete in the best possible way due to the absence of the project manager during working time.

Some screenshots of the game execution are following presented, considering different phases and places where the project manager interacts with the game. Figure 2 shows where the Project Manager character starts the phase and is also where he or she rests, eats and does basic needs. In the office, as shown in Figure 3, the player can select the doors that will provide some actions, as hire or dismiss employees, monitor and control the evolution of the schedule and budget of the project, attend meetings with the team or clients, and analyze and make decisions concerning the employees and their allocation to activities.

The dashboard of current status of team members is presented in Figure 4 and shows all members of each role: developers, testers and supporting personal. The activity progress bar of each member is shown, as well as their status and location, and the overall information of the project as budget and client's evaluation.

Fig. 2. Project Manager at home

Fig. 3. Project Manager selecting the rooms of the office.

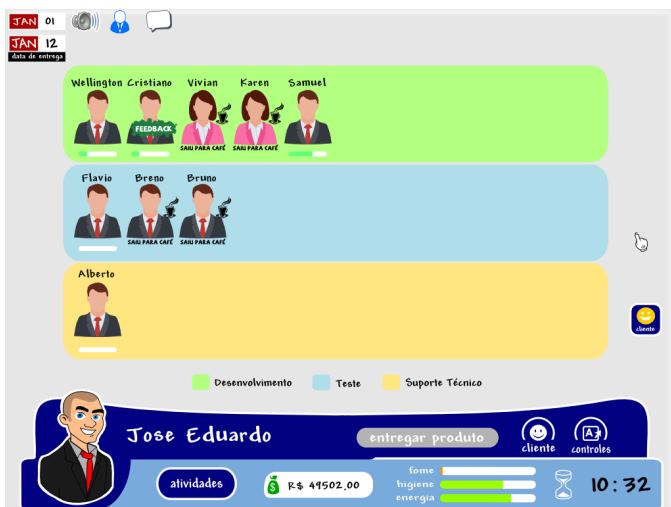

Fig. 4. Dashboard of team members.

Another important functionality of the game is presented in Figure 5, showing for each activity of the schedule: phase in the project's life cycle, complexity, current status, responsible employee and allocation conflicts. This dashboard has to be frequently accessed in order the player to know the current scenario and make decisions concerning the team allocation and even team composition.

As the project evolves in the game, it is necessary to monitor the activity of all team members in order to avoid having too many employees that are specialized in a role not anymore needed or with lack of members to other demanding activities. The game also presents a Gantt chart to show the progress of the different project activities.

Whenever the player makes a wrong decision, the game shows alerts of what went wrong and what could have been done to correct the action. It also presents the chapter and section in the PMBOK where the player could get more information about that specific topic.

Fig. 5. Schedule of the project

At the end of the execution, monitoring/control phase, when all scheduled activities have been finished in order to deliver the product, the last phase starts, showing its most important topics. A final score is presented as a result of the correct and incorrect decisions of the player during the game. The objective of the score is to compare the player's performance taking into account his or her previous run, or to compare the performance of a group of participants or even an entire class.

V. EVALUATION AND DISCUSSION

The evaluation consisted of a practical use of the game by a group of 35 professionals. The participants were software development professionals, all with a higher education degree and attending to a specialization course. The execution of the game took 60 to 90 minutes in order to perform all steps of game.

After playing the game for the first time, participants were asked to answer a structured questionnaire. The evaluation instrument was conceived with 51 questions addressing all the phases of the game and all matters of software project management the game intended to teach.

The first part of the questionnaire was dedicated to learn about participants' profile, asking him about previous professional background and current job and company. Among the organizations that they work for, a wide variety was identified from small local software development organizations up to global large ERP players.

A. Motivation

One of the first questions concerning the motivation to play the game was if the beginning of the game had something interesting that called their attention. It was observed that 84% of participants agreed with this statement: 40% totally agreed and 44% partially agreed. In the begging of the game all instructions are presented and there are some animations representing the initial phases of a project, and some concepts are presented (the project charter and work breakdown structure of the project), so it is possible to understand that graphical and interactive approaches are interesting and called

the participant's attention to the game. Also another motivation factor that was addressed was that 88% of the participants agreed that the design of the game is attractive, what was considered a great concern during the design and conception phases of the game development.

B. Relevance

The next section of the questionnaire considers the relevance of the game to the participant, and one question called the attention of the authors that asked them if the content of the game was relevant to their interests, and 96% agreed, also 68% of them totally agree, making this answer the largest amount of totally agree answer of all questions. So the participants were considered as very well interested in learning about project management and really involved with the execution and evaluation of the game.

According to one question stating that the participant had liked the game in the extent that he/she would like to even learn more about the matters addressed by the game, 92% of them agreed, so it is possible to infer that one of the goals of the game was achieved, when trying the teach and promote more interest in software project management.

Still in the relevance section, more than 92% agreed that the content of the game was relevant to their interests and that what they could learn with the game was useful. It was considered a very positive result because the first questions tries to identify if the content is relevant but the second question is more specific considering the learned content, this last being event greater the amount of participants that agrees with 96% against 92% of the previous question.

C. Confidence

The third section of the questionnaire evaluated the confidence of the participant when playing the game. Here it is possible to evidence that some participants had faced some difficulties managing the project proposed by the game. A significant percentage of them, 40% partially agree that the game was more difficult to understand than they would wish and 32% of them considered that the game had so much information making it difficult to identify and remember important goals of the game, as presented in Figure 6.

Fig. 6. Question: the game was more difficult to understand than I wish.

The three other questions addressing the confidence of the players presented positive results, showing that just 20% of the participants partially considered the activities difficult, 20% stated that could not understand a significant portion of the game material and, finally, just 4% of them found the content of the game so abstract that it was difficult to keep the attention to the game.

D. Satisfaction

The satisfaction when playing the game was measured with some questions and the first showed that just 56% had experienced the feeling of satisfaction when completing the exercises of the game, and 28% were indifferent to this matter, showing that the challenges could not generate a great satisfaction to the players. Another question, concerning if the feedback after the exercises or other comments of the game helped the player to feel rewarded for the effort was not conclusive due to the diversity of the results obtained, as seen in Figure 7.

The last result from this section was the statement that the player felt good when completing the game, with 48% agreeing, 28% being indifferent and 24% disagreeing. Some participants faced some problems to complete the game due to the time it took for them, so at the end some interactions were made faster than they would like, causing this result.

E. Immersion

Six questions addressed the immersion sensation when playing the game and most of them resulted in positive results, as 88% affirmed that had put effort to get good results, 16% affirmed that in some moments desired to quit the game, 74% felt stimulated to learn with the game and 76% had not noticed the time passing during the game.

Two other questions presented some more diffuse results, but it was expected because the challenges of the measured characteristics were greater. The questions were if the player lost consciousness of what was happening around him or her while playing, and if the player felt himself or herself more inside the game environment than in the real world. Both questions had approximately the same results of agree and disagree answers.

Fig. 7. Question: feedback after the exercises or other comments of the game helped the player to feel rewarded for the effort.

Fig. 8. Question: I like playing this game for a long period.

F. Challenge

The challenge of the game has showed adequate considering the first three items evaluated in this section of the questionnaire, all showing more than 76% of agreement considering that the participants had liked the game and did not felt anxious our tedious, also that the game kept them motivated to continue using it, and lastly that their skills had gradually improved as the challenges were overcome. Two other questions with less agreement stated that 68% of the participants consider that the game offers new challenges in and appropriate rhythm and 60% considers that the game is appropriately challenging, with tasks not too easy or difficult. In general, the challenge was considered adequate and also the gradual evolution of the phases.

G. Skills and competence

The skills and competence developed were evaluated as positive by 84% of the students that felt they were making progress, but the other aspects measured indicated some issues as just 64% of them felt succeeded, 48% felt competent and just 44% considered that had achieved rapidly the goals of the game. Some imposed tasks of the game, as the conception and monitoring of the schedule and budget of the project, are really challenging and the consequences of the decisions taken and the results to the project are not an easy task, especially for those with few or no experience in project management.

H. Fun

The section of the questionnaire that evaluated the fun when playing the game showed some diverse results. Some questions presented positive results as 80% of the participants affirmed they would like to play the game again, just 20% found the game with a bad dynamic, and just 12% were hoping the game to end soon. One specific question showed no convergence because when asked if when interrupted the participant was disappointed that the game had ended, almost one third of the participants agreed, one third disagreed and 40% were indifferent, leading the authors to consider that even the interpretation of the question could have generated this dubious result. Another question also have presented some diverse results, as presented in Figure 8.

The last question that tried the identify the fun of the game showed that 68% of the participants have not found problems in having fun with the game, but 20% were indifferent to this

matter and it raised an alert for the authors in order to identify the exact issues that causes this feeling, but some were informally identified as the large number of activities needed to compose the schedule of the project and the constant monitoring and control of the team and skills to accomplish the original plan.

I. Knowledge

The last section evaluated the knowledge of the player after the execution of the game, and all three items resulted in a very positive scenario, as 84% of the participants consider they can remember more information related to project management, 84% consider they can better understand the matters presented by the game and, finally, 84% stated that they can better apply the concepts related to the game. The last two questions had none of the participants disagreeing with the questions.

Considering that the participants were professionals holding an under-graduation diploma and had experience in software development projects, not necessarily as project managers, the results were considered to be very positive and indicate that this approach to teach software development project management concepts is effective and has a very wide field of application.

VI. CONCLUSIONS

Considering the challenges to hire experienced project managers, or even to train new ones, the Project Management Game 2D was planned and conceived to help inexperienced software project managers to learn common concepts and project management activities such as cost, time, risk and human resources management areas.

The game was conceived considering all phases of a project lifecycle and tries to stress all major milestones and some important artifacts involved within software development projects. The player, in the role of a project manager, is immersed in a project that has limited human and financial resources, as well as a challenging schedule, and is challenged to take decisions that will be analyzed and evaluated by the game, receiving feedback of mistakes and tips to learn how to deal with specific situations.

All decisions have consequences and will affect the rest of the project, making it a very dynamic and involving experience. At the end of the play a score is shown and, along with all messages presented during the execution of the game, they show the performance of the project manager. This will stimulate the student to improve his knowledge and play the game again.

The mechanism implemented to control the character's personalities is based on the theory of Five Big Factors [19] and also implements if-then rules based on a decision tree to determine the state of each project team inside the game. The skill to deal with the employees and the large possible combinations of factors are important issues that the player has to deal with during all phases of the simulated project.

The evaluation of the game was made applying a structured questionnaire to professionals that have played the game and answered the questions concerning the following sections:

identification and experience, followed by the specific evaluation of the game considering the motivation, relevance, confidence, satisfaction, immersion, challenge, skill and competence, fun and knowledge. In all sections it was possible to evidence that the game has met its goals, with special attention to motivation, relevance, satisfaction, fun and knowledge.

This work may be improved in two areas: in-game improvements and evaluation process.

Regarding in-game changes, one feature that is intended to be implemented in the future is a “save and continue” option, as the current version of the game just implements a pause option. It is also planned to implement other aspects of PMBOK that were not implement in the first version. Also an important activity that will soon be performed is the translation of the game from Brazilian Portuguese to English, in order to expand the target professionals and students who could use the game to learn concepts of project management in an autonomous way.

The evaluation process may consider other approaches, like meta-cognitive strategies [22]: recording, modelling and thinking aloud. The PMG-2D game may benefit from this student self-conscious analysis due to its subjective nature regarding the knowledge acquisition. Such approach may help to identify what parts of the game play are not helping the students to make better decisions. Another step to improve the evaluation process will be submitting it to a group of professionals to play the game for two or more times. As reported by [18] the participants that played the game Lost in the Space for several times, showed a considerable improvement in their performance, demonstrating the learning process success due to the recurrent execution of the game.

Abstract—We propose a new active learning activity called “slecture” (a contraction of the words “student” and “lecture”). In this activity, students create online lectures based on the in-class lectures of their course instructor, and post these online lectures on a publicly accessible website. As an experiment, slectures were integrated into the mandatory assignments of a large engineering graduate course with a diverse student population. In our implementation, the students were free to pick the topic (from a list provided by the instructor), medium, and language of instruction. The students’ slectures were peer-reviewed at the end of the semester, and full credit was given for timely completion of the assignment. In a semester-end survey, students indicated that they learned more from making a slecture than from the other active learning techniques employed throughout the course. Furthermore, nearly 60% of the students rated the learning value of making a slecture at least as high as that of attending the lectures. The high level of enthusiasm for the slecture creation, especially among students who rated the learning value of the classroom lectures lower than the rest of the class, suggests that this activity may be a good way to engage students and stimulate learning.

Keywords—*active learning, learning-by-teaching, online lectures, graduate students*

I. INTRODUCTION

Active learning has become a common pedagogical approach in undergraduate engineering classrooms in the past years, including flipped classrooms, clicker use, and project-based learning. Such types of “learning by doing” and others have been shown to engage students and promote learning [1]. One reason active learning is effective is because it reaches students who learn better via different channels than traditional lectures [2]. By employing a variety of teaching strategies, an instructor can more successfully reach students who have different learning styles.

On the graduate level, much of the discussion of active learning has focused on training graduate teaching assistants to integrate active learning methods in the undergraduate

courses they teach [3]-[5] or on integrating peer review work in graduate courses [6]-[8]. The somewhat limited literature on active learning in graduate engineering courses raises the question whether these students also can benefit from other types of active involvement in their classes. However, there is a need to convince sometimes reluctant graduate students of the benefits of these other activities [9]. Hofstede’s work on “(in)tolerance of ambiguity,” later expanded by Selinger, has shown that students from collectivist/ambiguity-intolerant cultures, from which many engineering graduate students come, may be uncomfortable with pedagogical contexts which are not as structured or instructor-centered [10].

Nevertheless, instructors at many levels of education anecdotally note that their own knowledge of their course material has increased by the need to explain it to their students. Thus, it is not surprising to discover the multidisciplinary richness of the “learning-by-teaching” literature [11]-[13]. In fact, one study found that preparing for, and then actually teaching some information may result in long-term learning for the person doing the teaching [14]. Many of these “learning-by-teaching” activities include the use of online platforms as a way to further engage these students who have grown up in a digital environment [15].

Building on the learning-by-teaching principle, co-author Boutin developed an innovative active learning activity she named “slecture,” a contraction of the words “student” and “lecture.” As described in Section II, slectures are online lectures created by students based on the teaching material of a professor. These online lectures are posted on a free and publicly accessible peer-learning website; they are not formally reviewed or graded by the instructor before being posted. The goal of this active learning activity is to increase student engagement and learning, while promoting the development of students’ communication skills.

This paper describes a simple mechanism for integrating slectures within a graduate course. It also describes a small pilot experiment in which we implemented this mechanism and surveyed the students to gather their impressions of the learning effectiveness of this new active learning activity.

Our preliminary results indicate that the students involved in the experiment found the educational value of creating slectures to be almost on par with that of attending the

classroom lectures. In fact, those students who were less satisfied with the classroom instruction than the rest of the class actually showed a preference for developing slectures over attending the lectures. In contrast, other forms of active learning with which we experimented were perceived as less valuable, from a learning perspective, than both the classroom instruction and the slecture creation. While our data is too limited to enable us to draw any firm conclusion, the results of this small pilot experiment are very encouraging.

II. BACKGROUND ON SLECTURES

Slectures were invented by Boutin in 2010 as part of an online learning project called Project Rhea [16]. The goal of Project Rhea is to encourage students to create learning material and share it with their peers online. This is done through a publicly accessible website on which the material is archived and organized.

Slectures were invented as a mechanism to encourage students to create online learning material on the Project Rhea website. The idea is to have students create online versions of their professors' courses. While the students get permission from the professors to use their teaching material, it is the students who bear the responsibility for the accuracy or correctness of the online courses they publish.

The first slectures were created in 2010 by Maliha Hossain, a master's student in the School of Electrical and Computer Engineering at Purdue [17]. These slectures were based on the image processing lectures (ECE637) of Prof. Charles Bouman. Hossain subsequently created slectures for a graduate course on the topic of random variables (ECE600) taught by Prof. Mary Comer [18].

These online courses thus created generated a significant amount of interest, not only from students who subsequently took these graduate courses for credits but also from web users from around the world who found their way to the Project Rhea website through search engines. Hossain praised the activity for helping her learn the material significantly better than had she merely taken the courses.

III. INTEGRATING SLECTURES INTO GRADUATE COURSES

It seems plausible that a large number of graduate students could benefit from making slectures for their classes, but few students can commit the time necessary to build slectures for an entire course, as Hossain did. However, one can build an entire online course by dividing the semester's material into short topics and asking each student to create a slecture for one specific topic; by combining the slectures for all topics together, the material for the entire semester then can be made accessible online. This is an activity that can easily be integrated inside an existing graduate course as a homework assignment.

The issue of quality may be a concern: one could imagine that not all students would put in the effort to create excellent material, which would affect the value of the resulting online course. One way to mitigate this is to assign more than one student per topic, thus covering each topic more than once, potentially in different ways. While this creates a healthy amount of competition among the students covering the same topic, the probability of obtaining at least one usable slecture per topic is increased. The quality concern can be further alleviated by encouraging students to publish under their real name, thus strengthening ownership and responsibility. While

this cannot be mandatory because of FERPA and other privacy issues, we found that the vast majority of students quite willingly did so.

IV. PILOT EXPERIMENT

Our study was conducted in 2014 in a graduate course on machine learning taught by Boutin. The enrollment for the course was fairly large for a graduate course, with 66 students from multiple disciplines, including computer science, mathematics, as well as electrical, computer, civil, nuclear, and industrial engineering. There were both masters and PhD students in the class with a mixture of domestic and international students. Because of the widely varied backgrounds of the students in the class, the lectures were conducted in a flexible style, with the instructor adapting her instruction to students' questions as they arose.

Making a slecture was a mandatory assignment for the course, counting for 8% of the course grade. The course was divided into 16 topics by the instructor, with each topic covering about one week of the course material. For the reasons of quality mentioned in Section III and due to the large number of students in the class, each topic was covered by more than one students. To increase the diversification between the slectures covering the same topic, we allowed students to choose the medium of instruction (text, video of student explaining at the blackboard, video of a hand on paper with audio, or a PowerPoint presentation with audio). Since there were many international students, we further increased the variability by allowing students to choose the language of instruction.

Each slecture was peer-reviewed by another student in the class towards the end of the semester. The peer review was posted online in the Comments/Questions section of the slecture, and counted for 2% of the course grade. The peer review allowed all students to receive feedback on their slecture, a task which would have been overly burdensome for the instructor alone to undertake. Full credit was given for timely completion of the slecture/peer review, regardless of correctness or clarity.

In addition to the slecture creation, the course also included three open-ended homework assignments. Specifically, after some pattern recognition techniques had been covered in class, the students were instructed to find a data set and use this data set to experiment with these techniques for comparison purposes. The nature and extent of the experiments was not specified, so the students were free to build their experiments as they saw fit. A description of the experiments, along with the results and conclusions, were to be presented in a formal report. Each of the students' reports was subsequently double-blinded peer-reviewed. This was done through the Project Rhea website, which includes an application (Mediawiki extension) for double-blind peer review. Thus, each report was anonymously reviewed by another student following specific guidelines. In particular, when preparing the peer reviews, the students were instructed to summarize the work described in the report, comment on the positive aspects of the work, and provide constructive feedback regarding the aspects of the work that could be improved. They were also asked to give a grade based on a pre-specified rubric. However, the students were reassured that the grade assigned by their reviewer would not necessarily be the grade assigned by the course instructor.

TABLE 1: STUDENT-PERCEIVED LEARNING EFFECTIVENESS FOR DIFFERENT CLASSROOM ACTIVITIES

	Classroom instruction	Hmwk	Peer-review of other student's hmwk reports	Read peer-review of own work	Make a slecture
Av. Score (out of 10)	8.24	7.71	6.98	6.48	8.17
SD	1.91	2.36	2.5	2.45	1.94

TABLE 2: STUDENT-PERCEIVED LEARNING EFFECTIVENESS OF SLECTURES VERSUS CLASSROOM INSTRUCTION

	Rated slecture higher than classroom instruction	Rated classroom instruction and slecture equally	Rated classroom instruction higher than slectures	total
# students	14	11	17	42

V. RESULTS

A total of 60 students successfully completed the slecture assignment. Of those, 40 chose to do it in the form of a “text” (i.e., Mediawiki mark-up language with equations typed using Latex code), and the remaining 20 chose to produce a video (either a video of the student explaining at the blackboard, the student’s hand on paper with audio, or a PowerPoint presentation with audio.) Ten students produced slectures in languages other than English; two students provided an English translation for their foreign-language slecture.

While the students were provided with lecture notes to use as the basis for their slecture, the material created by each student tended to be quite unique beyond the choice of medium or instruction language. For example, some students chose to cover the topic in detail, adding mathematical proofs, background material, or new examples. Other students provided a concise summary of the material, focusing on presenting the theory in a complete and logical fashion but without any extraneous material.

Students were surveyed at the conclusion of the semester to ascertain their preferences for the different active learning techniques employed in the course. Specifically, they were asked to rank on a scale from 1 to 10 (10 being the highest), how much they learned from a) classroom instruction, b) homework assignments, c) peer reviewing someone else’s assignment, d) reading the peer review of their own homework assignments, and d) making a slecture. Of the 66 students enrolled, 42 students responded.

Table 1 summarizes the average score and standard deviation (SD) for each activity. As one might have expected, the average score for “classroom instruction” is the highest. Although our results are limited, a tailed t-test indicates that the comparison is statistically significant for two of the

comparisons, namely “classroom instruction” versus “peer-review of hmwk” ($p=8.3 \times 10^{-4}$), and “classroom instruction” versus “read peer-review” ($p=6.9 \times 10^{-7}$). The two other comparisons, “classroom instruction” versus “hmwk” ($p=0.0615$) and “classroom instruction” versus “make a slecture” (with a very large p value at $p=0.4142$) are too close to be statistically significant at the 5% level). Indeed, the score for “make a slecture” is nearly as high as that of “classroom instruction.” More detail is given in Table 2, where we see that 17 students said they learned more from attending the lectures than making a slecture; 11 indicated equal preference for the two activities; and 14 said that they learned more from making a slecture. Thus, nearly 60% of the respondents (25 out of 42) indicated that creating a slecture was at least as valuable, from a learning perspective, as attending class.

The high perceived value of the classroom instruction is illustrated in Fig. 1, which shows the distribution of the scores for this activity. Indeed, most of the scores are tightly clustered near the top. However, there were some students (five out of 42—nearly 12%) who were less satisfied with the classroom instruction than the rest of the respondents: these are seen as the few scores scattered between one and seven.

This clustering of scores suggests using the value of seven as a threshold to divide the students into two groups: those who were generally satisfied with the educational value of the classroom instruction, and those who were not. Comparing the scoring pattern of the students satisfied with the classroom instruction with those who were not reveals an interesting pattern. In fact, as shown in Table III, the students who gave a high score for the classroom instruction did not tend to prefer any of the active learning activities over the classroom instruction. Among this group, the slectures were the learning activity that was the least disfavored, with a score only 0.3 points below the classroom instruction score, on average. In contrast, the students who were less satisfied with the classroom instruction preferred all three active learning activities over the classroom instruction, on average. Within this group, making a slecture was the most preferred activity, with a score of 1.6 points above the classroom instruction score, on average.

Fig. 1. Histogram of Classroom Instruction Scores

TABLE 1: PREFERENCE OF ACTIVE LEARNING ACTIVITIES OVER CLASSROOM INSTRUCTION

Classroom instruction score	Average of difference between slecture score and classroom instruction score	Average of difference between peer review score and classroom instruction score	Average of difference between hmwk score and classroom instruction score
<7 (5 students)	1.6	0.2	0.4
>7 (37 students)	-0.3	-1.46	-0.64

VI. DISCUSSION

The fact that, overall, attending the classroom lectures was the preferred learning activity supports research that indicates that students who have not been previously exposed to active learning may prefer the type of instruction to which they are accustomed [10]. Other research also points to potential cultural and nonverbal explanations for some students' discomfort with online peer review [10]. However, when we split the students based on their perception of the educational value of the classroom instruction, the pattern that emerges suggests that a fraction (about 10%) of the students may be significantly more interested in active learning activities, and less in the traditional lectures, than their peers. Among the active learning activities with which we experimented, these students showed a marked preference for

making slectures. On the other hand, even the students who enjoyed the classroom lectures ranked making slectures higher than the other active learning activities, ranking it nearly as high as the classroom instruction.

Thus, slectures appear to be generally a well received way of engaging students in a graduate course, including students with different learning styles. This could be because of the inherent nature of the work, which has a very student-centered focus that promotes creativity; other than being restricted to choose from a list of relevant topics, all the other decisions on slecture format and content were left to each individual student to make. It is possible that this freedom allowed the students to draw on their preferred learning styles.

Several students commented on the efficacy of the "learning-by-teaching" aspect of creating their slectures. "Teaching is definitely the best way to learn!" one wrote. "This is like studying for tests in groups and teaching each other," another commented. Several noted that they planned to go online to review their classmates' slectures to improve their knowledge of a particular topic.

What the students may not have realized while immersed in the creation of their slectures, is that in order to convey technical information, they also got practice in communicating effectively to Project Rhea's vast unseen audience. This is a professional skill that they will likely use in the future, whether working in industry and collaborating with colleagues in other countries, or in academia, teaching Massive Open Online Courses (MOOCs) or other online courses.

Abstract — This paper aims to specify strategies for learning scenarios that incorporate ubiquitous features to support pedagogical practice. Thus, the development aims to verify if the resources of technology with context awareness promote significant changes in teaching practice, and can impact positively or not the effectiveness of learning and engagement of learners. In this regard, a reference ubiquitous environment called Youubi was used to support learning activities based on context. It consists of a framework of services that are easily integrated from applications in API format. In order to achieve the objectives of this research, the proposed method consists of three (03) phases. The first phase was a systematic review of the ubiquitous learning environments in order to identify which architectural features and their learning processes are used in learning scenarios based on the context. In the second phase an installation designed with the Youubi ubiquitous environment proposed a learning scenarios and new pedagogical practice for teachers in higher education. The third stage will be the design of high fidelity of ubiquitous learning scenarios prototype. After that, the actions will consist in validating the ubiquitous learning scenarios. In this paper we present the results of the systematic literature review. From these outcomes, we will generate pedagogical strategies for ubiquitous learning scenarios. These may also be used as recommendations to improve of current ubiquitous learning environments as well as the design of the Youubi environments.

Keywords-component: Educational Practices; Ubiquitous Learning; Framework; Effectiveness.

I. INTRODUCTION

The ubiquitous computing and location technologies have gradually been inserted in education as a differentiated practice to support indoor and outdoor learning. Environments that incorporate ubiquitous technology in pedagogical activities seek to enhance the learning spaces of learners through their daily activities in an integrated and continuously

way. This type of environment can be regarded as a factor that favors in a unique way the effectiveness of practices that increase the engagement of learners in learning through user interaction mediators resources with devices such as bar code labels, Global Positioning System (GPS), labels or RFID tags (Radio Frequency Identification) and wireless sensor networks. We can understand that the ubiquitous learning is characterized by the provision of learning services intuitively mediated by these built-in features in order to encourage learning in the right place at the right time. Thus, it is important to analyze new pedagogical approaches using these resources to support learning situations that may occur at any time and place and integrated into the context form. Ubiquitous technologies are accessible through devices such as tablets, smartphones and smart watches, which combined with the interactions of people and artifacts available in the environment, contribute to new experiences in the daily lives of people.

However, this new way to share and access information still far from be taken advantage when it comes to teaching practices in the classroom. Many of these devices are used personally and isolated from favoring context of social interactions that help the cooperative learning practices enriched by technology. In this sense, [1], [2], [3] and [4] discuss the possibility of new forms of learning using these devices, not only in the classroom, but also in many places that can help the teaching-learning process. Thus, mobile devices emerge as mediators that expand the possibilities, scenarios and forms of interaction, expanding the learning beyond the borders of the traditional classroom. Mobile and ubiquitous technologies enable learning within the context and ubiquitous mobility, due to the new models of existing interactions on mobile devices such as sensor technologies [5] [7].

Faced with this new scenario, educational environments need to develop a new model, Ubiquitous Learning (u-learning) or Ubiquitous Education [6], supporting educational processes that can be accessed at any time, anywhere integrated with the context both virtual and real apprentice, enabling significant changes in pedagogical practice in the classroom. Technologies that support this type of model situations cause learning through activities integrated with everyday life, and continuously [8].

Thus, this research focuses on exploring the activities of inadequate behavior in learning situations that incorporates the ubiquitous computing resources. We seek to analyze the effectiveness of this technology in the educational context in order to promote meaningful learning. The central question in this research is: The appropriateness of learning activities using ubiquitous situations creates more favorable conditions for effective learning?

The guiding hypothesis of this research is: The appropriateness of activities in ubiquitous learning situations promotes the student's ability to accomplish proposed activities. To validate it, a stage that is in progress, we seek to develop the pedagogical model of communication of u-learning environment Youubi. The designed ubiquitous learning environments allow assess whether, on the one hand, the resources of technologies with context awareness, promote significant changes in pedagogical practice. On the other hand, may or may not have a positive impact on the effectiveness of learners to promote a significant improvement in their learning.

This paper is organized as follows: Section II presents the u-learning environment Youubi. Section III discusses aspects related to learning environments based on the context. Section IV presents the original proposal of the methodology to be used in the search. Finally, section V presents the first results of the research.

II. YOUUBI U-LEARNING ENVIRONMENT

It is a ubiquitous learning environment, distributed under an open source license and developed based on reference architecture (Figure 1).

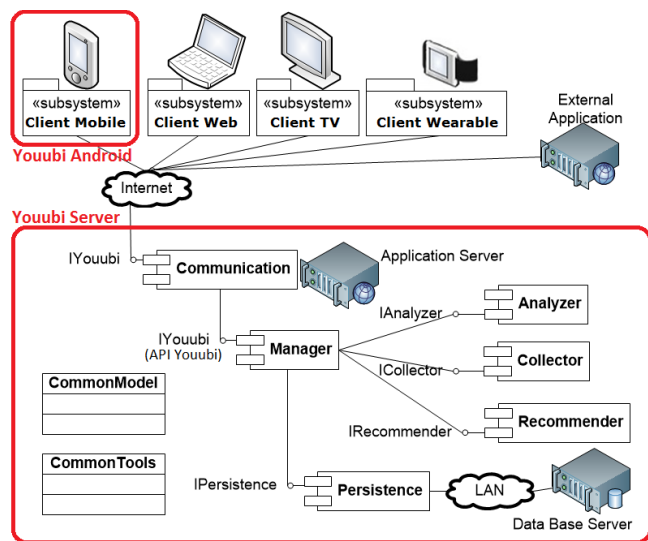

Figure 1. Architecture Youubi System [9].

In addition, to implement its communication layer in Web Service, the services offered by the server can be consumed

by the following platforms: mobile, Web, TV, smart watch and other systems via an API (Application Programming Interface) [10]. Main components:

- **Communication:** implements the Web service communication layer, with RESTEasy framework, which provides the services of Youubi API over HTTP requests (Hypertext Transfer Protocol).
- **Manager:** receives requests from clients and implements their respective business rules, updates the user behavior indicators based on interactions with the system.
- **Collector:** responsible for collecting data on other systems that provide access API such as Google, YouTube, Wikipedia, Facebook, Twitter, OpenRedu, Moodle, and others.
- **Analyzer:** responsible for the periodic review of the data stored in the database in order to identify new information that can enrich the user profile.
- **Recommender:** responsible for analyzing the data stored in the database to generate recommendations for all elementary Youubi entities, based on the context of the users.
- **Persistence:** responsible for the storage of data in the database, which ensures the insulation between the rules of persistence and business.
- **Common Tools:** consists of a number of utilitarian methods such as conversion algorithms. This component can also be used by both the client applications as the server-side component.
- **Common Model:** composed by JavaBean classes that represent the architectural entities. Among the main model classes are the elementary entities (Person, Post, Event, Challenge, Location and Group), which respectively represent the user and the content and activities handled by the environment.

Youubi was being adopted in this research because it is designed to support learning activities based on the context of learners. In order to test the architecture and perform experiments with students and teachers in a real environment, one mobile client was implemented and integrated to the u-learning environment Youubi. Accordingly, it is an open source application and the usability was already evaluated with real users [9].

III. ASPECTS RELATED TO LEARNING ENVIRONMENTS BASED ON CONTEXT

In essence, the technologies based on the concept of u-learning are context sensitive. An application is classified as 'context-sensitive' if it uses information about the context of relevant entities in its domain to provide information or services to its users [13]. Therefore, the information that makes up the learner's context can be, for example, his identity, physical status, behavior, location, social interactions, interests, device used and other environmental information obtained by sensors. Thus, the information can be used to deliver content and services closer to the context of each learner [13], as well as to adapt learning strategies for each student [12]. In addition, this set of requirements is a key factor in the process of monitoring the student. It is possible to be aware of its' context, their learning practices and how she/he is acting [11]. In this sense, to provide effective use of services through ubiquitous resources is essential to have a clear definition of tasks, collaborative activities, which shall

be made available, and finally, how will the student interaction with these elements according to its context.

So, to model educational activities that promote learning effectiveness with use of ubiquitous technologies, it is indispensable to have a clear definition of: the tasks, the type of activity to be provided, the information to be made available, how will be the interaction of the student with these elements according to the context and with the quality of the designed interaction design [14]. In this sense, [3] states that when designing a learning environment supported by mobile technology is needed further evaluation of usability in order to assist designers in the design of activities. When designing learning activities that incorporate u-Learning resources, they must be designed in constant negotiation over the design process, with a view to the dynamics of the services offered by mobile technologies.

IV. PROPOSED METHODOLOGY

The methodology consists of three (3) phases:

Phase I: In the first step was performed a systematic literature review (SLR) on ubiquitous learning, in order to outline the current knowledge about the different architectural approaches and learning processes involved in learning paradigm ubiquitous. In the second stage we will apply methods of ethnographic research with teachers of a *Computer Licenciade Degree* in the Federal Institute (IF) called '*IF Sertão Pernambucano*', to capture the teaching practice with the use of technology in the educational process. To procedure the ethnographic research, we referred the structured model of dimensions and components [10], as a builder for dimensions of modeling to be used in data collection through interviews. The third step is to design strategies for learning activities based on the findings of the RSL and compiled data from ethnographic study of users to design learning scenarios for the u-learning environment Youubi.

Phase II: The second phase comprises the prototype design of high fidelity of ubiquitous learning scenarios involving techniques of Design Thinking. To [15] Design Thinking is grounded in methods and models that emphasize, communicate, encourage and explain the features, capabilities and behaviors inherent in the human being, allowing their wishes, needs and experiences are the starting point to design solutions, products and services. Currently, there are several approaches to Design Thinking, however, for the development of this research, we adopted the proposal of the Hasso Plattner Institute of Design at Stanford (d.school), pioneered the use of DT in the middle academic [16].

Phase III - Consist of the planning and execution of the experiment to validate the hypothesis of this project. The results generated will be specified in the form of pedagogical strategies for ubiquitous learning environments that promote learning effectiveness with the use of ubiquitous technologies. These may be used as recommendations for improvement of current ubiquitous learning environments as well as in the design of new environments.

V. CURRENT STAGE OF THE PROJECT

In the case of a project in development, we describe in this section the first results found in the research.

A. First Results of the SLR

According to the research questions of Section 1, we define a set of relevant terms that guided the mapping of existing ubiquitous learning environments, their ubiquitous technologies employed as well as the pedagogical models used to promote ubiquitous learning. The organization of the SLR, follows the guidelines [17], in three stages: planning, execution and presentation of results.

For planning, the key terms for the preliminary search based on the problem of research on ubiquitous learning were initially identified to generate the search strings, according to the terms described in TagCloud of Figure 2.

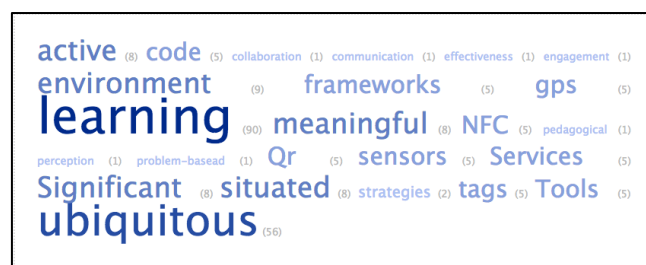

Figure 2. TagCloud words to search String.

After the search string definition, primaries studies were conducted in those chosen main databases in computing: ACM Digital Library (<http://dl.acm.org>), computer & Education, IEEEExplore (<http://ieeexplore.ieee.org>), SpringerLink (<http://link.springer.com>), ScienceDirect (<http://www.sciencedirect.com>).

In the implementation process, an automatic and manual search was performed on each digital library. Then, an iterative process was used to exclude non-relevant articles to the exclusion criteria.

The exclusion criteria were applied according to the analysis of the summary, keywords, full text screening and finally the duplicate jobs. Similarly, the procedures were performed until the final list as described in the Figure. 3.

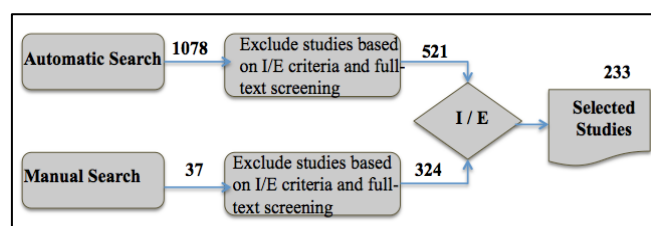

Figure 3. Process Research and Studies Selected.

Automatic and manual query took place between November (2014) to January (2015) and two researchers extracted the data. It is observed that the SpringerLink library, was the largest vehicle of relevant studies on ubiquitous learning. However, other vehicles were identified as relevant when the survey was conducted. The results for each digital library, conference and journal are shown in Figure 4.

Figure 4. Total Found by Conference.

The ubiquitous learning architectures found in the preliminary findings of the SLR such as the location [18] Hello [19] and Cauls [20] showed no exceptional or different features of u-learning environment Youubi [10] as described in Table 1.

TABLE I. LIST OF ARCHITECTURE AND ITS UBIQUITOUS FEATURES.

TABLE CLASSIFICATION OF ARCHITECTURE MODELS				
Features Ubiquitous	1° Model (LOCAL)	2° Model (HELLO)	3° Model (CAULS)	4° Model (Youubi)
Tools	RFID, mobile device	QR code, camera, mobile device	RFID, mobile device	SmartPhone GPS, Google Maps
Immersion	High	High	High	High
Adaptability	High	Low	Low	Low
Invisibility	Yes	Yes	Yes	Yes
Located Activities	Yes	Yes	Yes	Yes
Education Dynamics	Yes	Yes	Yes	Yes
Interactivity	Yes	Yes	Yes	Yes
Type of Learning	M-Learning and U-learning	U-learning Activities	U-learning Activities	U-learning

In [21] and [22] is reinforced this context for education, in the sense that ubiquitous support can allow the development of educational programs, using dynamic information obtained from the physical context of learners. This scenery is recognized through the results shown in Table 1. The Ubiquitous Learning Environment Youtube was selected in this research as reference by support the same features. The important point in this process is related with the access the code and proximity the development team that are willing to collaborate to improve the environment, thus facilitating the construction process and gathering information from the real student's context.

Finally, the first phase of the filtering of the review articles is being completed and from these results, this research will be able to start the second phase.

Increasing Student Engagement Through the Development of Interdisciplinary Courses:

Linking Engineering and Technology, the Sciences, and the Humanities

Abstract — The changes in the defining ideas of the contemporary world, the exponential growth of knowledge, and the expansion of technological innovations have created a need for a critical examination of the convergences and connections between the Sciences, Engineering, and the Humanities. Today, there are areas of study so complex that they go beyond the confines of a single discipline. Examples of such areas include (1) the comparative study of concepts of mind, consciousness, and machines, (2) the critique of the technological culture through appropriate and alternative technology approaches, and (3) the questions surrounding cosmology, evolution, and beliefs. In response to this, we have developed interdisciplinary, team-taught, general education courses on artificial intelligence, appropriate technology, and the origins of the universe that respond to the above challenges, while fostering the ability of our students to use skill sets and concepts from different and divergent disciplines in order to examine such complex areas of study. The preliminary results indicate that, while there is a need for continuous retooling of the course model to better reflect the General Education goals and the university culture, this is a successful course model for our institution. The data also suggests that this type of interdisciplinary intervention in the beginning years of university study positively impacts the development of students' abilities in these areas.

Index Terms — interdisciplinary courses, student engagement, first year experiences, critical thinking, integrative learning

I. INTRODUCTION

The past few decades have witnessed an explosion in information in science and technology that directly impact our lives and call for an examination of the connections between Science, Technology, and the Humanities. These intersections form the crux of critiques of artificial intelligence, the appropriate use of technology, and the origins of life; three areas which influence our conceptions and our place in society and the world. While, technology and science are integral and formative parts of our culture, not neutral entities, they have the ability to alter how our senses inform us about the external world and help form one's own view of reality, structures of meaning, and identity [1]. Very few of the University of Puerto Rico, Mayaguez's (UPRM) General Education (GE)

requirements examine the reciprocal relationships between science/technology and society/culture or the associated convergences. To remedy this situation, our educational project, "The Convergence of Science, Technology, and the Humanities", aims to examine the convergences in our culture through a set of interdisciplinary team-taught, theme-based GE courses that enable students to explore the links between the sciences and the humanities, with the goal of improving our students' engagement in their own learning. Given the complexity of the three above areas, an interdisciplinary approach is needed for the study of their diverse elements [2 - 7], with Klein and Newell [3] indicating that such a format provides a base and process for examining topics, questions, or problems that are too broad to be dealt with by a single discipline or profession [3].

Scholars [8 - 11] indicate that colleges and universities are using interdisciplinary courses to enhance and focus on developing students' integrative skills, while addressing topics that are by their very nature intrinsically broad, multi-faceted and, therefore, beyond the scope of a single discipline. To be successful, these courses depend upon the integration of perspectives and tools from multiple disciplines for a more complete inquiry of the subject matter [9, 11, 12]. While there are concerns about the effectiveness and problems associated with team-teaching [9, 10, 13], in our project it became clear that if a teaching team maintains good communication lines and the members seek a deep collaborative experience, the development and offering of the course flows more smoothly.

Because UPRM is mostly a Science/Engineering university, the creation of interdisciplinary GE courses that examine the above mentioned intersections is an important addition to our GE curriculum. Professors from widely diverse disciplines are collaborating to develop and offer three interdisciplinary, thematic, team-taught GE courses that contextualize current debates and questions that inquire about (1) the expanse and limits of artificial intelligence (AI); (2) the ethical, social, and technical choices that distinguishes appropriate use of technology (AT); and (3) the theological, social, and scientific debates that arise in connection with the study of cosmology, evolution, and belief (CEB). Given the depth and complexity of these areas, an interdisciplinary, team taught approach is well suited and provides the best tools for considering these

topics [7- 9, 11, 13].

II. COURSE DESIGNS AND OUTCOMES

A team of three professors was assigned to each of the three thematic areas. Each team began designing the course format, syllabus, readings, assignments, and evaluation rubrics at least one year prior to offering the course. As part of this process, each team hosted a conference of visiting scholars who had expertise in both the specific theme and in pedagogical methods for interdisciplinary education. This included use of such interdisciplinary pedagogical methods as writing for learning, case studies, group research, and student led discussions [13 - 14]. The visiting scholars were presented with annotated draft syllabi of the courses for their responses, which further engaged the team members in a critical dialogue on course content, design, and pedagogy.

Two formats for the course were designed, both of which are based upon the mega-section concept and are cost neutral in terms of the number of students per professor. The first format, which was used in the AI and CEB courses, divided the students (up to 30 students per professor) into three separate sections. Each professor then met separately with each section on an alternating basis, with some general meetings for all participants scheduled during the course of the semester. The second format, used in the AT course and employed at some point in the other two, convened the entire class in a large classroom or auditorium. In all cases, for accounting and grading purposes each teaching team member was assigned up to thirty (30) students.

Due to the differences between the courses, the following presentation of the results (description, design, results) will be divided by course topic.

A. *AI: Mind, Consciousness, and Machines*

Core theoretical questions in AI research (and contemporary computer science and cognitive science in general) are core theoretical questions in the modern history of psychology and the philosophy of mind. An interdisciplinary course on AI, team-taught by a Computer Engineer, a Philosopher and a Psychologist, introduced a class of undergraduate students from diverse disciplines to the main areas that influence AI research, such as the rationalist/empiricist divide [15], the nativist/operationalist debate in psychology [16 - 17], classical computationalist models vs. connectionist models in Computer Science [18], neural nets and debates in Neurophysiology [19 - 20], as well as the basic premises of Computer Science [21 - 22], evolutionary Biology [23], Linguistics [24], Philosophy [25 - 26], Psychology [27 - 29], and Robotics [21, 30 -31]. This course has been offered twice (2010 and 2012). In the second offering, there were 17 enrolled students, with 80% of the students being from Engineering and the remaining from the Natural Sciences.

One of this course's main objectives was, through an introduction to diverse disciplinary perspectives on the topic of AI, to develop the students' critical thinking skills. Students were introduced not only to established paradigms, but to current debates and movements in the field, while the professors' job was conceived more as a facilitator to raise questions, rather than as a dispenser to introduce the students

to conventional professional wisdom. The professors quickly realized that the students needed instruction on general critical thinking skills. Forensic debates (in which the student was not aware ahead of time of which thesis they would be defending), mutual student grading and, of course, professorial debates were particularly well-matched to the interdisciplinary environment. The final grade distribution 29% -A, 5%-B, 12%-C, 18%-D, 0-F, (5 withdrawals, 1 incomplete) highlight both the benefits and the problems associated with this type of course.

The final course assessment activity was a general meeting with the students about the course. The students indicated that their writing skills had improved and that they developed greater understanding of what needed to be done to establish and defend a point of view. This is supported by the final grades in the class (i.e., the relatively high number of A's) and the professors' own observations. This was exciting, as professors initially thought that the most significant pedagogical achievement would be an increase in comprehension (owing to the diversity of the material). Increased comprehension was also evident, particularly in student reports, but they also developed a greater appreciation of the range of diversity in professional opinions; that academic and scientific disciplines generate disagreement as frequently and as productively as they do consensus, both inside particular disciplines and, of course, across them. This seemed to be a particularly valuable lesson so far as the students were concerned. The students also reported that they enjoyed seeing the professors interact and that the professorial debates were favorite class periods.

It was difficult to arrange the distribution of credit hours and classroom time, as well as registration, grading, and course organization for a team-taught, inter-departmental course. As the first group to offer a course, professors struggled with organization and subsequent courses learned as much from what went wrong as from what worked. The first time this course was offered, in 2010, it was organized around the concept that the students would meet separately with each professor for one of the scheduled class periods of the week, with periodic meetings of the complete group for the interdisciplinary discussions. The first course evaluation results, halfway through the semester, clearly indicated that the students preferred to meet with all three professors at the same time. This is the format that was followed in the second half of the 2010 course and the whole of the 2012 offering. The feedback from the students strongly indicated that this is the preferred meeting format.

B. *AT: Alternative and Appropriate Technologies: Technology for What? Technology for Whom?*

The overall goal of this course was to foster critical thinking about the humanity/technology relationship, and to inspire creative thinking about alternatives. The course enrolled 72 students (64 engineering, 8 non-engineering; 30 1st year, 22 2nd-3rd yr., 20 4th yr. or beyond) and was taught by faculty from Philosophy, Electrical Engineering, and General Engineering.

Using Schumacher's concept of Appropriate Technology [32] and elaborations by Willoughby [33] as the central theoretical framework, students critiqued practices of

technology both in the global North and in the global South. Additional ideas from Philosophy of Technology and elementary science were interwoven to encourage students to construct views beyond any single framework, and to elicit diverse views on what constitutes human progress.

Instead of attempting a detailed description of the course, professors provided a brief tour using electronic devices and media as a cross-cutting case. The students entered largely sharing the common view that technology is morally and politically neutral. This instrumentalist view is challenged by Albert Borgmann's theory on the endangerment of "focal things and practices" due to what he calls the "device paradigm" in which technologies provide goods and services invisibly, hiding the many consequences of our behaviors (e.g., we do not directly see carbon emissions when we turn on the lights) and erode lifestyles that reflect unity of effort engender human commitment [34]. A related idea elaborated by Héctor Huyke [35] is that over-availability of such devices produces distance between people, rather than nearness (e.g., think of a family at dinner, with each person on the phone rather than conversing with each other). Accordingly, the design of technology should take into consideration the strengthening of close human ties and foster meaning in life's activities [34]. Yet, introducing electronic devices in developing communities is often considered to be an "appropriate technology" [36]. However, the proliferation of these devices and their necessary infrastructure is generally managed by multinational companies whose principal motives are profit, raising questions such as those posed by Riley (e.g., should engineers resist global neoliberal economic policies?) [37], Practical Action (e.g., how is the community's wellbeing considered?) [38 - 39] and Willoughby (e.g., is the technology at a scale commensurate with the community's ability to manage and use it?) [33]. Parallel to these questions, mini lessons and exercises were presented to explore technical details of power requirements for operating such devices, and the broader environmental implications of diverse technologies for producing energy. In sum, students were able to reflect on the relative merits of seeking technological parity with the developed world, procuring better technological alternatives, and effecting behavioral changes to best promote quality of life and genuine wellbeing.

The principal assignments consisted of three written essays, in which students needed to apply critical thinking skills to (1) explain an important aspect of a theoretical framework on the humanity/technology relationship; (2) analyze a case from the perspective of that framework; (3) discuss a possible weakness of that framework; and (4) deliberate for or against the validity of the framework in a specific context. To evaluate students' critical thinking skills, an assessment rubric was developed based on these four elements. After the first essay was graded, students had an entire class session work in small groups to discuss the rubric with samples of their graded works, and a second class session for a plenary discussion summarizing the small group discussions.

Based on the rubric (10 pts. max.), the average scores on Essays 1 and 2 were as follows: Essay 1: (6.4, 6.6, 6.9); Essay 2: (7.1, 7.9, 6.9), where each triplet represents scores ordered by cohort (1st yr., 2nd-3rd yr., 4th yr. or beyond). For Essay 3, a group essay, the average scores were (8.0, 7.6), where the

pair represents scores ordered by groups with a (majority, minority) of 1st year students. These results suggest that there was general improvement in students' critical thinking skills as the course progressed, and that this improvement was most (least) demonstrated by lower class (upper class) students. We speculate that by being less encumbered by years of compartmentalized learning and teaching, entry level students are more motivated to freely investigate interdisciplinary questions critically. Although we are unaware of any studies that directly support this conclusion, our results cohere with those from a study of First-year Interest Group (FYIG) participants at UW-Madison, in which first year students choose to enroll in a set of theme-based courses. According to this study, "Faculty have also remarked that their FYIG students *often* outperform their upper class, and in some cases, even graduate students on some critical thinking tasks" [40, p. 248, emphasis on 'often' added].

Another positive outcome of the course is that several students were motivated to continue to be active in Appropriate Technology. Two students from our class took a special topics class about structural mechanics and building with bamboo [41]; one student started a "social business" with a limited profit motive and a commitment to employing fair labor and environmental practices [42]; one student plans a capstone design project in Electrical Engineering incorporating ideas of appropriate technology applied to the irrigation of a local bamboo farm; and nearly a dozen science and engineering students have subsequently chosen to take classes in Philosophy of Technology, Engineering Ethics, and general Ethics.

C. CEB: Cosmology, Evolution, and Belief

The course, "Cosmology, Evolution, and Belief," provides an introductory examination of the dynamic process of evolution of three different objects: the Cosmos (with their fundamental constituents and natural laws) [43], Life (from its origin to human beings) [44 - 45] and Belief [46 - 47] (from primitive cultures and ancient civilizations to present societies). In this course professors from Physics, Biology, and Humanities collaborated to present, discuss, and clarify these topics. The course is designed for first or second year university students. There were 64 total students enrolled in the course with 56% from the Natural Sciences, 21% from Engineering, and the remaining 23% from the Humanities. The student evaluation system was based on two exams (8th and 15th weeks), class participation, quizzes, homework, and attendance. Each professor used the last three evaluation methods differently.

With regards to the academic results, the average grades on partial and final exams, quizzes-works, and participation for the students who completed the course (there were three withdrawals) were 24/30 (exam 1), 21/30 (exam 2), 22/30 (other assignments), 9/10 (attendance), with an overall total average of 76%. All three areas utilized many bibliographic and audio visual references. The cosmology section used 12 references, which included the textbook *Introduction to Cosmology* [43], which was written specially for the course. The evolution component used 22 references, ranging from scientific articles to book fragments; and the belief section employed 12 references.

Formal quantitative assessment was not developed for this course. Although, professors offered an assessment test to gather students' background about the course topics. They also offered a survey at the end of the course to probe students' degree of satisfaction. The majority of the students were highly satisfied with the course. Some of them were more engaged with a specific subject matter, depending on their personal interests. Critical thinking and integration of topics were assessed on exams questions. Most students were able to integrate different views presented in class about the topics, which translates into the 76% grade average. However, a few failed to develop critical arguments in their exams, or refused to answer the questions altogether.

The course design was similar to the 2010 iteration of the AI course, in that it was originally divided into three separate sections with each professor rotating through each section and offering his lectures three times (during weeks 2-7 and 9-14). The interdisciplinary discussions were to take place in weeks 1, 8, and 15, when all registered students and professors would meet together to discuss, analyze and synthesize ideas. However, once professors concluded the first cycle in the eighth week, they decided to adopt a different approach for the remaining weeks of the course. All three sections were fused together and the professors attended all lectures. This new format promoted interesting discussions among students and all three professors during the classes. In the final course assessment, 75% of the students expressed that they preferred this second format. During the course, all three perspectives were taken into consideration while analyzing specific issues. For example, professors discussed the ethical and biological impact of transhumanisms and technology on the continued evolution of the human species [48 - 49].

III. CONCLUSIONS

The project's original goals were that an interdisciplinary perspective would help increase our students' engagement in their learning and, subsequently, their critical thinking skills, as well as the understanding of the links between the Sciences, Technology, and the Humanities and the preliminary results support this. While the assessment only measured the work during the course of one semester for each course, the students did demonstrate improvements in their critical and integrative skills during that time. This was observed in all three courses, through the use of class discussions and assignments.

All three courses surveyed the students at the end of each associated semester in order to gather information regarding their degree of satisfaction with the course format and subject matters and their views of their own understandings of the areas of study. The majority of the students were highly satisfied, with some going so far as to say that "For the first time in my 6 years in college I found a piece [of] hope for the system, thanks to you [for] having developed this course" and "It was an overall great experience and I'm glad we all had some part in it" (in reference to the CEB course). The students agreed on the positive impact of discovering the intimate relationship between the disciplines included in each of the three courses.

The team-taught format also demonstrated positive results in regards to the level of student engagement. In all three courses, student engagement was high, which was supported

by the increased level of class participation and fewer students using electronic devices during the class period. This was especially noted by professors in the 2010 iteration of the AI course and the CEB course. By changing the format of the classes from meeting in separate sections (with occasional interdisciplinary interventions), to one of all participants meeting together in one single section, not only were the students better able to perceive the convergences and divergences of the topics, but their levels of engagement in the class noticeably increased. As one of the professors observed, there was a notable increase in student attention, attendance, and participation as soon as they began meeting as a single section, instead of in separate sections.

However, organizing this type of course does present various difficulties during the course design and its subsequent offering. First of all, it requires extensive pre-course development, as well as good communications skills between the participating professors and the teaching teams needed to meet on a continual basis during the academic year before offering the course. In addition, each team of professors experienced a fairly steep learning curve to understand and learn each other's professional language, attitudes, and core beliefs. Further complicating the situation we confronted obstacles in regards to the administrative aspects. To offer such a course, a university needs to have well defined administrative procedures in regards to 1) teaching load, 2) publicity of the courses, and 3) student registration. We observed this while working on the course preparation and student registration for the course. Regardless of the obstacles, the whole process proved to be enriching, with one faculty member even remarking that he felt that the experience was like having an internal sabbatical.

IV. THE FUTURE

We envision that this model will be employed throughout the University to enrich the curricula and support better student engagement. To this end, professors from the Schools of Agricultural Sciences, Engineering and Business Administration are designing interdisciplinary courses along these lines. These curricular innovations will result in interdisciplinary team-taught courses between Engineering and Business, as well as a new multidisciplinary capstone course, which are scheduled for implementation on August 2015.

ACKNOWLEDGMENTS

We would like to acknowledge the contributions of Professors Marcel Castro and Luis Jiménez from Engineering; Héctor Jiménez from Physics, Lucas Avilés and Esbal Jiménez from Agricultural Sciences; and Roberto Seijo, José Vega, Moraima De Hoyos from Business Administration.

Latinas' Resilience and Persistence in Computer Science and Engineering

Preliminary Findings of a Qualitative Study Examining Identity and Agency

Alberto Esquinca, Elsa Q. Villa, Elaine Hampton, Martine Ceberio and Luciene Wandermurem

College of Education

El Paso, TX U.S.A.

asquinca@utep.edu, elmein2@utep.edu, evilla@utep.edu

Abstract— Most professions have reached gender equity with the exception of computer science and engineering. To understand the mitigating factors influencing Latinas' enrollment and persistence in engineering and computer science, an interdisciplinary team of scholars at a majority Hispanic four-year institution has undertaken a three-year project to explore these phenomena. The following overarching question has guided us: What is the relationship among identity, resilience, and persistence of Latinas in computer science and engineering? The study was framed using a sociocultural theory of identity drawn from the work of Gee and from Holland, Lachicotte, Skinner, and Cain. Our findings suggest the majority of women encountered and dealt with some kind of adversity in their career trajectory. Their ability to overcome this adversity depended on many factors, such as the role of peer groups, family, and professors. Eighteen of the 26 participants referenced group participation phenomenon as beneficial to their success. They also identified spaces that accommodate group interaction including: the library, homes, local coffee shops, and university study areas.

Keywords—*women in engineering; narrative analysis; qualitative study; sociocultural theory of identity.*

I. INTRODUCTION

The disciplines of engineering and computer science have served as preeminent and prestigious fields of study, yet have been historically underrepresented in gender despite other professions reaching parity [1]. With engineering as “one of the few remaining of sex-segregated disciplines” [2, p. 1], only eighteen percent of engineering degrees are awarded to females with two percent awarded to Latinas [3].

Local and national pre-college outreach endeavors have addressed this disparity in the last 20 years, including the National Center for Women in Information Technology, the Computing Alliance for Hispanic-Serving Institutions, Grace Hopper Regional Consortia, CRA-W, ACM-W, and Tapestry. Although female enrollment numbers are far from parity (under 19%, with Latinas representing only 9% of the total number of females) in computer science and engineering, they would no doubt be worse without their dedication.

The disproportionately low share of Latinas earning undergraduate degrees in engineering is an indicator that the discipline could face its own crisis point. To resolve the crisis,

it is crucial to listen to the voices of Latinas already in the field. Our study was designed to further understand the ways that educational institutions may help recruit and retain these and other minority women in engineering and other STEM fields.

This study applies qualitative research methods to investigate the experiences, from their youth through university life, of Latinas toward enrolling and persisting in engineering studies. Located on the U.S.-Mexico border, the research site is a Hispanic Serving Institution where female enrollment in engineering is twenty percent --slightly higher than the national average.

To understand the mitigating factors influencing Latinas' enrollment and persistence in engineering and computer science, an interdisciplinary team of scholars at a majority Hispanic four-year institution has undertaken a three-year NSF-funded research grant project to explore these phenomena. The following overarching question has guided us: What is the relationship among identity, resilience, and persistence of Latinas in computer science and engineering?

II. THEORETICAL FRAMEWORK

We draw on a sociocultural theory of identity construction to understanding how participation in socio-cultural contexts mediates identity. In particular, we draw on the theoretical perspective of Holland, Lachicotte, Skinner, and Cain [4] who describe particular sociocultural contexts as “figured worlds,” or social configurations, such as family, school, and other social institutions. Holland et al. [4] describe figured worlds as “a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (p. 52). In a figured world, individuals shape subjective meaning of themselves as actors who participate and navigate as they move in, through, and out of these worlds throughout their lives; these social configurations shape how one makes sense of the world and how one perceives oneself in that world. This perception is how an actor “authors” herself—an embodied self in a particular social configuration [4, p. 32] where actors' participation and position can be one of privilege or subordination [4,5].

Using a figured worlds theoretical framework in their study of middle school girls of color in science classes and laboratories, Calabrese Barton et al. [4] focused their study on “identity work,” rather than identities specifically, and defined it as

actions that individuals take and the relationships they form (and the resources they leverage to do so) at any given moment and as constrained by the historically, culturally, and socially legitimized norms, rules, and expectations that operate within the spaces in which such work takes place. Individuals author possible identities through identity work over time both with and against the norms of the worlds they inhabit. (p. 38).

While we examined identity work in our investigation of three Latinas as they participated in similar activities as pre-college youth, for this paper we focus on their narratives.

Narratives or stories told to mediate identity construction in the figured world of engineering and computer science studies. It is through the stories people tell about their experience where we can come to understand how they make sense of their lives within this world. Through telling a narratives we are able to understand a number of things. For instance, we may understand the significance of events a narrator assigns to particular events, the value that have, the important people in narrator’s lives, the significance to be had from hearing particular stories and how the narrator understands herself within the frame of this figured world.

III. RESEARCH DESIGN

Twenty-six (26) participants were selected using purposeful sampling [7]. They were interviewed using an ethnographic method of deep interviewing developed by Seidman [8], which combines life history using focused, in-depth interviewing to provide rich descriptions of participants’ life experiences. These interviews provided research participants an opportunity to construct meaning of their life history in making their respective career choice, and their current experiences in navigating barriers and/or gateways as a female engineering student. Each interview lasted approximately 90 minutes. The three open, in-depth interview questions were:

- (1) What experiences brought you to engineering?
- (2) What has been your experience as an engineering student?
- (3) What it will mean for you to be an engineer?

Probing and clarifying questions are asked of the participants based on what they share in answering these questions. For example, they may mention a class where they were one of five females. The interviewer would then ask, “Tell me what that meant for you” or “Could you tell me more about that experience?” In this manner of collecting data, the descriptions of their life experiences were thick as they provided details of their experiences.

The team is in its final phase of analyzing these data using the following analytical methods: narrative analysis, constant comparative, and life charting. For this paper, the unit of analysis is the narrative, defined by narrative plot elements [9]. For this paper we purposefully selected narratives in which narrators included a crisis point where they wondered aloud if they identified as engineers. More than one third of participants presented what we termed a “narrative of uncertainty” due to the words narrators used, such as “doubt,” “not sure,” and “don’t know.”

Data were analyzed using an approach to narrative analysis that has a long tradition. It has been used in research for [10,11, 12] approximately five decades. This sociolinguistic approach to narrative analysis relies on linguistic markers to identify narrative structure. The following elements are found in narrative structure: a Setting (in which the narrator reveals the who, when, what, where of the story), a Catalyst (where the narrator identifies a the situation leading up to a crisis), Crisis or Problem (the narrator mentions an issue that complicates the situation), Resolution (the narrator says how the crisis issue was resolved), Evaluation (the narrator elaborates on the significance of the story), and Coda (closes out narrative). Analysis relied on linguistic cues, such as speech tone, rhythm, and vocabulary choice [13] as well as content to determine the structural elements of a narrative.

IV. FINDINGS

The findings from the data analysis of our larger study are: (1) negotiation of adversity in Latinas’ non-academic and academic lives; (2) being female in a male-dominated space; and (3) the development of engineering identity, which is informed by the roles of (a) affinity spaces; (b) supportive people; and (c) engineering-related artifacts and play experiences.

For this paper, we will focus on the negotiation of adversity in Latinas’ academic lives.

More than one third of participants volunteered what we termed a “narrative of uncertainty” i.e., they used particular phrases, such as “doubt,” “not sure,” and “don’t know” or questions (“I wondered if engineering was for me”). Our analysis pointed to recurring themes in Latinas’ narratives of uncertainty: 1) Crisis points revolved around events in lower division courses— what some of them call “weed out” or “gatekeeper” courses; 2) participants drew on their communities of practice to make sense of these difficulties; and, 3) a number of participants identified their mothers as the figure who confirmed engineering as the right career choice for them.

1) *“I wasn’t really sure that I was smart enough...”*

Many of the participants were among the brightest and most talented students in middle and high school, with some of them earning scholarships and/or attending engineering magnet high schools.

Early in their engineering coursework, participants began to question whether engineering was the right path for them.

Table 1 shows the courses in which participants told us they began to doubt themselves. In the second column, the courses where narratives of uncertainty are set are presented. Significantly, these courses are all lower-level courses, suggesting that participants' moments of uncertainty came early in their college career—not later.

Pseudonym and engineering major	Spaces of local struggles	Resources for resolving crises/struggles
Amber (Electrical)	Pre-Calculus (lower division course)	Her mother, school counselor
Autumn (Mechanical)	Physics (lower division course)	Self-motivation to become a NASA engineer
Briana (Mechanical)	Chemistry (lower division course)	Parents, sister, professor
Britany (Industrial)	Electro-Mechanical Systems (lower division course)	Change of major would delay graduation
Elena (Civil)	Statics (lower division course)	Upper division students; parents
Gabriela (Mechanical)	Calculus II (lower division course)	Her mother
Gina (Mechanical)	Dynamics (lower division course)	Her professor
Juliet (Computer Science)	Intro to CS	Her professor
Karla (Civil)	Didn't see the application of concepts in Statics and Mechanics of Materials (lower division courses)	Her family, especially her mother
Natalie (Civil)	Physics and Dynamics (lower division) Structural Analysis (upper division)	Self-motivation

TABLE I. SUMMARY OF NARRATIVES OF UNCERTAINTY

An example of one such narrative is Autumn's, a mechanical engineering major, who is now employed at NASA. She revealed that Physics I was when she doubted her identification with engineering.

[In] one of my classes, we were learning about moments and statics, equilibrium forces and things like that, and I'd never been exposed to that. So I was completely confused. I was really lost. And yeah, I was going back and forth thinking, this is pretty difficult. I'm not sure that I'm grasping these concepts and. "Is engineering really right for me?" You know? 'Cause I guess I'd gotten accustomed to everything comes easy, and it wasn't coming easy.

Like Autumn, all of the participants who volunteered a narrative of uncertainty pinpointed lower division courses as the moment when they began to wonder. Similarly, research has shown that lower division courses are a significant barrier for female students and students of color [14]. This finding suggests that colleges of engineering interested in retaining females might do well to target these (often large) courses.

2) *"If it weren't for those friends who are upper division students..."*

As noted above, narratives always contain a disclosure of how crises were resolved. Often narrators name other key people at this stage. Here, participants identified the resources and key people they turned to in order to resolve conflicts. Table 1 also shows the key people narrators named at the resolution stage of their narratives.

A few students drew on affinity groups [15], which served as support mechanisms that helped them navigate challenging coursework [16]. For instance, Elena constructed affinity groups with upper division students in a Statics course in which she needed guidance:

But that's what all the upper division students would tell me, "Just – just get through it. Just get to your upper division. Just keep fighting. Just keep working at it. And once you get to your upper division it's going to be a lot easier." So I think if it weren't for those friends that I had made who are upper division students, I don't think I would've done as well as I wanted to in the class afterwards.

Note that Elena's narrative is set when she is a lower division student, in a "weed out" course that may often lead to moments of uncertainty for many students.

Similarly, Gina, Briana and Juliet said that they relied on professors in moments of uncertainty. Gina said that she would often meet with her affinity group, and together they would visit the professor. A combination of these relationships signaled to Gina that engineering was the right space for her. She said that, when faced with difficult homework, she first worked by herself; followed by an internet search; then asked her friends; and, when doubts persisted, they asked a professor.

V. SIGNIFICANCE AND RELEVANCE

This paper contributes to the body of research on women's persistence and resilience in engineering, where they are significantly underrepresented. It confirms what other studies have shown, namely that gatekeeper courses posed a threat to these women's persistence in engineering [14]. However, the paper also adds new information regarding the ways in which successful women resolve and make meaning out of these experiences. Moreover, research has also shown that social support serves to curtail the loss of underrepresented students, particularly women, in STEM fields [17]. In this paper we drew on women's narratives to show the specific actors who

serve as support for undergraduates, namely their peer groups, professors and families.

Abstract— Engineering and computing at university both have a long tradition of co-operative education which plays a vital role in developing students' applied skills and giving confidence to both students and potential employers. Co-op education refers to relevant work experience integrated into a course. The main motivation for students in completing a co-op program, or *placement*, is in their increased employability skills; however, students cite other benefits such as increased interest in their subjects at university, improved grades on return from placement and support for career decisions. A study was designed to explore the reasons why students did not take a placement, and we considered both those students who tried but were not successful in securing a placement and those who did not apply for placements. The qualitative study revealed that students who applied but were not successful had in some cases limited their options by being selective in the placements for which they had applied. For some, it came down to excessive competition for the roles. For those that did not apply, stated reasons included anxiety about their abilities, sacrifices (such as giving up part-time paid work and apartments), concern about losing their study skills and difficulties in reconciling family and social commitments with the time requirements of full-time work. This paper explores the findings and asks how we can make co-op programs work for students.

Keywords— Professional Identity, Employability, Computing

I. INTRODUCTION

In the UK, there has been considerable interest in the prospects for computing science (CS) graduates when they leave university. A higher percentage of CS graduates are unemployed than the overall average. Indeed 13% of CS graduates are unemployed after 6 months, compared with engineering 9% and mathematics 9%, while the overall figure for all subjects 8% [1]. Undertaking a work placement during study has been found to enhance employability (for example [2], [3]). However, a recent report from the National Centre for Universities and Business (NCUB) highlighted the dwindling number of computing students undertaking placement, down from 30% to 26% [4].

Different models for student co-op programs or placements exist, however for the purpose of this study a placement is considered to be paid work with a company for a period of between 3 months and one year. The reduction in numbers taking a placement highlighted by the NCUB study relates

specifically to the 'standard' one year paid placement which normally attracts some academic credit, certainly some academic oversight for example, access to a placement tutor and pre-placement support. Before computing courses give up entirely on the one year model, which has been shown to be a good option for employers [5] the reasons behind the reduction in uptake should be explored.

This paper describes a study of second year computing majors at a Scottish university. The study was designed to explore the reasons why students did not apply for the one-year placement. Where students applied but were unsuccessful the study asked about their perceptions about why they had been unsuccessful to date in their applications.

II. BACKGROUND

The university has a one year paid placement which attracts academic credit, enabling students to graduate only 6 months after the non-placed students, and with significant industrial experience to complement their technical skills. The university places approximately 40 students every year which normally constitutes about a third of the second year student cohort. In addition, the university is active in a Scotland-wide paid placement project, e-Placement Scotland, designed to work with employers to create placement opportunities and advertise them across all Scottish universities and colleges [6]. These placements are most commonly 3 month summer placements and do not attract academic credit. The e-Placement Scotland project team organizes presentations at each university in Scotland with a view to promoting placements and explaining the application process. Project resources include an application website, CV advice and interview preparation techniques. The university itself encourages students to apply for both types of placement and to take part in pre-placement activity including CV workshops, mock interviews and mock assessment centers. To increase the quantity and quality of applications for placement, new interventions were designed. The main intervention was the introduction of a structured program, Placement Academy, run during the first semester, designed to prepare students to make applications and be prepared for interviews. Initially

there was a high level of engagement in the Academy events however attendance dropped off during the semester. The sample in this study comprises students who applied for placement and were placed, those who applied but were unsuccessful, and those who did not apply.

III. THEORETICAL FRAMEWORK

Student co-op education offers work based learning opportunities and has been found to be an effective way to provide relevant employment skills, experience and awareness of employer culture. The evidence that placements are valuable to students both in terms of employability and academic achievement is strong (for example, [4], [7], [8], [9]). Research suggests that student placements (at times referred to as work integrated learning, co-operative education and work based learning) enhance student skills, knowledge, competence and experience ([10], [7], [11]). Students gain relevant and paid employment whilst employers seek commitment, communication skills and specific aptitudes pertaining to degree type. Students who have taken a placement are at a distinct advantage over students who have not when applying for work after graduation [12]. Employers benefit from student placement too. Recent research suggests that graduate recruiters estimate 37% of graduate vacancies will be filled by applicants who have already worked for the organization as a placement student [13]. Employers cite other advantages including bringing new skills into an organization and having a specific task completed [5].

However, research in the UK shows there are declining numbers of students participating in placement [13]. Brooks and Youngson [12] suggest students do not see future remuneration in placements, 'long term benefits are not always appreciated with fewer students engaging in the process'. Lowden reports upon the high expectations of the employer, 'graduates need to demonstrate a range of skills and attributes that include team working, communication, leadership, critical thinking, problem solving and often managerial abilities or potential' [14]. His report acknowledges that these are often acquired through work placements and calls upon higher education institutions to create opportunities for student placements of 'significant duration' (p. 25). Docherty states that students are less geographically mobile than they were 20 years ago and are often unable to take placements that are too far away from their abode [13]. He further suggests that students are reluctant to move away from their cohort, and that they may need to maintain their paid employment and thus cannot risk a placement.

In a study of computing courses, declining participation rates were acknowledged in the National Centre for Universities and Business (NCUB) report, 'on average 26% of third year computing undergraduates- and 6% across all years – undertook a recorded work placement' [4]. In a study of higher education institutions in the UK, Banga & Lancaster found that placement staff cite a lack of motivation as the most significant factor (23% of respondents) in students not applying for

placement, followed by students not feeling prepared to apply (21%) and lacking confidence/ fear of rejection (21%) [15].

In terms of university interventions to prepare students for placement and encourage uptake, Feldmann and Sprafke note the lack of empirical research on how placement can be implemented effectively and they further point to the importance of longitudinal studies to gain deeper insights into student development of competences whilst on placement [16]. A longitudinal study following students onto and through placement into graduate employment may have benefits in providing reasons for students to participate.

Student motivations for taking a placement include to improve job prospects, support their career decisions and to earn money [5]. These are all positive reasons for students to apply. Less is known about the reasons behind those students who are eligible deciding not to apply and the factors that students themselves believe act as barriers to successful applications. Based on the literature review, the following research questions emerged:

(1) What reasons do UK students cite for not applying for a work placement? (2) What local and cultural issues lie behind students not going on placement?

IV. METHODOLOGY

A mixed methods approach was taken using both a quantitative and a qualitative approach. A questionnaire was designed, based on the findings of the literature review, to ask students in the second year of the course whether they had:

- **(Group A) Applied successfully for a placement:** students were then asked about the recruitment process and how they had prepared
- **(Group B) Applied but had not yet been successful in securing a placement:** students were asked about the number of placement jobs they had applied for and the nature of their applications to date
- **(Group C) No applications made:** students were then asked whether they had been actively engaged in the preparation activity and the reasons why they had not applied

Three separate questionnaires were used, based on the situation of each student interviewed. The questionnaire mixed factual questions about age, country of domicile and ethnicity combined with open questions about their experiences of placement. Specific questions were asked about a range of pre-placement activity that had been offered and about their experiences of applying. Placement data was uploaded to NOVI for analysis.

V. RESULTS AND DISCUSSION

During three separate interview sessions, all second year students attending class were invited to participate. In total, 71 interviews were conducted (n=71). Of these 19 had secured a placement, 18 had applied but had not yet secured a placement and 34 students had not applied for any placements. Overall,

90% of the participants were male, 10% were female; 63% of the participants were aged between 17 and 22, 26% were aged between 23 and 28; 10% were aged between 29 and 34 and; 7% were aged between 35 and 40. The characteristics of the three categories of students are given in Tables I and II.

TABLE I STUDENT CHARACTERISTICS: GENDER

Characteristics	Category		
	<i>Successful</i>	<i>No placement yet</i>	<i>Not Applying</i>
Female (n = 7) 10% of total	16%	11%	9%
Male (n = 64) 90% of total	84%	89%	91%
Total (n=71)	100%	100%	100%

TABLE II STUDENT CHARACTERISTICS: AGE

Characteristics	Category		
	<i>Successful</i>	<i>No placement yet</i>	<i>Not Applying</i>
Age 17-22	53%	50%	76%
Age 23-28	31%	17%	15%
Age 29-34	10%	17%	6%
Age 35-40	5%	17%	3%

Students were initially asked whether they had been aware of the possibility of placement before applying for the course. Of those that had applied successfully 53% had been aware, of those applying but not yet successful 56% had been aware. Of those that were not applying for placement 71% had been aware of placement opportunities. A larger percentage of students knew about placement but were not applying which suggests that publicizing opportunities for placement does not necessarily influence intention to apply for a placement. The data collected from each of the three categories is now explored.

A. Group A - Applied successfully

This participant group, who had applied and secured a placement, is of interest in this study as a means of comparing their responses with the other two groups. On average students in second year had applied for 4 placements.

Table III shows their responses to the question of whether they wanted to do a placement as part of their course.

TABLE III STUDENT RESPONSES REFLECTING PLACEMENT PREFERENCE

Statement	Student responses as %		
	<i>Strongly agree/ agree</i>	<i>Neither agree nor disagree</i>	<i>Strongly disagree/ disagree</i>
I wanted to do placement as part of my course	79%	21%	0%

Participants were asked about their level of engagement with the pre-placement preparation activity and 90% of students had attended placement presentations, the Placement Academy program or a mock interview with the careers service. Table IV reflects their engagement with preparation activity. Participants could select multiple activities.

TABLE IV STUDENT RESPONSES REFLECTING PRE-PLACEMENT ACTIVITY

Student responses as %			
<i>Placement Academy</i>	<i>Placement presentation</i>	<i>Careers Interview</i>	<i>No activity</i>
52%	52%	26%	10%

Students were asked if they thought there were any drawbacks to going on the one year placement and 17% said that graduating later than their peers was a drawback and 11% said that they would be out of synch with existing classmates. Childcare and 'current job retention' issues were mentioned but did not feature highly in this survey.

B. Group B - Applied but not yet successful in securing a placement

Students had on average applied for 6.5 placements and 63% had been for interview. Only one student said that he would not be applying for further placements. This student had already applied for 29 positions entirely through his own efforts and had instead decided to get some relevant work experience through a work-integrated professional practice course at the university. Taking this student out of the total placement applications, the average number of placements that had been applied for reduced from 6.5 placements to 5 placements.

Group B were asked whether they had wanted to do a placement as part of their program and Table V summarizes their results.

TABLE V STUDENT RESPONSES REFLECTING PLACEMENT PREFERENCE

Statement	Student responses as %		
	<i>Strongly agree/ agree</i>	<i>Neither agree nor disagree</i>	<i>Strongly disagree/ disagree</i>
I wanted to do placement as part of my course	94%	0%	6%

Participants were asked if they had taken part in pre-placement preparation activity and the responses are shown in Table VI.

TABLE VI STUDENT RESPONSES REFLECTING PRE-PLACEMENT ACTIVITY

Student responses as %			
<i>Placement Academy</i>	<i>Placement presentation</i>	<i>Careers Interview</i>	<i>No activity</i>
67%	50%	50%	17%

Asked about their motivations to apply for specific placements all students cited good experience and 83% mentioned future job prospects as a reason to apply.

C. Group C - No applications made

This group of students was also asked if they had originally wanted to do a placement as part of their course. The responses are given in Table VII.

TABLE VII STUDENT RESPONSES REFLECTING PLACEMENT PREFERENCE

Statement	Student responses as %		
	<i>Strongly agree/ agree</i>	<i>Neither agree nor disagree</i>	<i>Strongly disagree/ disagree</i>
I wanted to do placement as part of my course	41%	35%	24%

They were also asked about pre-placement preparation activity and their responses are given in Table VIII. When asked whether anything more could be done to help them be successful 35% mentioned advice related to the application process and 25% mentioned mock interviews.

TABLE VIII STUDENT RESPONSES REFLECTING PRE-PLACEMENT ACTIVITY

Student responses as %			
<i>Placement Academy</i>	<i>Placement presentation</i>	<i>Careers Interview</i>	<i>No activity</i>
26%	9%	3%	32%

The participants were then asked specifically why they had not applied for placement and their responses are given in Table IX. Students were able to select multiple reasons.

TABLE IX STUDENT PERCEPTIONS OF REASONS FOR NOT APPLYING.

Reason for not applying for placement	Percentage citing
Prefer to concentrate on degree	44%
Length of time taken to complete the course	29%
Already in work	29%
Placements not relevant to course	23%
Location of placements unsuitable	12%
Did not know about placement	12%
Not interested	12%
Unsure how to apply	9%
Value social interactions at university	9%
Financial reasons	6%

Table of student perceptions of reasons for not applying.

There was a chance to provide an explanation and students mentioned the following: worried about the level of knowledge that was expected of them, not yet ready and confident about applying and for some they had just arrived at university as direct entrants to the course and felt they had just become accustomed to the course and did not want to leave it so soon after arriving.

To reflect further on why the students had decided against applying we asked if students could see any drawbacks in undertaking a placement. Their responses are summarized in Table X.

TABLE X STUDENT PERCEPTIONS OF DRAWBACKS.

Drawback	Percentage citing
Length of time taken to complete the course	35%
No drawback	26%
Missing out on teaching	15%
Unprepared/ anxious	12%
Lose part-time work	3%
Finance – want to get graduate job	3%

When asked, in the future, what type of placement would suit them best, 82% of students stated that they would prefer a 3 month summer placement.

D. Discussion

Students in all three groups had participated in the pre-placement preparation activity and in all three groups over 40% of students had wanted to do a placement as part of their course. The group who expressed the biggest commitment to doing a placement were Group B who had been applying without success (94%).

This study shows that timing of the placement on a course is critical to student uptake. This echoes findings in the US [17]. It is clear from student responses that the one year placement following on from two years of study was a good model for students: they had consolidated knowledge and were more confident in their approaches to placement. Direct entry students either felt they were not yet ready or were concerned about leaving the course just as they had settled in to a study routine.

The findings contradict the perceptions of placement staff that students are not motivated, as reported in [15]. Instead there was anxiety about leaving the course (44%) and a perception that placement would be a distraction from concentrating on their studies (29%), with only 12% saying they were not interested in a placement. The following quotes from the study echo much of the sentiment surrounding placement uptake in year 2 of the course.

“It would increase course length overall. Could lack up to date knowledge relevant to course when you return”

“Worried about expected level of knowledge - didn't want to be unprepared, felt I lacked possible experience”.

Further to this, 29% of students note the problem of maintaining their current employment and issues with continuity, *“I was unsure how my work would be flexible about it”*.

Through analyzing data from all three groups it was apparent that certain advertised placements were popular and received many applications, and students were aware of the competitive nature of these placements. Although this did not deter students from making applications it was noted as a factor for failure to succeed. To increase their chances in a competitive situation participants stated that they would most value advice on making applications (35%) and gaining experience of interviews (25%).

When asked about the placements Group B participants had applied for, there was evidence of students being too selective in their applications. Most had applied for software development placements with specific and immediate benefit to their course of study, however many of the advertised placements related to IT support and network administration. Most of the companies mentioned were located in same city as the university.

In all groups there was a good level of engagement with the preparation activity (90% for placed students, 83% for those applying and 68% for those that were not applying). This preparation work included CV workshops, presentations from former placed students and mock interviews. Even students not applying found the activities useful and insightful.

E. Limitations of the Study and Further Work

The main limitation of the study is the focus on a single year of study. A further study exploring student attitudes across all years and the different geographical locations of placements would be useful in establishing more general claims for increasing placement uptake.

F. Recommendations

This study has highlighted the need for further research but initial observations for specific recommended actions would be:

- Encourage students to be less selective in their preferred roles by placing less emphasis on selection criteria when marketing placements.
- Encourage students to consider roles that are not specifically related to their degree choice.
- Continuation and further development of e-Placement Scotland and the Placement Academy program in terms of support offered to students.
- Look into offering travel reimbursement schemes for students who take a placement far away from their place of residence.
- Consider the possibility of childcare vouchers/ fund to aid the uptake of placements for students who have responsibility for dependents.

VI. CONCLUSION

Our study was designed to explore the reasons why students did not go on placement and our participants fell into three groups: those who had successfully applied, those who registered an interest and applied for placements but had not managed to secure a placement and finally those who did not apply for placements.

The study revealed that participants in all three groups engaged to some extent in preparation activity designed to increase uptake of placement. The study revealed that students who had not applied for placement had encountered both real and perceived barriers that included a preference to concentrate on their degree studies and, for the one year placement, the length of time taken to complete the course. For summer placements there was anxiety about their abilities, giving up part-time paid work and a lack of suitable placements available.

The experiences of students who registered an interest varied. Some students were overly selective in the roles they applied for, leaving only a narrow opportunity for a successful outcome. Some students had not undertaken the extensive preparation required for often quite complex and demanding application processes, while some students were simply unsuccessful through the selection process due to the numbers of applicants. The study captures rich data relating to each of these experiences

By capturing student perspectives, the study uncovers ways to increase participation in co-op education to the benefit of computing and engineering students. Two key elements are uncovered which can play an important role in increasing participation; communication of the benefits of situationally appropriate placements; and contextual pre-application preparation. While the data underpinning these elements

comes from students, the elements themselves are aimed at both students and employers.

The data from this survey highlights the local, social and cultural factors of running a student placement program. Diversity of placement options is crucial alongside knowledge of placement programs in a local context. It is essential to offer students considering a placement a high level of support and pastoral care.

Perspectives on Volunteering for Initiatives for Women in Computing: a Case Study

Virginia Grande

Department of Information Technology
Uppsala University
Uppsala, Sweden
virginia.grande@it.uu.se

Abstract— Initiatives for women in computing exist since the 70's. However, little research has been done to study the effect they have on the women involved. Hence, this case study presents observations of the perceived value of the initiatives from the perspective of these women. This is a case study of one of the organizations contributing to this kind of initiative, the ACM (and its branch ACM-W), and how its volunteers see this work. The study is based on semi-structured interviews that were thematically coded and analysed. Results show that, depending on their generation, volunteers have different motivations and target their efforts at different audiences. Interviewees also reflected on how to further support women in computing. Finally, implications for future studies and lines of action are presented in the paper.

Keywords— Computing education, gender and computing, women in computing, voluntary work

I. INTRODUCTION

Women in computing, conscious and unconsciously, experience different difficulties during their career. Some of these issues are common regardless of the age range of the women, whereas others apply more to a particular generation. For this paper, we have chosen to follow the classification that Patitsas et. al used for their thorough presentation of the history of women in computing in the US. It is based on the time when women started their studies in computing: First Generation (60's-70's), Second Generation (80's-90's) and Third Generation (00's-10's). While the First Generation were *"simply getting on in a man's world"*, the Second Generation was preoccupied with *"being a woman in a man's world"* [1]. Members of the Third Generation, like the members of the other generation's, experience subtle unconscious bias: bias applied by people they interact with or by that member to herself, i.e. self-applied bias [1, 2, 3].

Women face these kinds of issues as students [4], as professionals in industry [5] and as professionals in academia [6]. Women may have to deal with an unpleasant and discouraging environment, e.g. women hitting the "glass ceiling", i.e. not being promoted to positions in the higher levels of their organizations. This has been known as "vertical segregation"[7]. These are some of the main factors for women

to quit their studies or jobs in the field: the issues accumulate and can cause a "death by a thousand paper cuts".

Low participation of women in computing results in a lack of diversity, which is very detrimental for organizations, as *"diverse teams are more effective: they produce better financial results and better results in innovation"*[8].

Thus, it is crucial that action is taken in order to support and keep women in the field. Initiatives for women in computing emerged (and continue emerging) as a response to this need. These initiatives were created mostly by women of the Second Generation, who shaped these movements primarily as a way to provide younger women with what they thought they would have needed when entering the field [1].

This paper introduces some perspectives from volunteers in women in computing initiatives on how and why women, not only from the Second but also from the First and Third Generation, are nowadays working together in the pursuit of gender equality in computing. Although these initiatives have been active since the 70's, little research has been done to study the effect it has on the women working in the initiatives. Our focus is on the particular case of the Association for Computing Machinery (ACM). After a summary of the background material in section II, we present the method chosen (section III) and some of the themes found in interviews with volunteers in the ACM (section IV). Finally, based on these results, we discuss future areas of work that aim at further supporting women in computing initiatives.

II. BACKGROUND

There are many organizations that aim at supporting women in computing. This paper focuses on actions taken primarily in North America and Europe, as issues faced by women differ depending on geographical area, e.g. low female enrollment rates in computer science is not an issue in some areas outside of our chosen regions [3].

There are organizations for women in computing that have been active for long and attract many women (and men), e.g. the Anita Borg Institute, opened in 1987 [1, 9], had the first

The Grace Hopper Celebration (GHC) of women in computing in 1994 [10]. In 2014, GHC had over 8000 participants [11].

In industry, companies are increasingly showing their concern about the lack of diversity in their teams by publishing their statistics related to their workforce (composed predominantly of white males) [12] and by starting different lines of action related to gender and computing. One of the latest examples of the latter is Google's campaign on unconscious bias [13].

In academia, universities are increasingly supporting initiatives related to gender and computing, e.g. by having committees focused on addressing gender-related issues (e.g. the Gender Equity Group at the Department of Information Technology at Uppsala University [14]) and by encouraging students to take part in student organizations focused on gender equity (e.g. the ACM-W Student Chapters, explained in more detailed below). Successful examples of program reforms and other changes may be found in the US, where universities such as Carnegie Mellon, Harvey Mudd and the MIT are seeing an increase in enrollment and graduation rates, thanks to their initiatives for women in computing, e.g. supporting female students to attend women in computing celebrations, and modifying study programs [15, 16, 17]. Similar actions have been taken in Europe, e.g. in Uppsala University [18].

Common ways of addressing issues related to gender and computing include providing women with scholarships and mentorship programs, networking opportunities (e.g. conferences, local groups, mailing lists), and positive female role models. These actions have been proved to be beneficial for their target audience [19].

The Association for Computing Machinery (ACM)

The Association for Computing Machinery (ACM) defines itself as *"the world's largest educational and scientific computing society, [that] delivers resources that advance computing as a science and a profession. ACM provides the computing field's premier Digital Library and serves its members and the computing profession with leading-edge publications, conferences, and career resources."* [20].

ACM-W, the ACM's council for women in computing, *"has been an active advocate for women in computing"* [21]. ACM-W's lines of action include the female student and professional groups network ("ACM-W Student/Professional Chapters"), a scholarship program for students to attend research conferences, and different kinds of support for the organization of regional celebrations of women in computing [21, 22]. ACM-W Europe is currently organizing the womENCourage 2015 Celebration of Women in Computing, an event that provides networking opportunities, role models and training in computing and gender-related topics [23].

III. METHOD

The qualitative study consisted of semi-structured interviews. 12 women that volunteer in ACM-W initiatives were interviewed.

The interviewees are the author's co-workers in her different roles as a volunteer within the ACM. This study was hence done with an insider perspective, conducted by one of the participants in the community: the author has in-depth local knowledge that was used for this case study [24].

The interviewees were grouped in the aforementioned generations: First and Second Generation (6 interviewees) and Third Generation (6 interviewees). We have made no division between the First and Second Generation, as several interviewees belonging to the former were -in some cases, also - studying in the late 70's and/or early 80's, thus making the division too blurry to be relevant to our study.

There was variety in the interviewed volunteers' experiences in voluntary work within the ACM, and in their knowledge of the actions that the ACM takes. This variety is related to the positions held within the organization: they ranged from roles in local representations of the ACM - by students at campus or professionals both from industry and academia (the aforementioned ACM Chapters)-, to senior professionals chairing committees at different levels and structures. All interviewees have participated in organizing a celebration for women in computing.

The core questions focused on why women join ACM-W initiatives, what was their experience as a volunteer and what could be done further, i.e. suggested future lines of action. Based on the answers, follow-up questions were asked.

The interviews were conducted mostly using videoconference. When not possible, email was the chosen alternative. They lasted 20 minutes on average and were all conducted in English. The researcher also took notes and recorded the interviews.

Notes from the interviews were read, and some themes were identified and assigned to categories. This was an iterative approach and the themes were refined with every iteration, which results in the final themes presented here. More themes will be identified following the same method.

IV. RESULTS

During the interviews, many different topics were raised. Work has, and still is, being done in further analysing the data and build on the conclusions drawn from it. Thus, the material to be presented in this paper had to be selected from the original available data set according to the following criteria: we have chosen to summarize the interviewees' statements on their motivation to join the initiatives, their target audience, and a few of their suggested lines of action. As, according to the interviewees themselves, there is a shortage of volunteer

time, we analyze what motivates volunteers and what they regard as relevant future work, in order to support focusing future efforts on increasing the attraction of supporters and collaborators of initiatives in women in computing.

Motivation

Almost all women stated the need to “*build a lasting sense of community, so that women no longer feel isolated and alone*”. Although the women of the Second Generation stated that they did not see low numbers in female enrollment during their studies, later in their career they did notice that “*too often, [they were] the only woman at the meetings at work*”. In contrast, interviewees of the Third Generation stated the low rates of female enrollment in their programs and, consequently, of a support network formed by peers that they found relatable: “*It’s fun to hang out with the guys but at some point you want to ask someone where to get a haircut and the guys can’t tell you that*”.

Women of both the Second and the Third Generation seemed to find their mentors a very valuable asset and a positive influence in their career, and thus they aim to provide the same for younger women: “*It’s not impossible to succeed in conditions with no role models and no support, but it’s very difficult.*”

Target Audience

When asked who they were doing this work for, or who they thought benefited from these efforts, interviewees referred to different groups. Another answer was “myself”: several women mentioned that they had developed different skills and broadened their network thanks to their participation in ACM-W’s initiatives. Some interviewees stated that efforts seem to focus on women doing their studies at a university level, though the volunteers also pointed out their work for women of the Second Generation and for a younger (the Fourth?) generation, mainly through -formal or informal- mentoring.

Proposed Lines of Action

It was commented that “*ACM-W succeeds tremendously well, with an all-volunteer staff.*” Due to the voluntary nature of the work, there was some concern related to the effort involved: “*[volunteers] donate service hours at a personal cost to themselves.*” It was considered important to reflect on actions aimed at “*prevent[ing] burn-out among project leaders.*”

Suggestions were discussed in the area of improving the organization in itself: training ACM volunteers in inclusive leadership and hiring paid staff to support the ACM-W volunteers were some of the ideas proposed.

The interviewees also commented on the need to broaden the scope of the current efforts, broadening the target audience to children and teenagers: “*raising awareness of the need to change the education system so that every child has the opportunity to be trained in computer science.*” Men should

also be involved in initiatives to support women in computing: “*after all, 80% of ACM members are men*”.

V. DISCUSSION

For this study, the author had an insider’s perspective as an ACM volunteer interviewing colleagues. This fact influenced the responses in aspects such as the level of detail in their explanations of ACM activities: the interviewees assumed that the interviewer already had most of this knowledge. Due to their collaboration in the organization, interviewer and interviewees had a more relaxed discussion than what may have been the equivalent of having a stranger asking the questions. This results in more honest answers.

If, according to our results, the motivation of these volunteers comes from the wish of providing themselves and others with a network, actions with this goal should be taken by relevant organizations, e.g. increasing the number of social events on and off campus for students, after-work activities for professionals. A network for whom? The Third Generation focused on the network at a university studies level, i.e. trying to get more female students in the field (and reducing their dropout rates), while the First and Second Generation also mentioned how important it was for them to have women breaking the glass ceiling and to establish a more gender-balanced environment at work.

A possible explanation of this difference is that the pool of experience from which the volunteers draw their material for mentorship and other related activities varies according to generation. As explicitly discussed with one of the interviewees, it seems very difficult to help women who are ahead of oneself in their career path. How could one know how to support them? The answer to this question is hard to find if we focus on advice and mentorship. However, other kinds of support, e.g. distributing information about events targeted at female academics, are possible for virtually any volunteer, regardless of age and level of experience. Reflecting on how to raise awareness of these alternative ways of volunteering for all volunteers is thus recommended.

Concerns related to volunteers potentially being burnt out may be addressed by the organization by including stress and time management in a volunteer training program. Another aspect of this plan, mentioned in the results section, is education related to inclusive leadership. This training may not necessarily be reduced to just the ACM: one way for other institutions to support initiatives in computing is providing similar training to the members of their community. However, our data shows concern about not only about time management but also about recognition: what value are we giving to work in initiatives for women in computing? Is the – lack of – recognition one of the factors that volunteers consider when deciding whether to devote a particular “free” time slot of their time to volunteering or to a different – more prestigious – activity? How is the organization where a

volunteer has a paid job supporting this volunteer's activities within, in the case of this study, ACM-W? Positive examples that answer this last question are flexible schedules that allow volunteers to attend ACM events, and even funding of a number of hours per week to work in gender and computing related activities.

Volunteering for initiatives for women in computing, and mentorship programs have clearly been seen by the interviewees as a great asset. How can organizations in industry and academia further support women and men for a gender-balanced environment? Having local initiatives, such as the aforementioned Gender Equity Group at the Department of Information Technology at Uppsala University, or a local ACM-W Chapter, provides women studying or working in an organization with a support group. It also allows them to take an active part in this kind of initiative, with the benefits stated above. Additional available options include, but are not limited to: funding attendance to celebrations of women in computing and - primarily for students - to research conferences, organizing local celebrations and networks, and providing the option to take part in a mentorship program.

The ACM provides institutions with material and support to start and maintain initiatives for women in computing. So far, women have been the main gender represented in the ACM-W team; the next logical step seems to pursue a mixed approach, i.e. targeting these efforts at both men and women. It could be argued that this is already underway. However, this is not a trivial step. Little has been studied about how to be a male advocate for women in computing: how do (wo)men perceive actions against sexism if they come from a man? What actions can a man take in order to "walk a mile" in the shoes of a woman in computing? It is crucial to involve men in initiatives such as the ones organized by ACM-W, as vertical segregation leads to a striking fact: most of the power in organizations is held by men. The inclusive leadership training mentioned in this section is one of the ways to provide men in these positions with the background necessary to support initiatives for gender equality in computing.

Although the ACM works on building the CS curriculum, our results show that volunteers believe that a more focused effort on educating younger students is needed in order for this target audience to be reached before it is too late.

Based on this study we suggest that future research in the area focus on the theory of communities of practice [25] and interpret how to build a better community for women in computing based on our results.

ACKNOWLEDGMENTS

This study is being made with the support from ACM-W. I would like to thank everyone that participated in the interview study, and those who have given valuable input to this paper.

Software Engineering Education –

Does gender matter in project results? – A Chilean Case Study

Maíra Marques
Computer Science Department
Universidad de Chile
Santiago, Chile
mmarques@dcc.uchile.cl

Abstract— Teaching software engineering in a practical course in academia is considered one of the best strategies to help students understand what they will face in industry. Teamwork, coordination, communication are soft skills that are demanded in real life, but how to improve these courses to be more effective and yield better results is not clear. Software engineering – as with most computer careers – is known to be short on women, but the participation of women improves diversity to student teams. Women may have personal characteristics that are different from the ones we normally see among male software engineering students. Do, mixed gender software teams have better project results than one-gender teams? After assisting software engineering courses for four years, I observed mixed gender teams to be better. With this idea in mind I performed a case study where I analyzed the behavior and the results of software projects over nine semesters. The obtained results show that mixed gender teams were more effective and coordinated.

Index Terms— Software engineering education, gender influence, effectiveness, teamwork

I. Introduction

Software engineering (SE) is a discipline oriented to applying a systematic, quantifiable approach to the development, operation, and maintenance of software [1]. As any engineering discipline, it is tightly linked to the industry; therefore, the software engineering curricula used in computer science programs need to prepare students for the world of industrial software development [2].

Fox and Patterson [3] pointed out that while new college graduates are good at coding and debugging, employers complain about other missing skills that they think are equally important (e.g. working with non-technical customers, working in teams, etc.). The usual faculty reaction to such criticism is that they are trying to teach principles.

It is well known that the industry needs people able to work in teams to develop and maintain software. However delivering young professionals that are proficient in technical and operative issues is a great challenge for educational institutions [4] [5] [6] [7]. Begel and Simon [8] pointed out that universities are striving to prepare students for the industrial

scenario and to become lifelong learners, able to keep pace with the software engineering advances. Typically the universities tend to adequately teach the technical aspect of software engineering, but do not address operative issues such as managing projects/risks, defining/adjusting software processes, and performing teamwork.

Teams are the basis of software development organizations today, since the challenge and complexity of projects has made software projects unachievable for individuals. In this setting, professionals are not only required to have state-of-the-art knowledge and technical abilities. It is assumed that software will be built in cooperative and diverse teams, but the reality of software engineering teaching is sometimes different. Effective teamwork requires mastering specific abilities, such as leadership, coordination, conflict management and other skills. This implies that if higher education wants to meet the requirements of the students' future professional lives, it has to address the acquisition of such and have the technology to support the transference process. [9].

The participation of women in science, technology, engineering, mathematics programs and careers is disproportionately lower than that of men [10] [11]. Zeldin and Pajares [12] showed with a comparative study that social persuasion is one of the primary sources of self-efficacy beliefs for women in technology fields of study.

Women and men may have different goals when they participate in project-oriented courses; women's goals are more oriented towards teamwork and peer learning, than men [13]. In environments that are male-dominated, however, social learning strategies such as help seeking can be perceived as weakness [14], which may create situations that negatively influence the motivation, self-efficacy, and future engagement of students. Project-based learning presents opportunities for the pursuit of social learning goals, and evidence suggests that hands-on project activities contribute positively to the learning and satisfaction of both men and women [15].

Women are normally under-represented in IT educational programs and in the IT workforce [16]. But specifically in software engineering, there is not much reported on the gender difference. Nelson [17] stated in a recent article that diversity is important and that woman in computer science in general are

not encouraged to pursue a computer science degree. He also speaks about some case studies that helped increase the participation of women. Diversity needs to be increased and stimulated in all areas because it results in diverse points of view that are needed to solve different problems. In Chile, our reality is not formally known; there is only anecdotal information about gender subjects, with few factual data reports.

At Universidad de Chile, we teach software engineering using a hands-on methodology where students have to develop their projects and deal with the client in their own way. Of course they are not just thrown to the lions (clients). The lions are known (inside clients) and they have full support of the instructor's team.

In order to identify if there is a difference among the results of software engineering projects in academia related to gender, two hypothesis were proposed: mixed gender teams are more coordinated (H1), the participation of women in software engineering teams makes teams work more effective (H2).

In this case study I will show that software engineering teams that have female participation as team members are more effective and have better odds of achieving positive results.

II. Background

The wide use of technology creates very complex situations that professionals in IT need to be able to manage [19]. Typically, most of the situations that engineers find in practice differ from those they found previously. Therefore, engineers must be able to use engineering concepts that they have learned during their education to create solutions for real-world problems [4]. However, it is well known that the software industry is usually unsatisfied with the level of real-world readiness possessed by new engineering graduates entering the workforce [4] [20] [21].

Parnas [22] defined three steps required to produce software engineering programs: (1) define the possible tasks that a software engineer is expected to perform, (2) define a body of knowledge required for the software engineer, then (3) transfer such knowledge as a training program. This definition clearly identifies the need for transferring the most important knowledge to the students and also the skills required to use it in future developments. This definition is aligned with the role that Denning states for software engineers [4]. These definitions suggest that we need to address two main challenges: (1) identify and transfer the key knowledge to the students, and also (2) encourage students to develop the skills required to apply such knowledge in real-world work scenarios. According to Parnas [20] [21] [22], these challenges should be addressed through hands-on experiences that expose students to some frequent problems before they become stranded on their own.

There are also other researchers that identified challenges on other aspects of the transference process: teaching software processes with traditional methods (expositive lectures) [23] [24], educational challenges [25] and features of the development process or evaluating the work performed by the students [2] [26].

According to the selectivity hypothesis [27], males process information in a heuristic manner – paying attention to cues that are highly available and salient in the context. Females process information in a comprehensive manner, attempting to assimilate all available possibilities. In our problem solving and project development, the selectivity hypothesis implies that males and females will respond differently to different insights, which should impact problem-solving decisions. These differences imply that the information, the environment presents and how the environment presents information will impact on decisions and on how females and males interact and contribute to a project.

In this work, coordination will be measured as a coordination self-efficacy measure, where we define self-efficacy as the strength of belief that one can complete a task. The role of self-efficacy is especially pronounced for women in engineering programs [28]. In the social cognitive theory model of self-efficacy proposed by Bandura [29], three factors that contribute to self-efficacy are identified: mastery experiences, vicarious experiences (i.e., identification with role models) and social persuasion (positive feedback from others). Mastery experiences, of course, are what educational experiences generally seek to specifically provide.

Project-based courses reflect authentic engineering experiences as they facilitate a sense of domain mastery and thus lead to an increase in engineering self-efficacy [30]. Self-efficacy is also closely related to motivation, as a student's confidence directly impacts his/her course of action [30, 31]; self-efficacy in engineering and related domains is a prerequisite for both choosing an engineering major and persisting in it [28, 20]. Finally, engineering self-confidence and self-efficacy can vary with demographics; they are notably lower for women than their male counterparts [32, 32]. There is evidence that men show increases in self-efficacy (across a range of constructs) after taking project-based courses, particularly those in which they build a physical prototype, but no similar evidence was found for women [3].

III. Related Work

Glass [34] points out that when he entered the workforce in the late 50' there were no shortage of women practitioner's, but in the middle 80's something changed and the rates of women entering the computer science field in general dropped out. And we are still suffering and seeing that. In South America, things seemed to be a little bit different. Although there is no official data to refer to, people that were working in the field back in the day when computer science began in Chile, report that there was a shortage of women since the beginning.

Some authors propose single-gender classes as one of solutions for this issue [35] [36] [37] [38]. They report that one-gender classes make males or females perform better on overall courses. But all these authors were talking about courses in general and not about project courses, where students have to deal with each other and have to face the reality of dealing with a client. The main idea of the software project courses is to simulate the reality of what they will face

in real life when they start working in industry. In real life it is not feasible to choose to work just with one gender.

The Credit Suisse Research Institute [39] reports on an extensive analysis demonstrating the importance of having diversity on almost all company levels. In their investigation they even report that companies that have females on their board perform much better than companies that have only male board members

Burnett [40] reported an evaluation about the pluralism of gender related to spreadsheet use (feature-related confidence, playful exploration and usage in general). Her results show that there are differences in gender and that mixed genders completed each other in terms of accomplishment than one-gender teams.

IV. Experimentation Scenario

One of the last two software engineering courses at the computer science program at University of Chile is Software Engineering II (CC5401). It is a mandatory class for fifth year students (out of a six-year undergraduate program). For this study we monitored teams during nine semesters. The primary goal of this course is to teach students software engineering in a "hands-on" way, by resembling an industrial setting.

Students are put in teams of 4 to 7 students, according to their capabilities by a MBTI based tool, in use in the last five years [41]. Each student chooses the role they want to have on the team, and if more than one team member want to perform the same role, students have to agree among them.

The projects are real projects that have real clients and a problem that can be solved with information system software that should be addressed in the 15-week course time frame. The students must arrange weekly meetings with their clients and the course have four milestones where they have to deliver something tangible. In the first milestone, they must explain that they understood their client's problem, and show a mock-up solution of the software. In the second milestone they must show a demo of the software with the basic features that the client required. With the third milestone they must show the demo of the full software. And finally in the last milestone, they must deploy and deliver the software to the client. In each one of these milestones, the instructor evaluates student's presentations and the client evaluates the demos. After evaluations, students receive a grade between 1 and 7.

Teams are also supposed to use an iterative development lifecycle in each one of their milestones. And during the iterations they have to produce documents regarding user requirements, software requirements, design specifications, test cases and integrated tests.

In this context there are some challenges that are not minor, and they put some restrictions in our context such as:

- Type of student - 5th year students, neither used to and not prone to working in teams.
- Small projects - since the course has only 15 weeks, the projects need to fit this short time frame of development, and all the projects should have equivalent average size (around 100 function points).
- Real clients – clients are internal to the university, they

normally do not expect much of the project, and they do not fully commit with it.

- Technology – most projects are brownfield ones, meaning that students do not have much of a choice in the technology that will be used in implementation of the solution.
- Type of project – all developed products can be classified as Web information systems, and typically the complexities are similar.
- Roles – each team has defined roles (project manager, analyst, designer, developer and tester) and, depending of the size of the team, there could be more than one team member with the same role.
- Product quality – to guarantee the quality of the product, students should use some of the software engineering best practices and provide quality verification.

Trying to help students minimize these challenges, students have to meet their monitor weekly, and the monitor is someone outside the evaluation team. Students are assured that anything they say to the monitor will not have repercussions on their grades or on instructor perceptions of their team. Monitors lead the meeting, asking the students questions according to the milestones. They also assist students with guidance in technical and social problems that they may have. Monitors do not tell teams what they should or should not do. They are not project managers, coaches or scrum masters.

In this work, nine semesters of the software engineering course are reported (from 2010 until 2014). In total we had 151 students and only 16 of them were women (10.60%), 27 teams were formed and just 10 of them had women's participation. And due to the lack of women it was not possible to set up a software engineering team of women.

Methodology

In order to assess the students' self-efficacy (coordination), a formal peer-review assessment was conducted. Such assessment have been used and evolved in this course over the last seven years. The assessment determines how well each person fits with the behavior expected from a teammate. The students were assured that all opinions would be anonymous and that there would be no formal grades given based on that peer- assessment process.

The instrument used to perform the peer-reviewing process considers eight items that should be rated. The rates were indicated using a five-point Likert scale (from 'strongly disagree' to 'strongly agree') [42]. The evaluated items were the following:

1. He/she assumes the project as a team effort, providing support in project tasks.
2. He/she is able to seek help when problems are found.
3. He/she fulfills his/her tasks properly, working transparently and generating the most value out of each working day.
4. He/she demonstrates initiative to achieve project success.
5. He/she shows a communicative attitude facilitating the teamwork.
6. He/she has maintained good communication with client, generating value to project execution.

7. He/she demonstrates interest in improving performance on the execution of his/her activities and role within the project.
8. He/she is able to admit to mistakes and accept criticism.

These questions are interpreted through five concepts: commitment (1, 2), communication (4), coordination (5), attitude (3, 7, 8), contribution (2,6). These five concepts are our reading and interpretation on what is relevant to teach software engineer. Given the nature of the collected data, a research approach inspired by the grounded theory was chosen to conduct this study. According to Glaser and Strauss [43] grounded theory is the discovery of theory from data systematically obtained from social research.

In order to analyze the effectiveness of the teams, and validate our second hypothesis (the participation of women in

software engineering make teams work more effective) I took into consideration the final grades of software projects, considering mixed and non-mixed gender teams and the deployment and use of the software (successful project) as measures. Provided that the instructor, teaching assistant, course content and dynamics did not change during the observed semesters we can consider these teams comparable.

V. Results

Figure 1 shows women participation during the nine semesters being reported. Only sixteen female students enrolled in the software engineering course during the period being observed (approx. 10.6%).

Figure 1 – Women's participation

A prior analysis of grades was performed with the students that were enrolled in these nine semesters to check if the female participants generally performed better than the males (in terms of grades). Only two female students were among the top students, and 15 male students that participated in this research were among the top students. We can say that the amount of top women participating in this sample is comparable with the amount of women participating in this sample.

In order to evaluate first hypothesis (teams that have women as team members are more coordinated) we used the results of the peer-reviewing process, as a way of self-efficacy perspective. Because they represent the teammates opinions, which probably are more accurate than the instructor, teaching assistant or monitoring opinion.

Figure 2 shows the obtained results for the peer evaluation and the concepts derived from the peer evaluation questions.

The results indicate that our hypothesis is aligned with the results that mixed gender teams have better coordination (in terms of self-assessment) than male only teams. The difference between mixed gender teams and male teams is 0.81; mixed gender teams are 20% higher in terms of self-perception than male teams. The other concepts have differences but they are not so significant as to be statistically valid (commitment 9.7%, communication 7.8%, attitude 9.6%, contribution 9.4%). The median of the concepts of the male teams was: commitment 5, communication 5, coordination 4, attitude 4, contribution 5 and collaboration 4; for the mixed gender teams the median values were: commitment 5, communication 5, coordination 5, attitude 5, contribution 5 and collaboration 5.

Looking in the roles performed by women in projects, there is no clear tendency; the women performed all the team roles that we have (project manager, tester, analyst, designer and developer); the only role that have just one female was the

designer; all the other have proportional female participation. So, the women roles are not a relevant data to our results.

Figure 2 - Peer Evaluation

To analyze our second hypothesis (H2 - the participation of women in software engineering teams makes teams work more effective) the project grades and the software deployment were taken into consideration.

Figure 3 shows the project grades and the course final grades for male teams and mixed gender teams. The grades of mixed gender teams are 16% higher when we are talking about project grades and 13% higher when we are talking about final grades.

Figure 4 shows the project results. It also shows which projects were successful and which were used by the client (deployed) for the mixed gender teams. Figure 5 shows the same for the male teams.

The mixed gender teams have 10 projects. From these, 9 of them were deployed resulting in a success rate of mixed gender teams of 90%. The male teams have 17 projects and only 7 were implanted, so the success rate of male teams was 42%.

We conclude that the second hypothesis is aligned with our results, and that the participation of women on software engineering teams makes teams work more effective (H2).

In order to ensure that the data source used in this study is valid and reliable, the Cronbach's Alpha coefficient was calculated from the eight questions of the peer-review form, from the 138 respondents (total of 151 participants) and we had

a Cronbach's Alpha of 0.82. The closer Cronbach's Alpha coefficient is to 1.0 the greater the internal consistency of the items is in the scale. According to Gliem and Gliem [44], a value of Cronbach's Alpha of 0.8 from Likert-type scales is good and is considered a reasonable goal.

VI. Threats to Validity

Analyzing the threats to validity of this case study, we found that the internal validity within the course is not a problem, since students may respond differently at different times. But, each time a student takes the course the project will be different. Cronbach's Alpha shows that there is consistency in the answers of students. The major threat regarding the conclusion validity is the quality of the data collected. The students are expected to answer the peer review assessment in the most truthful way, but sometimes students took the comrade behavior, and did not evaluate a colleague properly. Another threat is the project grades. To minimize this threat the grades are given by instructor, teaching assistant and client/user. The construct validity has one threat; the subjects are part of a course, where they are graded; this implies that the students may bias their data, as they believe that it will give

them a better grade. To minimize this threat at the beginning of the course the instructor stated that the peer review was voluntary and anonymous.

VII. Conclusions

In this paper we have described a case study comparing the results of mixed gender teams and male teams in student software projects in academia. Two hypotheses were proposed: mixed gender teams are more coordinated and are more effective. The results show that in our context our hypotheses are aligned with the outcomes.

This paper has two main contributions: unfortunately, we found that female participation in software engineering (CS degree) is not so different from studies in other countries [45]. The paper also contributes to finding that the mixed gender teams can improve the results of software engineering teams in academia. This is reportedly happening in other areas. Mixed-

gender teams offer more coordination and focus to student teams, help them focus their efforts on what really matters.

Mixed gender teams in software engineering education improves the results of software engineering teams in academia. Students learn to work on real-world projects with substantially better results.

The next step considers a more in-depth study on the gender subject, analyzing the recorded data from team meetings, an evaluation of which skills are increased in a mixed gender software teams in academia and why mixed genders perform better in terms of self-efficacy.

Abstract—Work/family conflict is often cited as a concern for attracting and retaining talent in professional careers. STEM careers have been noted as particularly discouraging to professionals, especially women, for work/family concerns among other reasons. However, little research has explored the work/family attitudes of prospective professionals in these careers. This paper explores the work/family attitudes of graduate students in computing. Based on data from the Computing Research Association's (CRA) Center for Evaluating the Research Pipeline (CERP) 2011-12 nationwide survey of 1286 computing graduate students, our analysis explores at the aggregate and by sex, the connections between graduate computing education, work/family issues, and career expectations. The analysis of the data reveals work/family issues are important to those in advanced education planning careers in the field. Computing graduate students are strongly influenced by work/family issues in their decision-making regarding advanced computing education. Graduate computing students report high levels of knowledge of work/life strategies and express confidence about their abilities, and their likelihood, for balancing work and family. These findings should help graduate educators and prospective employers concerned with diversity understand the work/family concerns of computing students and future computing professionals.

Keywords—gender in computing; work/family attitudes; computing education; computing careers.

I. INTRODUCTION

Work/family conflict is increasingly cited as an area of concern for attracting and retaining talent in professional careers [1]. STEM careers have been noted as particularly discouraging to professionals, especially women, for work/family concerns among other reasons [2]. However, little research has explored the work/family attitudes of prospective professionals in these careers.

To address the lack of research in this area, this paper explores the work/family attitudes of graduate students in computing. Based on data from the Computing Research Association's (CRA) Center for Evaluating the Research Pipeline (CERP) 2011-12 nationwide multi-institutional survey of 1286 computing graduate students, our analysis examines at the aggregate and by sex, the connections between work/family

issues, graduate computing education, and career expectations. The analysis assesses several work/family influences on choosing graduate education. In addition, this study examines computing graduate students' knowledge of strategies to balance work and family and the level of confidence they have in their abilities to employ these strategies in their own lives. The findings of this research should help educators, employers and others concerned with diversity understand the work/family interests of current and prospective computing students and future computing professionals.

II. LITERATURE REVIEW

A. Gender, STEM Education and Career Intentions

A variety of important features of social and educational institutions steer women away from pursuing education and careers in STEM fields including lack of accurate career information, lack of encouragement, and gender and occupational stereotypes [3, 4, 5, 6, 7, 8, 9, 10]. Recent research suggests that work-family issues may be among those important aspects discouraging women from education and careers in STEM. Research on educational and career choices in STEM fields proposed a negative relationship between family-focus and interest in pursuing STEM education and careers for all students and, especially, for women [11, 12, 13, 14]. Other research [12] finds that concern over work/family balance issues in STEM occupations increases relative to non-STEM occupations as women proceed through college.

These findings suggest that students who persist in computing will exhibit less influence than most students from issues related to family concerns or other issues about balancing work with other aspects of life. Moreover, women in computing would be less concerned about work/life issues than the majority of women, and those in the more advanced levels, such as doctoral study, would be least concerned. Women with concerns about work/life issues likely would be filtered out of computing before even starting, or as they progressed through levels of education.

B. Work and Family Research

Prior theory and evidence suggests that work/family concerns impact students and professionals as they navigate through educational and career domains [15]. Some of this

work argues this impact is gendered; that men and women have different concerns and influences on their choices to pursue further education and professional careers [15]. Family-related issues, such as caregiving responsibilities and other family-oriented matters are perceived as an important aspect of female gender roles. As women enter previously male-only domains in the public sphere such as advanced education and professional careers, the private sphere often remains a female-dominated domain [16]. Even though younger generations have shown a more dual-centric (career and family) focus [17], when these spheres collide, women are more likely than men give primacy to family issues [18].

Computing is an interesting field in which to explore these issues. As a profession, computing suffers from serious underrepresentation of women [19]. Despite an especially positive job outlook, only a small proportion of those choosing to study computing at the undergraduate and graduate level are women [19]. Even fewer women choose to pursue careers in the field [20].

Recent research reveals many women in computing careers face difficulties in the workplace. One study showed a high rate of attrition for women who start computing related careers in the private sector. Hewlett et al. (2008) found that over 50% of women are gone within 10 years due to, among others issues, a masculine culture of work environments and the excessive time requirements of the work [2]. Also disheartening is that half of these highly qualified women leave their positions for jobs outside their STEM field [2]. It is these concerns about the prospects for work/family-friendly careers that may add to the propensity of women to opt out of pursuing further education and to choose alternate options for careers, even amongst those who have persisted in computing to the graduate level. Further salience of work/family issues is revealed in a study of female STEM faculty which argued that the institution of meaningful work/life policies would likely lead to greater satisfaction and, thus, retention of female scientists in academia [21].

Computing and other STEM careers are not alone in suffering from the loss of women due to work/family issues. Work/family balance issues have been cited as major factors in pushing women out of other professions such as law, medicine and business [22, 23, 24, 25, 26]. Research has also suggested that work/family concerns have influenced women to opt out of areas of study leading to careers in fields they perceive as incompatible with their family aspirations [1]. Given that work/family issues have affected professionals in other careers what impact, if any, might these concerns have on graduate students as prospective professionals in the field of computing? Do computing graduate students differ by gender in their focus on work/family issues?

III. HYPOTHESES

We hypothesize that work/family issues will be important to the majority of computing graduate students. If gendered expectations relating to work/family issues exist, we would expect to find that women are significantly more likely than men to report the influence of family/personal responsibilities and lifestyle on their decision to pursue graduate education in

computing. Similarly, if work/family gender differences maintain we would find women citing greater knowledge of work/life balance strategies and expressing significantly more concern, and less confidence than men, in their ability to achieve work/life balance.

IV. DATA AND METHODS

The data utilized in this analysis comes from the Computing Research Association's (CRA) Center for Evaluating the Research Pipeline (CERP) graduate student survey. Distributed during the spring of 2011 and 2012, the survey was completed by 1286 graduate students completing their degree program during the academic year from a broad range of computing departments at universities across the U.S. (N = 96 departments). We define computing departments as those offering graduate degrees in a computing discipline, including computer science, computer engineering and information sciences. A list of sampled institutions is available upon request.

The CERP survey assesses graduate students' professional experiences, their knowledge about professional development and the strength of their professional network as they progress towards a career in computing. The goal of the survey is to have students reflect and report on their experiences in their degree program; and to gauge students' plans for the future. These data allow us to explore at the aggregate and by sex, the influence of work/life issues on computing graduate students including the influence of family and lifestyle concerns on their decision to pursue further education, their knowledge of work/life strategies and confidence in their ability to achieve work/life balance.

We operationalize the measures of work/family focus as follows:

Education:

Family Concerns

- Did family or personal responsibilities discourage or encourage you in choosing to seek, or not to seek, a PhD in computing?

Lifestyle

- Did having the kind of lifestyle you want discourage or encourage you in choosing to seek, or not to seek, a PhD in computing?

For both education questions, respondents were given a scale from 0 = Not Answered, 1 = Strongly Discouraged, 2 = Somewhat Discouraged, 3 = Somewhat Encouraged, 4 = Strongly Encouraged, 5 = No Influence/Not Applicable. The resulting data were recoded so that "No Influence" = 0, "Any Level of Influence" = 1, and "Not Answered" = missing.

Careers:

Knowledge:

- Rate your current knowledge of strategies for work-life balance?

For the knowledge question, respondents were given a scale from 1 = None, 2 = Almost None, 3 = Some, 4 = Quite A Bit, 5 = Don't Know/Not Applicable. The resulting data were recoded so that "Some/Quite a Bit" = 1, "None/Almost None" = 0, and "Don't know/not applicable" = missing.

Confidence:

- How confident are you that you can successfully develop a satisfying work-life balance?

For the confidence questions, respondents were given a scale from 1 = Not At All Confident, 2 = Only Slightly Confident, 3 = Moderately Confident, 4 = Very Confident, 5 = Don't Know/Not Applicable. Resulting data were recoded so that 0 = "Not at all or Slightly Confident" (formerly 1 and 2) and 1 = "Moderately/Very Confident" (formerly 3 or 4). A response of 5 was set to missing.

Analyses of our key variables were performed on respondents replying to the gender question. This specification resulted in 727 valid cases for analysis, 517 men and 210 women.

V. RESULTS

Results from the CERP graduate student survey show that male and female graduate students in computing are remarkably similar in their knowledge and confidence related to career and family domains. Despite literature suggesting gender differences on work/family issues for prospective professionals in demanding careers, the data suggests no significant or substantial gender differences exist.

The descriptive statistics of the CERP Graduate Student Survey sample show a demographic profile of computing graduate students that is largely in line with the averages for graduate computing students at American universities. As Table I shows, they tend to be young and mostly male (a median age of 27 years old, 71% male).

Table I also specifies the family and caregiving status of respondents. The median age of graduate students is 27, about the age and time in their life cycle when they are starting to form families. 38% of respondents are either married or in a long-term committed relationship and 11% have the primary caregiving responsibilities for at least one child. Interestingly, there are no significant gender differences in those reporting primary child caregiving responsibilities (10.2% and 12.9% for men and women, respectively.)

While not affecting the majority of graduate students, work/life balance issues played a direct role for a substantial minority in the constraints placed on pursuing a career in computing. For instance, 23% of respondents reported that dual career concerns and the need to coordinate with a spouse/partner's job location constrained their own job search.

TABLE I. CERP GRADUATE STUDENT DEMOGRAPHIC PROFILE

	N	Categories						
		Men				Women		
Gender	727	71%				29%		
Age	693	Median Age of Respondents						
		27

Family Status	726	Married/LT Relationship				Primary Caregiver of Children		
		38%				11%		

A. Work/Life Balance and Computing Careers

1) Knowledge of Work/Life Balance Strategies

Graduate students in computing rate their knowledge of work/life balance strategies high, with 84% of all respondents reporting they have "Some or Quite a Bit" of knowledge regarding work/life balance strategies. Knowledge in this area ranked sixth, behind knowledge in a range of job search elements such as resume writing (95%), job searching (93%), knowledge of career next steps (93%), job application knowledge (93%) and time management strategies (86%). Graduate computing students reported their knowledge of work/life balance strategies exceeded their knowledge in other key areas pertaining to their prospective careers such as developing a professional network (72%), effectively using that network (64%), working productively with a mentor (64%), effective teaching strategies (61%), negotiating a job offer (59%), mentoring students and interns (58%), finding their own mentor (53%) and their knowledge of the tenure process (51%). Knowledge of work/life balance strategies was ranked much higher than a variety of important career related factors. Less than half of computing graduate students reported knowledge of supervising students and interns (48%), new faculty expectations (47%), and appropriate volunteer opportunities (45%). The majority of graduate students reveal a lack of knowledge in research related matters such as developing research collaborations (44%), starting their research programs (41%) and obtaining research funding (34%). Contrary to expectations, there were no significant differences evident between men and women in their knowledge of work/family balancing strategies. As shown in Table II, more than four-fifths of men (83%) and women (87%) report that they have good knowledge of this important area of their life. Neither analysis of variance nor correlations showed any significant or substantial difference in the knowledge men and women have of work/life balance strategies.

TABLE II. KNOWLEDGE OF WORK/LIFE BALANCE STRATEGIES

	Male (% knowledgeable)	Female (% knowledgeable)	Correlation between gender & knowledge
How would you rate your current knowledge of work-life balance strategies?	83%	87%	-.05 two tailed significance = .27

2) Confidence and Work/Life Balance

Confidence runs high for graduate students. In general, graduate students report a high level of confidence for a variety of factors pertaining to their prospective computing careers. Graduate students see themselves as confident in setting career goals (87.4% saying they are moderately or very confident), managing their time (85.9%), planning steps for achieving their career goals (84.9%) and finding a job (83.9%). Out of the twelve factors, confidence in developing a satisfying work/life balance ranked as the fifth highest area of confidence (82.8%). Confidence in work/family balance ranked higher than confidence in other areas such as getting promoted on time (77%), developing professional networks (72.2%), teaching classes (66.9%), mentoring students (64.6%) and negotiating a job offer (62.6%). Graduate students pursuing research careers in computing had the least amount of confidence in their research prospects with 41.9% reporting confidence in starting up their research program and only 36.5% showing confidence in gaining research funding. Neither analysis of variance nor correlations showed any significant differences in the confidence perceived by men and women regarding work/life balance. Table III shows that approximately four-fifths of the women and well over four-fifths of men in this sample reported confidence in their ability to develop a satisfying work/life balance.

TABLE III. CONFIDENCE IN DEVELOPING SUCCESSFUL WORK/LIFE BALANCE

	Male (% confident)	Female (% confident)	Correlation between gender & confidence
How confident are you that you can develop a satisfying work-life balance?	84%	79%	.06 two tailed significance = .15

B. Work/Life Balance and Computing Education:

CERP respondents were asked a series of questions regarding influences on their decision to pursue graduate education in computing, ranging from the influence of undergraduate advisors to immediate employment opportunities. On average their strongest influences on educational decision-making were “the kind of work I want to do” (84%) and “the kind of lifestyle I want” (80%).

1) Influence of Family/Personal Responsibilities

Table IV shows that family/personal responsibilities played a role for the majority of students continuing in computing

further education (67%). Both men (67%) and women (68%) report these factors as an influencing their choice to seek a PhD in computing. According to both an analysis of variance and correlations, there are no statistically significant differences between males and females in relation to the influence of family or personal obligations on their decision-making related to pursuing a PhD in computing. The relatively high percentage for both males and females reveals the importance of this factor for the educational decision-making of computing students.

TABLE IV. INFLUENCE OF FAMILY/PERSONAL RESPONSIBILITIES ON DECISION TO PURSUE PhD IN COMPUTING

	Male (% influenced)	Female (% influenced)	Correlation between gender & influence
Did family or personal responsibilities discourage or encourage you in choosing to seek, or not to seek, a PhD in computing?	67%	68%	-.02 two tailed significance = .70

2) Lifestyle

Lifestyle concerns exert an important influence on PhD education choice. A majority (80%) of graduate students report their desired lifestyle was important for their choice to seek a PhD in computing. Analyses of variance and correlations reveal no statistically significant gender differences with respect to the importance graduate computing students placed on lifestyle issues when choosing to pursue advanced computing education. Here again the relatively high percentages for men and women (81% and 75%, respectively) reported in Table V suggest that these are concerns that influence most prospective computing professionals.

TABLE V. IMPORTANCE OF DESIRED LIFESTYLE ON DECISION TO PURSUE PhD IN COMPUTING

	Male (% influenced)	Female (% influenced)	Correlation between gender & influence
Did the kind of lifestyle you want discourage or encourage you in choosing to seek, or not to seek, a PhD in computing?	81%	75%	.06 two tailed significance = .16

DISCUSSION

The results show that male and female graduate computing students share largely the same influences on their decision-making regarding their intentions to seek a PhD in computing. Similar to undergraduate computing students [28], men and women graduate students do not differ in their perception of the role that family/personal responsibilities or the role that desiring a particular lifestyle played in their decision-making regarding pursuing graduate education.

Work/family issues matter to computing graduate students. Graduate students report a high level of knowledge about work/life balance strategies and have confidence they will be able to enact these strategies to achieve a satisfying work/life balance in their computing careers. No substantial differences exist between men and women on either levels of confidence or knowledge about work/life balance strategies.

CONCLUSION

Work/family issues are important to computing graduate students. This research shows work/family concerns influence both male and females in similar ways. Gender differences in work/family influence, knowledge and confidence do not appear in computing graduate students. These findings suggest that either gender differences have been overstated and/or STEM fields such as computing effectively filter out those with even higher levels of interest in balancing work and family. Further research comparing computing students who choose not pursue graduate education with those who do would illuminate whether or not significant differences exist in these populations with regard to gendered attitudes toward work/family issues. As evidenced by the results of this study, we suspect that those with very strong interests in work/life balance are filtered out of the field before reaching graduate level studies.

The findings from the present study reveal that work/life issues are of interest to the majority of prospective computing professionals, both women and men. Educators, employers and others interested in attracting and retaining more and diverse students into computing would benefit from taking these factors into account in their recruitment and teaching strategies. Stressing the availability of high quality, flexible jobs that allow for opportunities to develop a satisfying work/life balance would address some of the myths and negative stereotypes often associated with computing careers.

Student evaluations of team members: Is there gender bias?

Joyce B. Main, Matilde Sánchez-Peña
Engineering Education Department
Purdue University
West Lafayette, IN, US
sanch105@purdue.edu, jmain@purdue.edu

Abstract—The ability to work effectively in teams is a critical learning outcome for engineering students. It is also among the ABET requirements and a skill desired by employers for it is integral to innovation, product development, and to a positive working environment. Many engineering courses provide students with opportunities to develop their team skills through projects, in-class activities, and other assignments. Peer assessment of team skills increases student accountability to teammates, helps students gauge what is expected from them, and assists instructors in assigning course grades; however, there are few studies examining whether gender bias occurs during peer assessment. This work aims to fill this gap, identifying whether gender bias exists in students evaluations of their team members. This study examines whether there are differences in how students evaluate team member course performance based on that team member's gender. We used a randomized experiment inviting 590 first-year engineering students to rate and evaluate a fictional team member. Using identical vignettes, except for the character gender, participants were asked to rate the fictional team member in terms of their skills and qualities. The results indicate that there is no difference in how students evaluate the fictional team members by gender; although there was some evidence of higher scores given to females on their contributions and punctuality. This absence of gender bias supports previous findings and open other research questions about the differences identified. As well as the evolution this absence of biases during the students' educational experience. These results suggest that peer assessments may be an effective method to provide students with additional feedback regarding team skills.

Keywords—team skills, peer evaluation, gender bias

I. INTRODUCTION

The engineering profession requires the interaction of multiple agents to develop integral solutions to problems. Engineers first must consider final users when designing such solutions. Furthermore, since the engineering expertise tends to be specialized, engineers from different disciplines have to work together to build better solutions. All this implies that the engineer must have the skills required to work in teams. This has derived on the authorities of the field recognizing teaming skills in engineering as a required characteristics of our graduates. For example, ABET has detailed that engineering graduates from its accredited programs must have “an ability to

function on multidisciplinary teams” [1] and the National Academy of Engineering has cited that “engineers need to work in teams to be effective” [2].

The ability to work effectively in teams is also a desired skill by employers. Teaming has been denoted as an integral part of product development, process improvement, and manufacturing activities [3]. Organizational researchers, have pointed out that teaming combines connection between people, listening of the views of others, coordination of actions and cooperative decision making; and this process involves the development of affective and cognitive skills which result essential to the success of organizations [3]. Edmondson [4] have stated that teaming is crucial to innovation because the teaming process brings together different participants to produce something new, their different skills and expertise can be enhanced with their interactions and therefore attain superior results.

Engineering undergraduate courses provide students with opportunities to work in teams. Borrego et al. [5] presented a literature review on how the knowledge about teamwork that has been derived from industrial and organizational psychology have permeated to the engineering education arena; and to what extent this interaction has been successful. The authors concluded that through the use of findings from psychology, engineering and computer science instructors can be able to develop strategies to minimize negative behaviors in teams and positively influence student teamwork outcomes. Shuman et al. [6] considering the extent to what teaming and other ABET required skills were prone to be taught and assessed, argued that project-driven classes, if properly structured, could teach students the necessary skills to work in teams effectively.

One strategy that has been used to measure the effectiveness of this training on teaming is peer-evaluation [7]. However, few is known about the interaction of these evaluations and other characteristics of the team members such as gender. In order to use peer-evaluations as a reliable way of measuring gains in teamwork skills, these evaluations should be first free of any bias. This work analyzes the extent to what students generate a biased evaluation of their peers based on their gender. Our research questions are:

A) Is there any gender bias on the preference to work in teams?

B) Which are the reasons that students give for choosing or not choosing working with students in teams?

C) Do students rate men and women differently in regard to performance on teams?

The evidence gathered here will help on designing strategies to teach teamwork skills in engineering education effectively considering any existing effects due to gender.

II. LITERATURE REVIEW

Most professions nowadays need their practitioners to be good team members. Therefore it is a skill that should be developed in the training of such professionals. Areas such as management, business and healthcare [8-10] rely heavily on the teamwork skills of its practitioners. Engineering is not the exception, since it requires a high level of interaction with either customers, other engineers, or other professionals.

In engineering education, students are exposed to different venues where they are able to increase their teaming skills. Since their first year, students are required to work in group projects [11], and this evolves up to more relevant endeavors such as capstone projects [12]. To ensure the effective learning of teaming skills among undergraduate engineering students, they need feedback on their development of these skills. One strategy to attain this is the use of peer assessment. Some of the advantages of using peer assessment include: increase of students accountability to teammates, prevention of "social loafing." Peer assessment also helps students know what is expected of them and how they will be evaluated [7]. Furthermore, it has also been documented that the use of peer assessment helps instructors addressing potential team issues [5, 13].

Other advantage of the use of peer assessment for instructors, is that it provides an additional measure of individual student's contributions to group work, therefore helps on the assignment of grades [7, 13]. Since grades can have significant implications for students in terms of their eligibility for programs or scholarships and future employment, it is important that the influence of peer assessment in their grades is as objective as possible.

Gender bias has been documented in a wide variety of working and academic situations. Snipes, Thomson and Oswald [14] presented an empirical investigation where they found gender bias in the evaluation of service quality, favoring males with higher evaluations. Other research analyzed whether there existed a gender bias in teaching evaluations of faculty members given by students. Even though there was no evidence of such bias, the author was able to document evidence that female faculty members were "subject to culturally conditioned gender stereotypes," since female professors were expected to offer higher levels of personal support than male professors [15]. An experiment performed by Moss-Racusin et al. [16] showed a strong evidence of a gender bias favoring males students when applying to laboratory position. The results pointed out that the female

students were seen as less competent by faculty reviewing the applications. Some other randomized experiments have proved the existence of gender bias in academic and professional settings. An study presented by Milkman et al. [17] showed evidence of gender and racial bias made by professors at U.S universities when it comes to reply to potential PhD students. Professors had a higher response rate favoring white males and lower rates of response to females and minorities.

This evidence of gender bias in different types of evaluations makes relevant to analyze the gender dynamics of peer assessment in student teams. Many research efforts have explored this effect already; however, their conclusions about the influence of gender on evaluations of others still show mixed results.

Different studies have identified a negative effect of gender, favoring male over female students. Scherpereel and Bowers [18] analyzed this dynamics in a junior level business class and reported that women team members self-rated themselves significantly lower than men after receiving peer feedback. In a controlled experiment, Heilman and Hynes [19] tested the level of credit given to women in a fictitious male-women dyad carrying out a project. The students assessing the dyads evaluated the female members as less competent, less influential and less likely to lead during the execution of the presented results, unless the ambiguity of the given information was reduced.

Also at the undergraduate level, some other works have reported an absence of gender bias in peer assessments of contributions to group work. Kaufman, Felder and Fuller [20] explored the differences between given and received ratings by gender in a peer rating system implemented among two chemical engineering courses at the sophomore level; their results concluded that there were no significant difference between the received ratings or the given ratings by gender, i.e. women and men received and gave similar mean ratings.

Falchikov and Margin [21] performed a meta-analysis of forty-eight quantitative studies in peer assessment. The authors compared the ratings given by the students and those given by the teachers across all studies and found a high correlation between peer and teacher marks. In a follow-up study the authors explored the effect of gender bias and found very small effect sizes when comparing the levels of peer assessment obtained by gender [21]. Tucker [22] explored the existence of bias in online self and peer assessment tools, with the analysis of 1,500 participants at two universities and following the methodology created by [21] they found no gender bias in six case studies, although in some of the cases they found also significantly higher ratings given to women when compared to men.

This contradictory evidence motivates this research to assess the level of gender bias in peer assessment at the

undergraduate level among engineering students. It is envisioned that the results obtained here will help shaping the educational experiences to overcome these barriers on teaching teaming skills.

III. DATA AND METHODS

The participants on this study were 590 first-year engineering students at a large research university in the Midwest. They were surveyed during a class of the first-year engineering program. The students were given vignettes about a fictional team member. The vignettes were identical, except for the name of the fictional team member, which was varied by gender. These vignettes were developed based on actual feedback from prior peer assessments from the students in previous editions of the course. An exemplar of one of the four vignettes used and its corresponding change in gender is shown below:

“Emily/Steve is an enthusiastic and helpful team member. She/He attends meetings on time and contributes to completing assignments. Lately, Emily/Steve has been distracted by a personal problem. She/he has missed 3 of the last 5 meetings. During the 2 meetings she/he attended, she/he spent most of her time texting...”

Two other names (Xin and Sanjay) were used to reflect the culturally diverse body of students at the school, ending up with a total of 4 names combined with 4 vignettes, and also The students were then required to do an evaluation of the fictional team member using a Likert scale for some characteristics. As well as expressing their interest on having the fictional member in their team and their reasons for it. The questions presented to them were:

Would you want to have a team member like [fictional team member name]: (Yes/No)

Why or why not? (Open-ended)

Please rate [fictional team member name] on the following items: (Likert Scale: 1-5)

- Is a reliable team member.
- Is a trustworthy member.
- Attends meetings regularly.
- Attends meetings on time.
- Contributes to completing the team’s assignments.
- Increases the quality of the team’s assignments.
- Creates a positive experience for other team members.

Information about the age or gender of the participant students was not available, but the collection of this information is envisioned as an improvement in future research endeavors. The final distribution of the male and female vignettes across students is detailed in Table I, where it can be seen that the amount of male and female vignettes distributed were comparatively close to each other (42% and 58% respectively). The vignettes were distributed randomly across students in a selected group which make this a quasi-experimental design.

TABLE I. DISTRIBUTION OF THE MALE AND FEMALE VIGNETTES.

Vignette Gender	Frequency	Percentage
Male	246	42%
Female	344	58%
Total	590	100%

We used data from this evaluation to verify if there was any gender bias on the preference of working with the fictional team member, and how he or she was graded. Results to our research questions are presented in the following section.

IV. RESULTS

This section describes the results to each of the research questions posed previously, the statistical tools used and specific considerations for each analysis are mentioned in each corresponding section.

A. Is there any gender bias on the preference to work in teams?

Since the vignettes were identical except for the name of the fictional team member, students were asked: *Would you want to have a team member like [fictional member name]?* Their answers only had two classes (yes/no) and when accompanied with the vignette gender classes, generated the cross tabulation presented in Table II.

A Chi-Square test failed to reject the hypothesis of independence between the gender of the vignette and its selection as a team member (Chi-Square test = 0.0134, P-value = 0.908). Therefore, there was independence between the gender of the vignette and their willingness to work with the fictitious student, i.e. they were equally willing to work with either the female and male fictional members. This supports Tucker’s [15] results about the absence of gender bias when using peer assessment. Absence of data about the gender of the students answering the evaluation limits further analyses by subgroups, such as identify if this lack of bias is consistent across male and female rater students.

TABLE II. CROSSTABULATION OF VIGNETTE GENDER AND PROPENSITY TO WORK WITH THE FICTIONAL CHARACTER.

		Want on Team		
		No	Yes	Totals
Gender	Male	144 (41.5)	102 (42)	246
	Female	203 (58.5)	141 (58)	344
	Totals	347	243	590
		%	58.8	41.2

Note: Quantities in parenthesis represent percentages within the No/Yes classes

B. Which are the reasons that students give to chose working or not working with students in teams?

1) Thematic coding of open-ended responses

When asked about why they accepted or rejected having a team member as the one described, they reported reasons related to the fictional member characteristics and also related to their own perception of the situation. This section describes the themes identified for either accepting or rejecting working with the fictional team member.

a) Reasons for Yes

When analyzing the 243 cases of yes, i.e. accepting working with the fictional member, 29 codes were identified, but only three of these codes were more recurrently mentioned (~50). The most prevalent code was that the fictional character “will try harder/improve,” followed by the fictional team member was “helpful” even though he/she was not collaborating as usual or expected anymore. The third most recurrent code was that the fictional member “still contributes” to the team. From these codes we observe that students agreeing to work with the fictional member put a higher weight on the first part of the description they received, and have the hope that he/she will be able to perform to those standards again.

Other characteristics the student mentioned about the fictional member to defend their decision were that he/she was enthusiastic and hard-working, and that “things happen” showing empathy for what the fictional teammate was going through. Figure 1 shows the word cloud obtained from the coded themes from the open-ended responses. No further analysis considering the vignette characteristics was performed.

Fig. 1. Wordcloud of reasons for yes.

b) Reasons for No

According to the open coding and thematic analysis of the open responses of the 344 students reporting that they would

not like to have the fictional member in their team. The most recurring code was the fictional member “poor attendance” with 145 occurrences. The second most mentioned code was that the fictional student “does not contribute/work” (102 students). The code with the third highest number of mentions was that the fictional student was not able to “separate work and personal life” (84 students).

Opposing to the arguments used by students accepting working with the fictional team member, those unwilling to work with him/her were more focused on the second part of the information provided. They did not make a tradeoff between the previous contributions of the team member but made the decision of continuing working or not based on his/her current situation. Also, the reasons for no mentioned by students, were more highly cited concurrently rather than alone, and the variety of reasons was also higher than those reasons mentioned for the yes. Figure 2 contains the word cloud generated with the codes for the students that did not want to work with the fictional member.

Fig. 2. Wordcloud of reasons for no.

It could also be argued that the main codes were based on information listed in the vignette (poor attendance, does not pay attention, does not participate, is helpful). However, there were many other codes where students extrapolated the information they received to more complex situations with particular consequences. For example, those accepting on working with the fictional member mentioned things such as he/she will try to improve and that the situation he/she lives is unfair. While those rejecting working with the fictional member cited things such as an extra load of work for the other team members, or causing bad scores due to his/her disengagement.

C. Do students rate men and women differently in regard to performance on teams?

To test this question we compared the ratings given to the fictional team members in the questions presented in the methods section, they included: reliability, trustworthiness, attendance, punctuality, contributions to team assignments, increments in quality of team assignments, and their creation of a positive experience for other team members. The general mean scores in each area are illustrated in Figure 3. The highest scored area was punctuality while the lowest was attendance, which was consistent with the vignette descriptions. The mean scores by gender are not presented here, since for the purposes of comparisons we chose to work with medians, due to the non-normal nature of the data.

Fig. 3. General scores of the vignette characteristics.

The evaluations were made in a Likert scale (1-5, where 5 was the highest possible). We used a Mann-Whitney U test for the comparison of medians. This tool uses the mean sum ranks to compare the median score levels between males and females. The summary of the different tests for each of the described characteristic is presented in Table III. According to these results the only significant difference in the evaluation of students by gender was contributions (p -value<0.05) and punctuality (p -value<0.10). The identified differences favored females with a higher mean rank sum. Therefore, students gave better scores to females when compared to males in their contributions on team assignments and slightly better scores in punctuality to group meetings.

TABLE III. STATISTICS RESULTS OF THE EVALUATED AREAS BY GENDER

Evaluated Areas	Mean Rank Sum		Test Values		
	Males	Females	U	Z	p-value
Reliability	303.2	289.9	40415.5	-1.014	0.311
Trustworthiness	299.1	291.1	40881.5	-0.607	0.544
Attendance	303	290.1	40457	-1.015	0.31
Punctuality	280.4	305.4	38621.5	-1.845	0.065
Contributions	276.4	306.4	37569.5	-2.268	0.023
Quality	286.9	299.8	40128.5	-0.987	0.324

Positive Experience	306.9	287.3	39492.5	-1.469	0.142
---------------------	-------	-------	---------	--------	-------

Effects sizes ranged from 0.024 to 0.093.

From these results we can see that women were better evaluated in contributions and punctuality. Since there was no evidence of a bias in the students' preference to work with the fictional member based on their gender, we also analyzed if there were any existing differences in the given scores depending on the student decision to work or not with the fictional member. In other words, if the student have decided not to work with the fictional member, we would expect the student giving lower scores to him/her.

From this analysis, the medians comparisons resulted as expected, most of the evaluated areas had lower scores for the fictional members that were not selected than those selected. The only area where there was no difference when considering their selection status was punctuality, i.e. the median evaluation for punctuality was not significantly different between the fictional members selected than those that were not selected. Our results support each other; having no difference in the evaluations of punctuality between selected or not selected fictional team members is consistent with the fact that even though there were some differences between males and females in punctuality scores there did not favor the selection of females better than males.

V. DISCUSSION

The absence of gender bias in our experiment is consistent with Tucker's [22] findings, whom reported effect sizes in the same range than those found here. A possible explanation for this may be related to the fictional nature of the team members presented. It has been shown that the nature of the commitment and the time span of a team project influences the students' efficiency communicating and making decisions [23], therefore, a lack of real commitment perceived by students may relate to the results obtained.

Also, Alfonseca [24] have reported that the different learning styles influence the efficiency of people when working in teams. Awareness of these differences can make place to being more permissive when working in teams.

Other possible scenarios for obtaining these results may be related to previous evidence about women working styles. Reference [23] have reported that women prefer to work in teams, therefore the perception of this trait can be reflected in the lack of differences among genders. Besides preferring it, women have also been reported as being better team players [23], which can be perceived by their peer evaluators. These propensity, perceiving women as more prone to work in teams and good at it, can also hide some leniency errors [7]. This would be an interesting area for further study.

Also, the only significant difference implied better scores for women in contributions and punctuality. Considering contributions, this is an insight that actually contradicts existing literature [19] that have pointed out that males are better rated in their contributions to the team. In terms of punctuality it is possible that a gender stereotype is influencing this results.

Among the limitations of this study is the lack of background information about the rater students. Having their gender, age or other descriptives would help on identifying any particular effects within particular groups. For example, identifying any existing bias supporting groups of the same or opposite gender as the rater. Also, the students underwent a teamwork training as part of their preparation for their first year in the program, therefore there may exist some mixed effects due to this training, and it would be interesting to have the assessment made before this training is given to verify if the present results hold.

In addition, there was a limited amount of vignettes and fictional team members to combine; increasing the amount of combinations could help on strengthen the results presented. This could include more names from ethnically diverse backgrounds, or vignettes with different proportions of good and bad information about the fictional team member. Finally, the fact that the students rated fictional members could have influenced the rater students' thoughtfulness to make their decisions. Therefore, we acknowledge that the fictional nature of the task may have an impact in our results.

VI. CONCLUSIONS

This work aimed to identify if there was any gender bias present when first-year engineering students decided if they wanted to work with a fictional team member or not. Based on quantitative analyses of our data, we conclude that there is no gender bias when accepting or rejecting to work in teams with these fictional members. Students accepted and rejected males and females fictional team members in approximately the same proportions. However, the rater students' gender was not known to analyze further relationships between their gender and their proclivity to accept or reject fictional team members of the same or opposite gender.

Students accepting to work with the fictional team member were more focused on the positive information they were given in the vignette. On the other hand, students who were not willing to work with the fictional team member were more focused on the information about his/her negative experiences, circumstances or actions which were presented secondly in the vignette. Students accepting the fictional team member were more empathetic of his/her situation, while students rejecting the fictional member usually projected their behavior as having negative consequences for the whole team.

We analyzed the scores given to the fictional team members in terms of their reliability, trustworthiness, attendance, punctuality, contributions, quality and positive experience, and there were no significant differences in their median scores by gender for most of them. The only areas where females were scored higher were contributions and punctuality. This opposes to Heilman and Hynes results [19] and at the same time that could be a signal of the presence of some gender stereotypes that usually judge women as more responsible than males when they are evaluated under the exact same circumstances.

VII. IMPLICATIONS AND FUTURE DIRECTIONS

Our results support the conclusions made by Tucker [22] about the absence of gender bias in peer assessment. However, at the professional level there is still evidence that some gender bias exist within professional organizations [25]. This discrepancy between the results obtained among college students and those drawn from professional practitioners call for further analysis about the evolution of gender bias attitudes among students. It is necessary to start unpacking the reasons why is this persisting if the training experiences of our students give other evidence. It would be interesting to explore if at some point the transfer of "unbiasedness" from the collegiate experience to the post-graduate professional experience is not happening. A promising strategy to start analyzing this inquiry would be to generate longitudinal analyses that would allow to observe the trends and changes among students during their college life and their experience after graduated.

Other strategies that could be explored is the connection of teamwork efforts in class with work in industry. It has been documented that it is required that the training of our engineers needs certain level of fidelity where we connect "the similarity of the training situation to the students' present and future working conditions" [6]. Other future directions in this line include the analysis of working teams in industry to verify if the gender bias reported by literature holds when it comes to peer assessment. Making connections between classroom teaming skills and professional engineering practice is essential among our graduates, and this is why we suggest that more inquiries in this line are necessary.

ACKNOWLEDGMENT

We thank Jake Davis for the initial coding of the students' open responses and his valuable insights during the analysis stage.

Abstract—Women are underrepresented in STEM fields, and their attrition from the STEM pipeline begins in high school. In this study, the performance, attrition, and course selection of women in mathematics and science subjects were examined in a school where STEM Project Based Learning was introduced. A four-year longitudinal study was conducted. Data from high-stakes tests, course taking patterns, and retention were examined. Results indicated that these women's scores improved in mathematics and science, and more females opted to take physics than did males. Moreover, female student attrition was lower than that of males and decreased markedly after the introduction of STEM PBL to the classrooms. These results indicate that implementing STEM PBL activities in classrooms is promising for improving female participation in STEM.

Keywords—STEM, gender, Project-based Learning, high-stakes tests

I. INTRODUCTION

The purpose of this study was to examine how science, technology, engineering, and mathematics (STEM) project based learning (PBL) affected the success of high school women in mathematics and science using a four year longitudinal study. PBL and cooperative work have been linked to an increase in motivation [2,3]. Moreover, advanced course taking practices in mathematics and science have been shown to influence the pursuit of a post-secondary STEM career [4].

The driving question focusing this study was: Are there differences between the males and females in achievement, retention, and course selection before and after their teachers implemented STEM PBL activities over a four year period?

A. Women and STEM

The number of people who received a STEM degree in college has declined in the United States. The percentage of STEM degrees awarded in the United States in 2002 was less than the average for STEM degrees awarded outside the United States [5]. Interest in STEM and the pursuit of STEM careers have been deemed vitally important in the preservation of the United States' role as an international leader and innovator [6]. Within the United States there was a disparity between the number of women and men in STEM majors and professions [7]. Women comprise over half of the population in the United States, yet they have been underrepresented in STEM professions. While women have gained nearly equal employment in many non-STEM professions, such as law (47.62% women) and business (41.45% women), they have remained a minority population in STEM careers, such as engineering (20.94%) and computer science (20.56%). Women, if interested and engaged in STEM, could play a major factor in positioning the United States and themselves for greater opportunities.

The increased involvement of women in STEM professions could have benefits for women on an individual level as well as for the nation as a whole. Students who graduated with degrees in one of the STEM fields reaped the benefit of higher paying jobs with those employed in STEM professions earning 26% more than their peers earned in non-STEM professions [8]. Employment opportunities were also better for STEM professions with projected job growth of STEM related careers at 17% by 2018 in comparison to 9.8% for non-STEM careers [8]. The nation could benefit from greater female involvement in STEM professions because women could offer a new voice and perspective within these predominantly male fields [9]. The fact that the number of STEM degrees, particularly in Computer Science, Engineering, Mathematics, and Physics,

have been overwhelmingly earned by men, indicated that there was a large segment of the population within the United States that could be engaged in STEM [10]. The focus then turned to answering questions of when and why women have chosen to not pursue STEM careers as well as what can be done to remedy this issue.

Identifying the time period in which women's interest began to shift away from STEM is important in determining the point at which the greatest gains can be made. In early grades the scores of boys and girls on science and mathematics standardized tests were equivalent [11]. Additionally, it has been shown that women's STEM achievement levels did not differ much from men's achievement levels in middle school [12]. In high school, the gap between men and women's performance on mathematics and science related assessments has become evident. When considering scores from 42 countries participating in the Program for International Student Assessment (PISA), males were found to perform better than females in mathematics and science [13]. The percentage of males outscoring females in high school mathematics and science has decreased in the past 30 years, but unfortunately the difference between scores of males and females has remained fairly stable for the last 20 years [14]. While many state tests mandated by No Child Left Behind have shown that the gender gap has been minimized or erased, these tests were also shown to fail to evaluate the complex problem solving skills required to be successful in STEM majors and careers [15]. The international differences in gender performance and the somewhat inconclusive results on state tests have forced researchers to more heavily investigate what was happening (or not) in high schools that may be further indicators as to why there existed a gender gap in STEM professions.

Apart from standardized testing, the type and number of advanced courses taken in high school can be an indicator of student ability and interest in subject areas. Students who completed challenging coursework in high school were more likely to complete a college degree [16], and those who completed Advanced Placement¹ mathematics were more likely to major in STEM related fields when compared to those who did not complete the courses [17]. In 2013, 49% of Calculus AB and 41% of Calculus BC test takers were women, but women were still a small minority of the total number of students who took Advanced Placement Computer Science A (19%), Physics B (35%), Physics C: Electricity and Magnetism (23%), and Physics C: Mechanics (26%) courses [18]. The choices that women made in high school about the advanced coursework that they completed gave insight into why the number of women who earned undergraduate degrees in mathematics was similar to the number of men who earned mathematics degrees, while a large gender gap was still evident for computer science and engineering degrees [19]. High school was evidently a turning point for many people, and in particular for women, in their ability and pursuit of STEM course work.

After high school, the gap between men and women in STEM professions was solidified by selection of a major. The

percentage of women entering STEM fields after high school was much lower than the percentage of men entering the same fields [20]. Adding to the gap, women were more likely to switch from a STEM major to a non-STEM major during their first year of college when compared to their male peers [21]. For those who took more STEM courses, women's attrition rates were higher than men's rates [22]. While some STEM majors such as Biology saw a minimal difference in attrition rate, others, such as Computer Science, saw an extreme drop in the proportion of women [21]. This loss of students in STEM majors was considered to be a "leak" in the STEM pipeline and was a loss of potential innovation and leadership.

Women either avoided or dropped out of the STEM pipeline for various reasons. Stereotype threat was identified as a factor that may have inhibited the success of women in quantitative STEM pursuits. Stereotype threat caused an individual to act in a stereotypical way, regardless of their ability or interest, in order to preserve the group stereotype and his or her membership in it [23]. The negative implications of stereotype threat became evident during standardized test taking, in which women who were faced with challenging mathematics problems may have begun to doubt their ability to successfully answer them because of the stereotype that cast women as inferior math students. Stereotype threat can reduce the achievement of students on standardized tests even if they were academically gifted [23]. Informing women about stereotype threat was shown to be an effective means of reducing the achievement gap between men and women on mathematics tests [24]. Women who fell prey to the stereotype that math was for men could view themselves as outsiders in their math classes. While men looked forward to mathematics classes, women did not feel very comfortable in mathematics classes, were usually afraid to ask questions [25], and were less confident in their ability to do mathematics [26, 27]. Following stereotypical gender paths could force capable women out of the STEM pipeline.

While the stereotype that math is for men may prevent capable women from pursuing STEM, general differences have been found to exist between men and women that could have made a career in STEM less appealing to women. Women were found to be more interested in people and social life [22]; therefore, the science and mathematics curriculum was irrelevant to many of them [28]. Women were more motivated by communal goals (opportunities to work with or help others) than men traditionally were, and this posed a problem when many STEM professions such as engineering and computer science were not seen as fulfilling those communal goals [29]. Women may have found the role of the stereotypical scientist, viewed as someone who spends their life in a lab with no outside interests, as being unattractive or unaccommodating. However, these stereotypes have been changing; the idea of being a scientist and "a real person" has become more acceptable. This new image of scientists might motivate women to pursue science careers [30, 31]. The current lack of female scientists was an issue because women lacked role models and colleagues to inspire or support their STEM aspirations [31]. The women that pursued STEM in spite of these stereotypes and lack of role models have paved the way for women in the future to have what they did not. These

¹ College Board, AP, Pre-AP, Advanced Placement, and the acorn logo are registered trademarks of the College Board.

stereotypical views of women and STEM professions have been evolving and by doing so may form a bridge eliminating the gap between the two.

B. Project Based Learning

What is project based learning? A review of the diversity of definitions found several consistent components [32]. In project based learning, students are presented with challenges that require an interdisciplinary solution that ultimately results in some form of tangible product or presentation. In order to complete the task, students engage in problem-solving, design, and investigation. Teachers facilitate the group work but do not control it. This approach to learning is exceptionally different from the traditional teaching method and offers students real world applications of the knowledge that they are gaining in school.

The introduction of PBL activities in classrooms had a number of favorable results. PBL helped increase student motivation, especially when the teachers were motivated to use PBL themselves [3]. Students were more prone to learning new concepts when they knew that learning these concepts would help them complete their projects [2]. Moreover, PBL taught students teamwork, research [33], presentation, and management skills [34]. PBL also instilled internal motivation in the form of perseverance after having failed a few times before eventual success and increased awareness of the interrelatedness of what students were learning [35]. PBL made learning “varied and fun” (Ravitz, 2008, p. 4), and allowed students to explore their learning in depth. The exploration process encouraged creativity [35], and inquiry [36] resulting in deep understanding.

In STEM PBL, students worked collaboratively to complete a project and “to seek out the answers for their questions” [3]. During the STEM PBL process, students followed an inquiry based approach and an experimental design to reach their goal. PBL applied to STEM subjects “provides the contextualized, authentic experiences necessary for students to scaffold learning and build meaningfully powerful STEM concepts” [1]. Students had to play an active role in their own learning, which led to self-actualization and intellectual growth [36]. Women usually preferred depth in whatever they learned [2, 28]. Therefore, it is possible that STEM PBL would encourage these women to take advanced STEM courses and pursue STEM careers.

C. Women and STEM PBL

Females have not benefitted as much from traditional instruction as males have [26]. “Women have a greater interest in people than in things... and may respond more positively to ideas in context than in isolation” [22]. Therefore, the use of cooperative groups and scientific inquiry was suggested to increase the representation of women in science careers [28]. Female students enjoyed cooperative learning because they also perceived it as a chance to interact and improve their social skills [2]. Projects that focused on creating solutions that make the world a better place and help others could also increase the interest of women in STEM fields [9, 37]. Therefore, new methods for teaching mathematics and science that focus on opportunities to think and to discuss ways of

improving the world, like STEM PBL, might increase women’s motivation to attend mathematics and science classes. STEM PBL has provided this because it is based on contextualized projects and teamwork.

II. METHODOLOGY

Mathematics, science, and English standardized test data were collected over four years from a school district where professional development on STEM PBL was the major focus. The first year of data, in which the teachers had not received any professional development on STEM PBL, served as the baseline. The professional development on STEM PBL took place during the summer between the first and the second year and was sustained throughout the second, third, and fourth years. Throughout the second, third, and fourth years teachers were assisted and guided in the design of PBL activities and were given feedback on their lesson designs and implementations during classroom observations.

A. Participants

The students were chosen from the high school where the teachers most effectively implemented STEM PBL. These teachers were observed each year for STEM PBL implementation and given scores ranging from 1 to 5 on 27 items divided into six main categories. A mean score of 3 on each category was considered an average implementation; therefore, adding the means of the six categories, a total score of 18 was considered an average implementation. By the third year, these teachers were considered to be above average in STEM PBL implementation and were closely grouped across the six indicators (see Figure 1).

Fig. 1. Teacher’s mean level of STEM PBL implementation.

The same students were tracked for four years of high school, starting in grade 9 and ending in grade 12. When these students were in grade 9, the teachers had not yet been exposed to PBL training and, therefore, neither were the students. In grades 10, 11, and 12, these students participated in various PBL activities in their mathematics and science classrooms. For all analyses, the 08-09 ethnicities were used because they were the most complete set of ethnicity data during the four years. The problem with ethnicities is that they are self-

reported and students bubble their own ethnicity. Therefore, ethnicity varied from year to year. Some variation, though minimal, existed for Hispanic students who may have initially selected Hispanic and changed to White in a subsequent year, or vice-versa. There were no variations in responses from Black students; however, there were some years when an ethnicity was not selected.

In the first year of score collection, there were 186 students in grade 9. Because of the high attrition rate in the district, only 127 of these students remained in school for four years. Out of the 127 students, 24 did not have scores for all years and, therefore, were removed from the data set. The final sample size was 103 students with 52 females and 51 males. This was a loss of 59 students in four years. However, what is noticeable is that 34 students of the 59 left in the first year, and only 24 of the starting 186 left in the second, third, or fourth year. To compare the results obtained in this study to the broader literature, a search was conducted using ERIC EBSCO and ERIC CSA using the search terms “girls or females or women” and “high school and STEM or science or math” for the publication year 2010. The search yielded 113 unique articles. Of the 113 articles 23 were reports from the Center on Education Policy and did not contain data disaggregated by gender, 16 others could not be located, four were dissertations that did not report academic improvement, 37 were qualitative reports without aggregation of findings or estimates of improvement, and 15 were quantitative studies that did not disaggregate results by gender. Of the remaining articles only one provided sufficient information to compute effect sizes for the results. Therefore, the benchmark effect sizes are based only on a single study with our Cohen’s *d* estimates of effect for our study. The estimated change in ability and coursework plan from grade 9 to grade 11 in females’ math was 0.0 and .423, in females’ science was .239 and .821, in males’ math was .296 and .345, and in males’ science was .471 and .334.

B. Procedures

Mathematics, science, and English Texas Assessment of Knowledge Skills (TAKS) scores and course matriculation data were collected for each of the students in each of the three years. Students are allowed to take their exit tests in grade 11, and as a result, a lot of students did not have TAKS scores for grade 12; therefore, grade 12 scores were not included in the study. Because there is no state test for science in grade 9, only grades 10 and 11 TAKS science scores were considered. Moreover, English scores were included to provide a basis for comparison because STEM PBL was not used in these classes, and the STEM professional development did not focus on English learning objectives. Therefore, changes in mathematics and science should be uncorrelated with changes in English scores when the changes are attributable to the STEM professional development. Data were analyzed using significance tests, graphs, confidence intervals, and Cohen’s *d* effect sizes.

C. TAKS

In Texas, during the years of the study, students were administered TAKS exams in the spring of each year. Students took the mathematics portion of the TAKS each year starting in

grades 3 through 10; after grade 10 students were required to pass the Exit Level mathematics TAKS in either grade 11 or 12. Students took the science portion of the TAKS in grades 5, 8, 10, and Exit Level (either grade 11 or 12). Students took the English portion in reading from grades 3 through 9 and in reading and writing (ELA [English and Language Arts]) in grade 10 and Exit Level. In mathematics and science, the test items were multiple choice items. On the 10th grade and Exit Level ELA tests, two additional question formats were included: a) open-ended short-answer questions and b) a written composition. TAKS tests were not timed so students were permitted the time they needed to complete the test; some even stayed after regular school hours to finish. Seniors needed to pass the Exit Level TAKS test in order to graduate from high school [38].

III. RESULTS

A repeated measures MANOVA was used to determine whether the scores for each gender had changed over time in mathematics, science, and English. The change in test scores in mathematics was statistically significant for both males ($p_M < .001$; partial $\eta^2 = 73\%$) and females ($p_F < .001$; partial $\eta^2 = 65\%$). The variation in mathematics test scores was 73% accounted for by being male and 65% accounted for by being female. Based on the previous analyses, the means for both genders increased statistically significantly over the years ($F_1 = 33.7$; $F_2 = 36.6$; $F_3 = 41.3$; $M_1 = 34.5$; $M_2 = 36.9$; $M_3 = 43.8$). The males’ means were slightly higher than the females’ means at the beginning of the study. With the introduction of PBL to the classes, the gap between gender means narrowed. However, in the third year the gap in score means between genders increased slightly again in favor of males (see Figure 2).

Fig. 2. The means of mathematics scores for males and females over three yrs.

In science, the change in scores was statistically significant for both females ($p_F < .001$; partial $\eta^2 = 28\%$) and males ($p_M = .044$; partial $\eta^2 = 7.9\%$). The effect size for the females was reasonably large and nearly three times as large as the effect size for males. While the difference for males was statistically significant, the obtained effect size does not merit much

interest. The rate of change in females’ scores was larger than the rate of change in males’ scores; however, males still performed better. One reason may be because the males had a higher starting mean ($M_1 = 40.39$) than females ($F_1 = 34.9$); therefore, females had more room for improvement and narrowed the gap ($M_2 = 41.8$; $F_2 = 38.3$) (see Figure 3).

Fig. 3. The means of science scores for males and females over two years.

The science scores show the least growth over time. When considering females by ethnicity there was modest growth for all females regardless of ethnicity (see Figure 4). The obtained effects were small but consistent for Black, Hispanic, and White, 0.19, 0.13, and 0.14, respectively. There may be more possible explanations but one stands out. The science test is not administered in 9th grade but in 10th and 11th. Therefore, the base year or inception of STEM PBL was not estimated but instead it was the middle year or second year of the intervention. So the comparison might not indicate the magnitude of the growth as compared to mathematics or English.

Fig. 4. 95% confidence intervals for females by ethnicity for science scores.

For females and males English scores increased statistically significantly over time ($p_F < .001$; partial $\eta^2_F = 96\%$; $p_M < .001$; partial $\eta^2_M = 85\%$). For the first two years, the changes in the means of the two genders were fairly similar ($M_1 = 32.3$; $F_1 = 32.0$; $MM_2 = 46.1$; $F_2 = 46.4$). Due to the change in the test from assessing reading to assessing ELA, the magnitude of the effect was over estimated. However, there was a slight decrease in the females’ means in English during the last year ($M_{F3} = 45.0$) and the gap between the means of males and females widened slightly in favor of the males ($M_{M3} = 46.4$) (see Figure 5).

Fig. 5. The means of English scores for males and females over three years.

All the students took the following mathematics and science courses, which were required: Algebra I, Algebra II, Geometry, Biology, and Chemistry. Around half of the students, 51% of the females and 50% of the males, chose to take Principals of Technology I (PTI), which was an engineering course. Only 16% of the males chose to take Physics, while 42% of the females took Physics. Sixty percent of females and 68% of males chose Precalculus, and 16% of females and 26% of males took AP Calculus. The choice to take AP Biology was 16% for females and 14% for males (see Figure 6).

Fig. 6. Percentage of males and females who chose to enroll in classes.

When the study began, in grade 9, there were 186 registered students, 87 females and 99 males. Out of the 186

students, 153 students (82%) were registered for the second year in grade 10 (85% females, 79.8% males) in addition to 18 new comers, resulting in 171 students in grade 10 for that year. In grade 11, 148 of the 171 (86.5%) remained at this high school (87.6% females; 85.5% males), with an addition of 25 newcomers to make a total of 172 students. Out of the 172 students, 151 (87.7%) stayed (93.7% females; 82.6% males), and 28 newcomers registered to give a total of 179 students in the fourth year. The overall trend was that females were increasingly retained over the four years whereas males had a consistent attrition rate (see Figure 7).

Fig. 7. Percentage of male and female attrition from one grade to the next.

To determine the impact of STEM PBL for females by ethnicity, the 95% confidence intervals were calculated and shown in Figure 8. The overarching message was that there were no initial differences between ethnic groups. There was greater variation in the scores for White females while Hispanic females had the smallest variation. However, for females across the ethnic spectrum, their scores increased longitudinally. There was a statistically significant difference between the 07-08 and 08-09 school years and 09-10 for Black and Hispanic females. By the end of the 09-10 school year there was no difference in scores evidenced by ethnicity. Hispanic females experienced the greatest gains with statistically significant differences in each of the three years favoring the subsequent year. That is, STEM PBL benefitted females within ethnic groups similarly, and by the third year all females were on par. While some groups exhibited greater gains, all groups showed practically important growth. The Cohen's d effects for Black, Hispanic, and White were 1.13, 1.08, and 0.61, respectively.

Fig. 8. 95% Confidence intervals for females by ethnicity on mathematics performance longitudinally.

Finally, the comparison between performance by gender would answer the question, "Did STEM Project-based Learning afford females the opportunity to bring their level of performance equal to that of their male counterparts?" The results showed that females and males started out fairly equal in mathematics. By the end of the three years both groups showed statistically significant gains from year 1 (See Figure 9). However, at no point in the longitudinal study did one group outperform the other; that is, they both showed important gains each year that were close to equal. The Cohen's d effect for females and males longitudinally was 1.06, and 1.05, respectively.

Figure 9. 95% confidence interval by gender for mathematics performance longitudinally.

IV. DISCUSSION

There were several interesting results that could point to the benefits of STEM PBL for both genders but especially for narrowing the gender gap in performance and interest in STEM fields for females. Firstly, the increase in science and

mathematics scores cannot be attributed to maturation because the females' science and mathematics scores means increased in the last year while their English language arts (ELA) scores decreased. PBL activities were only introduced in mathematics and science classes and not in English classes. Therefore, one possible explanation for mathematics and science improvement in the third year is the use of STEM PBL activities in these classes. Moreover, these PBL activities were more developed in the last year because the teachers had more experience with these kinds of activities after having implemented similar activities the previous year as well as continuing professional development and classroom support for refining and implementing PBL lessons. The rate of change of English scores was in a different direction from the rate of change of mathematics and science scores, indicating that the underlying causes of change were different for math and science as compared to English.

The literature indicated that females were usually found to perform better in English, while males usually performed better in mathematics and sciences [13, 14]. However, in this study, even though the males outperformed the females in science, the females' science scores improved much more than the males' science scores. If males have greater interest than do females in STEM courses, it would be expected that performance of females would increase a small amount, if any. This indicates that the active STEM PBL lessons may have contributed to the narrowed gap between females and males in science. In English, however, the males' scores improved more than the females' English scores but not to a practically important degree. These analyses in total show that females did not show improvement in all subjects nor to the same degree. It was unlikely that the increase in females' scores in science was due to a school initiative to improve TAKS scores overall. If that were the case, it would be expected that females would improve their English scores accordingly, particularly in view of the fact that females have shown greater interest in English than science courses and fields of study.

The profound increase in both females' and males' test scores in English from grade 9 to grade 10 can be attributed to the change in testing style in English TAKS from reading to ELA. In grade 9, students were only tested for reading and only had to answer multiple choice questions. On the other hand, in grade 10 students were tested for reading and writing as well as answering essay style short answers and writing a composition. The subjective nature of these short questions and composition sections may have contributed to improved scores because students could receive partial credit for the short answer questions.

A second interesting result was that the percentage of females who left the high school decreased over the years. One could argue that the majority of students who lose interest in high school and leave do so after their first year. However, the percentage attrition for males leaving this high school was consistent and did not decrease like the percentage attrition for females. STEM PBL activities seemed to have stemmed the attrition of females in the high school in the study. Therefore, STEM PBL activities may attribute to retention of girls in high school.

The third interesting result was the STEM course selections made by students. The greatest differences in course selections between males and females were in Physics, where the number of females who chose to take physics courses was almost three times the number of males who chose physics, and in AP Calculus, where the number of males who made the choice for AP Calculus was higher than the number of females. In comparison to a similar study [39], around 25% of men and women took Physics in high school and 7.4% of the women and 8% of the men took AP Calculus or an equivalent course. Moreover, less than 10% of the students took Precalculus, compared to 60% or more in this study. STEM PBL might have been a contributing factor to the choice of taking Physics, Precalculus, and AP Calculus for both males and females. This result is harmonious with prior study results showing that females were more interested in STEM courses and fields when they were able to see benefits to individuals and to society rather than just experiencing the course content outside the possible applications of interest to them.

Females' mathematics and sciences scores increased over the years with the introduction of STEM PBL to the classes. Moreover, the attrition of female students decreased with the years. Whether PBL was the direct cause for the increase in scores and decrease in attrition cannot be answered by one study alone. More studies are needed to follow females that are exposed to STEM project based learning and to track them through post secondary education. Studies that involve both performance and attrition in STEM courses and majors combined with surveys or interviews that give insight into the reasons both males and females persist or drop out of STEM majors would be particularly useful in understanding the problem and searching for possible solutions to the STEM pipeline issues related to all students, particularly females.

Abstract— The study reported in this paper examined the connectedness of STEM faculty to others both within and across academic departments who might be potential resources for diffusion of Learner-centered practices, and the impact of participants' social networks on their Learner-centered beliefs and practices. The research question under investigation was: To what extent is the degree of social connectedness among faculty within and among STEM departments related to the degree of implementation of Learner-centered practices? Participants were recruited from Physics, Chemistry, Mathematics departments, and from departments in the College of Engineering. The sample began with 21 randomly-selected faculty from each department engaged in the STEM instruction of first and second year engineering students. The second level consisted of the colleagues identified by the first level as people they utilize as resources for improving their instruction. The connectedness of faculty in the network was examined using network analysis, focusing on both number of connections, and depth of connections. Attitude and Observation Protocol measures were used as outcomes. Results show that faculty classified as Learner-Centered had deeper and more extensive social networks. Results are discussed in terms of the need for intra- and inter-departmental faculty professional development experiences that both introduce and encourage faculty to trial new tools and techniques, but that also run for the long-term, supporting collaborative organizations of faculty working together to transform early engineering experiences.

Keywords—learner centered, instruction, professional development

I. INTRODUCTION

Recent research has shown that learner centered practices are infrequently used in engineering pedagogy. Learner Centered instruction is defined by the American Psychological Association as comprising a set of cognitive and metacognitive factors, motivational and affective factors, developmental and social factors, and individual differences (see Table 1) [1]. It is assumed, generally, that to be learner centered, pedagogies need to simultaneously address key concepts, skills, and dispositions in a domain, *and* account for the knowledge,

predilections, and social characteristics afforded by students in a manner that is dynamic, adaptive, and personally relevant.

In a recent meta-analysis of 119 studies across grades K-20, Cornelius-White, found that learner-centered variables such as non-directive verbal interactions, incorporation of higher-order thinking, encouraging learning and challenge, and adapting to individual and social differences correlate significantly with cognitive and affective student outcomes (e.g., mathematics achievement, science achievement, participation, motivation, and others). Relationships among these variables average $r=.34$, indicating that the overall influence of learner centered practices accounts for about ten percent of desired outcomes--a significant relationship [2].

The hypothesis underlying the study reported here is that faculty practices are the primary mechanism by which potential changes in student learning and motivation are effected. While faculty attitudes may support practical change, and while student beliefs and attitudes may mediate their learning behavior, it is precisely the conditions of learning that are responsible for the nature and extent of learning, *and* students beliefs about, and self-regulatory strategies recruited while learning. One of the problems in studying learner centered practices is that they cast a fairly wide net. Many different pedagogical techniques may be employed effectively and be called "learner-centered." As such, learner-centered instruction can be thought of as heuristic—incorporating rules of thumb that can be used in the moment to tailor instruction to the needs of students. The following heuristics have been shown to be effective in structuring learner centered pedagogical environments[3.] As can be seen, learner-centeredness requires a shift from presenting content to enervating and supporting the actual learning modalities and outcomes for students.

Table 1. American Psychological Associated Learner Centered Psychological Principles

Cognitive and Metacognitive Factors Nature of the learning process: The learning of complex subject matter is most effective when it is an intentional process of constructing meaning from information and experience. Goals of the learning process: The successful learner, over time and with support and instructional guidance, can create meaningful, coherent representations of knowledge. Construction of knowledge: The successful learner can link new information with existing knowledge in meaningful ways. Strategic thinking: The successful learner can create and use a repertoire of thinking and reasoning strategies to achieve complex learning goals. Thinking about thinking: Higher order strategies for selecting and monitoring mental operations facilitate creative and critical thinking. Context of learning: Learning is influenced by environmental factors, including culture, technology, and instructional practices.
Motivational and Affective Factors Motivational and emotional influences on learning: What and how much is learned is influenced by the learner's motivation. Motivation to learn, in turn, is influenced by the individual's emotional states, beliefs, interests, and goals, and habits of thinking. Intrinsic motivation to learn: The learner's creativity, higher order thinking, and natural curiosity all contribute to motivation to learn. Intrinsic motivation is stimulated by tasks of optimal novelty and difficulty, relevant to personal interests and providing for personal choice and control. Effects of motivation on effort: Acquisition of complex knowledge and skills requires extended learner effort and guided practice. Without learners' motivation to learn, the willingness to exert this effort is unlikely without coercion.
Developmental and Social Factors Developmental influence on learning: As individuals develop, they encounter different opportunities and experience different constraints for learning. Learning is most effective when differential development within and across physical, intellectual, emotional, and social domains is taken into account. Social influences on learning: Learning is influenced by social interactions, interpersonal relations, and communication with others.
Individual Differences Factors Individual differences in learning: Learners have different strategies, approaches, and capabilities for learning that are a function of prior experience and heredity. Learning and diversity: Learning is most effective when differences in learners' linguistic, cultural, and social backgrounds are taken into account. Standards and assessment: Setting appropriately high and challenging standards and assessing the learner and learning progress - including diagnostic, process, and outcome assessment - are integral parts of the learning process.

1. The actions of the instructor focus on students learning as opposed to presenting material.
2. In ethically responsible ways, instructors share decision making about learning with students. Teachers control less, but students are involved more.
3. Content is used to build a knowledge base, to develop learning skills and to foster learner self-awareness of their abilities. Teaching approaches account for students' learning modes and strategies.
4. Instructors and students, together, create learning environments that motivate students to accept responsibility for learning.
5. Assessment activities are used to promote learning and to develop self and peer assessment skills, not to evaluate performance primarily.

Unfortunately, research shows that learner-centered practices are used only infrequently by post-secondary STEM faculty [7]. Part of the problem concerns the fact that an instructor's perception of student-centered pedagogy may not align with the reality of their classroom practice. Ebert-May et al., for example, reported on results of a national biology professional development program consisting of 6-12 days of workshops on scientific teaching over three years [4]. While faculty engaged in the professional development self-reported they were using a student-centered learning strategy, observation of their practice revealed that, in reality, three-fourths were lecturing with instructor-centered teaching. The authors maintain that the professional development was not sufficient to sufficiently change the nature of their teaching practice. So the majority of participants, had not actually progressed into a true embodiment of learner centered practice. Ebert-May et al., hypothesized that a possible reason for the lack of efficacy of the intervention was lack of social support for their changing beliefs, thus hindering their translation into new classroom routines and activities.

In support of this general hypothesis, McKenna et al., studied engineering faculty developing student-centered conceptual change instructional methods. Faculty worked collaboratively with learning scientists to promote effective task and instructional sequence design. The researchers found that the greater the extent of collaborative reflection between engineering faculty and learning scientists, the greater the shift toward student-centered practices[5].

Other researchers (e.g., Borrego et al.) have used Everett Rogers' model of diffusion of innovations to characterize faculty change through professional development [6] [7]. They found that faculty tend to only progress through the earliest stages of change: *awareness* and *interest*, and tend not to move to actual practice. The key issue here is that, without change in students' learning experiences, little chance of improving learning and motivational outcomes exists. Alternatively, if

change occurs too slowly, it may be so ineffective, it may take years or decades for instructional practices to catch up with students needs. Altogether, this paints a pretty bleak picture of faculty practice and faculty development. However, Borrego et al., also cite confining evidence that providing support *in the form of collaborative interactions among faculty* during the third and fourth *decision* and *trial* stages of can provide a successful progression to the higher stages of diffusion of innovation.

A. Social Network Analysis

Recently Judson & Lawson studied the degree of faculty connectedness in high school STEM teachers [8]. They recorded the degree to which teachers served as resources for others, in a addition to seeking out others for assistance in improving their instruction. They found that the degree to which individuals served as sources of information—i.e., where others came to them for help, strongly predicted their implementation of constructivist pedagogies. In the current study, these practices, assessed on the Reformed Teaching Observation Protocol [9] are deemed close analogs to Learner-centered practices as defined by the APA and Weimar.

These findings suggest that social support for faculty is a key mediating variable determining faculty practice. There have been many articles reporting how faculty, particularly adjuncts and teaching faculty feel unsupported and isolated in University STEM departments [10]. Where practical change occurs, research has shown that collaborative professional development can be one of the key design elements of the effort [4].

This study examines the extent of faculty social networks across University STEM departments, and the relationship between faculty connectedness with their learner centered attitudes and classroom practices.

B. Research Question

The research question under investigation was: To what extent is the degree of social connectedness among faculty within and among STEM departments related to the degree of implementation of Learner-centered practices?

II. METHOD

A. Participants.

Twenty-one different instructors (13 Engineering, 4 Physics, 2 Mathematics, and 2 Chemistry) across nine departments were chosen for the study. All instructors teach at a large, urban, Southwestern University in the United States. Faculty participants were randomly selected from the list of faculty teaching required STEM courses for freshman engineering students. Two participants hailed from the Mathematics Department, four from Physics, four from Chemistry, four from Biomedical Engineering, two each from Freshman Engineering, Electrical Engineering, and Civil Engineering, and one each from Materials Science, Computer Systems, and Mechanical/Aerospace Engineering. Faculty were provided small stipends as compensation for their time.

This study utilized four data collection methods: Faculty interviews, faculty surveys, observation protocol scores and qualitative classroom observations

B. Interviews

Each faculty member in the study participated in one one-hour semi-structured interview focused on their practice, and on the supports and barriers they encountered in their efforts to improve their practice. Interviews consisted of twenty-four questions focusing on topics of teaching practices, teaching resources used, teaching environment, course and departmental policies, self and departmental evaluations, and departmental and interdepartmental collaboration. Interviews were audio-recorded upon permission.

The Glaser and Laudel approach to qualitative content analysis was chosen to analyze the interview data. Qualitative content analysis is a theory-guided method that extracts *qualitative* content using units of meaning originating from the same theoretical framework that guided the *quantitative* data collection. The goal of this analysis was to determine contextual and potentially causal factors in the qualitative data that “mirrors” the quantitative [11]. Specifically, we used this method to ascertain the common resources faculty used to support instruction, and then determine the extent to which use of resources supported Learner-centered instruction as defined by the quantitative measures (below).

A key portion of the faculty interviews involved a set of questions focusing on the social network related to instruction within which each participant operated. Three questions were asked:

1. With whom do you collaborate regarding improvement of instruction?
2. With whom do you discuss teaching-related topics? and
3. Who comes to you to discuss instruction?

The interviewer probed instructors to create a comprehensive list of others, both within their department and outside their department. Responses also indicated that several faculty rely on colleagues outside their university for information and support. A total of eighty-three persons were nominated using this process, across all participants. These responses were then entered into an adjacency matrix, where connections between any two nominees was coded as 1, and lack of connection was coded as 0.

C. Approaches to Teaching Inventory (ATI)

In addition to the interview, each instructor completed a twenty-two item revised edition of the Approaches to Teaching Inventory survey to measure faculty perceptions about their own teaching. The ATI is a valid and reliable self-reporting tool designed by Trigwell and Prosser assesses the extent to which faculty teach with an approach toward

Table 2. Total, Mean and Standard Deviation of the Number Of Connections Nominated by Participants Across Academic Departments.

	Civil Eng.	Comp. Sys.	Mat. Sci.	Mech. /Aero.	Elect. Eng.	Math	Fresh. Eng.	Chem.	Phys.	Bio Eng.
Mean (S)	2.2 (1.5)	1.8 (1.5)	2.0 (1.7)	1.25 (0.5)	1.5 (0.7)	1.0 (0.8)	5.1 (5.9)	1.8 (2.3)	2.3 (2.3)	3.0 (4.0)
Total	6	4	6	4	2	4	13	7	15	19

instructor-centered knowledge transmission versus student-centered conceptual change [12]. Items on the ATI fall into four dimensions: 1) Conceptual Change Intention, measuring the degree to which instructors are aware of, and support the development of student understanding in the class (e.g., I see teaching as helping students develop new ways of thinking in this subject); 2) Student-Centered Strategies, measuring the extent to which instructors utilize pedagogical strategies that focus on student learning (Teaching in this subject should help students question their own understanding of the subject matter); 3) Information Transmission, the extent to which the instructor emphasizes getting information to the student (e.g., I think an important reason for running teaching sessions in this subject is to give students a good set of notes); and 4) Teacher-Focused Strategies (e.g., My teaching in this subject focuses on delivering what I know to the students). The first two dimensions promote Student-Centered classroom practice, while the latter two promote Teacher-centered classroom practice. Reliabilities of the subscales range from $\alpha = .73$ to $.75$. Of course, it was expected that all instructors will incorporate some beliefs from each of these 4 dimensions to more or less degree in their own teaching perspective.

D. Classroom Observation Protocol and Qualitative Observations

For each course, three classroom observations were conducted for a total of 63 observations. Sections to be observed were randomly selected from the list of required freshman engineering courses taught in each department. The Reformed Teaching Observation Protocol (RTOP) was used after each observation to identify specific teaching practices associated with reformed teaching. The RTOP is a classroom observational protocol that quantitatively characterizes the extent to which faculty implement student-centered behaviors in their own classroom practice. It has high reliability and validity. Published reliabilities of RTOP subscales are: Lesson Design and Implementation ($\alpha = .915$), Propositional Knowledge ($\alpha = .670$), Procedural Knowledge ($\alpha = .946$), Communicative Interactions ($\alpha = .907$), and Student/Teacher Relationships ($\alpha = .872$).

The overall RTOP has a reliability of $\alpha = .954$. As classroom practice can vary across days and specific learning objectives, RTOP scores for each participant's three observations were averaged to gain a typical view of their practice, resulting in a single set of scale scores for each

participant. In addition to RTOP scores, qualitative classroom observation field notes were gathered during each course observation including details about class environment and student-instructor interactions. The classroom observation field notes were used to provide relevant information in conjunction with the reformed protocol results and to provide any needed context when examining the relationship between the classroom teaching practices as reflected in the RTOP score and the teaching beliefs reflected in the instructor interviews and survey responses [9].

E. Social Network Analysis

Social Network Analysis is a set of analysis techniques that characterize the number and type of connections among members of a social system. It uses mathematical concepts from graph theory to map the links (relationships) between nodes (people). Any adjacency matrix listing the connections among individuals can be turned into a vertex-edge graph, which illustrates visually, the density of connections within and cross-connections across departments. We follow the method of Judson & Lawson [8] who used this method fruitfully to predict the relationship between high school STEM teacher connectedness and dimensions of the RTOP.

III. RESULTS

Figure 1 below shows the connectedness among all participants and the persons participants nominated those with whom they engaged in collaboration, or conversations about teaching quality. Both the density of connections within departments, and the connectedness across departments are of importance here. It is clear from the area comprised of each department in Figure 1 that Bio Engineering, Freshman Engineering, and Physics have many players involved in the design and implementation of first year instruction for engineers. It is also clear from the density of connections in each department that the interconnections among members of Bio Engineering, Physics and Freshman Engineering is higher than the other departments. What is also apparent is that there are few connections across departments.

Table 2 presents the mean number of people nominated by participants whom they felt they either collaborated with, or whom they had regular contact with regarding teaching or course improvement. A quick glance shows that colleagues in Bio Engineering, Freshman Engineering, and Physics do have many more reported connections than faculty in other departments. A few participants in departments, most notably

Figure 1. Vertex-edge Graph of the Connecteness of Faculty Participants

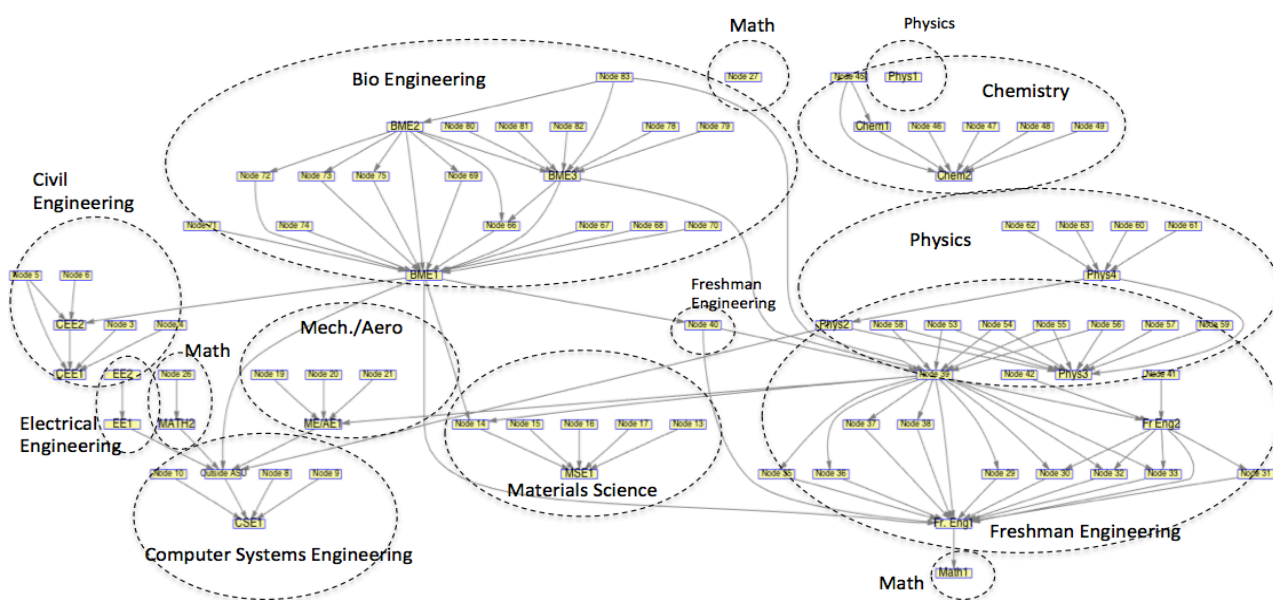

Table 3. Pearson Correlations between degree of connectedness and dimensions of Faculty Learner-Centered Attitudes (ATI) and classroom practice.

Concept Change Intention	Student-Focused Strategies	Info. Trans.	Teacher Focused Strat.	Conceptual Change/Student Focus	Info. Trans./Teacher Focus	Lesson Design/Impl.	Prop. Knowl.	Proc. Knowl.	Com. Inter.	Student/Teacher Rel.	RTOP Total Rating
.236	.374	-.322	-.181	.357	-.289	.704**	.084	.629**	.493*	.572**	.594**

*p<.05

*p<.01

ATI Dimensions: Conceptual Change Intention, Student-Focused Strategies, Information Transmission, Teacher Focused Strategies, Conceptual Change/Student Focus composite, Information Transmission/Teacher Focus composite.

RTOP Dimensions: Lesson Design and Implementation, Propositional Knowledge, Procedural Knowledge, Communicative Interactions, Student/Teacher Relationship, and RTOP composite.

Mathematics, Mechanical/Aerospace Engineering, and Electrical Engineering, appear to have few, if any connections at all.

To test the hypothesis that more connected faculty, on average, engage in more learner-centered practices, scores on the ATI beliefs instrument and RTOP observational instrument were correlated with degree of connectivity for each participant (see Table 3).

As can be seen, correlations are moderate to high across most dimensions of learner-centered faculty beliefs, and classroom practice. The direction of relationships are all in

the expected direction, indicating a positive relationship between connectedness and learner-centeredness in general, and a negative relationship between connectedness and teacher-centeredness. RTOP scores were generally very strongly related to connectedness, with *lesson design and implementation* showing the strongest relationship. This dimension focused on strategies that account for students' prior knowledge, engagement of students as members of a learning community, encouragement of alternative modes of investigation and problem solving, and using students ideas to help direct the lesson. The second highest correlation centered on procedural knowledge, a dimension emphasizing rigor of ideas, multiple representations, and engagement in hypothesis building and testing. The least correlation centered on *propositional knowledge*. This dimension focused on the subject matter knowledge of the teacher, the abstractness of the content, connections to other disciplines, and the coherence of the conceptual understanding promoted by the lesson.

ACKNOWLEDGMENT

This material is based upon work supported by the National Science Foundation under Grant No. 1226586.

It is also important to note that none of the ATI dimensions were significantly correlated with connectness. While technically this indicates no systematic relation between the variables, the relatively small number of participants in the study yields relatively low power. With an earlier study showing significant positive relationships between ATI and RTOP scales, we feel there is still merit in reporting these correlations as consistent with theory. However, it is the overall pattern of the relationship, not each individual correlation that should be examined.

IV. DISCUSSION

Results indicate that faculty connectness is at least moderately correlated with learner-centered attitudes, and relatively strongly related to learner-centered practices.

These findings echo those by Judson & Lawson, who found that the indegree of high school teachers' social networks related strongly, at about the same magnitude as the present study, with their RTOP scores. These were interpreted as indicative that constructivist teaching practices, a close analog to learner centered practices, are highly related to the degree to which teachers are seen as resources by their colleagues [8].

The authors report that, in a social network, the degree to which an individual is seen as a resource, where their colleagues come to them for assistance, is an indication of their leadership. Moreover, the number of people in a network with large indegree indices indicates closeness of collaboration. Friedkin & Slater suggest that such sources of advice and creativity can be more influential in the social network than more formal leadership roles [13].

In summary, the research reported in this paper provides further evidence that faculty culture is moderately to strongly related to quality practice—at least as a mediating variable for learner centered instruction. Faculty with more connected social networks displayed higher scores on conceptual change and student focused attitudes, and lower scores on information transmission and teacher focused attitudes, than faculty with fewer connections. Moreover, faculty with larger social networks scored highly on all learner-centered variables with the exception of the propositional knowledge subscale on the RTOP. Some caution must be urged here. None of the correlations for faculty attitudes were statistically significant. However, the strong correlations for faculty practice variables lends support for our original hypothesis.

We are currently surveying nominees *not* in our original sample, to further examine the connectness across the entire network. With this larger set of data, we hope to be able to determine factors of social collaboration that relate to improved instruction and student outcomes across the larger community of faculty.

Preparing for an Academic Career – the Engineering Faculty of Tomorrow

Susan C. Schneider and Jennifer L. Bonniwell
Department of Electrical and Computer Engineering
Marquette University
Milwaukee, WI USA

susan.schneider@marquette.edu; jennifer.bonniwell@marquette.edu

Abstract—To prepare our interested graduate students for careers as engineering educators, a three year graduated teaching experience has been developed combining face-to-face teaching experience with a seminar and workshops to provide some formal training in STEM higher education instruction.

The department's "Academic Careers" seminar provides an introduction to the three major aspects of the academic career – teaching, research and service. Students also enroll in our Preparing Future Faculty and Professionals Program (PFFP). In the graduated teaching experience, students work first as teaching assistants, then as a member of the instructional team for a course helping to develop and deliver instructional materials and then, in the third year, the students have full teaching responsibility for a significant segment of that course. Feedback is provided to the students from seasoned engineering educators.

Participation in these experiences allows our students to begin their academic careers with confidence. To date, five students have completed this program; there are four students currently in the program. The training program is more completely described in this paper together with program assessment information from former participants, both graduate students and their undergraduate students, and how the program has been modified based on these assessments for the current participants.

Keywords— *teacher training; higher education; graduate students; academic careers*

I. INTRODUCTION

There are a variety of ways by which an engineering graduate student in – say, Electrical Engineering – who's interested in a career as a university professor in EE, can obtain valuable training for a faculty position while working on one's Ph.D. research. Some of these ways include nationwide programs such as the Preparing Future Faculty (PFF) program, to programs developed specifically within engineering disciplines at particular schools, and to various mixtures of both models. The teaching program at Marquette University in Electrical Engineering is an example of the mixture model.

The PFF program began in 1993 as a joint effort between the Association of American Colleges and Universities and the

Council of Graduate Schools [1]. Marquette University and the University of Wisconsin at Milwaukee (UWM) were selected to form one of the original seventeen regional clusters. From 1993 to 2003, Marquette and UWM served as a central hub for other colleges and universities in Wisconsin for PFF-related events and programming. Since 2003, the Marquette University Graduate School has continued the PFF program at Marquette, providing funding for significant PFF programming including an impressive list of workshops on teaching topics.

Over the years, the PFF program has been adopted – either completely or with local modifications – at over 45 doctoral institutions such as Purdue University and the University of California-Los Angeles. Faculty from the University of Cincinnati describe the organization of their PFF discipline specific engineering program covering the planned PFF activities, preliminary results, and program benefits [2]. The faculty from the University of Cincinnati revisited their PFF implementation after twelve years to determine how to modify it for the modern future faculty needs [3]. Another example of modifying an existing implementation of a PFF program is discussed by faculty from Clarkson University and Northwestern University [4]. They present their current PFF program and describe multiple changes they have made. They have made their general PFF program specific to engineering which allows them to build a series of presentations covering the following topics focused for engineering educators: hiring, tenure, teaching, curriculum reform, grant writing, and service. They also discuss the various types of engineering educational institutions at which future engineering faculty might consider employment.

Other institutions have presented alternative or supplemental programs that are based on or are similar to the PFF program [5-10]. In addition to their PFF Program, the University of Cincinnati also had a Science and Technology Enhancement Program and developed a study plan to determine how participating in the program had an effect on the students [5]. Another group of faculty does not mention having a PFF program, but they discuss a course in faculty development [6]. The course covers topics such as lecture preparation, ethics, course content, teaching methods and techniques, and other

key components relating to daily faculty’s duties. A “teaching apprenticeship” program at the University of Notre Dame incorporates direct teaching experience with informal meetings to expose the students to engineering education research and practice [10].

In addition to the studies on the implementation and content for programs devoted to training future faculty, there have been studies on the expectations of the future faculty [11-15]. Faculty from the University of Washington introduce their Engineering Teaching Portfolio Program and interview the fifteen graduate students who participated in the pilot offering [7]. The participants are graduate students who are interested in a faculty career and are asked to discuss what they perceive to be the daily responsibilities of a faculty member. Alternatively, another group interviewed graduate students and requested that they reflect on the research mentorships they had [12]. Specifically, they wanted the graduate students to focus on how their research mentorship helped prepare them for a faculty career. These discussions are insightful because they show misconceptions that current faculty did not realize future faculty had and help pinpoint areas that might need to be clarified for future faculty. This would ensure the future faculty would have a good expectation of the career path ahead of them. It would also be more likely to produce effective faculty members.

Lastly, there have been multiple evaluations by faculty of their current future faculty training programs [16, 17]. Faculty from Virginia Tech interviewed former participants in their Teaching Fellowship program to evaluate the effectiveness and success of their program. The feedback they received from the fellows was collected and a list of modifications to the program has been identified [16].

This paper introduces another method for faculty development, focusing on the teaching development aspect. The program was developed specifically to provide appropriate teacher training and experience to students in the department’s fellowship program supported by the Graduate Assistance in Areas of National Need (GAANN) program of the Office of Postsecondary Education, Department of Education. The teacher training program followed in our department combines our PFF workshops with a department seminar course and a three year progressive teaching experience that is the heart of this program.

II. PROGRAM OVERVIEW

The goal of our program is to prepare our interested graduate students for careers in higher education in electrical engineering; three aspects of which are teaching, research and service. To accomplish training in teaching, we have developed a three year progression of teaching experiences in conjunction with a seminar course and workshops used to provide some formal instruction in pedagogy with emphasis on STEM disciplines. The graduate students who receive fellowships in our program are competitively selected from

among those in the department who express interest in academic careers.

There are three phases of face-to-face classroom teaching practice – first as a general cohort teaching assistant, second serving a support role as a member of the instruction team for a course and finally taking on the instructor role for the course. Each phase takes place in one or two semesters of three consecutive academic years.

Simultaneous with the teaching practice, students participate in the department’s Academic Careers (AC) seminar course as well as the university’s Preparing Future Faculty and Professionals (PFFP) program. These two activities mesh together to provide instruction in research-based pedagogy and andragogy techniques. Both the seminar course and the PFFP workshops provide supportive learning activities to promote well-rounded faculty by addressing not only teaching but also the research and service aspects of an academic career. Participation in these experiences is intended to foster confidence in our students when they begin their careers. To date, five students have completed this program; there are four students currently in the program. In the following sections, a more complete description of the program is provided. Program assessment information from former participants, both graduate students and the undergraduate students they taught is also discussed together with how the program has been modified based on these assessments for the current participants.

III. PROGRAM DETAILS

As mentioned in the previous section, formal instruction on teaching together with classroom based experiences are incorporated into all three years. Table I shows the focus for each component of the teaching training -- face-to-face (F2F) teaching practice, the department’s Academic Careers Seminar (AC) course and Marquette University’s PFFP workshops—for each of the three years. In the first year, when students are working as teaching assistants, students will receive most of their instruction in educational practice through the seminar and the PFFP workshops. In the second and third years, as the student’s level of responsibility in the classroom increases, the AC and PFFP continue to provide timely resources for education and also begin to incorporate activities to address the research and service aspects of the academic career.

Table I: Teaching Training Yearly Schedule

<i>Program Year</i>	<i>F2F Teaching Practice</i>	<i>Primary focus – AC and PFFP</i>	<i>Secondary focus – AC and PFFP</i>
First	General TA	Educational Practice	Research (Publications, Presentations)
Second	Instruction team member	Educational Practice	Research (Proposals, Funding)
Third	Lead instructor	Practical support (AC)	Academic Job Search, Service

The Academic Careers weekly seminar is a one credit course taken by the students each semester. Students in the teaching program also participate in the Marquette University Graduate School PFFP Certificate Program. Students will generally attend between three and five two-hour PFFP workshops each semester. Every attempt is made to coordinate PFFP workshops with AC topic discussion to reinforce and/or practice the concept. Students are awarded a notation on their university transcript upon completion of the eight PFFP Certificate Program requirement.

Focus for the instruction in teaching in the Academic Careers Seminar is provided through the textbook by P. C. Wankat and F. S. Oreovicz, *Teaching Engineering* [18]. Topics covered include the “how-tos” and pros and cons of various teaching styles - lecture, project-based, co-operative learning and learning styles; the definition of various student learning styles and how to incorporate strategies to accommodate them within the course learning experiences; how students develop intellectually; teaching with technology such as the use of course management systems for quizzes, surveys, on-line and hybrid teaching modes; syllabus and test creation; grading issues and academic honesty; and others. Supplemental materials from the ASEE, the IEEE, and current papers drawn from archival sources (journals, proceedings, etc.) are also used.

Students implement at least two different learning assessment methods from *Classroom Assessment Techniques*, by Cross and Angelo [19] and summarize the results with improvement recommendations. Students learn to incorporate activities to promote student achievement of the “A through K” list of attributes of successful engineers required by the engineering accreditation agency, ABET, into their teaching. Senior EECE faculty members share their expertise on effective teaching in this seminar.

The eight PFFP Certificate Program requirements include completing workshops and classroom instruction activities in (1) Theory and Research on Effective Teaching in Higher Education; (2) Specific Teaching Skills; (3) Obtaining Feedback on Teaching; (4) Assessing Student Learning; (5) Teaching with Technology; (6) Applying and Interviewing for Positions; (7) Obtaining External Funding and (8) Teaching Portfolio. Students automatically meet PFFP requirements 1, 2, 3, 4, and 8 through their department teaching experiences; requirements 5, 6 and 7 are met through participation in the PFFP workshop program co-sponsored by Marquette University’s Center for Teaching and Learning. Regularly scheduled PFFP workshops include “Effective Course Design”, “Syllabus Construction”, “Learning Objectives,” “Assessing Student Learning.” Every effort is made to dovetail the topic schedules of the Academic Careers seminar and the PFFP workshops so, in the AC seminar, the concepts of the workshops can be more fully explored and tried out, if possible.

The face-to-face classroom experience starts when students serve as half-time (10 hours/week) teaching assistants with grading responsibility in one of the electrical engineering undergraduate laboratories or for an electrical engineering class during their first year in the program. They hold a minimum of three hours per week of office hours for the class to which they have been assigned to provide assistance to students. All teaching assistants work directly with the instructor assigned to teach the laboratory or course. The course for which the student will serve as instructor in the third year is selected by the project directors together with the student and her/his research advisor prior to the second year of the fellowship.

During the second year, the student serves as part of the instructional team for the course for one semester to both observe the day to day classroom instruction by an experienced faculty and to work collaboratively with that faculty member to develop curriculum materials such as lecture notes, electronic resources, handouts, homework assignments, tests, supplemental reading, etc. to support pedagogy for the course. These materials are used by the student when, in the third year, the student assumes responsibility for that same course including appropriate instruction, grading and grade assignment, and supervision of any assigned teaching assistants. The same faculty member from the second year serves as the student’s teaching mentor for this third year experience.

During the third year instructor experience, the faculty member monitors the student’s classroom performance to enhance their presentation skills and ensure proper coverage of course material. The teaching mentor visits the classroom daily during the first two weeks of class; if satisfactory progress is noted, visits are then conducted weekly for the next month and then every two weeks. Each visit is immediately followed by a meeting of the student with the mentor to review. The mentor provides feedback to the student about handouts, exams, and homework and project assignments to ensure that course objectives are met. Formative assessment of teaching performance with frequent feedback is stressed. In addition to regular recurring review by the teaching mentor, students’ teaching is evaluated by two senior faculty members via the EECE Department Peer Review of Teaching program to provide additional guidance and support. Summative and formative assessment occurs when students are evaluated at the end of the semester by the students through MOCES – Marquette University’s Online Course Evaluation System. The MOCES data is reported to the Chair and compared to department, college and university averages. Each student is required to complete an annual “Graduate Student Activity Report” (GSAR) modeled after the Faculty Activity Report at Marquette University at the end of each academic year, listing their teaching work, their research work, and their service work. This teacher training provides baseline information on teaching performance from

which the students can build on as well as develop strategies to affect such improvement.

Research, service and finding the first academic job are also covered in the Academic Careers seminar and the PFFP workshops. Topics such as best practices to supervise/mentor graduate students, responsible conduct of research, research methodology, technical writing, presentation skills and proposal writing are covered. The students develop written statements of their teaching philosophy and a personal research statement; these statements are included in their teaching portfolios. Other aspects of the interview process are discussed – such as suggested questions for the interviewee to ask so that they have a good feeling of how they will fit into the new department.

The students develop and maintain a professional portfolio through which they document their teaching and research abilities. They attend an educational conference in their three years as students, such as the ASEE annual exposition or the ASEE North Midwest Section conference or the IEEE/ASEE Frontiers in Education conference (FIE). In addition, students are encouraged to also perform some type of service to the profession.

IV. ASSESSMENT AND PROGRAM MODIFICATIONS

The five graduates from the first cohort of students who participated in this teaching training program were recently surveyed. From this first cohort, two are employed in university teaching positions in engineering (one tenure-track, one full-time adjunct); of the three who are employed full-time in industry, one is an adjunct faculty member in an electrical engineering program teaching one class per semester, another has just this semester taught an EE course as a part-time instructor for the first time. All of this first cohort report that the teaching experiences in the program were of significant value to them; two of them have specifically taught their “third year course” again using some of the materials they developed during their training.

Recommended changes/improvements to the program focused primarily on the Academic Careers seminar. It was suggested that the AC seminar be used to discuss the experience of the people currently going through the 2nd and 3rd year instructor roles to provide “real-time” feedback for the student teachers as well as insight for students who are getting ready for these experiences. It was also recommended that discussion and/or instruction be added to the AC seminar for several more modern teaching modalities such as synchronous hybrid distance-education classes, asynchronous video lecture classes, and completely online self-paced classes, all of which seem to require vastly different teaching strategies than those used for traditional lecture formats. In addition, it was recommended that the appropriate use of prepackaged course material (lectures, quizzes, other supporting material) available from the book publishers also be covered because it was felt that for a novice lecturer prepackaged material can be

most effective and time efficient and open educational resources (OER) are also normally good starting points for developing one’s own material.

Another recommendation from the first cohort involved carefully choosing and scheduling the courses for the third year teaching experience. For the first cohort, two required junior level program courses and one senior level elective course were taught by the “student teachers” during a single academic year. Even though all students were mentored by full-time faculty as described, some of the undergraduate students expressed dissatisfaction with multiple exposures to inexperienced teachers. Due to this, it was recommended that, as much as possible, the scheduling of multiple same-level classes taught by program students during the same academic year be avoided if possible.

Additional assessment from the directors of the program also provided recommendations – most importantly for the third year teaching experience. It was felt that to have the full responsibility for a course is too burdensome for the students in the program because during that same year, students are expected to also complete the dissertation research, writing, and defense.

Virtually all of the recommendations from our first cohort have already been or will be shortly incorporated into the teaching program for the second cohort of students who are currently within the first or second year. An even closer connection has been made between the concepts and schedules of the PFFP workshops and the AC seminar so that the AC seminar can supplement the PFFP workshops with specific examples of how the topics of the workshop translate to STEM disciplines – what’s the same, what’s different – and now serves as reinforcement for PFFP topics. Also, in the AC seminar, attention has been directed to learning about the flipped classroom and the creation of appropriate supporting materials for the flipped or on-line class. All the current students in this second cohort are creating appropriate modules as narrated slide presentations and/or video presentations for a single topic in each of three different classes; a three-phase power module for Circuits II (sophomore year), several VHDL modules for the digital electronics course (sophomore), and a mathematics review module to prepare students for the Linear Systems class (junior). These materials will be used by the students when they assume responsibility for the instruction of those topics within the named course. By incorporating the flipped classroom technique in the third year experience, we are able to (a) reduce the workload for the students in their final year of the program while (b) still giving them significant “solo” teaching experience and (c) possibly reducing the perception of our undergraduate student of multiple exposures to novice teachers. These materials may then be used by the students when they assume the faculty role – just as many of our first cohort students have done.

V. CONCLUDING REMARKS

The three year graduated teaching experience that has been developed which combines face-to-face teaching experience with a seminar and workshops to provide some formal training in STEM higher education instruction has proven to be very successful for our program. Almost all of the first group of students who participated in this program have either become faculty or have taught part-time in an electrical engineering program at a university or community college.

ACKNOWLEDGMENTS

The authors would like to thank graduate students, Laura Alderson, Alex Baker, and Alia Strandt for their assistance in collecting the assessment survey data. In addition, we thank Dr. Edwin Yaz for his support as Principal Investigator of the EECE Department GAANN program and Dr. Fabien Josse as the project co-director.

Innovative Faculty Cohort Hire at the University of San Diego

Susan M. Lord, Lisa Baird, Jane Friedman, Perla Myers, Sandra Sgoutas-Emch, and Michelle M. Camacho
Electrical Engineering, Biology, Mathematics and Computer Science, Psychological Sciences, and Sociology
University of San Diego
San Diego, CA USA
slord@sandiego.edu

Abstract—The University of San Diego (USD)’s NSF ADVANCE grant, AFFIRM (Advancement of Female Faculty: Institutional climate, Recruitment and Mentoring), focuses on addressing issues related to race and gender for faculty in Science, Technology, Engineering, and Mathematics (STEM). Although a majority of undergraduate students majoring in most STEM disciplines at USD are female, there are not nearly that many women faculty. As part of the grant proposal, the AFFIRM team was promised two new faculty positions by the Provost. In Fall 2013, the team met with the Dean of the College of Arts and Sciences and the Dean of the School of Engineering and the idea of hiring a faculty cohort to facilitate mentoring, diversity, and interdisciplinarity emerged and was approved. Over 200 candidates from diverse backgrounds applied. The candidates that came for on-campus interviews were so impressive that the Provost and Deans agreed to additional hiring opportunities, leading to a cohort of eight female faculty in the STEM fields including four women of color. In this work-in-progress, we discuss our innovative cohort hiring process, and share feedback from members of the cohort, and lessons learned. This innovative process could serve as a model for other campuses.

Keywords— *ADVANCE; cohort hire; interdisciplinary; female faculty;*

I. INTRODUCTION

As part of the University of San Diego (USD)’s NSF ADVANCE grant, AFFIRM (Advancement of Female Faculty: Institutional climate, Recruitment and Mentoring), we are focusing on addressing issues related to race and gender for faculty, particularly those in Science, Technology, Engineering, and Mathematics (STEM). Typical approaches to diversifying faculty have not been successful suggesting more innovative approaches are needed.

Although a majority of undergraduate students majoring in most STEM disciplines at USD are female, there are not nearly that many women faculty. A goal of the grant was to promote opportunities for women in STEM fields and have a more representative faculty. In 2014, the team achieved a milestone towards this goal when a cohort of eight women faculty in STEM disciplines was hired. In this work-in-progress, we discuss our innovative cohort

hiring process, feedback from members of the cohort, and lessons learned. This process could serve as a model for other campuses.

II. HIRING PROCESS

A. Cohort Hire Idea

In the proposal to NSF, the AFFIRM team was promised at least two faculty positions in STEM and Social/Behavioral Sciences by the Provost. After that Provost left, the Interim Provost honored that commitment.

In Fall 2013, the third year of the grant, the AFFIRM team met with the Deans of the College of Arts and Sciences and the Shiley Marcos School of Engineering as well as the Vice Provost for Inclusion and Diversity to discuss and formulate a method of advertising the new positions. Both deans had started in Fall 2013. The idea of hiring a faculty cohort to facilitate mentoring, diversity, and interdisciplinarity emerged and was enthusiastically approved. Typically science and engineering faculty position advertisements are written tightly and prescriptively, but the team, with the support of the administration, tried something different.

Cohort or cluster hires have been used to diversify faculty and appear in several universities best practices for hiring faculty policies. Institutions including the University of Illinois Chicago and North Carolina State find that these types of hire improve the retention of faculty of color, enhance socialization, and reduce feelings of isolation [1, 2]. Other work points to the importance of obtaining a critical mass of faculty of color to help build community and increase retention [3]. Such hires are becoming more common although there is not currently much published peer-reviewed literature on this topic.

An invitation was sent to all eligible departments inviting them to be included in this hiring effort. All departments that accepted the invitation were listed on the ad, filed a recruitment plan, and included discipline-specific language as needed. Of the eligible departments, only Psychological Sciences chose not to participate. A copy of an advertisement is shown here and was available online [4]. Note that candidates were asked to provide additional

information (shown in bold) beyond what is typically requested.

Job Advertisement

The University of San Diego (USD) invites applications for a cluster of new Assistant Professor positions in STEM (Science, Technology, Engineering, Mathematics) and/or Social Sciences associated with a funded National Science Foundation ADVANCE grant initiative (<http://www.nsf.gov/crssprgm/advance/>). The positions will begin in September 2014 and may be housed in one or more of the following departments:

Biology, Chemistry and Biochemistry,
Marine Science and Environmental Studies,
Mathematics and Computer Science,
Physics, Sociology or
the Shiley Marcos School of Engineering.

The successful candidates will:

- hold a Ph.D. in a STEM or social science discipline, and
- have demonstrated a commitment to teaching and research, mentoring undergraduates, and fostering a climate of inclusion and diversity.

It is anticipated that these faculty members will work as an interdisciplinary cluster to build opportunities for faculty/student collaborations and promote interdisciplinary strength within the undergraduate core curriculum. We endeavor to build a cohort of teacher-scholars who will offer a strong contribution to the diversity and excellence of USD through teaching, scholarship, service and collaboration.

Please submit by January 15th to WEBSITE:

- Your curriculum vitae.
- Statement of teaching philosophy.
- Your research statement/plans.
- A statement addressing the following:
How do you envision yourself working as part of an interdisciplinary cohort?
How will you promote interdisciplinary collaborations in the undergraduate curriculum?
Explain your approach to, and experience with, mentoring female students and students from under-represented backgrounds.

Have four recommenders submit letters of recommendation to AFFIRMsearch@sandiego.edu by the deadline. At least one of the recommendation letters should specifically address teaching and one should specifically address your track record in terms of mentoring female students and students from under-represented backgrounds.

B. Applicant Pool and Interviews

Two hundred seventeen applications were submitted. The racial/ethnic distribution of the applicant pool is shown

in Table 1. In the pool, 45% of the applicants were women, 48% were men, and 7% declined to state.

TABLE I. DEMOGRAPHICS OF APPLICANT POOL

White (not Hispanic or Latino)	47%
Asian	28%
Hispanic or Latino	10%
Black	4%
Two or more Races	2%
American Indian or Alaska Native	1%

The AFFIRM team reviewed responses to the mentoring and interdisciplinary portions of the applications. Two AFFIRM team members commented on each file and made a recommendation of whether the candidate satisfied the initial criteria. Applications that passed this screening were forwarded to individual departments to be evaluated in whatever manner is customary in that department. Departments were asked to select up to three individuals for on-campus interviews.

The Provost agreed to allow each unit to interview up to two candidates. Candidates were required to meet with both Deans, the Vice Provost for Diversity and Inclusion, and members of the AFFIRM team, in addition to the customary meetings. These interviews occurred over a three week period concluding in early April. Each department was then asked to forward to the Dean their selected candidate(s) with a brief rationale. The AFFIRM team met in late April and given the strength of the candidates made the recommendation to hire as many as possible, without ranking candidates. Representatives from the AFFIRM team then met with the Deans and Provost.

C. Final Cohort

The candidates that came for on-campus interviews were so impressive that the provost and deans agreed to additional hiring opportunities. The Provost agreed to fund another line and three departments used open lines. Two departments (Mechanical Engineering and Psychological Sciences) hired women outside of the AFFIRM search who were invited to join the cohort. This brings the total size of the cohort to eight, four of whom are women of color.

These new assistant professors are in the departments of chemistry and biochemistry, biology, industrial and systems engineering, mechanical engineering, environmental and ocean sciences, mathematics and computer science, and psychological sciences.

III. FEEDBACK FROM THE COHORT

Members of the cohort were interviewed during their first semester at USD by the evaluator for AFFIRM. Highlights of these responses are included here.

A. Response to Advertisement

Respondents were asked to describe their reactions to the ad that was placed for their position and why they chose USD. The faculty offered the following comments:

- Wanted a teaching oriented college
- Attracted by the San Diego location
- Attracted by the quality faculty that already had positions in the department they were applying to
- Appreciated the interdisciplinary focus of the cohort
- Only expected that there were going to be two or three hires but like the cohort aspect
- They had some questions about who made the hiring decision. Was it the Chair, search team, AFFIRM, provost or who?
- Saw the ad as an effort to encourage women faculty of color in STEM but not exclusive to them.

B. Interdisciplinary Aspect of the Position

The faculty offered comments that coalesced around several general themes regarding the interdisciplinary focus of the AFFIRM initiative.

1) The interdisciplinary approach offers opportunity

- Interested in exploring the possibilities both for research and teaching
- “Collective work is at the core of my beliefs”
- If incorporated into my teaching it becomes a way for students to understand how a particular subject area has applicability in other STEM disciplines—could attract underrepresented students to the field.
- Could help our students in the job market
- Having AFFIRM being part of this hire shows there is a commitment to supporting ambitious research
- I *need* to work with faculty in other departments in order to do my research.
- I came from an interdisciplinary approach and it was very productive.
- Interdisciplinary work is the wave of the future; more journals are encouraging it.
- Excited about working with other members of the cohort on grants. Some have already begun conversations.
- Seen as a way to address more academically rich and challenging research questions and go for larger grants. Different backgrounds can stimulate creativity and create an environment that is conducive to research.
- Interdisciplinary collaborations really work for some faculty. Her work is so interdisciplinary that it was hard for her to find a job because universities don’t know where she fits.

2) The interdisciplinary approach also presents some challenges:

- Unfamiliar with that kind of work, not sure how it will work...

- Not sure what it really means in practice. “I’m trying to figure it out”. “Not sure the AFFIRM team knows how it will work either”. “How will AFFIRM develop interdisciplinary collaborations? Feel like it is being left to us to figure it out”.
- “I don’t really want to be pigeonholed to do interdisciplinary research”.
- Not enough time as it is to do my own research. Would need a shortcut to learn about other disciplines.
- Universities prize interdisciplinary focus but they don’t know how to put it into action. Not sure where the support will come from.
- The Chair’s support for interdisciplinary research will be very important. Some felt they had a supportive Chair and that their Chair honors team teaching.
- The orientation could be just a “token” or ideal; not actionable
- When thinking about the tenure process, seems like it might present problems. Tenure decisions are stressful. Not sure how interdisciplinary research will impact tenure

Others felt they were unlikely to work within the cohort as they sought out collaborators because they would want more expertise than the new faculty were likely to provide.

- More likely to reach out to national labs, professors at other universities or even USD professors but they would be folks with more experience than the new cohort of faculty.
- Not sure there is a structure in place to support the approach

C. Cohort Aspect of the Initiative

Everyone interviewed thought the cohort was a great idea, although some were more positive than others. They made the following comments:

- Cohort is great
- Wonderful colleagues who are going through the same transition that each of us is going through
- Difficult to transition to a faculty anyway so this arrangement would help
- Nice individuals but not really interested in being too involved, too busy.
- Coming in with a cohort of people really helps.
- Some individuals explained that they had already begun to have conversations about research.
- Several live in the same faculty housing and that is boosting their interaction.

D. AFFIRM Mentors

The AFFIRM grant provides for a departmental mentor and an outside of department mentor. Initially, the members

of the cohort were assigned only a departmental mentor. All felt that the mentoring was working and reported that they met formally on a routine basis with their mentor—some met also almost daily on an informal basis. From their perspective, having a mentor inside their department offered tremendous advantages. They explained they had discussions on the following:

- goal settings and planning
- department culture
- clarification on who to ask about issues
- discussion of teaching, students, class info, course materials, grade distribution
- tenure
- debrief what department expects
- research
- type of service
- what's going on and what to expect
- honesty and helpfulness

Everyone was aware that a mentor outside the department was going to be assigned as part of AFFIRM. Most thought that might be helpful. Some felt it could really be a help to get to know others at the university but they were also concerned that the culture outside their department might be very different and thus the advice may not always be that helpful. Many faculty also mentioned the support they receive from the Associate Dean of Arts and Sciences who is a coPI on the AFFIRM grant.

IV. LESSONS LEARNED

This type of cohort hire had never been done at USD before and therefore the process was very much a “just-in-time” approach. There was a steep learning curve that at times caused some confusion and breakdown in communication between the AFFIRM team and the departments that were hiring. Additionally, we did not start advertising for the positions until January which may have limited our pool. We believe any future cohort hires will run more smoothly and with a more typical timeframe because of our experiences.

Another lesson learned by the AFFIRM team is how essential it is to have good relationships with the administration to influence hiring practices. Having a coPI that is an Associate Dean and supportive Deans was invaluable. It was also important that the Provost's promise of new hires was obtained in writing since the Provost left soon after the grant was funded. The AFFIRM External Advisory Board (EAB), which includes a Provost with extensive experience with ADVANCE grants, was also helpful in the process. During their annual meetings with upper administration, they stressed the need to make progress on the promise of new hires.

The AFFIRM EAB praised this effort and its impact “This grant has provided USD with a new paradigm for establishing a hiring process that more closely meets the goals of this university. The interdisciplinary work of the new hires presents an opportunity for USD to move in

directions that represent a modern approach to the way science is done. This can only be viewed as a tremendous accomplishment. It certainly shows administrative buy-in to the goals of AFFIRM. It is no surprise that this set of hires is bringing positive attention to USD, and top universities around the country are looking to mimic it.” Articles on the cohort were published in the Chronicle of Higher Education and on the USD website [5, 6].

The AFFIRM EAB gave several recommendations to help insure the success of the cohort and future hiring at USD. Specifically, they recommended that “departmental structures be reviewed to ensure that the new faculty are treated fairly as they pursue tenure. The interdisciplinary work that the new faculty perform may not fit into the traditional career paths of faculty, and thus may be more difficult to evaluate. Allegiance to departments must be well-defined so that faculty understand their teaching commitments. This new approach is being carried out largely by untenured faculty. This could be a dangerous experience for the new faculty. As part of the mentoring this new cohort receives, we recommend that senior faculty who have experience with interdisciplinary research participate regularly.” In addition, they recommended that the USD administration “review the procedures that were used in this last search with a view as to institutionalizing them for future hires. If USD continues this implementation with the result of substantially increasing diversity of its faculty in the next few hiring cycles, it would position USD as a unique university.”

ACKNOWLEDGMENT

The authors would like to thank Dr. Lea Hubbard for conducting interviews, the Deans and Provost for their support, the AFFIRM EAB, and the AFFIRM cohort.

Tailor-Made: Meeting the Unique Needs of Women of Color STEM-SBS Faculty Through Mentoring

DeLois (“Kijana”) Crawford

Department of Sociology and Anthropology
Rochester, NY
drcgss@rit.edu

Abstract—Women of Color faculty have some of the worst outcomes of all other faculty in terms of attainment of tenure and promotion. They are much more likely than others to leave a university, file suits for discrimination and face hostile work environments and classrooms, and leave academe. It is to a university’s and society’s benefit to retain talented women of color and remedy these negative outcomes. This paper seeks to address the unique concerns and issues of Women of Color through the custom tailoring of mentoring programs based upon qualitative data analysis. Best practices and strategies will also be explored.

Keywords - Mentoring; STEM; African American; Latina American; Native American; Women of Color

I. INTRODUCTION

The underrepresentation of women of color (WoC), or AALANA (African American, Latina American, and Native American) female faculty in STEM (Science, Technology, Engineer and Math) and SBS (Social and Behavioral Science) disciplines at predominantly majority-group institutions in the U.S. is of great concern. Of faculty positions at the end of the first decade of this century, American-Indian women held 0.6 percent, Latinas held 4.0 percent, Asian American held 7.0 percent, while European-American women held 78.2 percent [3]

Delgado and Stefancic [10], Thomas and Hollenshead [20], and Cooper and Stephens [7] point out WoC faculty’s unique challenges in higher education. Compared to their majority-group female colleagues, WoC face additional barriers based on the intersections of race/ethnicity and gender. They live with multiple marginality [6,9,20,21]

The lack of effective mentoring contributes to the STEM-SBS WoC faculty’s low retention and advancement rate. Therefore, there is a need for RIT to establish mentoring programs that takes STEM-SBS WoC faculty’s unique circumstances into consideration.

II. LITERATURE REVIEW

Some form of mentoring is usually in place for new hires in many professions. Mentoring entails pairing up an experienced employee (the mentor) with a junior colleague (the mentee).

Working with a mentor can be invaluable preparation for a young professional. A mentor can help a junior employee learn about and adapt to an organization’s culture. He or she also can help a mentee get ahead by offering career advice [16]. Therefore, it would seem reasonable to expect mentoring to be beneficial in the professoriate where faculty are on probation longer than in almost any other profession and many WoC (women of color) faculty say they feel like they are on indefinite probation. However, it is well known that WoC are disproportionately denied access to mentoring due to the fact that academia has traditionally been dominated by majority-group males.

WoC in academe live with multiple marginalities [21]. Marginalization of women faculty, in general, persists as a result of exclusionary practices that foster a de facto segregation. This situation restricts opportunities for developing both formal and informal mentoring relationships by female faculty. In addition to gender marginalization, due to racial and ethnic marginalization, WoC face inequities and other obstacles in the pursuit of their career aspirations. As a result, they often develop feelings of isolation.

Many WoC recognize that mentoring and networking are important to their success [20]. However, in light of their extremely small numbers in STEM (Science, Technology, Engineering, and Mathematics) fields, they need much encouragement and support in order to survive; hence the need for the college and university administrators to provide WoC faculty with quality mentorship programs. Moody [17] believes “[M]entoring is *essential* for under-represented women in male-dominated fields..” Furthermore, she points out that “Mentoring has two dimensions: a senior person in the organization assists and advises a junior colleague regarding his/her career advancement and, secondly, provides to her less advanced colleague social/psychological support to enhance the mentee’s sense of well-being.”

A mentor should be “someone who will help you grow, move forward, challenge you, push you to be your best and...is going to advocate for you and your organization,” says Lacey Leone McLaughlin, director of executive education at the Center for Effective Organization at the University of Southern California’s Marshall School of Business [16]. The word “mentor” has its origin in Greek mythology. Mentor was a friend of Odysseus. The latter chose Mentor to educate and support his son, Telemachus, when he left for the Trojan War.

The term “mentor,” adopted in English, means someone who imparts wisdom and shares knowledge with a less experienced colleague. There are informal and formal mentors. The former provides informal mentoring that occurs naturally and is capable of providing significant benefits to both the mentor and the mentee due to the insights it provides to each. Alternatively, a formal mentor takes mentoring to the next level (a structured approach), expanding its usefulness, going beyond that of a single mentor-mentee pairing to enhance its value and effectiveness. There is evidence that mentoring benefits the mentee, the mentor and the organization. Therefore, in academia, effective mentoring has the potential to contribute to the career success of all faculty members. However, the mentoring model adopted by an institution is very important. It should have sufficient flexibility to adapt to the needs of the faculty without compromising the integrity, structure and quality of the program.

The MIT Report on the Initiative for Faculty Race and Diversity [14] recommends the need for establishing formal mentoring programs in all schools and departments, with training given to both mentors and mentees. Yolanda Flores Niemann [18] further emphasizes, “effective mentorship is critical to the success of women of color.” According to Christopher K.R.T. Jones, the Bill Guthridge Distinguished Professor of Mathematics at the University of North Carolina and a former recipient of the national Compact for Faculty Diversity, “African Americans and their under-represented faculty still receive little or no serendipitous mentoring. That’s an unconscionable gap that I see across the country. Formal mentoring programs, I agree, are the answer [17].”

It is very critical for an institution to provide a mentoring program that fits its institutional culture. The main mentoring models are: the traditional one-on-one, group-(or network) and peer-mentoring. At the University of Washington [25], for example, a network-based (or group) mentoring model is found to be appropriate for that institution. They did not find the one-on-one, single-mentor model to be an effective means for mentoring their junior faculty. They found a network of multiple mentors more beneficial than one-on-one mentoring to achieve the desired outcomes.

A. Institutional Context and Background

Founded in 1829, Rochester Institute of Technology (RIT) was an early pioneer in practice-based and cooperative education. Today, RIT is home to approximately 18,000 students (predominantly STEM majors) and is the third largest technical institution of higher education in the United States. Over one thousand full-time faculty (n=1068) support the academic and research enterprise in this tuition-driven, student-focused university. In 2014, women full-time faculty constituted only 32% of tenure-track faculty; 24% and 33% within STEM and SBS (Social and Behavioral Sciences) disciplines, respectively, and 40% overall.

RIT obtained an NSF ADVANCE IT project award (NSF ADVANCE 1209115) in 2012 entitled, *Creating Opportunity Networks for Engagement and Collective Transformation: Increasing the Representation and Advancement of Women Faculty at RIT* (or, simply, ADVANCE RIT).

ADVANCE RIT is an effort across RIT’s nine colleges, which includes STEM and SBS disciplines. The goal of the project is to increase the representation and advancement of women STEM and SBS faculty represented across ethnic, social, and cultural backgrounds. Over the past five years, RIT’s incoming classes have improved in quality and diversity and increased in size (20%). The faculty has become significantly larger, and less diverse.

III. METRODOLOGY

The present study entails analyzing data from two focus groups, consisting largely of tenure-track STEM-SBS WoC faculty, conducted at RIT during the spring of 2013. Participants were self-selected from a wide e-mail call, using the well-known snowball non-probability sampling technique. This approach was selected given RIT restrictions on providing race demographic data. Therefore, there was no way to identify prospective participants who identified with WoC groups. A scripted invitation that outlines the purpose of the project was sent out. It pointed out that the focus group discussion would be audio-and-video-recorded and that participants’ confidentiality would be preserved so that they could not be identified outside of the research group. Seven STEM-SBS WoC faculty, from science, math, and technology, participated in the focus-groups; four in one and three in the other. The focus group participants consisted of assistant professors and associate professors but were primarily junior faculty members. The participants have been at RIT for an average of four years.

A qualitative analysis of data obtained from the two focus group transcripts was performed using the constant-comparative method [4]. This enabled identification of patterns in the data sets to reveal similarities and differences.

The analysis entailed a three-phase approach. The first phase (open coding) permitted identification of ideas, themes, and issues. The second phase (focused coding) produced a reduced set of related ideas, topics and themes, and the third phase allowed for the identification of concepts that ties into the emic themes [19] that cut across the two focus groups.

IV. FINDINGS

As the research and analysis progressed, themes emerged from the meaning they represented for the subjects. In other words, the more prominent the themes were for an individual subject, the more likely it would be that they would attribute meaning to them in one or more area of their lives. Furthermore, prominence may be determined by the affect a subject uses when discussing it, or by the relative numbers of occurrence through the interview. Themes may also emanate through the wording of the interview when cross-referenced with ethnographer’s field notes and journals. In these cases, the notes may provide connections between theory and theme, creating an entirely different notion. The themes, as described by the subjects, were analogous with very personal events or social forces such as family influence, mentoring, networking in lieu of mentoring, creative mentioning, unique demands of

AALANA female faculty, or the power of education. More importantly, however, these themes granted a greater understanding about the role and function or lack of effective mentoring at RIT.

"It would be nice but right now I don't have an official constant go to person. It would be nice to have."

In general, this faculty member does not have a relationship where a senior member has taken an active role in her career development. She is not experiencing a process by which an individual of superior rank, special achievements and prestige is instructing her, counseling, guiding and facilitating her intellectual and career development. Furthermore, she is not being socialized to the rules of the academy by a senior member. She does not have someone who is accompanying her along her career to promotion and tenure. Her career development is not been viewed with a broad eye, seeing where she has come and where she is headed. For this respondent, mentoring has not empowered her to advance her career and receive tenure and promotion.

"...and I can't really pinpoint a specific thing. Just, you walk into a room sometimes and you are like, well this is odd or awkward and it takes a while to warm up. But that shouldn't be the feeling right. You should be able to walk into a room on this campus and feel like you are accepted. So no one does anything specific...but it's just a feeling you get when you walk into a room sometimes that, "hey, maybe I shouldn't be here."

The above respondent has gained entry into RIT and the profession but she finds that the environment is chilly and unwelcoming. This chilly environment may hinder her from attaining greater mobility and rewards. Her objective was focused on gaining entry into the academy and now she is being less successful in cultivating a mentor or mentors. This respondent might benefit from more than one mentor. Having several mentors would empower her more and give her more options. This might include a mentor who has interpersonal abilities or technical specifics in her profession for broad-based experiences. One mentor may make the initial contact in establishing a relationship with another mentor.

Kanter [15] noted that the centrality of power within formal organizations, along with obscure political structures, provide the means by which power mobilizes and distributes resources. Most white men want to maintain formal and informal positions within the power structure. They do this by establishing alliances with peers and sponsors. Peers and sponsors are therefore exceedingly important for women and AALANA women in particular because their sponsors, alliances, and peers are often more limited than those of males. In short, AALANA female faculty need access to the power structure that is available to majority demographics.

From stereotyping to tokenism, women of color face unique realities in the academic community. The above respondent feels excluded from communications and interpersonal activities that play an important part in promotion and tenure. This exclusion is also caused by their low numbers and their lack of entry into the formal and informal networks that provide support and opportunities to their white colleagues.

"So you have to sit there and think, is it just me? Honestly, there aren't enough of us on campus to be able to ask someone else besides you, "do you get the same vibe?" Who are you gonna ask?"

In view of the very small number of RIT's STEM WoC faculty, it is not surprising that the participants talked about a feeling of isolation and not belonging at this university. Much has been written about the negative sociological consequences of being the so-called "token" minority [20]. And there is the heavy load to be borne by being the tokenized numerical minority for performing service while having teaching and research responsibilities.

Racism and sexism are problems that concern and influence the behavior of AALANA female faculty. AALANA female faculty face a number of obstacles that make it difficult to achieve tenure and promotion. The two most prevalent obstacles they face are gendered and racial discrimination. The combination of which has been referred to as "double jeopardy" or the "double bind." Scott and Alexander [2] describe this double jeopardy when referring to African American women in particular, as: "preventing black women from formal networks such as higher educational training, and informal networks in which social relationships could possibly generate career benefits."

"Sometimes I think it's about being a women on this campus. Sometimes I do think it's about race. But no one ever says anything right?"

Although none of the respondents in this study had the benefit of a mentor in the traditional sense, all felt that mentoring was important and have or would like to assist others by being a mentor themselves. Many are involved in what can be defined as a history of relationships which have fostered individual growth. Some of these relationships are long-term, structured, formal and planned while others are spontaneous, short-lived or informal. One respondent stated:

"I have to agree with your definition of an advocate now that I'm thinking about it. So my department chair I would say is an advocate. Sometimes a mentor but not on the level of the other two, the formal and informal. If I need something he would definitely go to bat for me. Not personally, but yes definitely professionally."

Whereas the RIT STEM-SBS WoC faculty focus groups' participants recognize the value of a mentor, there appears to be some confusion concerning a formal versus an informal mentor and how either one may be able to help them to achieve career success. Not all of the participants said they have a formal mentor; however, they all said they have at least one informal mentor. One participant stated that she has a good relationship with her *mentor* whom she referred to also as her *advocate* due to the good relationship they have developed. She states that this person is her department chair. However, in order for faculty mentoring to be successful, the University must have an internal structure that supports an effective formal mentoring program. In addition, it is important to recognize the difference between a department chair-faculty relationship and that of a mentor-faculty relationship.

The department chair's focus is on achieving the goals and objectives of the department and the university while the latter is on developing the mentee professionally and personally. This distinct difference in their roles should preclude pairing new faculty with their department chairs in a mentoring program.

The lack of effective mentoring led to the creation of the P&T Smarts (informal) and P&T SMARTS (formal) program. These efforts grew out of the need to use a bottom-up management approach. A bottom-up management approach begins at a detailed view, with various segments combined to create a larger structure with a higher-level view. This approach gathered input from junior faculty at the lower levels as planning and decision-making are conducted. The nature of the P&T Smarts (informal) and P&T SMARTS (formal) missions most likely will achieve sustainable change that will build trust and communication. The loss of a substantial number of AALANA faculty at RIT points to the need to go beyond current programs and practices that the Institute currently provides and develop new programs that specifically target AALANA women to address the unique issues and needs they have as WoC faculty at a predominantly white institution.

A. *P&T Smarts (informal)*

This P&T Smarts will be facilitated by Dean Hector Flores (Graduate Studies Office) with the partnership of experienced faculty that will engage in informal mentoring and guidance. The process leading to tenure and promotion at an academic institution is sometimes fraught with tension and uncertainty. The purpose of P&T Smarts (informal) is to build a community of support and strategic thinking around issues of tenure and promotion. Experienced faculty and administrators will facilitate regular discussions on the various issues confronting faculty, engage in deep discussion about *smart* strategies and help develop a sense of common purpose and support that can eventually lead to a sustainable pipeline for success and a stronger community of teachers and scholars. Hands on exercises will be conducted as appropriate on issues ranging from networking, building relationships, to best practices to write and present scholarly work, building a strong and balanced promotion and tenure portfolio, etc. The only requirement for joining P&T Smarts is to commit 1-2 hours a month for reading or other assignments as appropriate.

B. *P&T SMARTS (formal)*

Under the leadership of Dr. dt ogilvie, Distinguished Professor of Urban Entrepreneurship, Former Dean of Saunders College of Business, and founder of the Center for Entrepreneurship (CUE), a CONNECT Provost Grant, Promotion & Tenure Strategies for Minority-women Academics at RIT for Transformative Success (P&T SMARTS) was funded with the primary goal to actively help non-tenure and tenure AALANA women faculty develop successful careers at RIT. It helps to retain them through a multi-faceted strategic approach that offers advice, feedback, guidance, and best practices that reflect a deep understanding of the unique issues and challenges that AALANA female faculty face.

Activities fall into several categories: mentoring and sponsorship, research and writing productivity, teaching

effectiveness classrooms that exhibit racial and/or gender oppression, time management, work/life balance, and professional SMARTS. Workshops will be designed to convey valuable information to the participants and provide training in how to develop and inculcate the skills into the faculty member's repertoire. This will be accomplished by improving communication, increasing transparency, providing consistency, and adding measures of accountability into the process.

Another important aspect of P&T SMARTS is the mentoring of the AALANA-Women faculty. Our model advocates that the participants develop a strategic mentoring plan, which entails that in addition to any mentoring provided by their units and mentoring by the team members, they develop a broad base of mentors for various aspects of their careers and look for cross-mentoring. That means they may look for writing mentors, teaching mentors, work/life balance mentors, mentors from their racial/ethnic group and mentors from other racial/ethnic groups, etc.

V. CONCLUSION

The unique experiences of WoC female faculty are often rendered invisible within the academy, obscured by scholarship devoted to either women as a whole or all people of color. The present mentoring initiatives at RIT have failed to capture the intersection of gender and race/ethnicity where the unique needs and experiences of women of color reside, silenced and masked within these contexts.

The lack of effective mentoring contributes to the WoC female faculty low retention rate and advancement rate. Therefore, there is a need for RIT to establish mentoring programs that takes STEM-SBS female faculty's unique circumstances into consideration.

The WOC social science research component seeks to remedy this oversight by giving voice to this subpopulation. Through implementation of the P&T Smarts (informal) and the P&T SMARTS (formal) seeks to tackle the lack of effective mentoring specific to women of color faculty by looking to the bottom-up approach to improve outcomes for female faculty as a whole.

By having examined the characteristics, lived experiences, perceptions, policies and institutional outcomes of women of color STEM-SBS faculty at RIT, unique barriers and catalysts to promotion and tenure and advancement are identified. The P&T Smarts (informal) and P&T SMARTS (formal) strategies or interventions will address these barriers.

Abstract— During the 2014 – 2015 academic year, engineering faculty members and students at California Polytechnic State University (Cal Poly) met monthly in a collaborative inquiry dialogue group to discuss the role of reflection in transforming engineering education. This project is part of the larger Consortium to Promote Reflection in Engineering Education (CPREE) headed by the University of Washington. In this paper we describe the activities of the Cal Poly group involved with CPREE and how these activities have transformed the thinking and actions of participants. Collaborative inquiry dialogue involves self-organizing individuals into a small group to address a compelling question through repeated cycles of experimentation and reflection on the results of that experimentation. In this context, the faculty members involved (including the authors of this paper) have been meeting to discuss how use of reflection in the classroom and/or in a collaborative inquiry dialogue amongst colleagues might lead to transformation in engineering education practice and outcomes. The dialogue group serves as a safe container that allows for the possibility of transformational insights by participants – insights that change their view of themselves, the world, and their relationship to it.

Using a qualitative self-report methodology in the tradition of an action research paradigm, we (the authors) reflected on what we believed we had gained from the collaborative inquiry dialogues. Broadly we have noticed that participation in the collaborative inquiry dialogue has led us to reconsider what reflection is and what it could be, to develop a greater appreciation for the role of reflective practices in engineering education, and to better recognize when reflection is occurring (and when it might not be) such that reflective behaviors can be encouraged and practiced. We also began to challenge

assumptions we had made about our teaching practices and have noted that the collaborative inquiry provides an environment in which development of new thinking is possible.

Keywords—collaborative inquiry; reflection; faculty; transformation

I. INTRODUCTION

In recent years there have been numerous calls to reform engineering education [1-5]. Most recently, Goldman and Sommerville [6] called for a significant reform not just to the content and pedagogy of engineering education, but to its very culture. They describe the engineering culture as rigid and focused on knowledge rather than on the human beings who operate within the engineering educational system.

We argue here that engineering culture might be altered toward a more human-centered perspective if more faculty, staff and students could be encouraged to reflect critically on the assumptions they hold about the nature of engineering education. We believe a change in culture of this sort would not only be a positive development, but would involve a transformation in both the quantification of the current system (i.e. better prepared students, more diverse students and faculty, etc.) and in its qualitative nature (i.e. the way that faculty, staff and students interact within the system, how power is shared, and how individuals are motivated to thrive). To this end we are engaged in an effort to promote critical reflection among engineering students and faculty with the

hopes that it leads to a transformational change in the state of engineering education at Cal Poly.

We did not embark on this voyage alone. In 2013 The Leona M. and Harry B. Helmsley Charitable Trust collaborated with the University of Washington to create the Consortium to Promote Reflection in Engineering Education or CPREE. CPREE is a consortium of 12 partner institutions ranging from very high research, large public universities to community colleges. The goal of this consortium of institutions is to encourage engineering faculty to incorporate reflective practices in their classrooms, thereby increasing the number of engineering students who have encountered reflection in their academic careers.

As a member of the consortium, Cal Poly not only seeks to encourage faculty to incorporate reflective practices throughout the engineering curriculum and across multiple disciplines, but we also aim to leverage funding from the CPREE initiative to facilitate a collaborative inquiry dialog within the College of Engineering that may lead to the transformational change described above. Our strategy to accomplish this goal is to engage a critical mass of engineering and non-engineering faculty and students in a collaborative inquiry on the role of reflective practices in bringing about transformation within the higher educational system. We acknowledge that we are participants in this system; systemic transformation therefore implies self-transformation. The technique of collaborative inquiry and its impacts on the first group of faculty and students (thus far limited to engineering disciplines) to participate at Cal Poly will be described later. First we begin with a brief discussion of reflection in engineering education as a transformative process.

II. REFLECTIVE PRACTICES IN ENGINEERING EDUCATION

Reflection is something that we are generally aware of and might even claim that we use on a regular basis. But arriving at a succinct definition of the concept is not trivial. According to the work of Moon [7], our common understanding of the concept of reflection involves three attributes: 1) that reflection is directly tied to learning and the representation of that learning, 2) that we reflect for a purpose, and 3) that it involves consideration of complicated issues for which there is not a single obvious solution [8,9].

The first significant advocate for reflection in education was perhaps John Dewey [8] who saw it as a crucial process for resolving dilemmas that one faces in every-day life. For Dewey, reflection is “Active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and further conclusions to which it leads . . . it includes a conscious and voluntary effort to establish belief upon a firm basis of evidence and rationality” [8, p.9]. Dewey believed that reflection was a process that could be used to serve education, but that it was limited to a purely individualistic and cognitive process. Habermas [10] extended Dewey’s thinking on reflection to

suggest that reflection is an emancipatory process that leads towards truth, freedom and justice.

Later Kolb [11] would position reflective practice within his larger experiential learning cycle. Kolb situates reflection as a process that brings the ‘concrete experiencing’ of events to the level of ‘abstract conceptualization’ as shown in Figure 1. The capacity of reflective judgment is necessary in order to achieve this level of abstract conceptualization. Kolb himself hypothesized that certain individuals might be better suited to particular aspects of his experiential learning cycle, leading to the possibility of preferred learning styles. Furthermore, he also postulated that one could develop ability in any one of the four domains of his learning cycle, including reflective observation. King and Kitchener [9] operationalized this thinking into their seven-stage developmental model of reflective judgment. Within their model, only the final two stages of development are designated as truly reflective, making the ability to make reflective judgments the most advanced stage. In their thinking, therefore, they saw reflective judgment as something that was not attained by everyone and was for most an adult activity. While the lower stages of their model are characterized by knowledge acquisition and reasoning ability, they posit that reflective judgment involves comfort with ambiguity and the lack of an expert solution to a given dilemma.

Figure 1: Kolb’s Learning Cycle [11]

Turning from a theoretical examination of reflection we can study how reflection is used in practice in engineering education. In their review of the engineering education literature, Turns, *et al.* [12], found relatively few publications related to the use of reflection in engineering education. They note that Ambrose [13] calls for greater inclusion of reflection in engineering curricula. Beyond this more general appeal, there are isolated cases of engineering education researchers recommending the use of reflection for various learning outcomes [14-19] and as a component of service-learning projects/activities [20-22]. Why there should be such a general dearth of reflection in engineering education, considering that the idea of reflection has been commonplace in higher education since the time of Dewey, is an interesting question. However, it appears that engineering education has largely been resistant to the inclusion of reflective practices. Perhaps this is because engineering has been defined by the content of the discipline and the expertise of the educators, rather than on a more holistic foundation as is found in the social sciences. Or perhaps there is a collective belief system among engineering educators that reflection is neither appropriate to engineering nor attainable by engineering

students. Regardless, based on the extensive history of reflection in education in general, we believe there is ample room for the inclusion of reflective practices in engineering education and the study of its impact. At Cal Poly we have chosen to explore reflection and reflective practices through a process known as collaborative inquiry.

III. COLLABORATIVE INQUIRY

Collaborative inquiry is a technique used by educators around the world to leverage participant experiences in order to address a captivating question of interest to the participants. It is a strategy derived from the work of John Heron [23,24]. Collaborative inquiry is generally a small group discussion process in which a group of peers frame and work to answer a captivating question through repeated cycles of reflection and action. It is a method both for conducting participatory research and for facilitating adult learning through experience [25]. Participation in collaborative inquiry is both voluntary and consensual [26]. The methodology “rests on the epistemic assumption that human experience is most validly understood when people are politically full participants in decisions so that they can most fully engage as their authentic selves leading to valid experiences” [26 p. 251]

Collaborative inquiry as a process can take different forms and Heron himself does not claim to have possession of the sole description of the method [24]. Bray *et al.* [25] argue that there are four important phases to collaborative inquiry extending over months, if not years, of discourse: forming the group, creating the conditions for inquiry, acting, and making meaning. Depending on the time scale of the collaborative inquiry group, the first two stages may be merged into one. In forming the group it is important to seek out both a diversity of participants and participants who are intrinsically compelled to answer the captivating question. The conditions for inquiry require a democratic sharing of power where all are free to contribute as they see fit. Acting involves testing out hypothesized models of reality, followed by both personal and group reflection in order to make meaning of the results of the hypothesis test in such a way that assumptions may be challenged and altered in the mind of the individual.

Collaborative inquiry is closely aligned with the theory of transformative learning [27,28]. Transformative learning as a theory is interested in the development of adult learners to change their frames of reference by critically reflecting on their assumptions and beliefs and consciously making and implementing plans that bring about new ways of defining their worlds [29]. Collaborative inquiry can be used as a technique to create the conditions largely considered to be essential to successful transformative learning. These include creating a democratic space in which participants are free from coercion, share power equally, and establish norms of inquiry that involve both hypothesizing alternative models of reality and also testing those models in the real world. Together these attributes of collaborative inquiry guide the individual to engage in critical reflection on personal assumptions and epistemologies. It is this critical reflection which leads the individual participant, through group dialogue, to change themselves and how they relate to the captivating question.

A key facet to successful collaborative inquiry is the contribution of experienced facilitation. Experienced facilitators will be knowledgeable with the principles of collaborative inquiry. They will be able to fluidly work with the group dynamics and simultaneously be able to critically reflect on the impact of their own assumptions, values and actions on the group and on the discourse related to the captivating question. Herron [30] and later Alcántara, Hayes and Yorks [26] identified a systematic structure of three modes of facilitation and six dimensions of facilitation (Table I). No one mode is ‘correct’ in collaborative inquiry. Rather it is important that the group experience a range of facilitative modes across all dimensions in order to maximize the richness of the experience of the collaborative inquiry group.

TABLE I. MODES AND DIMENSIONS OF FACILITATING COLLABORATIVE INQUIRY [26]

Dimensions	Modes		
	Hierarchical	Cooperative	Autonomous
Planning	Decide on process and content of group’s learning	Negotiate and seek agreement on what participants will learn and the process by which they will learn	Affirm group as it plans its own learning process
Meaning	Illuminate and make sense of participants’ actions and experiences for them	Partner with the group in the generation of understanding emanating from the process	Allow and support participants in the generation of their own meaning making
Confronting	Raise group’s level of self-awareness by pointing out behaviors and other issues affecting experience	Consult with group members, and invite them to raise each other’s awareness of the dynamics affecting their process	Create a climate for group members to practice confronting and consciousness raising
Feeling	Choose the methods of managing feelings and emotions to suit the purposes of the group	Work with the group to elicit views on and handling of feelings and emotions	Give group space to manage its own affective dynamic
Structuring	Design and supervise group learning methods and activities	Construct learning methods and exercises with group members	Delegate group control over the design and supervision of their learning
Valuing	Initiate care for group members, and commit to creating a climate that values each person	Build a community of value and mutual respect with participants	Entrust to the group the affirmation of self and others’ worth

IV. COLLABORATIVE INQUIRY AT CAL POLY

Beginning in September 2014, a group of 15 faculty from the College of Engineering at Cal Poly began the process of collaborative inquiry together. This collection of individuals represents a varied cross-section of the disciplines present in the college and includes faculty of all ranks including non-tenure track. Importantly, our collaborative inquiry involved ourselves as research subjects and coresearchers in the

tradition of an action research paradigm [31-32]. Experiments were situated in our own lives, rather than on 'others'. The group meets for two hours each month in a shared space within the campus library, having met a total of eight times by the writing of this paper. Over this period of time, several engineering undergraduate students have joined us in the inquiry.

It is worth mentioning that some members of the group had been meeting together for several years within a collaborative inquiry framework to examine the concept of change models in higher education, while other members of the group were entirely new to the process of collaborative inquiry. For the collaborative inquiry group described in this paper, the captivating question was "What is the role of reflection in transforming engineering education?" Our collaborative inquiry group is facilitated by Mr. Roger Burton, a change consultant for large corporations for more than a decade. Roger arrived at Cal Poly several years ago as part of a nascent partnership around research questions of sustainability. Prior to working on the CPREE project he had been facilitating the collaborative inquiry group on change models in higher education for about 5 years.

The collaborative inquiry group meets monthly for a two hour period. Meetings begin with a 'check-in' during which participants have an opportunity to share anything on their minds which may prevent them from being fully present in the ensuing discussion. The purpose of this ritual is to set down whatever is distracting one's attention. Things that people say can often be evocative, the discipline involves listening attentively and refraining from responding to whatever is said. It is the quality of the attentive listening that creates the safe environment for authentic reflection and self-change. We then move to a discussion of the previous meetings' homework and reflection on the results of the homework. The homework encourages participants to actively engage in reflection in their own lives and to observe the consequences of this reflection. What follows next is a discussion which typically centers on ideas of reflection in practice, transformation, and the relationship between the two. Finally the meeting is concluded with proposals from the participants about the homework for the next gathering. In this way, homework followed by discussion followed by homework, the participants are cycling through action and reflection as is crucial to a successful collaborative inquiry.

V. FACULTY AND STUDENT OBSERVATIONS

During the period of the collaborative inquiry and prior to the writing of this paper, we asked faculty participants to engage in a sort of reflection on their experiences in collaborative inquiry. Specifically we asked them the following three questions:

- a) In what ways has the collaborative inquiry group led to discourse that you might not have otherwise engaged in?
- b) What have you learned about reflection as a result of your experiences in the collaborative inquiry group thus far?

- c) In what ways have your understandings, ideas, assumptions, motivations, etc. been transformed by the collaborative inquiry group?

This section is a synthesis of the members' responses to these questions. Participant names have been replaced with pseudonyms.

For the first question, many of the participants noted that they had engaged in a dialogue around reflecting on reflection, something that they would not have otherwise done in their daily activities. Abigail observed that her participation in a collaborative reflection activity was ironic, given that she has requested that her students reflect in her courses, but she has not done it herself. For some this meant considering questions such as what it really means to reflect, how and when an individual reflects, and where reflection originates.

Participants have noted the creation of a cooperative environment in which it is safe to discuss challenging pedagogical and philosophical questions. For Charles the collaborative inquiry was a place to engage in critical thinking in a public way, something he has had neither the time for nor felt sufficiently safe to do in the past. Zhuang pointed out that we all come from different disciplines, backgrounds and levels of comfort with reflection, but all the collaborative inquiry participants are committed to improving engineering education. Because of this shared purpose all the participants respect each other and are able to engage in a dialogue that might seem "odd" in any other setting. The overall shared purpose comes from the group being self-selected and has enabled everyone to speak freely without fear of embarrassment, ridicule or censure.

For some, the collaborative inquiry led to a questioning of their own motivations for using reflection. As Sara remarked, "My participation in CPREE has helped to clarify that I tend to use reflections as a way to peer into student thinking and to have a 'conversation' with them."

The collaborative inquiry group has also allowed some to "back away" from the details of what they are teaching and to focus on the broader context of student growth and learning. In this way the regular meetings of the collaborative inquiry group invigorates a personal transformation into being a better educator.

As for what participants have learned about reflection in the process, question b), a common refrain was developing new models of what reflection is, its many benefits, and the many ways of using reflective practices in the classroom. Some noted that they had come into the collaborative inquiry with what they thought were well-established definitions of reflection in their minds, only to find that the collaborative inquiry dialogue led them to question what reflection was and what it could be. Even with these varied meanings of reflection, it is clear to many of the participants of the inquiry that we have a long way to go to identify the measurable benefits of reflection and reliable means of teaching it.

At least one participant noticed that in discussing reflection he came to realize that reflection was a method by which to make meaning from his experiences and that through reflection his experiences could be applicable beyond the immediate context of the original experience. This may have implications for engineering education as the practice of engineering does involve application of the same knowledge in differing contexts.

Another refrain among participants was the realization that students might not always reflect in an honest way when prompted by the instructor, but might instead provide a reflection that they think the instructor wants to hear. As Sasha reported:

“The students are simply writing what they think I want to hear or about a ‘transformation’ that they think I want them to undergo. I came to understand this well when we as a group forced ourselves to engage in reflective practices which possibly gave me insight into the experiences of my students. It seems to be a significant challenge for facilitators to create an environment where participants feel safe to share potential vulnerabilities when reporting on their reflective practices and what insights or personal transformations might have occurred.”

Finally, examining what assumptions and motivations have changed for participants, a wide range of responses were gathered suggesting that participation in a collaborative inquiry can have divergent meanings for each participant. George became more conscious of the need to reflect himself in order to bring transformation into the classroom for his students:

“A common denominator I gathered from our discussions is that a reflection involves thinking about our own experiences. This in turn made me think more about my experiences as an educator and what I want my students to achieve. It became clear to me, that in order to improve my effectiveness as an educator, I first need to reflect upon myself – thinking about my experience in the classroom – and identify possible changes I can implement. Reflection then leads to transformation – change I will implement – to provide students with a transformative experience.”

Abigail added that she has also learned “that faculty members play a conditioning role around the effects that ‘reflection’ has on the student. Their role includes the assumptions they hold about power in the classroom and the purpose of reflective activities. When the assumptions are unexamined, the influence is even stronger.”

Zhuang experienced a range of emotional responses to the collaborative inquiry. On the one hand, he acknowledged that the inquiry dialogues forced him to examine his own assumptions about reflection and even engineering education more broadly. But on the other hand, he now has more doubts about how to encourage students to reflect and how to determine the benefits of reflection. Zhuang recalls that:

“... while doubt is a negative emotion, it is appropriate here because I initially was overconfident about what I ‘knew’ about reflection. It’s not that I now know less ... it’s that I now know what I don’t know. I make fewer assumptions and that means I have to face more unknowns.”

Charles has begun to re-consider his motivations for teaching. He had originally been a teacher who wanted to excel in the classroom, to dazzle students with “ah-ha” moments. The collaborative inquiry has made him realize that teaching and learning is about the students’ lives in a significant way.

Some are challenging assumptions that reflection is a thing, but instead are seeing it as a process that we may be engaged in continually, either consciously or unconsciously. Others have come to recognize that in order for students to experience transformative learning it may be necessary for faculty to undergo a similarly profound transformation. Sasha illustrates this perspective when she says:

“facilitators must also reflect and be open to changes that occur in their views and themselves and their interactions with the world that are made apparent by this reflective process. It is only from this open vantage point that they can reasonably attempt to create the necessary safe environment in which their participants can also engage in the reflective process.”

Some participants have even observed that the collaborative inquiry is in itself an intervention in the traditional engineering education culture and that through this inquiry we are calling into question our identities as “experts”, our purpose in teaching, and our habitual practices and assumptions. This has encouraged some to engage more deeply into research on reflection, not merely practice. Sasha, for example, stated:

“I am interested in looking at what factors would influence the validity of collected reflective artifacts. In this way, I think the rigor of my future explorations will be improved. I am also feeling an increase in motivation to study this and find ways in which to get my students to authentically reflect on their experiences.”

Lastly, one faculty participant noted that the collaborative inquiry dialogues are a place to relax our expectations, to open up and to simply be human. This reinforces the notion of collaborative inquiry as a genuine exploration of the human condition as suggested by Heron [24].

The student participants in the collaborative inquiry, some of whom are authors on this paper, contributed to our thinking about the impact of the collaborative inquiry as well. One student, Michael, pointed out that normally there is a significant power differential between students and faculty such that he would not feel safe having a conversation with faculty about pedagogy. But in the collaborative inquiry group, he felt at ease to discuss pedagogical practices

including use of current models in educational practice from Mezirow and Argyris for example.

Armando observed the value of the collaborative inquiry in promoting free discourse not just about reflection, but about the challenges of engineering education. He particularly enjoyed hearing how faculty struggle with the larger issues within the context of their everyday activities. He offers that “[the] freeform discussions not only expand my horizons, but also remind me of the power of simply taking the time to sit down and talk with others.”

Michael also found that even in classes where reflection is not assigned, he still needs to reflect because for him reflection was a key aspect of developing as a human being, not just as an engineer.

The student authors concurred that the CPREE collaborative inquiry group has provided an environment where it was okay to reassess their preexisting notions and, perhaps, to change their mind.

VI. FUTURE DIRECTIONS OF INQUIRY AT CAL POLY

Currently 15 faculty and 4 students have participated in the collaborative inquiry group on reflection and transformation in engineering education at Cal Poly. During the next year we aim to increase the number of faculty participants to 35 and recruit as many as 25 student participants. One of the challenges we will face in reaching this goal is that we must reach out to faculty who might not otherwise consider themselves proponents of change in engineering education. To encourage people to participate we will provide modest stipends for participants during year 2, and will provide books on reflection practices to participants.

Another challenge will be managing collaborative inquiry groups with so many potential attendees. While not every participant will attend every collaborative inquiry meeting, having several dozen people participate simultaneously in collaborative inquiry groups may not be feasible. To overcome this obstacle, we may need to break up into smaller, parallel collaborative inquiry groups facilitated by faculty who are currently participating, also known as a federated collaborative inquiry [25]. Each collaborative inquiry group would begin with the same approximate agenda, but would be autonomous in the sense that the group members drive the direction of the group.

Lastly, we intend to recruit a diverse population of students to join the faculty in collaborative inquiry. To achieve this, we are establishing working relationships with several student organizations (e.g. Society of Women Engineers, Society of Hispanic Professional Engineers, Society of Black Engineers and Scientists, among others) such that we can recruit inquiry participants from their membership. Small stipends will also be provided to the students to compensate them for their participation.

VII. CONCLUSIONS

In the College of Engineering at Cal Poly we have initiated the process of a collaborative inquiry into the relationship between reflective practices in and out of the college classroom and transformative learning. Collaborative inquiry is a process that democratically explores the experiences of participants through repeated cycles of action and reflection. It is a powerful qualitative research methodology that treats participants as agents of change rather than simply objects to be studied.

We have carried out several collaborative inquiry dialogues amongst our group of engineering faculty and engineering undergraduates. Through these dialogues we have gained much insight into the meaning of reflection, its role in our professional and personal lives, and how it can be used to help our students experience a more transformative educational experience. Specifically faculty observed that they were engaging in a conversation that they would not otherwise have had due to the collaborative inquiry, nor at the depth of thinking they experienced. Faculty also noted that they were developing new models of what reflection was and how it could be used in various settings. They were also becoming more attuned to the conditions that were necessary to elicit honest responses from students completing reflection activities as part of their courses. They realized that transformation for students might require that faculty themselves undergo a transformative process through regular reflection on their part. In other words, in order to enable change in the students, the faculty would have to undergo a change process themselves.

Students too contributed to the collaborative inquiry process and the findings in this paper. In particular they noted that the collaborative inquiry created a space that was safe for them to enter into dialogue with faculty despite the ever present power differential. They appreciated hearing faculty perspectives on the challenges facing engineering educators, and they enjoyed being challenged to reassess their preexisting ideas and even to change their minds.

Cal Poly will continue its collaborative inquiry into the 2015-2016 academic year, with plans to expand the number of participants to 35 faculty and up to 25 undergraduate students. The hope is that by increasing the extent of dialogue among and between participants we can affect change in the College of Engineering that would make the educational process a more human-centered endeavor.

Teaching computer programming

Practices, difficulties and opportunities

Sandra Milena Merchán Rubiano

Bogotá, Colombia
{smerchanr,orlandolopez,egomez}@unbosque.edu.co

Abstract— It is highly recognized that difficulties involved in teaching programming in an introductory course, arise from the cognitive process complexity that is necessary for developing this ability. Previous studies on the best first programming language or the best first programming paradigm have been conducted. Even, the most appropriate integrated development environment (IDE) for novice programmers has been inquired, and the most appropriate problem solving strategy to teach to write computable solutions has been researched. From the investigation in a sample of Bogota universities, and from a holistic perspective, this paper presents an overview of the most common practices and difficulties in teaching these courses, providing important information to help diagnose possible weaknesses in the current process of teaching as well as providing some elements to consider in the design of new strategies, resources and planning criteria for these formative scenarios.

Keywords— *Computing education research, teaching computer programming, introductory programming, programming pedagogy, novice programmers*

I. INTRODUCTION

Providing a suitable environment for learning computer programming for beginners is a topic of ongoing research since the 1970's [1], [2], even though it has been the focus of attention literary from the birth of electronic computing at the end of the Second World War [3].

Making computer programming learning more effective is socially important for the learner, as well as the novice programmer, the software industry which has held a growing demand in the quantity and quality of professionals, and for instructors and teachers interested in increasing the number of computer programming students by forming competent and competitive programmers.

There are elements that typically integrate the basics of the teaching-learning process in computer programming such as the languages, paradigms and programming environments, in addition to problem solving skills as a central focus of the process. Since the findings introduced in this paper, we invite readers to consider such elements within an integrated approach, given that they have usually been studied

individually and not as a set of variables that constitute the teaching environment.

Studies have been done regarding the most suitable language for teaching computer programming [4]-[6], as well as research on the most suitable integrated development environments [7]. However, the research conducted in this paper is an opportunity to fully consider additional elements involved in teaching programming, not only from the educational background, but also from the technological components with the perspective of problem solving skills.

This paper presents characteristics about teaching practices in introductory computer programming courses for undergraduate programs offered in Bogotá, in 2013, and it is organized as follows. Based on background revision, Section II presents the elements that typically build up a process of teaching computer programming and the role they play on it. This presentation structure serves also to show the results of this study. Section III introduces the methodological issues of this research, Section IV shows the results and their analysis and, the last section, shows some conclusions and recommendations associated with research findings.

II. TYPICAL COMPONENTS IN TEACHING COMPUTER PROGRAMMING

Part of the educational foundation of computer programming refers to Piagetian constructivism, but puts greater emphasis on Papert's constructionism [8], that is, an approach in which the world and knowledge are constructed and constantly reconstructed through personal experience, recognizing the inherent dynamics of reality and conceptualizing intelligence as an adaptation to the changing environment.

Papert [9] emphasizes the dynamics of change, learner's autonomy and an ecological or systemic vision of the learning process. All of these taking into account the competence of learning how to learn [10], which is also a key component in computer programming courses.

In this first section, components building up the set of the teaching computer programming practice are identified and explained. These components are those which have traditionally been taken into account in previous inquiries, such as programming languages, development environments, programming paradigms and problem solving strategies. Nevertheless, they have been frequently addressed isolated from their environment and other conceptual elements, but also isolated from situational elements [10], all of them integrating the computer programming teaching environment as object of study.

A. The role of the programming language

Although by 1956 the FORTRAN programming language [11] was created, and by 1960 the ALGOL programming language appeared at the computer scenario [12], it was only until the 70s that a programming language was designed [13], [14], that even its success in teaching (an learning) computer programming, it was not effective in the development of commercial applications, or at least not as much as Cobol [15], [16] that was created in 1959. Since 1970, some researchers [4]-[6] stated that the first step in teaching programming is the choice of the first programming language or suggest that it is a key element [17]. Those researchers develop their academic discourse around the programming language [18], [19].

The teacher is exposed to risks when teaching programming courses for novices in which the emphasis is on the programming language. One of the risks is that the novices focus their attention on syntax issues and not on the computational semantic power of the language, which at the end of the day is what allows to build solutions using computer programs. This approach prevents novices to understand that the main role of a programming language is to serve as a mean to express computational solutions proposed in the training exercises. Moreover, choosing a standard de facto language in the industry offers the advantage of training the student to develop skills that the market is looking for. However, it can also generate a bias of the concept of the student regarding the futility of learning other languages [20] and, besides, it can reduce the environment in which students develop the ability to learn to learn [10].

While the artificial language is an unavoidable element concerning the teaching of computer programming, especially for novices, the research that was conducted found that perhaps it should not be a decisive element in teaching practices. This should not be understood as a statement that teaching programming language concepts and structures are inappropriate [21] - [23]. The aim of learning programming language concepts and structures is to develop skills and competences to understand a wide range of artificial languages.

B. Computer programming development environments

Computer program development environments available today highly contrast with those available in the early years of computer programming. The interaction between the programmer and the computer during 1960's and 1970's was

minimal. At the present time, computer and programmer are very close. As other users, computer programmers during 60s and 70s had a punched tape or a deck of punched cards as a computer interface. Privileged users had a TTY terminal to edit files and issue commands. The process used to be linear and composed by five separate phases, e.g., editing, compiling, relocating, executable code generation and, if everything was correct, execution (Fig.1). Through the use of either control cards or control lines, the programmer issued commands to the computer (or the computer operator at the computer center) to determine what program or programs should be executed on the (source) file.

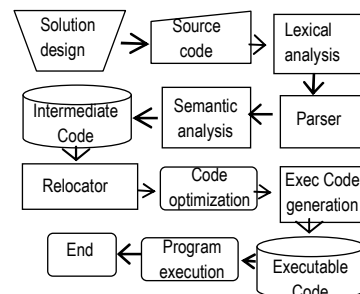

Fig. 1 Linear process of editing source code, compiling, understood as lexical analysis, parsing, and semantic analysis. Then a relocation phase, optionally going into a code optimization phase and, finally, generation of executable code and its execution.

The advent of microcomputers in the late 1970s and their consolidation in the next decade, brought the development of programs which allowed the programmer to edit the source file and, from the same program options menu, invoke the compiler, without any human intervention.

Contemporary IDEs, also known as suites or studios, are programs in which software tools or programming tools have been packaged [24]-[26]. Software tools such as: text editor (often specialized in creating visual aids on lexical and syntactic elements of a programming language), a compiler, with all its phases from the lexical analysis to generation of executable codes, a debugger and a program to design GUIs (graphical user interfaces) [27] share the same user environment. This increases the complexity of using the same IDE application and implies that the novice user adds another task to the process of learning computer programming: learning to use an IDE.

There may be different IDEs available for each of the operating systems. Let's say that the programming language (C, for instance) maintains constant between different operating systems. When using that programming language (C) in a Linux operating system there are a plenty of IDEs available. Moving the source code to iOS®, Android® or Windows®, just for the sake of reference, does not guarantee that the same IDE is available in the new environment. On the other hand, some IDEs may be more suitable for commercial usage, while others may be fitter for academic purposes. Besides, because of its nature, IDEs are not standard for all programming languages.

The use of a programming language can determine the use of a defined range of IDEs because there is not a universal

IDE. This, in turn, can generate an impact on the learning process since, empirically, it is known that students can direct their effort to understand the use of IDEs and overlook learning how to program a computer, or override learning the programming language itself. Therefore the choice of IDE is also an issue to consider.

Thus, the linear process of computer program development, an offline process from the perspective of the programmer, became an interactive process (Fig. 2). The expectation was that this new interactive process would improve software production leading to a final software product fulfilling at least high-quality standards, in terms of error free, well-documented, clear source code, leading to reductions in maintenance costs.

Usage of IDEs facilitated in part the interaction between the (learner) user and the computer, but a risk in this case has been the assumption that learning to use the IDE by the student is intuitive and therefore not time-consuming or exhibiting minimal difficulties [28], besides, the assumption that the learner is able to distinguish that learning to use the IDE is only a means to construct computer programs.

C. Programming Paradigms

A programming paradigm can be understood as a set of practices to solve computable problems, design its models and translate them into computer programs, practices that are adopted and used by a community of programmers over a period of time, based on the concept of Kuhn [29]. Consequently, the paradigm determines the style of programming, the time that the program testing can take, the results of software metrics and possibly the programming language in which it is (or have to be) encoded.

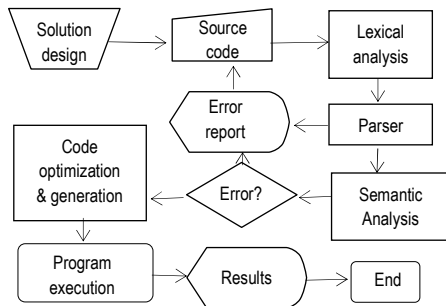

Fig. 2 Description of the interactive process of computer programs development, which by means of an IDE app, offers to the programmer the software tools that are supposed to be sufficient to build

Available literature shows no general agreement on the classification of programming paradigms, and even some documents tend to interpret these paradigms as a criterion for classification of programming languages or only identify them as "approaches" [30]. In this article, a tripartite categorization is adopted, and it is based on the criterion of how the solution to a computable problem is defined:

i) Imperative paradigm: in which the expression of the operation to be performed is privileged, i.e., how to do it; ii) declarative paradigm, in which the expression of what is sought is privileged, i.e., what to do; and iii) a third category in which other guidelines are grouped to privilege other

concepts or emphasis is made in the abstraction of other elements in the context of the computable problem (Table I).

TABLE I. PROGRAMMING PARADIGMS

Category	Programming Paradigm
Imperative	Free Structured/Modular Procedimental Object Oriented Event Oriented
Declarative	Logical Programming Functional Programming
Others	Heuristics Agent Oriented Concurrent (by processes) Aspect Oriented Rule based Restriction based

Thus, free programming called as *spaghetti* programming, is essentially an imperative form, in the same way that the structured programming paradigm refers to procedures and modules. The object-oriented programming paradigm and the event-oriented programming paradigm are categorized also within the imperative paradigm category.

The paradigm of logic programming and functional programming are classified under the category of declarative programming paradigms.

While the concept of object-oriented programming can be traced back to 1966 [31], it is at the beginning of the 1990s when the tradition in teaching programming in the structured paradigm is challenged by the object-oriented paradigm [33]. And an analog academic discussion to that given in the selection of the programming language, develops in the arena of programming paradigms, especially in the confrontation between the paradigm of structured programming and the paradigm of object orientation (OO).

It is not under discussion if the OO paradigm should be taught, since the software industry demands this skill. The discussion focuses on when it is more appropriate to introduce it. Literature shows that the OO paradigm produces better performance in students when they learn it before the structured programming paradigm [32]. Students who first learn the procedural paradigm, experience serious difficulties, in some cases insurmountable when changing to the OO paradigm [33], [34]. That is not to say that learning the OO paradigm is less difficult than the procedural paradigm [35], [36]; so it is recommended to do it gradually [36], [37], starting from the object-oriented paradigm gradually and then, if necessary, move to the paradigm of structured and procedural programming.

Nevertheless, there are studies that suggest that there is no significant difference concerning the order in which programming paradigms are taught, the difference mainly relies on the language that is used for novice programmers [38].

D. Problem solving strategy

Despite the extensive development of programming languages and programming paradigms, some researchers insist that neither the programming language, nor the programming paradigm or the integrated development environment are important elements in teaching, but rather the design process and concept-oriented on problem solving, not on paradigms [39] and that all students should be taught to program computers as an extension of the knowledge they already possess, that is mathematics.

Therefore, it is recommended that instructors include strategies for develop problem solving skill, in the classical sense, by induction [39], and through the use of top-down approach, with verifiable practical results [40]. This means that the programming learning environment is not restricted to the software applications of integrated development environment (IDEs), but involves the development of cognitive processes and improve competences on real world understanding, also. Algorithmic thinking is just one of those skills steps related to those processes and competences.

E. Other elements involved in teaching computer programming

As in any teaching process, the issue under study: the programming language paradigm or IDE, is not the sole determinant in the success of the teaching process. Some studies have pointed out motivation as a key element to be considered and strengthened in any teaching process [41]. A three-level hierarchy of the difficulties in teaching/learning Java programming language has been proposed [42], within these categories, difficulties in teaching programming can be examined. The first level establishes three criteria: (i) cognitive difficulties, (ii) programming difficulties and (iii) image difficulties (or perception).

In the second and third levels, within the cognitive difficulties, teaching strategies are identified (classes, tutorials and laboratories), learning style (comprehension and memorization) and motivation (genuine interest, prospects of career and family pressure). Programming difficulties themselves are grouped into difficulties regarding multiple processes (translation, algorithms, coding), educational skills (problem solving, precision) and multiple skills (syntax, structure, semantics, style). Finally, the criterion for self-perception difficulties (or perception) is comprised of interest (creativity, enjoyment when performing the task), reputation (public image and career), and finally, pace of instruction (academic year, course intensity and evaluation).

III. METHODOLOGY

A research study was conducted in order to unveil the practices developed by teachers and the difficulties in teaching computer programming in undergraduate programs in some universities in Bogotá, and those features related to students' learning processes; finding useful information for the design of new teaching strategies, teaching resources and planning criteria for courses in the academic area of teaching computer programming [43].

A literature review was carried out to establish the advances of research on the topic (typical elements conforming computer programming teaching) in order to contextualize and guide the study. The study was conducted based on a qualitative research approach. An instrument for collecting data was designed and an analysis on teaching practices was conducted.

A. Sample Determination

As the main interest of the study relies on characterizing teaching practices in introductory courses on computer programming, different universities in Bogotá with academic programs that include this type of courses were identified. The academic programs that were taken into account were the ones registered and recognized by the Ministry of National Education of Colombia. As a criterion of homogeneity for the sample [44], within this group of programs, we identified those courses in which the main goal is to teach the fundamentals of computer programming, establishing such courses as units of analysis [44]. In the sample, we identified introductory courses to programming within programs of Systems Engineering, Environmental Engineering, Industrial Engineering, Electrical Engineering, Mathematics and Computer Technology.

After identifying the courses, universities and programs were invited to participate in the study and, by sampling volunteer participants [44], we included the teachers that teach the introductory courses as subjects of inquiry, in order to gather the information required to characterize their teaching practices, and other useful items for analysis. Since the research study is an in-depth case study, it required at least 6-10 cases [44]. The study involved 17 courses (units of analysis) belonging to 8 academic programs from Universidad El Bosque, EAN, Fundación Universitaria San Mateo, Universidad San Martín, Uniminuto, Fundación Universitaria Konrad Lorenz, Universidad Manuela Beltrán and Universidad Central.

The methodology for data collection was based on the actions and skills of the actors involved in the programming teaching process. It included the implementation of a structured interview with twenty-two questions for teachers who were asked about their teaching and assessment practices, bearing in mind resources, tools, paradigms and languages used for teaching programming, as well as the difficulties encountered in the process. The texts of the interviews were transcribed for further information processing.

B. Information Processing

From the initial research question: What are the practices and difficulties in teaching introductory courses on computer programming?, the analysis of the information was developed in three stages. In the first stage, called encoding, the gathered information was organized under initial criteria previously established from the axes of inquiry obtained from the interviews and the research purposes. They allowed us to obtain an overview of the information and the data collected. In the second stage, called analysis, similarities, relationships and differences were recorded, which consequently led to the

emergence of the categories of analysis. In a third stage, and taking into account the conceptual framework that was presented in the state-of-the-art revision, the results of the research were outweighed and contrasted to finally describe the findings in each category.

C. Classification Stage

In this stage, we selected, classified, cut and coded all interview texts in accordance with their relevance to each of the defined criteria and sub-criteria (Table II).

TABLE II. BASE ANALYSIS CRITERIA

Base Analysis Criteria	Subcriteria
Teaching/learning context	Contents Teaching strategy Assessment strategy Learning goals
Tools and resources	Development environments Programming languages Others
Paradigms	
Difficulties	
Strategies for improvement ^a	

^a Emerging criteria

The criterion "Teaching/Learning context" groups information that provides a general characterization of training environments. The criterion "Tools and resources" includes information related to the languages, programming environments (IDE) and other resources used in the courses. The criteria "Paradigms" and "Difficulties" are considered to be part of the research interests. "Strategies for improvement" is emerging as a possible category.

D. Analysis Stage

This stage was developed in two different phases. In the first, called "screening" [45], initial relationships were found in the information contained in the criteria, by listing and mixing, they gave rise to the categories of analysis.

The second phase called "*web of relationships and final categories*" [45], common elements, relationships and differences in the information within categories and subcategories were sought, finding a web of concepts that when observed in the light of all elements that constitute a process of teaching and learning computer programming, become the final categories of information that serve as a basis for the interpretation of results. Table III shows the final category structure resulting from this stage.

The categories related to languages and programming paradigms, development environments, solving problems skills and difficulties in the process are intended from the objectives of the study and data collection.

In this case, finding that teaching practices that characterize the context depend mainly on languages, paradigms and selected IDEs, the "Teaching/learning

context" category and its subcategories mingle with the "resources and tools" category, yielding the "Other teaching practices" category, which together with "Opportunities for improvement" gather what teachers say and reflect on their practice.

TABLE III. FINAL ANALYSIS CRITERIA-RESULTS CATEGORIZATION

Base Analysis Criteria	Subcriteria
About programming paradigms and languages	As a guide of concepts, contents and learning goals. <ul style="list-style-type: none"> • Java. • OOP and Structured Programming. As a guide of preferred IDEs <ul style="list-style-type: none"> • Java As a guide of learning strategies <ul style="list-style-type: none"> • Java As a guide of languages and preferred paradigms. <ul style="list-style-type: none"> • Java, PHP, C++, Python, UML, C#, HTML5. • OOP, Structured Programming, Procedimental, Dynamic, By Blocks, logical and Functional. As a language linked to a paradigm <ul style="list-style-type: none"> • Java and OOP
About development environments	For Pseudolanguages and Flowcharts. For OO Languages To modellings
About solving problems skills	As a teaching strategy As a teaching goal As a difficulty As an opportunity
Difficulties in the teaching process	Cognitive Of programming process Of image and perception Other difficulties
Other teaching practices (emerging)	Other contents Other learning strategies Other assessment strategies Other tools and resources
Opportunities for improving (emerging)	Changes of the courses Motivational Didactic Other improvement strategies

With the structure of final categories, an overview concerning the teaching practices and difficulties presented in the teaching environment of computer programming is provided. Additionally, these categories allow teachers and researchers to address such difficulties and reflect on them from an integrative perspective.

E. Interpretation Stage

Having organized the results into categories and subcategories [45], we proceeded to identify the role of paradigms, programming languages and development environments, how problem solving is discussed, and some features of the teaching process that are considered as debilitating. In the final stage called intense analysis, which deals with one category at a time, in terms of the conditions of variation, interactions, strategies/tactics and consequences, useful information was found in order to design new teaching strategies. The interpretation process ended with the

integration of categories building answers to the research question and establishing the conclusions of the study.

IV. RESULTS ANALYSIS

A. *The role of programming languages, programming paradigms and development environments*

Some teachers mentioned structured programming and even 'dynamic programming' as the paradigm of their choice for teaching. However, many reported they adopted the object-oriented programming paradigm, because it provides "better logic and organization", understanding them as the ability to provide a solution, because it allows the reuse of code, and even, because "it is more focused on the real world" in the sense that this skill is demanded in the labor market. For the same reasons, the language that is usually referred as the first language in teaching computer programming is Java. The use of this language should be evaluated by the inherent uncertainty of its 'durability' in the market, and because of the restriction or bias the students are exposed to by learning a unique tool for computer programming.

Other languages that appear during teaching practices are 'pseudo-code', as a first step for writing algorithms, PHP for web development environments; C# and C++ for the applicability of the language in various environments. Python is mentioned because of its simple and easy-to-learn syntax.

As for programming environments and preferred tools to support learning, some teachers mentioned the use of Notepad, Notepad++ and SublimeText in the early stages of learning, so that students understand that it is not always necessary to use development environments such as Eclipse or Netbeans.

Teachers also argue that using computer programs such as Notepad++ prepares students for an eventual and less traumatic transition to operating systems different than MS-Windows. In the panorama, other tools like BluJ, DFD, StarUML, NetBeans, DevC++ and Visual Studio have appeared.

It is worth noting that the predominance of Java and the object-oriented paradigm becomes more important when planning instruction. While reviewing responses from teachers when asked about programming languages, as it was expected from the state-of-the-art revision, the programming language defines several contents and learning objectives for the courses, becoming then the goal and not the means, relegating problem solving strategies to a second instance. In this regard, the next section shows how this issue was confirmed.

B. *Problem Solving*

In general, problem solving is mentioned as an important learning goal, combining other skills such as analysis, abstraction and solutions design. However, when reviewing the prevailing teaching strategies used in instruction, none of them relates to the development of skills to problem solving. This seems to agree with the fact that teachers mentioned dealing with problems, analyzing them, design and implementation of solutions to real world problems using a programming language, as the relevant difficulties students show when learning to program a computer. As a result,

teachers suggest that course didactics must provide means to develop this capability.

C. *Weakening agents in the teaching process.*

Regarding the inquiry on practices, some facts were perceived by teachers as debilitating agents for the learning process: students fail to devote to study and need more autonomous practice. These seems to be either because they work by day and study at night, which restricts their available time and, thus, they should allocate time between classes, or because students do not assume responsibility to manage their time yet.

In relation to educational skills, determined within the constraints of programming per se, in the third hierarchical level the set of difficulties in teaching Java programming language [42], teachers mentioned other debilitating factors in the process, such as lack of skills in mathematics and logic associated with the difficulty to abstract. Besides, they mentioned students show deficiencies to read and understand texts in Spanish (including poor knowledge of spelling in Spanish and scarce skills in text composition), problem analysis and students' refusal to read in English. In the same hierarchy of difficulties, those called perception, the lack of basic knowledge in mathematics, vocation and love for programming, also seem to prevent success in the learning and teaching process.

Given these debilitating factors, this study asked for pedagogical strategies. Results allowed to identify that those used in teaching programming courses are closely similar to those used when teaching math courses: an exhibition of topics provided by teachers, possibly with visual aids to visualize and outline solutions, followed by experiments on the computer in scenarios called "laboratories". There is no reason to think that these practices vary significantly in other universities in Colombia.

In the "laboratories", teachers repeat what was taught in class and assign sets of exercises to be done by students outside the classroom. Solutions to such exercises are assessed based on their performance or progress (direct approach), or by means of "tips" given by the teacher and, by delivering the solution, or by means of teacher-led workshops and guided practices (indirect approach). Other formative didactic activities such as class projects, programming marathons, quick response contests and programming challenges were also found.

These findings confirm the need to develop the ability in students to solve problems in computer programming courses. It seems that teaching practice by itself does not lead towards this aim. Teaching program focuses rather on mastering the use of programming languages and software tools. Furthermore, the teaching strategies that seek to develop problem solving skills are not present during teaching practices. These issues are recognized as major drawbacks in students, which directly affect their performance in computer programming courses.

D. *Other Teaching Practices Found*

The learning goals and assessment strategies stated in the inquiry were reviewed, and a clear correspondence with

educational and expressed difficulties were found, because the learning objectives that appear as major in the courses are the construction of computer programs using paradigms, languages and specific programming environments, understanding and applying the concepts related to them. In a few cases, it is sought to develop social and emotional skills such as teamwork.

The fact that the practice of examining students (quizzes) at the very start of each class is justified because it "forces (students) to devote at least 20 minutes before class to review the topics studied" is worth highlighting. This follow-up process and other coercive means implemented by teachers arise as an answer to a set of external situations to the very exercise of teaching that are expected to be solved by asking the teacher to "motivate" their students. Other summative assessment practices such as oral defenses, presentations and exams are included. Other formative assessment strategies also appear as extra class exercises, labs and research exercises. Other teaching contents are the algorithms and the writing techniques, software architecture, graphical user interfaces and in some cases databases.

It was notorious to observe in responses received from teachers that no mention was made of the incidence of the use of a specific operating system in the teaching of computer programming. It was not mentioned the reading of the source code as a competence or as a learning activity, which is one of the skills that the ACM Computer Science Curricula 2013 [46] states as *core-tier1*, which means, as one of the basic or core competencies.

E. Opportunities for improvement

From the emerging categories, improvements in the teaching-learning process proposed by teachers such as the inclusion of activities in courses to develop logical-mathematical skills, modelling and problem solving, focusing didactics on drilling-practice and assessment for rewards may be emphasized.

Other teachers suggest leveling up students in algorithmic, mathematics, reading and logical comprehension, either before or at the beginning of the course. Additionally, they suggest incrementing the number of hours devoted to courses as a way to improve, given that insufficient time was also stated as a debilitating issue for a complete and integral accomplishment of syllabus objectives.

As stated before, the landscape of practices and difficulties in teaching computer programming must be analyzed from a holistic perspective, observing the cause-effect relationship between them and the pedagogical thinking behind that generates such a scenario. First, it is clear that the hidden curriculum understands computer programming as a mechanical task, so the consequence is that programming courses design is task-oriented and not to the skills of solving problems and modeling computational solutions. However, this reality is not recognized by teachers because while they are the architects of said reality, they demand students to have superior abilities. On the other hand, paradigms, languages and development environments are used as necessary tools in the task of programming, but the

possibilities that they offer as learning resources is not considered, adding another useless load to the teaching process.

The panorama of practices and difficulties also reveals that it is not possible to achieve success in teaching programming if it is not seeking to develop skills throughout (or prior to) the students' learning process; skills that are also important for other disciplines and also for a student's life. Then it is recognized that the times assigned to programming courses will never be enough to achieve it.

V. CONCLUSIONS AND RECOMMENDATIONS

Since computational thinking is a nuclear academic competence of the XXI century [49], [50], considering a possible generalization of the results found in other scenarios not dealt with during this research, teaching computer programming needs to be deconstructed and redesigned. First, the development of skills for problem solving, communication, mathematical thinking and learning how to learn should precede, or at least to be paralleled with the intention to teach programming. This would mean that computer programming courses should not be taught early in the curriculum, but perhaps as said skills are being acquired (or already have been) later throughout a student's formation. Second, it is necessary that IDEs, paradigms and languages support the development of such skills, analyzing its relevance to the implicit cognitive processes in the skills being sought, apart from the criterion of popularity or market demand for use. Third, it must stop using transmissionist teaching strategies oriented to the task, for which it is also necessary that curriculum designers, principals and faculty members think about what "being" an engineer means, and how computer programming supports this essence. To understand this, and making students understand it too, adds motivation and autonomy to their learning process.

Once the results of this research have been presented, it can be stated that the difficulties in teaching computer programming, and the non-achieved objectives in the process of instruction, resulted from the design of courses, which do not take into consideration the didactics oriented towards problem-solving skills development, logic, understanding and abstraction of real world, written expression and/or appropriate use of natural language.

Additionally, student evaluation should stop being used as a coercive instrument to become a true assessment method of teaching and learning, and therefore, capable of monitoring the development of the skills described above. Then, the challenge is to teach computer programming by having students develop "learning to learn" skills, or as it is expressed in the ABET, the "recognition of the ability to learn throughout life", to solve problems and express solutions in an artificial language remains the same as from the beginning of the 1970's [12], [47], [48].

ACKNOWLEDGMENT

The researchers want to thank all the teachers from universities in Bogotá who accepted the invitation to answer the anonymous questionnaire via internet that was one of the data collection instruments these results are reported from.

Abstract-Formal languages and automata (FLA) theory have fundamental relevance to the base of knowledge in the computer science area, especially focusing on scientific education. Usually presented by a discipline, the teaching-learning process of FLA is characterized by the high level of abstraction, and it is considered difficult due to the complexity of language formalisms. As support for the learning process, tools have been used to simulate language formalisms. However, the simulation is not enough to reinforce the construction of an abstract concept. In this paper, we present an FLA teaching-learning methodology based on the development of simulators as an approach to clarify the formalism for the students. Through developing their simulators, students are exposed to the data structure and algorithms to handle the formalism. Consequently, students have the opportunity to make the concept concrete.

I. INTRODUCTION

Formal languages and automata theory have fundamental relevance in the computer science area. To a graduate student, especially those who have the academical career as a life goal, it is considered an important knowledge acquired. It is usually presented in a course where the high-level of abstraction characterizes the teaching-learning process of it, and it is seen as difficult due to the complexity of language formalisms.

A common way to exemplify the formalism is using sketches to make a visual representation of an abstract concept. Besides that, drawing take too much time and make usage of static images do not help with the interaction between student and formalisms. For this reason, many tools were used to support the teaching-learning process, and all of them are able to generate a visual illustration of a formalism.

Additionally the use of simulation tools generates an interactive form from an abstraction and helps students to understand the logic behind the visual form. On the other hand, the simulation is not enough to reinforce how the construction of a formalism is done. The teaching-learning process needs to be helped by software capable of formalism interaction, enhancing the learning logic; it still needs to be capable to

demonstrate how to create a formalism with programming languages and paradigms.

Several tools have been developed to present formalisms structure [1], [2], [3], [4], [6], [5], [7]. They help the learning process contributing to build a concrete knowledge, minimizing difficulties faced by students with the high level of abstraction [8]. The tools by themselves are not enough, the different perspectives of teaching and developing require methodological approaches to organize the usage of mechanisms to support the teaching-learning process [9].

The experience of modeling a simulator provides the opportunity to the student write their understanding of a formalism in a code architecture [9]. As a result, providing challenges and making connections to different representations of a common abstraction as a Finite Automata and Turing Machine, as many others that can be developed into a common structure.

The main goal of this paper is present a formal language and automata theory teaching-learning methodology based on constructionism [10]. In our methodology, students are exposed to data structure and algorithms, developing their simulators as an approach to clarify the formalism in favor of knowledge construction. Consequently, students have the opportunity to make the concept concrete.

As a result, different years, before and after the methodology application, students' grades were collected and compared yearly. The positive results are observed in students' grades, besides their increasing interest and motivation in learning.

In order to present this teaching-learning methodology, this paper is organized as follows: Section 2 presents some tools available in the literature; Section 3 presents the methodology proposed, and a brief description of a developed simulator, a tool to represent and visualize formalisms and their operations; Sections 4 presents the results of the methodology application; Section 5 presents the final remarks.

II. RELATED WORKS

This area covers many classes of formal languages like presented by Chomsky hierarchy [11]. It can be divided into topics where each topic explains and present a formalism with the necessary theory and implementation guidelines.

The formalism is related to language, grammars, and regular expression recognition with finite automata. Apart from Turing, Mealy, Moore, Norma, and Post machine; besides the automata variance with determinism, non-determinism, and push-down automata [12].

Our course introduces this area to students, from raw to complex, teaching about:

- 1) Finite state automata and regular grammars;
- 2) Push-down automata and context-free grammars;
- 3) Linear-bounded machine and context-sensitive grammars;
- 4) Turing, among other machines, and phrase structure;

We use, as a guide, the course topics to compare different formalism simulators. Analyzing each one with their conceptual-implementation. As conceptual understanding, students need to be taught about the theory to represent and solve problems with machines and grammars. In the other hand, the implementation understanding represents the knowledge to create a data structure capable of formalisms recognition [9].

JFAST [1] is a Java finite automata simulator focused on visualization and interactivity to active learning techniques to improve mastery of difficult concepts. It is characterized an easy-to-use graphical software tool for teachers and students, with an emphasis on the introductory level of finite state machine topics. The simulator goal is enhancing teaching effectiveness in this subject, particularly for less advanced computer science students, on the other side, the simulator is limited for automaton representation.

JFLAP [2] is a theoretical computer science framework written initially in C/C++ and after that ported to Java. It was built to design and simulate several variations of finite automata, push-down automaton, one-tape Turing machines and multi-tape Turing machines. Besides that, **JFLAP** allows the conversion between grammars and regular expressions if they are equivalent by Chomsky hierarchy [11]. **JFLAP** is one of the most complete tools developed in this area, it is capable of several conversions from one representation to another.

In the following we present some of the supported conversions [13], [14].

- 1) nondeterministic finite automaton to a deterministic finite automaton;
- 2) nondeterministic finite automaton to a regular expression;
- 3) nondeterministic finite automaton to regular grammar;
- 4) regular grammar to an automaton;
- 5) nondeterministic pushdown automaton to a context-free grammar;

Visual Automata Simulator (VAS) [3] is a tool for simulating, visualizing and transforming finite state automata and Turing Machines. It is characterized to be an application capable of creating and simulate any deterministic or non-deterministic finite automata, as well as Turing Machines. The tool present a complete implementation about Turing Machines and finite automata, but could be improved if others representations were implemented to be used by advanced computer science students.

Auger [4] and **FSM** [5] are simulators that can visually represent a finite automata to grammar recognition, both of them are limited by the finite state automata and regular grammars which represent the lowest level of complexity on Chomsky hierarchy [11]. **FSM** stands out compared to **Auger** because it is an on-line application.

Automatograph [6] is a deterministic finite automata simulator and is a beta software, still in development, which have been used to help in the teaching-learning process with regular grammars and finite state automata. The goal of the application is to validate characters chains with an automaton created by the user and showing the steps of recognition until the automaton reach the final state.

Deus Ex Machina (DEM) is a simulator capable to provide a generic platform for designing and running different kinds of automata, such as finite state, push-down, linear bounded automata and Turing, registers and vectors machines, apart from, Markov algorithms. It was built on an icon-based interface where students can sketch an automaton using vertex and edges. The software implements step-by-step run, showing how a given input string is processed as the execution of the automaton. Besides that **DEM** includes save, load and print functions for all representation [13].

A cellular automata simulator [7] is described as a compiler that have been developed for high-speed simulation. Cellular automata are a way to understand and simulate the behavior of complex systems; this simulator is an example of a particular usage of automata to help to understand the usage in a case studying. It is characterized as a temporal and discrete spatial system, capable of updating many cells at high speed with high precision.

As presented there are many tools capable to represent the formal languages and automata theory formalism, and usually the authors present the tools focusing on a feature available. They spent much time creating an icon-based interface to interact with the student, showing how the formalism work, but do not present a way to build it. Also, tools are not bound to a methodology [9]. It is important to use a tool like a support to the teaching-learning process, but an adequate methodological approach is needed to improve the teaching and the learning part, providing a better understanding of the subject.

III. METHODOLOGICAL APPROACH PROPOSED: SIMULATORS CONSTRUCTION

Making an analogy to the learning process of data structure and programming language, the capability of understanding an abstraction or a formalism are the most difficulty faced by the students [16]. On the other hand, the highest level of abstraction it is correlated with the programming concept and their theoretical relations [17]. Comparing this points with the formalism faced in formal language and automata theory, we discover that the abstraction, as a step to conquer knowledge, need to be helped by educational software or simulations tools, in the order to simplify and create a visual representation of an abstraction concept. The methodological teaching approach underlies the teaching-learning process and is responsible to guide the knowledge providing strong personal development.

In the following we present a Simulator to illustrate and explain the proposed methodology appliance. The purpose of

this section is to demonstrate, through a simulator developed by a student, how specific and deep knowledge was acquired in the classroom. Focused on finite state automata, regular grammars, Turing Machine and phrase structure.

The stated Simulator is an application based on Multi-Formalism Modeling, and it was developed by a student in JavaFX [15], known as a multimedia framework developed by Oracle Corporation based on multi-platform and web applications development. The current version of the framework allows desktop, browser and mobile development, and it is compatible with Smart TVs, video games, and Blu-rays players. Besides that, JavaFX can be executed by the common JRE or JavaME.

The simulator has a visual icon-based interface to interact with the user. The software front and back-end work together to create, represent and simulate formalisms. The first screen of the simulator is presented in Figure 1, where the user

can choose to simulate finite automata or multi-tape Turing Machine.

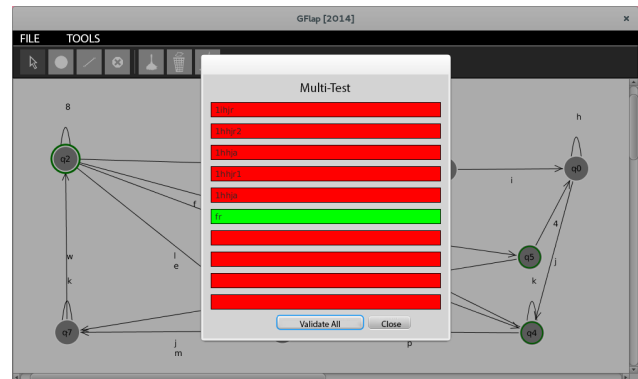

The tool is capable of working with deterministic and non-deterministic finite automata, regular grammar and expressions, beyond single tape or multi-tape Turing Machines. Apart from the main functions, the software is capable of step-by-step solution, multi-test, regular grammars test and conversion from regular grammar to finite automata, and vice-versa.

Additionally, the student who developed the simulator created a history of tested inputs and a random automaton generator. Besides that, the software allows save images and XML files that can be opened on JFLAP [2].

At next, we present two examples to illustrate the usage of the simulator. The first one is an example of a multiple input test and the second one is a conversion from finite automaton to regular grammar using a random automaton. The result is depicted in Figure 2 and Figure 3 respectively.

Fig. 1. Start screen of the simulator

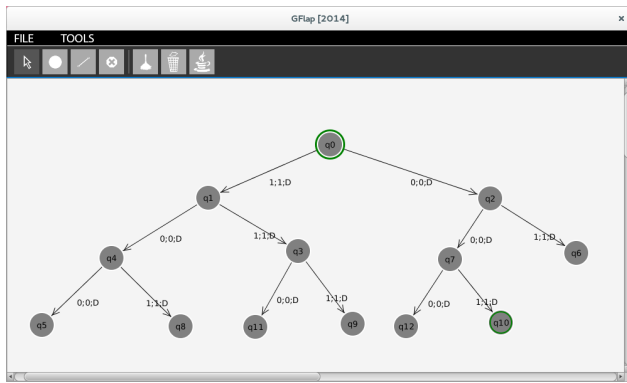

Fig. 4. Turing Machine example

The Turing Machine, single and multi-tape function, Figure 4 and Figure 5, are currently in development by the student. The final software will contain the formalisms from two complementary subjects, Formal Language and Automata Theory also to Theory of Computing. The result will be used to encourage the new students on the development, on the way to understand the formalisms in an easier and more didactic approach.

Fig. 5. One tape input for turing machine

For a final example of usage, we present, in Figure 6 to Figure 13, a full string recognition on a non-deterministic automaton previously presented as a random automaton. The string tested is "1ihj2r". On each step of recognition, if the single character is accepted, the color will be changed to blue, else the recognition will stop. The same rule is applied in each state if automaton state amend the last state will turn green, else stay gray and the recognition process stop.

IV. APPLIANCE RESULTS

The ease of understanding the abstraction and the formalism construction are possible by interaction with the finite automaton and the regular languages. The icon-based interface enables the interaction with the tool and allows visual operations, structure changes, and real-time viewing results. As a result of simulator development, different years, before and after the methodology appliance, students' grades were collected and compared yearly, and they are depicted in Figure 14 and Figure 15.

These results support the teaching-learning methodology, once it is fundamental for students in the computer science area, and it involves formalism recognition and languages generation that are used in compilers and programming languages. The positive results are observed in students' grades. We separate the results in year grades (Figure 14) and simulator grades (Figure 15).

At Figure 14, is presented an over years time-line, considering classes from 2012 to 2014, presenting students' grades. We can verify that the grades have become, on average, higher, compared to previous years. The final grade for each student presented above is an important factor to understand the results because the formula helps to see why a student has a bad or good grade at the end of the subject.

The minimum grade to approve a student is 05.00 of 10.00 points. To reach the points students are evaluated with one theoretical test on each trimester and the simulator presentation at the end of the semester. The student grade is the average of all evaluations made during the semester, but we use a clause

to make the average or not. First of all, we check the grades, and if both grades, tests, and simulator, are greater than or equal to 05.00, we sum grades and make an average. Else, the final grade is the lowest grade between test and simulator. The formula is presented at next.

$$test(T1, T2) = \frac{T1 + T2}{2};$$

$$final(T1, T2, SIM) = \frac{test(T1, T2) + SIM}{2};$$

$$grade(T1, T2, SIM) = \begin{cases} final(T1, T2, SIM), & \text{if } test(T1, T2) \geq 5.0 \\ & SIM \geq 5.0; \\ lowest(test(T1, T2), SIM), & \text{otherwise;} \end{cases}$$

Considering the formula, the results shown in Figure 14 does not focus its values on A-concept (grades between 8.0 and 10.0), the trend line denotes that the values are higher in its means, which shows that over the years more students are approved. The higher number of approved students is a result of the teaching-learning methodology, which made them more focused and stimulated in classes.

Besides the main results, we can observe an increase of students with grades between 3.0 and 4.0 in the years 2013 and 2014. Each case has examined separately by the teacher,

and it was concluded that these students, in particular, made an incomplete development of the proposed simulator. Despite the fact that the student has achieved good test scores, the

final grades clause give to that students the lowest grade, in this case, the simulator grade.

Fig. 14. Application based on Multi-Formalism Modeling

In Figure 15, is depicted the students simulator grades. The values follow a distribution that results in an arc on year 2014, while for 2012 and 2013, results are close to a sinusoidal line with growth between grades 3.0 and 5.0, which features a lower average between these years and less favorable values.

In both cases, Figures 14 and 15, we emphasize that the number of students between the years is not constant, which

changes the size of graphics and the position of the trend lines. However, to make any analyze we just considered the percentage of median results.

Having the discussed statistical analysis and the results depicted in the graph in Figure 14 and 15, it proves that the teaching-learning methodology is crucial to knowledge construction process.

Fig. 15. Application based on Multi-Formalism Modeling

V. CONCLUSION

In this paper, we present a teaching-learning methodology to support the formalism model construction about formal languages and automata theory. According to the methodology proposed, for each topic about the subject, the teacher must propose a simulator development as classwork or homework to guide the student on formalism understanding.

In order to present our methodology, we use a developed simulator, based on Multi-Formalism Modeling and it was developed by a student in JavaFX [15]. The simulator had a visual icon-based interface to interact with the user and was built to support students understand of FLA formalisms. The visual resources and the programming logic to built it aids the student to learn abstract concepts easier, in comparison to imagining how formalisms work and how they are represented.

This methodology was applied at São Paulo State University (UNESP), applying the methodology proposed during four years, considering the current year, 2015. Our evaluation consisted in compare students' grades yearly, before and after, the methodology appliance.

The ease of understanding and building the abstraction represented by the formalism are possible by the interaction with the formalism. User interaction is possible by defining operations, changes in the structure and real-time viewing results. It is intended to follow this proposed teaching methodology with the next class of LFA and extend the teaching-learning methodology to Theory of Computing, aiming to incorporate formalities related to context-free languages, context-sensitive languages, and recursively enumerable languages.

In general, the positive results are observed in students' grades and their evaluation. Also, according to the teacher, the students have shown interest and more motivation.

ACKNOWLEDGMENT

An Online Introductory Computer Programming Course Using Matlab: Design Steps and What to Expect

Asad Azemi
Pennsylvania State University, Brandywine Campus
Media, USA
azemi@psu.edu

Abstract— The usefulness of online and hybrid delivery methods in education has long been realized and with the advancement of computer and communication technologies and the Web based authoring tools, their effectiveness have been further extended. We are at a point that online and hybrid course offerings for undergraduates are quickly becoming an integrated and regular part of engineering departments' course offerings. Many institutions are offering online courses, as part of their regular schedule. In this paper, based on our experience that started with hybrid delivery and ultimately extended to a full online offering, we will present a set of recommended steps that can be used as a guide by those who are interested in designing an online introductory computer-programming course. We will then present a set of observations that we feel needs to be considered and discussed by the research community. The paper will include examples of students' comments, which were received in teaching evaluations, for hybrid and online offerings.

Keywords—online; computer programming; e-learning; hybrid delivery

I. INTRODUCTION

We are at a point that online and hybrid course offerings for undergraduates are quickly becoming part of institutions' strategies, as a way of providing more flexible course offerings to students and with the hope of some cost savings in the long run. We are also witnessing that a growing number of institutions are moving toward offering complete online undergraduate degrees and a degree in computer science is on the top of their list. In this paper, based on our experience that started with hybrid delivery and ultimately extended to a full online offering, we will present a set of recommended steps that can be used as a guide by those who are interested in designing an introductory computer-programming course.

In our previous works [1]-[3], we presented a hybrid e-learning approach to enhance distance learning. In this work, we describe our online development plan based on the hybrid approach. We first start with brief background information. Online learning has affected the traditional distance-learning format by transforming it from a static paper or videotape-based delivery to a more dynamic format by adding/substituting the web as the delivery media. While some studies reported high levels of student satisfaction with web-based course delivery [4]-[7], others found that students preferred the more familiar classroom-based environment [8]-[9]. Some of the difficulties associated with web-based learning, as reported by students going back a decade ago, still

exist. They include: the feeling of isolation due to a lack of interaction with peers or faculty; lack of prompt feedback about processes and progress in the course; and a need for students to better manage their time in order keep abreast of the course requirements [10]-[11].

In this paper we will present a summary of our implementation plan, which includes design and delivery considerations that can/should be considered by those who are interested in starting an online course development. The recommendations are general and can be used for any course. We will also discuss the unique aspects and challenges associated with designing a Matlab programming course versus a C++ course. Based on our experience, using various delivery methods and components for the past five years, we will then present a set of observations that we feel needs to be considered and discussed by the research community.

II. IMPLEMENTATION PLAN

A. Background

Perhaps the biggest difference in design and production of an online course versus its face-to-face counterpart is the amount of resources that it requires and the long payoff time for the allocated resources. In order to design a high quality online course, one needs to have access to an instructional designer or knowledge about instructional design concepts, consider hardware and software requirements, various learning styles, and ethical issues, among others. The biggest challenge for those who are considering designing an online course, for the first time, would be the challenge of anticipating all possible problems and issues that may occur during the delivery of the course and include preventive means in the initial design. The luxury of adjusting the flow of the course, which exists in a face-to-face course, is not part of an online delivery methodology. Based on the aforementioned observations and assumptions, we believe the best way to produce a high quality online course is to start from a face-to-face delivery, produce a hybrid delivery model, and finally move to an online production. Of course, this process takes a long time but the product will have a higher quality with less problems.

B. Design Considerations

The design process for an online course is a resource intensive task. The following were identified/recommended for this process.

- Goals and objectives of the course should be identified and an online delivery should be recognized as one of the approaches that can be used to achieve those objectives. This means that not every course should be delivered as an online course.
- Course objectives should be mapped to learning materials (video/audio/reading) and assignments.
- The web interface for the course plays an important role. It should be designed with the help of instructional design experts.
- Course materials should be designed to be short and precise and lengthy video/audio/reading material should be avoided. The length of a typical video segment should be limited to 20 minutes and should be followed by a link to a set of assessment questions or a worked-out video problem. In this approach, a typical face-to-face lecture is converted to two (15-20 minutes) video segments, each following with a set of assessment questions.
- Design test banks for quizzes and exams.
- In order to promote participation and eliminate/reduce the sense of isolation due to lack of interaction that is usually associated with online courses, a discussion forum should be set up for the course. It is recommended that each week includes its own discussion forum. Students should be encouraged to participate in these forums. Guidelines for how to use the forums including what can or cannot be posted should be provided.

C. Delivery Considerations

A welcome email should be sent two weeks before the start of the course that should include the following points.

- Inform students regarding course delivery methodology and the requirements for student participation. It is important to point out that a reliable Internet connection is a requirement for the course.
- Textbook requirement and ways to contact the instructor.
- Information about the course technology, including the course management system, which will be used for the course, any hardware-software requirements and/or recommendations such as webcam, headset, Matlab student software, etc.
- Date that the course website will be accessible.

D. Site Considerations

The course website should be designed so that the pages are not cluttered and are easy to navigate. Figure 1 illustrates the home page of our online Matlab offering for the summer session.

- The site includes links to information videos about the course and how to effectively use/navigate the site.

- Links to Homework, quizzes, exams, and discussion forums, which can also be accessed from the weekly page links.
- A link to late submission folder for cases that warrant such permission. Like the traditional offerings, late submission should be allowed as an exception with possible penalty.
- Weekly pages should include objectives, links to the learning material, homework assignments, discussion forum for that week, quizzes, Q&A session, and course resources. Figure 2 illustrates a sample weekly page of our online Matlab offering for the summer session. In this example, some of the video lengths are greater than the recommended 20 minutes. We are planning to edit and modify for the next offering.
- We are planning to include a 3-minutes video/audio summary of the topics covered for the week that will be placed at the top of the weekly page. This is to make sure that students can identify important topics that are going to be covered for that week.

III. STUDENT AND COURSE ASSESSMENTS

The following integrated, but separately assessable components were used in the assessment process:

- Homework assignments include exercises, related to the reading material, and programming assignments.
- Weekly quizzes were given with a 24-hours period of accessibility. Quizzes are timed programming assignments and are designed in such a way that allocated time would be enough for someone who has studied the required material. For the next offering of the course, we are requiring a webcam to be connected during the quizzes so that random still shots are taken and sent to the instructor. We believe that this will increase the integrity of the assignments.
- Weekly quiz questions are randomly generated from a quiz bank, related to the topics covered.
- Exams include conceptual questions and programming questions. Like quizzes, students are required to have a webcam connected during the exam, for the next offering of the course.
- Conceptual questions are randomly generated from a test bank and include multiple choice and true-false questions. This part is worth 20% of the exam grade and is designed to be accessible to students for a period of several hours, anticipating students from different time zones.
- Programming questions for exams are given at a set time; those who are at a different time zone are accommodated by providing them with alternative times.
- Although some online offerings require proctored exams, having such a requirement would not be an easy task for everyone, especially international students.

It should be noted that the assignments for an online course should be comparable with its face-to-face counterpart course and they should not overwhelm students.

IV. REMARKS AND CONCLUSION

Matlab has been designed as a tool for simplifying technical calculations/simulations. It has not been designed to be a “programming language.” With this in mind, some basic programming rules such as variable declarations, have been relaxed. This constitutes a challenge in conducting a programming course using Matlab, so that it does not turn into a “teach-a-package” course. Therefore, if one looks at Matlab from a purely computer science point of view, it would not be the first choice to teach a programming course. Another difficulty that we faced was the limited available resources in using Matlab as a “programming language,” versus the wide range of books that are published for use with general purpose programming languages. Reference [12] was selected as the course textbook from a limited textbook collection based on the aforementioned criteria.

Student ratings for the course have revealed several interesting points that can be further studied to analyze the current models used for online teachings and the reliability of student ratings and evaluations. Using an identical course structure with two different group of students in two summers, revealed noticeable differences in students’ evaluation. The difference was even more significant for a regular semester offering of the course. Students taking the course during the summer session had a much higher rating for the course than those who took it during the regular semester. We have identified two factors or possible explanations. The first factor is the GPA (Grade Point Average). Students with higher GPA had a more positive opinion about their experience. The second factor, we suspect, could be related to the decision process. Summer students wanted to take the course online and they saw the online offering as a huge convenience. Students, who took the course in the regular semester, were given only the online offering option and perhaps did not see this as their own choice. Even including extra help with the course did not help their performance or attitude toward the course. We are hoping to be able to present these data during the conference presentation of the paper, after the IRB (Institutional Review Board) approval. We believe this point needs to be further investigated by the research community. Finally, based on our experience we are recommending that the research community assess the idea of offering different online

versions of the same course to accommodate different learning styles and backgrounds.

Abstract— In this research, a Textual Programming Language (TPL) is used in programming education for primary schoolchildren because of the following reasons: (1) it is more practical to use the programming languages similar to the ones used for developing real applications, (2) typing statements could be easier for primary schoolchildren than generally thought, (3) there exist programming environments such as Processing that are easy to use and produce very attractive graphical outcomes. Teaching material for programming education with Processing was developed. In this teaching material, cartoons were used to explain difficult concepts. The learners who use this teaching material were supposed to draw some computational figures with chosen colors. Trial experiments of programming education using this teaching material was conducted to a cohort of seven primary schoolchildren (six 4th grade and one 5th grade children) in two consecutive weekend classes (one hour each). Since the authors' aim of this programming education was to create a sense of fun and excitement in the children and inculcate a desire to engage with computing, the motivation of the children was assessed using the questionnaire based on the ARCS (*Attention, Relevance, Confidence, and Satisfaction*) motivation model. The results were encouraging and suggested that TPLs could be used in programming education for primary schoolchildren.

Keywords—programming education; primary school; textual programming language; Processing

I. INTRODUCTION

Programming education for primary schoolchildren has been adopted in many countries in recent years. In the growth strategy approved by Japanese Cabinet in June 2013 [1], there was a statement saying, “In addition, the government will establish framework to continuously cultivate practical IT human resources through industry-university-government cooperation by the end of next fiscal year and promote IT

education including programming education from the compulsory education stage.” The “compulsory education stage” in Japan means primary schools and lower secondary schools. In the lower secondary schools, “measurement and control by programming” became a compulsory topic in the subject of Technology Education in 2012, therefore, programming is already compulsory. Though there are not many primary schools that have classes in which programming is taught, there are many after-school and weekend classes for primary schoolchildren throughout Japan that teach programming¹. In fact, Japan is not a front runner with regard to programming education for primary schoolchildren. The UK introduced a new national curriculum which includes practical experience of writing computer programs in 2014². Also, in Australia, primary schools began teaching students how to computer code in 2015³. Some other countries including USA, UK, Estonia, New Zealand, Israel, and Korea have already adopted programming as a formal subject in primary education, or are seriously considering doing so.

Many programming languages for programming novices have been developed. Some of them are Visual Programming Languages (VPL) in which composing elements of programming are represented with blocks or tiles that can be manipulated with mouse movements. Examples of VPL include Scratch⁴, Squeak Etoys⁵, Alice⁶, and Viscuit⁷. Others

¹ For example, <http://techkidscamp.jp/>, <http://coderdojo.jp/>.

² <https://www.gov.uk/government/publications/national-curriculum-in-england-computing-programmes-of-study/national-curriculum-in-england-computing-programmes-of-study>

³ <http://www.australiancurriculum.edu.au/technologies/digital-technologies/Curriculum/F-10>

⁴ <https://scratch.mit.edu/>

are Textual Programming Languages (TPL) in which traditional textual representation of program source codes are used. Examples of TPL include Processing⁸, Arduino IDE⁹, and IDLE (Python GUI)¹⁰.

VPLs are very popular in programming education for young children like primary schoolchildren and secondary schoolchildren, because they do not require knowledge of programming syntax and provide an environment where compile-time errors are nonexistent [2]. There is also a report saying that VPLs can form long-term opinions about the enjoyment of programming in the mind of children compared with conventional programming languages [3].

Though VPLs have such merits over TPLs, they also have some limitations such as not giving advanced students the opportunity to improve their skills, or allowing students to acquire bottom-up development process (selecting commands, and then combining them for desired effect). Though VPLs are widely used in programming education for young children, they are not widely used for professional software development. Therefore, at some stage, students should change the language to TPLs. However, it has not been acknowledged when TPLs should be introduced to the young children. Therefore, in this research, it was investigated if TPLs could be used in the programming education for upper primary schoolchildren.

In this research, a TPL is used in programming education for primary schoolchildren because of the following reasons: (1) it is more practical to use the programming languages similar to the ones used for developing real applications, (2) typing statements could be easier for primary schoolchildren than generally thought, (3) there exist programming environments such as Processing that are easy to use and produce very attractive graphical outcomes.

Teaching material for programming education with Processing was developed. In this teaching material, cartoons were used to explain difficult concepts. The learners who use this teaching material were supposed to draw some computational figures with chosen colors. Trial experiments of programming education using this teaching material was conducted to a cohort of seven primary schoolchildren (six 4th grade and one 5th grade children) in two consecutive weekend classes (one hour each).

Since the authors' aim of this programming education was to create a sense of fun and excitement in the children and inculcate a desire to engage with computing, the motivation of the children was assessed using the questionnaire based on the ARCS (*Attention, Relevance, Confidence, and Satisfaction*) motivation model.

This paper is organized as following. In the next section (section II), it is shown that VPLs are extensively used in the

related works. In section III, the approach of this research in which a TPL is used is presented. In section IV, the trial experiment of programming education is presented. In section V, the analysis of the programming education is presented. In section VI, conclusions of this paper are presented. Finally, in section VII, authors' future research is presented.

II. RELATED WORKS

Since after-school and weekend classes of programming education became popular worldwide recently, the number of papers concerning programming education in K-12 have been increasing. Smith, Sutcliffe, and Sandvik [4] reported on the first year of Code Club in 1000 UK schools. Code Club is a network of after-school programming clubs for primary schoolchildren in the UK founded in 2012. Technically-adept volunteers collaborate with teachers in the club, and adopt Project-based pedagogy. Their aim is not to develop skills. Instead, they try to create a sense of fun and excitement in the child participants and inculcate a desire to engage with computing. In the Code Club, they use Scratch [5] as the programming environment because of (1) ease of use by primary schoolchildren, (2) the range of media resources easily available, and (3) the support for saving and sharing projects via the Scratch website. They reported that the participants could appropriately use the concepts such as user input, control statement, and parallel execution.

MacLaurin [6] reported on a new visual programming language (VPL) for young children called Kodu which was integrated in a real-time 3D gaming environment. The purpose of introducing this new programming language was to provide a new "first programming experience" that mirrored the early PC era: play games, fix them up, and eventually create your own from scratch. Touretzky et al. [7] described a three-stage method of teaching programming to children beginning with Kodu, and progressing to Alice and Lego Mindstorms NXT-G. The idea behind this three stage method was that though highly introductory programming environment offers novices a smooth path to early success in computing, their limited expressiveness must inevitably lead to their abandonment in favor of more powerful conventional languages. They conducted a pilot study with these VPLs in a five-day computer camp for 31 children aged 10-17. They found that at least for older students, it could be better if they used more powerful programming formalism.

As seen in these and other papers, almost always, VPLs are used in programming education for young schoolchildren. Despite many positive impacts of VPLs, they also have some negative sides. Meerbaum-Salant, Armoni, and Ben-Ari [8] pointed out that students learning to program using Scratch show some bad habits that are contrary to recommended programming practices. Moreno and Robles [9] reinforced this allegation by analyzing 100 Scratch projects they downloaded. They found that the majority of these projects contained bad habits of (1) not changing the names of the characters assigned by the programming environment, and (2) repeating code in the same project, sometimes even in the same character programs.

Duncan, Bell, and Tanimoto [2] wrote up meaning and potential impact of learning programming by young students in

⁵ <http://www.squeakland.org/>

⁶ <http://www.alice.org/>

⁷ <http://www.viscuit.com/>

⁸ <http://www.processing.org/>

⁹ <https://www.arduino.cc/en/Main/Software/>

¹⁰ <http://www.python.org/idle/>

a comprehensible fashion. Because many countries are promoting programming education for young students now, this kind of research has acute importance. They collected arguments for and against the idea of teaching programming to young students. They discussed cultural factors, the change of school curricula, whether young students are really gaining computational thinking or they are just moving around blocks of commands to find good positions haphazardly in their projects, teaching and learning tools. In the discussion of teaching and learning tools, they categorized 47 tools into 5 levels (level 0 through level 4). Among those levels, Level 2 are for the age range of 8 to 14, and, interestingly, a few TPLs are included in this level.

Booth and Stumph [10] compared visual and textual programming environments used for Arduino in the context of end-user experiences. In their paper, the textual programming environment is the default Arduino programming environment, and the visual programming environment is Modkit Alpha Editor¹¹. The eleven participants in their experiment were not young children, instead they were adults of mean age 36.18. Their findings were: (1) when using a visual environment, participants felt more confident modifying a program than creating one, but creating programs made them feel more confident than modifying existing ones when they employed the textual environment, (2) visual environments provided a more positive experience, (3) coordination barriers proved to be more challenging aspect for participants in the visual environment than the textual environment, (4) both environments are not perfect and may be perceived as unsupportive or confusing.

III. USING VISUAL PROGRAMMING LANGUAGES

As can be seen from the previous section, VPLs are almost always employed in programming education for young children. It is especially true in Japan. To the best of our knowledge, VPLs such as Scratch, Viscuit, and Squeak eToy are used in most of the reports about Japanese programming education for young children. One reason for this could be the peoples' belief that typing English words required in TPLs was too difficult for the children because they did not learn English in primary schools. However, it is not that clear if typing English words are too difficult for Japanese primary schoolchildren.

Duncan, Bell, and Tanimoto [2] suggested that TPLs could be used in the programming education for students aged between 8 and 14. Also, some papers suggest that programming languages should be switched from VPLs to TPLs at some stages of advancement because most professional programmers use TPLs [2, 10]. Booth and Stumph [10] suggested that task type mattered in learners' self-efficacy rating, and TPLs would be better for writing programs from scratch.

From all these conditions and suggestions, it was felt that TPLs had merits over VPLs when being used in programming education for young schoolchildren. Of course, if practical programming languages such as C, C++, Java were used with

professional IDEs such as Eclipse, it would be too difficult for young schoolchildren, but there exist TPLs for programming novices such as Processing [11, 12].

The TPL chosen for teaching programming to primary schoolchildren was Processing. Processing's editor and display windows are shown in Fig. 1. It is a Java based textual language initiated by C. Reas and B. Fry that facilitate the development of visual projects [11]. The best thing about Processing is that though programming is text-based, the outcomes are not text-based, instead, these are visually attractive artworks. Besides this fact, Processing has many characteristics that make it suitable for being used in programming education for programming novices such as: (1) not requiring creation of Classes, (2) not requiring the codes for creating windows for visual programming, (3) providing many statements for drawing shapes such as ellipses and rectangles, (4) providing a way to check the spelling of reserved words by colors, (5) providing simple ways of making animation.

The authors have been using Processing in introductory programming courses for non-computing majors in universities, and have been assessing the motivation of the students [12-16]. The artworks that students could create were very attractive for the students, and they kept high motivation while learning programming. Therefore, it was authors' expectation that the primary schoolchildren would also express the same enthusiasm for programming with Processing.

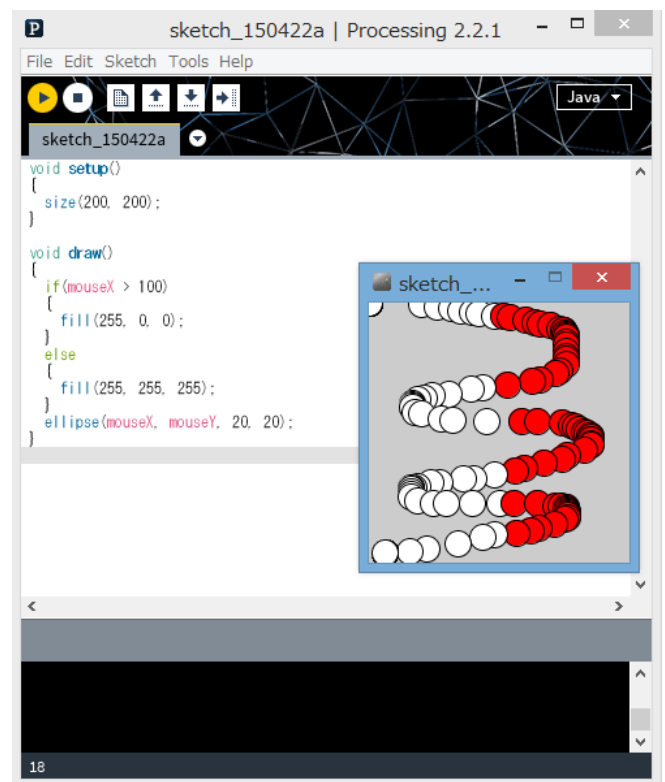

Fig. 1. Processing's editor window and display window.

¹¹ <http://www.modkit.com/>

IV. PROGRAMMING EDUCATION FOR PRIMARY SCHOOLCHILDREN

One of the authors has been teaching programming to primary schoolchildren in some weekend classes using robots and VPLs. Two others have been using Processing to teach programming to non-computing major students in universities. The curriculum and the teaching materials for teaching programming to the primary schoolchildren were determined from the experiences of these members of authors. The curriculum is shown in TABLE I. It is designed in such a way that the schoolchildren can understand the concept of programming, and can keep their motivation high throughout the classes.

TABLE I. CURRICULUM FOR THE PROGRAMMING EDUCATION

No.	Contents
1	What is programming
2	A tool for programming (Processing)
3	Statements used in Processing
4	Size of the display window
5	Positions in the display window (coordinates)
6	Drawing points
7	Drawing rectangles and ellipses
8	Coloring the shapes
9	Using variables
10	Changing behavior based on conditions
11	Repeating the same things
12	Program that generates movement

One of the characteristics of our teaching material is that cartoons are used. An example of the cartoons is shown in Fig. 2. The cartoons are there to explain difficult concepts in an easy-to-understand manner. There are three main characters in the cartoon: an apprentice witch called Momo, a soft toy called Kumao, and a professor. Momo always tries to lay an enchantment on Kumao to do something, but without much success. The professor explain why it doesn't work properly to Momo. In the cartoon, enchantment is a metaphor for programming.

The reason for teaching programming to young schoolchildren has been discussed in some papers. Some argued that there were two reasons: enabling students to understand what programming is all about, and enabling them to possess computational thinking (CT) which will be of use regardless of a student's career [2]. Others argued that their intent was to create a sense of fun and excitement in its child participants and inculcate a desire to engage with Computing, with skill development a secondary concern [4]. Our aim is similar to the last one. Since negative experiences, such as poor teaching, have a very strong and lasting impact on their interest in computer science career [17], enabling students to have positive experience during programming education is very important. For this reason, assessing the motivation of the participants while learning programming was thought to be important in this research.

In the past, the authors had been analyzing motivation of the learners in programming education using the authors' original questionnaire based on the ARCS motivation model [12-16, 18]. The ARCS motivation model was introduced by J. M. Keller [21-23]. This model has four factors (*Attention, Relevance, Confidence, and Satisfaction*), and each factor has three lower categories. Therefore there are twelve lower categories in total. The authors developed the questionnaire (ARCS assessment metric), and each question item in the questionnaire was designed to ask if each of the twelve lower categories in the ARCS model was satisfied. Each item was presented using a five-point Likert scale where answer 5 always corresponded to "agree" and answer 1 to "disagree". The lower categories and the corresponding question items of the questionnaire are shown in TABLE II. Though the question items in the table are in English, actual question items were in Japanese.

Fig. 2. A cartoon used in teaching materials

The authors conducted a trial experiment of programming education using this teaching material in two consecutive weekend classes (one hour each) in November 2014. Seven primary schoolchildren participated in the classes. Among those, six children were 4th grade and one child was 5th grade, four females and three males, only one student had previous programming experience. Those children could type Japanese words, could use a mouse, and had no problem operating personal computers. The weekend classes were conducted in a computer room in a primary school. The children used the notebook-computers the authors provided.

In the first class, Topics No. 1 through No. 6 in the TABLE I were covered. At the beginning of the class, programming concepts were explained using the cartoons. When the children drew the figures in the display window, they needed to know the units of distance and the concepts of coordinates. Distance and coordinates are measured in pixels, but the children did not know what pixels are. Therefore, authors prepared a compact microscope so that the children could actually view the three colors in a pixel and understand what pixels are.

TABLE II. THE QUESTION ITEMS IN THE QUESTIONNAIRE

<i>Attention</i>	
A1	Perceptual arousal: Did the programming education give you a pleasant surprise?
A2	Inquiry arousal: Did you feel that you wanted to learn more during the programming education?
A3	Variability: Could you study without getting bored because there were variations in the learning content?
<i>Relevance</i>	
R1	Familiarity: Did you feel that the learning content was familiar?
R2	Goal orientation: Did you understand the goal and the importance of the learning?
R3	Motive matching: Did you have chances to select the learning methods that were suitable to you?
<i>Confidence</i>	
C1	Learning requirements: Is the goal you should reach clear?
C2	Success opportunity: Did you have an occasion to feel that you had written your programs well?
C3	Personal control: Did you feel that you wrote your program well because of your efforts and ability?
<i>Satisfaction</i>	
S1	Natural consequence: Did you have occasions to use your newly acquired knowledge?
S2	Positive consequence: Were you happy when you made a good program?
S3	Equity: Was your accomplishment fairly evaluated with a consistent standard?

In the second class, Topics No. 7 through No. 9 were covered, but No. 10 through No. 12 could not be covered. At the beginning of the class, a review of the statement for defining the dimension of the display window was conducted. After that the children drew ellipses and rectangles, and moved them together using variables.

The ARCS assessment metric survey was conducted three times: middle of first class (after Topic No. 4), end of first class (after Topic No. 6), and end of second class (after Topic No. 9).

V. ANALYSIS

A. Computer Skill and Knowledge

Authors' particular concerns were if the schoolchildren could type English words correctly and fast. At first the children were claiming that they could not type English words as fast as typing Japanese words since they were used to typing Japanese words. But soon after that, they stopped saying that. They seemed to get used to it. Another concern the authors had was if the children understood the concepts of coordinates and pixels. The children seemed to understand these concepts after they viewed the pixels on the display using the compact microscope. Actually they enjoyed viewing the liquid crystal display using the compact microscope.

B. Scores of Four Factors and Sub-Level Categories

The results of the ARCS assessment metric conducted three times during the experimental weekend classes are shown in Fig. 3 and Fig. 4. Fig. 3 shows the mean scores of the four factors in the ARCS model as well as the mean score of all (four factors combined). For each factor, there are three bars corresponding to the three surveys conducted during the

weekend classes. An asterisk (*) indicates that the difference is statistically significant ($p < 0.05$).

For all of the four factors, it would appear that the score went up from first survey to second survey, and it went down from second survey to third survey. It is already known that the motivation of students fluctuate as the course progresses depending on the teaching contents and study environments [15]. Since first two surveys were conducted in the same class, study environments such as instructor, support staff, temperature of the room and so on, were the same. Only the teaching contents were different. The topics taught before the first survey were: What is programming (the cartoons were used here), Processing interfaces, Statements used in Processing, and Sizes of display window. The compact microscopes were used by the children to view the pixels on the screen during this time. The topics taught between the first survey and the second survey, were: Coordinates in Processing, and Drawing points. The students vigorously entered commands in the editors and changed the arguments during this time. Comments were also collected in the questionnaire, and all the comments in the first survey and second survey were positive, expressing enjoyment of the activities and gladness for being able to learn what programming was.

Fig. 3. The scores of the four factors

The third survey was conducted at the end of the second class, and the result was different from the previous two in that the scores appeared to be lower than those of the first and second survey. Especially, the third score of *Attention* factor went down from the second score by almost one point. In the second class, the children drew shapes with different colors, and moved the shapes together using variables. There were also, differences in learning environments in that a different instructor taught the children, and the number of support staff was less than that in the first class. Students' comments also indicated the drop of the scores. Four students gave positive comments expressing enjoyment, but two said "I do not have any particular thing to say." The last one said "It was fun, but it was hot here." This fact suggested the importance of the learning environments such as teaching skills of the instructors, number of support staff, and temperature of the room.

Fig. 4 shows the mean scores of the 12 question items corresponding to the 12 sub-level categories in the ARCS

model. Most of the sub-categories indicate the same tendency as the aver-all tendency shown at the rightmost group in Fig. 3. Categories C-2, and S-3 indicate different tendency. The score of C-2 went up from first survey to second survey, and to third survey. The question associated with C-2 (Personal control) was “Did you have an occasion to feel that you had written your programs well?” The answer to this question does not depend on the learning environment. Therefore, it could be that the students were confident with drawing the figures even if they did not feel comfortable with the learning environments. The score of S-3 did not go down from second survey to third survey. The question associated with S-3 (Equity) was “Was your accomplishment fairly evaluated with a consistent standard?” In the case of these weekend classes, evaluation meant the words of encouragement and praise. Therefore, it could be that the instructor and the support staff might have offered words of encouragement or praise to the children, even though other environments were not so attractive to the children. From this, it could be said that though the motivation of the children during programming education is influenced by the learning environment, some motivation factors (such as Personal control and Equity) might be less influenced by them.

Fig. 4. Change of the scores of the sub-level categories

C. Comparison with previous research

The results of four ARCS assessment metric surveys are compared in Fig. 5. Here, the bar graphs are arranged in such a way that the scores of the four factors in the same survey can be compared easily. In each group of bars, from left to right, there are bars of *Attention*, *Relevance*, *Confidence*, and *Satisfaction*. In the figure, (a) is the result of this research, (b) is the result of programming education for primary schoolchildren with robots and a VPL [18], (c) is the result of an in-house training (programming) of new employees in an IT company [19], and (d) is the result of a programming course for non-computing majors in a university [20].

As can be seen in Fig. 5, the four graphs (a)-(d) display a similar pattern of bars. Almost always, the scores of *Attention* and *Satisfaction* are above the scores of *Relevance* and *Confidence*. It is only the third survey in this research which displays a different pattern. One reason to this would be the small number of samples. Therefore, it is not possible to say anything strongly, but observing that the *Attention* score is the

lowest in the third survey, it would be possible to say that Topics No. 7 through No. 9 of the teaching material should be improved. It can also be noted that the scores of first and second survey of this research (a) is not less than the scores of the previous research. This is an encouraging result because this result suggests that the primary schoolchildren could enjoy working on TPLs and use them to learn programming.

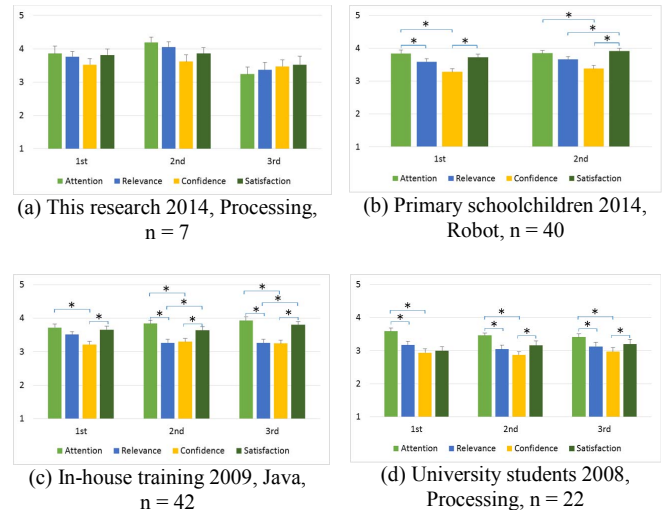

Fig. 5. Comparison with previous research

VI. CONCLUSIONS

In this research, using TPLs in programming education for primary schoolchildren was proposed, and teaching materials with a TPL was developed. The characteristics of this teaching material used includes (1) Processing programming environment which uses TPL, (2) cartoons are used to help children understand difficult concepts in programming. A trial experiment of programming education using this teaching material to a cohort of seven primary schoolchildren (six 4th grade and one 5th grade children) was conducted in two consecutive weekend classes (one hour each). Though 12 topics were prepared in the curriculum and in the teaching materials, the last three topics including conditional branch could not be covered due to the time shortage. The authors' aim of this programming education was to create a sense of fun and excitement in the children and inculcate a desire to engage with computing. For this aim, it was important to know the motivation of the participants in the trial experiment, and therefore, motivation of the participants in the class was assessed using a questionnaire based on the ARCS motivation model.

From the analysis of the motivation, the following findings were extracted:

- Primary schoolchildren of 4th grade and above can type the statements without much problem.
- Primary schoolchildren of 4th grade and above can understand the concepts of coordinates and pixels.

- Depending on the teaching materials, primary schoolchildren of 4th grade and above would be able to enjoy programming in Processing.
- The learning environments such as teaching skills of the instructors, number of support staff, and physical environment would influence the motivation of the children to learn programming.
- It could be that there are some sub-level categories in the ARCS motivation model that are not influenced by the learning environments.

VII. FUTURE RESEARCH

In the trial experiment in this research, there were only seven participants and only two weekend classes were used. Therefore, in future research, it would be necessary to test and confirm these findings extracted from this trial experiment in weekend or after-school programming classes with more students and for a longer period. Also, it would be necessary to compare TPLs and VPLs as the programming language used in the programming education for primary schoolchildren.

In the teaching materials used in the trial experiment, cartoons were employed, but the effects of the cartoons were not monitored. Therefore, in future research, we plan to include many more cartoons in our teaching materials and to monitor the effects of them.

In Japan, programming education is not yet compulsory in primary schools. Therefore, programming is taught in weekend classes or in after-school classes to the schoolchildren who are interested in programming. If programming education becomes compulsory, the ways of teaching programming might have to be changed regardless of the types of programming languages. Making programs and viewing the results on the screen or on the other gadgets would not be enough. We would have to devise ways to keep motivation of the children high during the programming education. Cartoon would be one of them, and compact microscopes would be another. Therefore, in future research, we would like to develop activities that would keep motivation of all schoolchildren high during programming education.

ACKNOWLEDGMENT

This work was partly supported by Grants-in-Aid for Scientific Research of Scientific Research (C) No.25350306 from Japan Society for the Promotion of Science.

Abstract—Unemployment has been a major concern in recent years. This is particular true for young people and in the case of Portugal for youngsters with a Higher Education degree. In this paper we describe the program “Acertar o Rumor”, a two years program to reconvert unemployed graduates in Engineering and Exact and Natural Science in experienced Java programmers. Particularly, we focus on the Programming courses of the program, where the two main programming paradigms, the procedural and the object-oriented, as well as principles and technologies for developing enterprise systems were taught. We describe the main methodologies and approaches followed and report the very positive results obtained with the first edition of the program till now. We finish the paper by proposing some recommendations and improvements for further editions.

Keywords—Unemployment; Human resources reconversion; Computer Science Education; Programming learning

I. INTRODUCTION

Unemployment is a major problem that the XXI century people face. Eurostat estimates that there are more than 23 million of unemployed people in Europe and this is especially true for young people. World specialists say that while this situation is not solved the economic crisis is not over too. Almost one quarter of people under 25 years old in Europe belongs to this group and in Portugal more than one third. In our case this is particular hard for youngster with a Higher Education Degree [1, 2].

One solution for these people has been to look for a job abroad and emigrate. This brings long-term social and economic consequences. On the other hand there is still a shortage of employees with digital skills across Europe. One of the Europe 2020 Strategy pillars, which aims at the growth of the European Union (EU) by 2020, is the European Digital Agenda. It “proposes to better exploit the potential of ICT in order to foster innovation, economic growth and progress”. In order to promote employment in this field, and in jobs requiring digital skills, the Grand Coalition for Digital Jobs and Skills was created. Among its objectives are:

“Training and matching for digital jobs (...)

Awareness raising – to attract young people to ICT, which offers rewarding and enjoyable careers to both women and men;

Coding - to raise awareness on the importance of coding skills [3].”

Many universities have postgraduate training programs in many subject areas, including ICT. Many of the programs involve ICT applied to a specific area. We can find examples applied to medicine, teacher training, engineering and more [4, 5, 6]. Also there are programs that were designed in a partnership with industry. Examples include [7, 8, 9].

All these factors contributed to the University of Coimbra (UC), namely the Department of Informatics Engineering, in a partnership with the company iTGROW, that aims to attract, select and complement the training of young engineers through a program of training on-the-job and to promote the development of skills valued by the IT market through trainees’ exposure to the best practices in the field of software engineering, to design a program for unemployed Masters in the areas of Engineering and Exact or Natural Sciences to reconvert them in experienced Java programmers. This program is called “Acertar o Rumor” (Adjusting the course, in a free translation) [10].

In this paper we start by describing the program “Acertar o Rumor” and its main principles. Then we describe the group of students that has been selected. After we move on describing the main courses of this program, namely Introduction to Programming in Java, Advanced Java Programming and Project. We focus on the methodologies used, the approaches followed and analyze the results obtained from the application of two efficacy surveys. Finally we present some conclusions of this first experiment.

II. ACERTAR O RUMOR PROGRAM

The program “Acertar o Rumor” is designed as a two-year program, with a first year of regular classes at the University of Coimbra and a second year of an internship at one of the companies that is enrolled in the program. This program aims to train graduates that have difficulty finding a job in their prior field of expertise in technical programming. It is strongly focused on the development of high-level Java programming

skills. At the end of the program, the trainee is able to implement a computational application, based on a set of well-defined specifications. As generic skills to be developed, we highlight: analysis and synthesis; organization and planning; problem solving; group work; autonomous learning; adaptability to new situations; creativity; concern about development quality and sustainability.

An entry requirement to the program is to have an undergraduate degree, or an equivalent one, in Engineering or Exact and Natural Sciences, or a foreign degree recognized by the Scientific Committee of the Department of Informatics Engineering as meeting the objectives of such a degree in any of the above mentioned areas. In duly justified cases, holders of an academic, scientific or professional curriculum vitae that is recognized as attesting the capacity to carry out the program by the Scientific Committee can also apply. It is expected that these candidates have strong potential to programming, since they were trained to employ mathematical reasoning in their field of expertise.

In order to keep teaching quality reasonably high, only 20 candidates are accepted in the program every year. The candidates must go through a very selective recruitment process, which includes individual interviews, problem-solving tasks in a team and logical and mathematical exercises, in order to assess their potential to become programmers, as well as their motivation and ability to learn new concepts. After the acceptance to the program, the candidate enrolls in the program at the UC and has access to the Internet, to an e-mail account and other facilities, such as printing room, library and canteen.

The training program is very intensive. As such, trainees have to work as in a full-time job in a total of 40 hours per week. Also they have to work in an open space scenario, similar to the way many IT companies usually do. The structure of the program plan is shown in Table I. The program includes both a theoretical basic training in some important IT areas and a theoretical plus intensive practical training on programming techniques, supplemented with a final project. The courses Introduction to Programming in Java (IPJ) and Advanced Java Programming (AJP) provide the necessary support for developing applications with some complexity using the Java programming language and up to date programming technologies. The courses Operating Systems, Databases and Network Communications and Internet Technologies provide complementary training on the specific topics and run simultaneously with the IPJ course, each one at a time. The Project is the last course in the program, before the internship, and allows the application of the programming concepts introduced in the earlier courses in the context of a broader practical application.

The final rating of each course, except for the Project, is calculated based on the weighted average of the grades obtained in two main components, a continuous assessment (50%) and an exam (50%). Project grade is obtained based on the quality of a presentation and a final report, with a public discussion of the results obtained.

TABLE I. ACERTAR O RUMO PROGRAM PLAN

	Operating Systems	1
	Databases	1
	Network Communications and Internet Technologies	1
2 nd semester	Advanced Java Programming	22
	Project	22

^a. European Credit Transfer System.

All these courses take place in the first 10 months of the program, from October to July. A student can only be approved in the curricular part and get the diploma if he/she achieves the approval in all courses. The student that does not obtain approval in any of the courses that precede the APJ course is unable to continue the program and does not have access to any kind of certification. The same happens to a student who, despite having had success in the first four courses, does not get approval in the APJ course.

III. THE TRAINEES GROUP

The group of selected candidates for the first edition of the program, out of 120 candidates, was made by 20 elements, 13 male and 7 female, or 65% and 35% respectively. Their ages were between 24 and 45 with a mean of 33.2 years. The selection process involved a set of written tests and an interview.

Four of them (20%) had got a Master Degree and 16 (80%) an equivalent pre-Bologna Degree (5 years College degree). The curricular areas of the corresponding degrees can be seen in Table II.

In terms of professional experience it varies a lot, since they have also diverse ages and it goes from no experience at all (these trainees have just finish the respective degrees) till 17 years of experience (just one case).

TABLE II. PREVIOUS TRAINEES' COLLEGE EDUCATION AREAS

Degree	Area	Number
Equivalent	Architecture	1
Master	Biomedical Engineering	1
Equivalent	Chemical Engineering	1
Master or Equivalent	Civil Engineering	5
Equivalent	Clinical Analysis	1
Equivalent	Eletrotechnical Engineering	2
Equivalent	Journalism	1
Equivalent	Management	1
Equivalent	Mathematics Teaching	6
Equivalent	Physics Teaching	1

IV. THE CORE PROGRAM COURSES

A. Course Introduction to Programming in Java

IPJ corresponds to the subject matters covered in the first two semesters of introductory programming courses of the UC Informatics Engineering (IE) degree, at the Bachelor level. It covers both the procedural and the object-oriented paradigms.

This course corresponds to 36 hours of work per week during three months (the first component), during which trainees learned the basic of both paradigms, plus a period of five weeks (the second component), where students had to develop a small Java project. In parallel, trainees had in turn one of the other basic courses (Data Bases, Operating Systems and Network Communications and Internet Technologies) in a schedule of just 4 hours of lectures per week and lasting 5 weeks each one of them, to complete the 40 weekly hours.

The course objectives are to acquire a sound knowledge of the principles of procedural and object-oriented programming using the Java programming language as a vehicle. The syllabus is shown in Table III.

In the first 12 weeks, the course was divided into lectures and lab classes. The first ones took 8 hours per week, lectured by a teacher of the Department, while the remaining 28 hours were the labs, where trainees solved a set of proposed programming problems supervised by tutors (experienced Java programmers recruited among the best Master and PhD students of the Department) applying the concepts taught in the lectures in a closer match. It was also the responsibility of the teacher to supervise the group of tutors that helped her running the course and organize their work. In the last 5 weeks, there were 16 hours per week of lab classes, accompanied by the tutors. The rest of the time the trainees had to work in the final project by themselves.

Part 1 (the procedural paradigm) took about 6 weeks and culminated with the first written exam. Part 2 (the object-oriented paradigm) took about 5 and a half weeks and ended with the second written exam. Part 3 ended with the public defense of the project and the final exam.

Cycles were introduced till the 2nd week and trainees showed no difficulties till then, but with this topic some revealed them, special the weaker ones. Because of this and before starting designing their own methods and to reinforce both cyclic structures and the method concept, the teacher decided to introduce graphical functions at this point of the

course. This was not explicit stated in the course syllabus, but proved to be an effective strategy, as gave the opportunity to train cycles more and, on the other hand, to visualize concepts. Diverse students learn differently and the teacher decided to capitalize on this approach [11, 12]. These problems also helped them to improve algorithm development. Also the use of arrays and matrices, which were not difficult for them, helped to clarify the cycle concept, due to its iterative nature.

It was quite difficult to do the shift from the procedural to the object-oriented paradigm. Particularly the concept of inheritance and the design of a class hierarchy was quite hard to apply in concrete problems. Object-oriented analysis and a brief introduction to Unified Modelling Language (UML) were presented next. The teacher decided to move them here, because she felt they needed to start designing problems more correctly from an OOP (Object Oriented Paradigm) point of view. But they revealed again many difficulties. In UML she introduced class diagrams and three types of relationships: association, aggregation and generalization [13, 14].

In Java containers the teacher introduced the general concept of the Java Collections Framework, but only referred to Generics and ArrayLists.

GUI was not in the initial syllabus plan, but the teacher thought it would be important to have some knowledge for the construction of concrete applications in the future. Thus, she have done only an introduction to Java Swing and let them explore it better during the project.

The project consisted of developing a multimedia kiosk for their local Town hall. It should provide information about the main tourist attractions, events, accommodation offers and restaurants of the municipality. It should have a GUI and menus in Portuguese and English allowing to switch between the two at any time. The application should take also into account two types of users with diverse privileges.

Course evaluation consisted of two components: A continuous component and a written exam, each contributing with 50% to the final grade. The continuous component would also be the sum of two subcomponents, the work in class during the course and a final project. Both contributed equally to this continuous component. The exam component could be attained as a single exam at the end of the course or as the sum of two equally weight exams done during the semester, one on the procedural part and the other on the object-oriented part.

TABLE III. INTRODUCTION TO PROGRAMMING IN JAVA SYLLABUS

IPJ syllabus	
<i>Procedural paradigm</i>	<i>Object-oriented paradigm</i>
A brief introduction to computer architecture Data types and operations Sequential structures Conditional structures Iterative structures Functions	Objects, classes, attributes and methods Encapsulation Inheritance Polymorphism Abstract classes and interfaces Java containers Object-oriented analysis Introduction to Unified Modelling Language

The work in class grade had an average of 79.3%. The average grade of the first exam was 74.4% and the second one was 73.5%. Only 14 students out of 20 (70%) tried the final exam and from this only 5 (36%) increased their mark. The average grade of the exam was 64.3%. This was not because the final exam was more or less difficult than the previous exams, but probably because, as they mentioned, they were quite exhausted after finishing the project. The average grade of the projects was 91.8%, extremely high as compared to that of regular Bachelor level courses. In fact the final quality of all projects was very high with four close to excellent and included features that were not requested, such as talking menus, sophisticated protection inputs, etc. The final grades' average was 80.2%.

There was a strong positive correlation between the continuous evaluation grades and the final grades of the course (0.94), which reinforces the idea that the teacher perception was quite correct as she knew very well each trainee performance and difficulties due to the relative small size of the class and the close relationship between teacher and students. This kind of teaching/learning strategy is one that the teacher defends for the learning of programming and that has given proven results in our programming courses of Design and Multimedia and IE degrees [15].

It was observed by the teacher that these students performed in class much better than IE Bachelor students. On one hand probably because they were very highly motivated, had experienced recently unemployment and the course evaluation scheme put a very high pressure on them. On the other hand, they were clearly better equipped in terms of mental tools, like problem-solving skills, critical thinking, etc., than the younger ones. This clearly favored the learning of procedural programming. On the contrary, when compared with the same IE Bachelors, they revealed more difficulties in learning the object-oriented paradigm. This may be due to the fact that they were older than the others in average, and so new skills are more difficult to learn, or because the time to learn them was shorter and time is needed to shift from a programming paradigm to another.

B. Course Advanced Java Programming

The aim of the AJP course is to give students a strong understanding of what is an Enterprise System, and how to

design and build enterprise applications using state of the art commercial frameworks, in particular, Java Enterprise Edition (JavaEE). Enterprise applications are characterized by their web-targeted technology, the large numbers of users and amount of data they have to handle, their distributed nature, and the need to enforce important quality attributes such as security, performance, availability, modifiability, maintainability and testability. The syllabus of the course is shown in Table IV. The definition of the syllabus was a process that involved consulting the industry, in order to understand which are the most valuable technical competences, and the Department Bachelor and Master courses on Distributed Systems and Systems Integration respectively.

The AJP course has a 14 week-long program. Each week students had 8 hours of lectures and 28 hours of lab classes. Lectures were critical to provide students with an initial understanding of what are enterprise systems, and the “mechanics” and tools of enterprise software development projects. Lab classes were used for developing software. Students had a total of 8 short projects to develop during the full length of the course.

Course staff was composed by a teacher of the Department and six tutors, which are industry experts and seasoned developers. Besides providing assistance to students in lab classes, tutors also reported on student progress and commitment. Course faculty opted for a coaching approach when dealing with students, providing guidance for students to accomplish their milestones by themselves. Tutors also maintained a daily record of what was happening in their classes. This diary served as a communication mechanism between faculty and everyone had to read it before their classes and write on it afterwards. Among the most important information on the diary was: discussion of the overall progress of students; identification of struggling students; major problems solved and how; open problems; comments and questions for faculty body. Since, every faculty was alone with the class, this diary was essential for guaranteeing that students got the same feedback from all teachers and that teachers were up-to-date with the class progress and problems.

TABLE IV. ADVANCED JAVA PROGRAMMING SYLLABUD

APJ syllabus

The development of web and enterprise systems cannot be learned without a strong emphasis on practice, since it is mostly based in a few strong, but general, programming concepts and characterized by a steep learning curve on frameworks and technologies. Thus, this course was structured to demand a strong commitment from students to self-learning and learning-by-doing. Besides the 8 hours of lectures per week, students had to develop 8 software projects with diverse sizes and complexity in the 14 weeks period. Each project focused on different subjects and had different learning and evaluation objectives. Projects gave students the chance to put into practice the concepts and technologies discussed in lectures. In each assignment, besides the regular objectives, the teacher defined additional challenges for top students. This optional "Go further" section was, for the greater part of the class, considered as being mandatory, which was a great indicator of the quality and commitment of this group of students. Projects were planned for groups of 2 students. Groups were defined by the faculty, with the aim of preventing the same group of students of working on more than one assignment together, making sure that in each assignment there were new groups.

The course had no written exam, the evaluation was divided in two components: projects and continuous assessment. In each project, the teacher evaluated the work being produced and the individual performance of each student. The evaluation of the work focused on grading the legibility of the code, the robustness of the code and software, the modularity of the solution, the correctness of the solution, the fulfillment of the assignment requirements, the overall structure and software architecture, and the existence of tests. On the individual side the teacher graded the effort of the student and his/her contribution to the project and the acquired competences.

Regarding continuous assessment, the tutors graded students in each lab class in terms of their assiduity, participation, and demonstrated acquisition of knowledge and competences.

Students also completed a self-evaluation of their performance for each project. This was a supportive instrument to help understand the students' perspective on how efficient the work on the projects was for achieving their learning objectives.

The objective of the first project was to diagnose the students' proficiency in Java programming. As a result of this assignment the teacher introduced two changes to the syllabus of the course that correspond to areas where students demonstrated difficulties or a complete lack of knowledge and that were not covered in IPJ: Exception Handling and Design Patterns.

The lowest grade of the course was 70% and the highest 90%. The average was 79.2% and the median 80%. In this analysis we left out the data of one student that did not conclude the course. These were very rewarding results. Furthermore, when comparing the correlation between the continuous assessment grades, gathered by tutors in lab classes, with the final grades, we observed a correlation coefficient of 0.85, which is a good indication that tutors were

able to work very closely with students and get to know and evaluate them very well.

Another aspect that it is interesting to evaluate is the impact in learning and in grades of the policy of blind pairing students for each assignment and defining new groups for each assignment. The chart in Figure 1 shows the relative performance of the 3 lowest and the 2 top performing students. It is immediately clear that top performers have a much unwavering performance, while low performers struggle and evidence high fluctuations. By crossing the information about the groups of students in each project and this chart, we concluded that:

- When Top Performers had lower scores, they were paired with low performing students. But, most of the times, pairing with low performers did not affect the best students' scores.
- When Low Performing students had lower scores, they were paired with other Low Performers.
- When Low Performer were paired with Top Performers, their scores improved drastically. A quick consultation of the course diary showed that these students benefited from the guidance and expertise of their colleagues and, at the same time, found themselves in a position where the quality of work, required by their colleagues, was higher.

During the course, it became clear to the teacher that students had to handle a large quantity of new information and concepts very quickly. If they failed to keep up with the new knowledge, there was not much room for recovering. Mainly because, in each project, the teacher introduced new concepts, but assumed that previous ideas had already been put to practice and assimilated. Thus, the rhythm of the course was high. To cope with this problem, the teacher gave more time for the execution of some projects, on which he knew that students would have the opportunity to revisit previous concepts. To one student, this was not enough. A student, which had already been struggling since the previous introductory course, was not able to recover and failed. On the other hand, a student that had recently been a new mother, and had to miss 4 weeks of classes in IPJ, was able to recover and finish the course successfully. Students had an additional difficulty, programming web front-ends. Initially all students had none or a very low knowledge of HTML, CSS and JavaScript. Since, the syllabus of the course did not include front-end programming, the teacher decided that the best way to cope with this problem was to do short workshops on the lab classes. The objective of each workshop was to get students familiarized with the tools and mechanics of front-end programming. Of course, workshops were not enough by themselves, students still had to further explore, study and practice by themselves.

One area of the course that still has a large room for improvement is Software Testing. Although it was mandatory in every project, students were never able to deliver thorough test results. Furthermore, the large majority had no structured testing methodology in place.

Fig. 1. Individual scores of the 3 lowest performing students and the 2 best performing students in the projects.

C. Project Course

The goal of the Project Course was to allow the students to develop an application in a very autonomous way, with very limited intervention of the teachers. The project was proposed by one of the companies involved in the course and consisted of developing a recruiting management software to a company, with different levels of users. The application to be developed was described in terms of mandatory and optional software requirements. The mandatory requirements consisted of opening of accounts for different type of users, search and opening of positions, and job applications, matching of position and application, notifications, generation of interview guides, interview feedback about an application and reporting. In addition, the software should allow a candidate to search for information about job openings and submit its application through an automatically generated web-page. The optional requirements consisted of LinkedIn integration and advanced reporting. The students were also free to add other optional requirements.

The students were split randomly into groups of two. A teacher was assigned to not more than 3 groups of students. Each group could seek advice from the teacher not more than 1/2h per week. At the end of the course, they submitted the code and a report and discussed, individually, the implementation with the teachers. The assessment was based on the number of mandatory and optional requirements that were performed as well as the quality and usability of the final application.

Individual grades ranged from 55% to 90%, with mean 76.55% and standard deviation 8.05%. Only in two groups there was the need to differentiate the grade between the group elements.

V. INTERNSHIP

Each student that concludes the first phase of the course at the UC is allowed to do an internship of 12 months in one of the companies that accepted to be involved in the program.

The goal is to acquire skills about software development in a realistic environment by integrating a team of developers working on a real application. Each company provided one or more internship proposals and was responsible for integrating, accompanying and reporting the progress of the intern. A teacher from the University also met the intern once per month. The internship was paid by the company, minimum 750 Euros per month.

A total of 10 companies from Coimbra, Lisbon and Porto accepted to be in the program and submitted 24 internship proposals, which were validated by the program coordination. The proposals consisted of web-portals development, web-services integration, ERP integration, and development of particular applications, such as maritime solutions, smart meters, biomedical sensors and games. The students went through the proposals during a week and ranked all of them. The matching between students and proposals was solely based on their grade, that is, the student with the best grade was assigned to his/her first choice, and the student with the second best was assigned to his/her first choice that was not yet chosen, and so on.

VI. SURVEY RESULTS

During the second year of the first edition of the program two surveys were passed to access the efficacy of the program – one for the trainees and another for the companies involved. First we analyze the one of the trainees that was anonymous.

By this time one of the trainees had left the program for personal reasons. 89.47% of the trainees answered the questionnaire, 41% females and 59% males. 47% were from Exact Sciences, 35% from Engineering, 12% from Social Sciences and 6% from other areas. The questions asked can be seen in Table V and Table VI.

To the question “What of the following technical issues taught during the training phase at UC are being used in the internship?” they answered: SQL 20%, JAVA 21%, Web RESTful Services 10%, Java Persistence API and JP Query Language 12%, Automatic tools: compiling, application server, repository and mapping between object model and relational 21% and Testing and Debugging 16%.

To the question “Are there other knowledge that you think should be taught during the training phase to ease your integration in the internship?” they referred: HTML5, CSS3, JavaScript, WebServices, jQuery, maven, Junit, Mockups, more on SQL, more on software testing, design patterns, more on Networks, Repository management, Agile development, development of scalable code, projects with bigger teams.

When questioned if they would recommend the program to a friend 94% said yes against 6% that did not recommend it.

Trainees’ final comments include:

“The program Acertar o Rumor is, from my point of view, an innovative method of people reintegration in the labor market.”

“I feel that I have made the right choice in participating in the program.”

TABLE V. TRAINEES' QUESTIONNAIRE ANSWERS

Question	Very Good	Good	Reasonable	Weak
How do you classify the process of internship assignment in the end of the program?	35%	53%	12%	
How do you classify the interaction with the organizing team of the program?	35%	59%	6%	
How do you classify the adequacy of the training to the work being done in the internship?	12%	76%	12%	
How do you classify the level of integration in your internship team?	8%	12%		
How do you classify the importance of the internship tasks to your professional development in IT?	71%	29%		
How do you classify the accompaniment that has been done by the UC supervisor?	24%	23%	35%	18%
How do you classify the accompaniment that has been done by the company supervisor?	47%	41%	12%	
How do you classify till now your experience in the program	53%	47%		

TABLE VI. TRAINEES' QUESTIONNAIRE ANSWERS

Question	Totally Agree	Agree	Disagree	Strongly Disagree
Content sequence was coherent.	41%	53%	6%	
Contents were adequate for the internship.	29%	53%	12%	6%
The time for doing the activities was sufficient.	23%	59%	18%	
Proposed activities were useful for learning consolidation.	47%	53%		
Contents are applicable in the internship context.	47%	47%		6%
Themes were interesting.	59%	41%		
Activities were motivating.	41%	47%	6%	6%
I felt involved in the activities.	71%	23%		6%
Evaluation methodology was adequate for program objectives.	6%	71%	23%	
Provided texts and papers allowed to deepen knowledge.	23%	65%	12%	
References were useful.	18%	70%	12%	
Provided support documentation was adequate.	24%	35%	41%	
The pedagogical team motivated me.	35%	59%	6%	
The pedagogical team was present when I had doubts.	23%	71%		6%
The pedagogical team fostered my participation.	18%	70%	12%	
The pedagogical team gave timely feedback, contributing to my learning in a suitable way.	6%	56%	31%	7%
The pedagogical team revealed interest in my difficulties.	19%	69%	12%	
The pedagogical team was clear when intervening.	12%	76%	12%	
The pedagogical team supported me solving problems.	18%	76%	6%	

"It was an interesting program where I learned a lot (...). From the beginning, with a practical emphasis and with the intention of integrating in a work team, it was a very enriching and rewarding experience. The general feedback is more than positive."

The survey for the companies had a 61.11% of participation. The questions asked can be seen in Table VII and Table VIII.

To the question "What of the following technical issues taught during the training phase at UC are being used in the internship?" they answered: SQL 14%, JAVA 20%, Web RESTful Services 18%, Java Persistence API and JP Query Language 16%, Automatic tools: compiling, application server, repository and mapping between object model and relational 16% and Testing and Debugging 16%.

To the question "Are there other knowledge that you think should be taught during the training phase to ease your integration in the internship?" they referred: more on databases and SQL, design patterns, more on testing and debugging, reuse, Angular, React, Bootstrap, JQuery, transactions, distributed applications and communication and organization skills.

To the question "What competences do you think "Acertar o Rumor" trainees have?" they answered: Motivation to the job 16.4%, Commitment: extra effort when needed 14.8%, Team

work capacities 16.4%, Assertive communication 6.6%, Analysis, synthesis and problem-solving capacities 9.8%, Organization and planning 8.2%, Autonomous learning 14.8%, Adaptation to new situations 11.5% and Other 1.6%.

From the point of view of the trainees we can see that they classified as Good or Very good or as Agree or Totally agree the majority of the questions asked and 94% would recommend the program to others.

TABLE VII. COMPANIES' QUESTIONNAIRE ANSWERS

Question	Very Good	Good	Reasonable	Weak
How do you classify the process of internship assignment in the end of the program?	55%	45%		
How do you classify the interaction with the organizing team of the program?	18%	82%		
How do you classify your trainee?	64%	36%		

TABLE VIII. COMPANIES' QUESTIONNAIRE ANSWERS

Question	Yes	No	Without opinion
Is it probable that you want to maintain collaboration with trainees after the internship?	82%		18%
Is it probable that you participate in future editions of the program?	82%		18%

From the point of view of the companies we can draw similar conclusions and that 82% intend to maintain the collaboration with the trainee after the internship, thus coping with unemployment, and the partnership with the UC (see Table VIII).

VII. CONCLUSIONS

In this paper we described a program developed in partnership between the University of Coimbra and iTGROW to reconvert unemployed Engineering and Exact and Natural Science Masters into experienced Java programmers. In what concerns the core courses of the program, from the observations in the classroom and the results obtained, it is possible to say that this was a very good experience in terms of teaching and learning, both for the teachers as well as for the trainees.

Two efficacy surveys were passed, one for the trainees and another for the companies involved in the partnership. The results show that both value the program quite well in several dimensions. This has led us to recommend the program for further editions. At the moment the second edition of the program is already running and the recruitment phase of the third is starting. However, we also recommend some improvements and minor changes.

One thing that should be improved is the unbalance between the IT basic courses (Operating Systems, Databases and Network Communications and Internet Technologies) and IPJ during the first term. It would be better to have some practice in the former and have 4 hours more per week to accommodate it, for instance. Otherwise concepts will remain quite vague and they are important too, especially to APJ and to the Project. On the other hand a small reduction in the IPJ labs would not affect them much in our opinion. Other changes already made were small adjustments in AJP in order to accommodate companies' requests.

But this experience also led to other reflections. One is that the Java programming language could be easily replaced by another one, like C# for instance, if this issue was felt necessary by the companies in the program. Also we think that this approach could be applied to other subject matters, like it is the case of a training course on Web Technologies that the Department is designing at the moment. Although in a shorter format and less ambitious, the goal is to provide extra ICT skills, for unemployed graduates of several curricular areas.

ACKNOWLEDGMENT

We thank Catarina Fonseca and Bárbara Rodrigues from iTGROW for the opportunity of working together in the design and implementation of this program. We also thank Prof. João Gabriel Silva that idealized this program.

Abstract— As the world's economy becomes global, graduate workforce readiness is increasingly necessary. There has been a gradual shift in industry expectations of graduates from exhibiting academic expertise in a chosen discipline to a commercially adroit candidate with a strong command of, and immediate ability to apply, a broad range of skills deemed essential in the workplace [1]. With the globalization of technology and the rapid changes in the way companies do business, it is becoming imperative that graduates start performing and processing from their first day on the job [2]. Design for Six Sigma (DFSS) is an approach that can be helpful in pushing towards better-prepared graduates for the workforce. This study aims to use current student project work to analyze preparedness, particularly in terms of students' abilities to organize and communicate their thoughts. Preliminary findings show that more needs to be done in institutions of higher education to align the process of executing projects in universities with what is widely employed in industry.

Keywords—Six Sigma; Design; Engineering Communication; Design process

I. INTRODUCTION

Design is a major component of engineering and managing the process of designing is equally an important component. As defined by ABET, Engineering design is the process of creating a system, component, or process to accomplish a goal. Furthermore, ABET outlines the criteria in engineering design that research institutions must contain. Some of these features include: development of student creativity, use of open-ended problems, development and use of modern design theory and methodology, in addition, realistic constraints, such as economic factors, safety, reliability, aesthetics, ethics and social impact [3].

In meeting these criteria, the use of a design process has been widely used in undergraduate curriculums with iterations ranging from a circular diagram to a block diagram of the design process [4]. Given the range of design processes available, there is no clear path on which design processes should serve as a baseline for higher institutions to follow in design classrooms. Given the emphasis on Six Sigma processes in industry, this study uses Design for Six Sigma (DFSS) as a framework to examine how students' engagement of the product development process within product design incorporates elements of DFSS. To accomplish this, our research question posits:

What elements of Design for Six Sigma (DFSS) are present in third-year engineering students' written work during a problem-solving design task?

II. CONCEPTUAL FRAMEWORK

A. Design for Six Sigma

Six sigma is a quality philosophy at the highest level, concerning all processes, and a quality measure at the lowest level. The term "sigma" refers to standard deviation, σ . Standard deviation or variance, σ^2 , is a measure for the dispersion of a data set around the mean value, μ , of this data. Six Sigma then stands for six standard deviations from the mean [5]. The Six Sigma methodology provides the techniques and tools to improve the capability of, and reduce defects in, any process. Originally developed as a set of practices designed to improve manufacturing processes and reduce defects, its application was subsequently extended to other types of business processes [5]. Six Sigma is often associated with the Total Quality Management (TQM) principles made famous by W. Edward Deming's 14 points theory. Deming's philosophies have been used in several industries with a focus on customer satisfaction and continuous improvement of systems [6]. Six Sigma DMAIC (Define, Measure, Analyze, Improve and Control) first appeared in 1979 when the Motorola organization wanted to take the TQM principles to the next level, which is how and when the Six Sigma methodology and DMAIC methodological framework were both born [7]. The DMAIC approach is used and a proven successful schema by many Fortune 500 companies in multiple sectors including General Electric, Dow Chemical, United Technologies, Motorola and Ford Motor Company as well as many others. These companies have invested over one billion dollars and have put hundreds of thousands of employees through the Six Sigma certification program [8].

There is recent research looking into the use of Six Sigma methodologies, on a par with industry, as a way to measure several aspects of academia. These areas include recruitment improvement strategies, attrition, and graduation rates among engineering students [9]; [10]; [11]; [12]; [13].

Over the years, Six Sigma has evolved immensely to not only consider products and services from a problem-solving, process improvement lens but to also as a way of looking at the engineering design process. Rather than focusing on streamlining a product or process to reduce defects, eliminate mistakes, or save money via Six Sigma, Design for Six Sigma

* Best in this context means the most reasonable solution

** P2:1 – Phase 2 Item 1 on the list from Table 1

(DFSS) is a methodology that can be incorporated at the onset of a design or process. Furthermore, it can be used to develop a new design, enhance innovation, or to reduce the need for redesign of an entire process and thereby prevent downstream errors [8].

Defined as a driver of unique synergy between engineering design principles and applied statistical analysis methods, DFSS adds another layer to product development called Critical Parameter Management (CPM). “CPM is the disciplined and focused attention to the design’s function, parameters, and responses that are critical to fulfilling the customer’s needs” [14]

B. Product Development Process

An effective product development design process combines the use of tools, best practices, and project management in the design process. This relationship between the design process and project management is critical to the success of an engineering design project. These critical parts are all used and taken into consideration at every stage in the DFSS process [14].

Figure 1: Critical Components in Successful Product Development [14]

During design development, modeling takes place between the first and second phase [14]. Using DFSS in the Concept, Design, Optimize, and Verify (CDOV) process, we will focus on the measure of students’ engagement of the product development process in these two defined areas. While there are four phases of DFSS, our study will focus on the first two phases. Within each of these phases (concept phase and design phase), there are four major characteristics to accomplish the task of product development. Figure 2 describes these characteristics.

Figure 2: Important aspects of the Concept and Design Phase in DFSS

III. METHODOLOGY

This study employs content analysis [15] using the DFSS framework (phases 1 and 2) to analyze limitations, assumptions, and engineering thinking of final responses for 14 student teams modeling activity tasks.

A. Setting

The setting for this study is a public research university in the western United States with a focus on engineering and applied science. This university is also one of the top public universities in terms of salary potential and ranked as one of the top engineering schools in the United States, serving approximately 2,600 engineering undergraduate students with an average class size of 33.

B. Participants

With a class size of approximately 55 students, the participants in this study were grouped into 16 teams of three or four chemical engineering students each; the class is a junior-level heat transfer course. In 14 of the 16 teams, all students consented to be a part of the research study. (See Appendix)

C. Task

Teams of three to four students worked on developing a mathematical model to predict the thermal sensation of touching kitchen utensils for a company that needed guidance selecting new materials for utensil handles. As they developed a model to make this prediction, the student teams wrote two memos. The first memo was an internal document describing detailed model development and highlighting the important physical properties (e.g., thermal conductivity, density, thermal diffusivity) that governed thermal sensation. After feedback from the course instructor (acting as project manager for the teams), each team revised their model, developed a working spreadsheet to predict thermal sensation for new kitchen utensils, and wrote a second memo to their client at the kitchen utensil company. This memo provided: 1) details of the team’s mathematical model (including assumptions and simplifications) that would allow someone who deals with utensil materials in the company to predict the touch sensation that a person would experience when using a utensil made of a given material at a given temperature; 2) a list of thermal and physical properties necessary for prediction of utensil sensation; and 3) a description of desired property values that a candidate material should have for use in developing a new product line. It also included thermal sensation predictions for material properties recommended for the new product line.

D. Data Analysis

The student teams’ memos were read by both authors and analyzed for key ideas of the design process. After the first coder analyzed the data, the second coder analyzed the data independently. Both coders then met to discuss differences and resolved them when necessary to come to an agreement on the evidence we proclaimed as the artifacts. The artifacts included the student’s recommendation memo and the final design proposal, classroom videos, and transcriptions.

Data analysis was conducted using a deductive coding strategy using the four major characteristics of DFSS in the concept and design phase using a preset category [16]. Since Six Sigma has its own language, we define the language of the requirements for successful exhibition of the phase 1 and 2 deliverable in Table 1.

** P2:1 – Phase 2 Item 1 on the list from Table 1

Design for Six Sigma	Definition
Phase 1:	
1. Gathering the voice of the customer data	Gather customer requirement
2. Refine and Rank Voice of Customer (VOC)	Prioritize customer requirements
3. Integrate and Align VOC with Voice of Technology (VOT)	Consider and align customer desires with feasibility from a design perspective
4. Generate system concepts	Idea generation
Phase 2:	
1. Identify and Resolve “conflicting requirements” using VOC data	Manage and confirm customer request against best idea generated and select best design
2. Construct subsystem Noise Diagram	Identify limitations and assumptions of the design
3. Select best concept	Select best idea
4. Generate a spatial integration model	Create a spatial model of best* design

Table 1: DFSS concept and design phase and definition

IV. RESULTS

The data below (Figure 3) shows the result of coding 14 student groups' data. One group scored 6 out of 8 with the mean score being 3.5. The assumption phase was defined by all 14 groups while selection of the best idea generated scored second highest while the creation of a spatial model of the best design scored third highest. The weakest area for the students was the customer related memo portions. Tying their work back to the VOC was a challenge for most of the students and explicitly acknowledging and addressing customer requirements was also weak although sometimes insinuated, communicating this information in the memo written to the customer was not obvious. Below is an excerpt from Team #10, which shows an exhibition of an explicitly stated P2:1**:

From the attached data, the group determined that wood would be the best material to use for the new product line as it would decrease the sensation range.

Below is an example of an explicitly stated P2:2:

We are assuming that we only looking at the contact area of the fingertips and the material of the spatula. We assume that when the finger is depressed against the material it is sufficiently depressed so that it can be accurately portrayed as a flat plate.

V. DISCUSSION AND IMPLICATIONS FOR THE CLASSROOM

Analyzing the third-year engineering students' written work using DFSS shows that organization of thought and communication of findings were the two main challenges for students. The ability to present design ideas and to make recommendation in an effective way to the client during a problem-solving design task is important to the idea itself. An idea that is communicated effectively can make the difference in acceptability. Deciphering what the students were trying to communicate is an area of opportunity that can be improved in the teaching of a design process with attributes such as communication which has been mentioned by many research studies [17][18]. A process like DFSS can be employed to improve the communication of data, results, and interpretation of customer requirements in student projects for industry focused assignments. Furthermore, using DFSS as a process for design can enhance the student presentation of their ideas and help organize these ideas in a systematic way. Defining roles and responsibility in project-based assignments in the classroom environment might offer students the opportunity to practice leadership and project management. For example, in designing a system, a systems engineer is necessary to monitor the cohesiveness of different components. Having such roles and responsibility defined can potentially be of value to students to gain different perspectives over the term of their schooling. The DFSS methodology has strength in all these areas where students can benefit. Given that DFSS is widely known in industry, it can serve as a learning tool in university-industry, problem-based learning environments in higher institutions.

* Best in this context means the most reasonable solution

** P2:1 – Phase 2 Item 1 on the list from Table 1

VI. FUTURE WORK

We plan on expanding this work to include several of the team conversation and data to understand the team dynamic in the idea generation phase and analyze this data to see how the student team employed the customer requirements in their brainstorming activity through the recommendation phase.

Perspectives on Engineering Design Learning: Realities, Challenges, and Recommendations

Waddah Akili

Principal, Geotechnical Engineering
3222 Evergreen Rd., Ames, Iowa, 50014, USA,
w.akili@isunet.net

Abstract- Design is considered by most to be the central activity of engineering. Also, it is known that engineering programs should graduate engineers who can design effectively to meet social and environmental needs. Though the role and perception of design across a wide range of educational institutions have improved markedly in recent years; however, both, design faculty & design practitioners argue that further improvements are necessary. One of the defining characteristics of design is that there is rarely a single correct answer to an engineering problem but, rather, an optimal or acceptable solution leading to a final design, presented as the best possible balance between technical as well as non-technical constraints. These non-technical constraints typically involve economics, politics, social and environmental issues, ethics, etc. And, while professional practitioners generally accept this understanding of design, students, by enlarge, tend to interpret the engineering design process as an unambiguous and clearly defined process supported by rigidly applied principles and processes of “the scientific method.” Students’ vision and mis-concepts of design do require proper alignment with prevailing conditions on the ground. Undoubtedly, the start of any design course should be preceded by exposure to *design thinking* and related processes. The paper reviews the role of design in engineering programs, and outlines the current research on how *design thinking* processes could be taught and learned. It explores also the currently most-favored pedagogical model for teaching design, namely: Project-Based Learning (PBL). The paper identifies several contexts for PBL, along with some available data on its success. Finally, the paper raises some of the questions that should be answered to identify the most effective pedagogical practices of improving design learning.

Keywords—*Design education, design thinking, convergent & divergent thinking, project-based learning, the hybrid approach, team environment.*

INTRODUCTION

Design is widely considered to be the most distinguishing activity of engineering. It has also long been understood that engineering institutions should graduate engineers who could

design effectively to meet societal needs. Historically, engineering curricula have been based largely on an “engineering science” model, referred to as the “Grinter Model”, in which engineering is taught only after a solid basis in science and mathematics. The resulting engineering graduates were perceived by industry and academia, at the time, as being “ill-prepared” for the practice. Despite steps taken to remedy the situation, through greater industry-academia collaboration; both design faculty and design practitioners argue that further improvements are necessary. Design faculty across a range of educational institutions still feel that the leaders of engineering schools (deans, department heads, tenured faculty) are unable or unwilling to recognize the intellectual complexities and resources needed to support good design education.

Fortunately, more and more educators are becoming aware of the issues of design, and steps are being taken world wide, to address the concerns of industry at large. One approach has been to form “symbiotic” partnership between industry and academia through senior capstone projects.

The capstone course has evolved over the years from “made up” projects devised by faculty, to industry-sponsored projects where companies provide “real” problems, along with expertise and financial support. In fact, design courses, in general, have emerged as a means for students to be exposed to some flavor of what engineers actually do; and also, could learn the basic elements of the design process by being involved in real design projects. There have even been formal proposals for curricular goals and assessment measures for design-based curricula. This argument is driven by a widespread notion that the intellectual content of design is consistently underestimated [1].

This paper reviews research on *design thinking* as it relates to how designers think, learn and make decisions, which is an important reason why design is not easy to teach. *Design thinking* is, in general terms, complex processes of inquiry and learning that designers perform in a systems context, making decisions as they move forward, often working collaboratively in a social setting, and eventually arriving at an optimum solution. The paper, also, focuses on the most favored pedagogical model for teaching design, namely: *project-based*

learning (PBL), as an effective way for students to learn design by experiencing design as active participants. The paper closes by making recommendations for ways to enhance design learning.

ON ENGINEERING DESIGN THINKING AND LEARNING

What does “design” mean in an engineering context? What are the qualifications of a designer? Can design be taught? And if so, who can teach it? These questions will be addressed in the paragraphs that follow.

Relevant Definitions, Thoughts and Processes: *Engineering design* as stated by Dym et al. in 2005 is: “a systematic, intelligent process in which designers generate, evaluate, and specify concepts for devices, systems or processes whose form and function achieve clients’ objectives or users’ needs while satisfying a specified set of constraints” [1]. This definition presents design as a thoughtful process that depends on systematic, intelligent generation of design concepts and the specifications that make it possible to realize these concepts [2]. Sheppard’s characterization of what engineers as designers do: “They scope, generate, evaluate, and realize ideas” [3]. In the context of engineering design, *creativity* is important, but it is not design! *Design problems* do reflect the hard fact that the designer has many constraints that may positively or negatively affect the outcome of the design, i.e., the designer has a client to satisfy and for whose benefit the item/artifact and/or project is being developed.

There are several approaches to characterizing *design thinking* and *design processes*. These characterizations, often associated with good designers, may include the following [2]:

- View design as an inquiry and/or iterative loop of *divergent-convergent thinking*,
- Focus on the “big picture” in all stages by including *systems thinking* and *systems design*,
- Handle *uncertainties* that are likely to arise,
- Arrive at decisions,
- Think and act as a member of a team,
- Think and communicate using known languages of design,
- Be familiar with relevant background and technical knowledge that lead to successful design

The starting point of any design project, irrespective of the object or nature of the project, is the **problem definition phase** characterized by asking relevant questions and attempting to find plausible/realistic answers. No sooner has a client or professor defined a series of objectives for a design project than the designer- whether in a consulting office or in a classroom- want to find out what the customer really wants. Questions such as: what is an economic project? How do you define the best design? What is a safe design? What are the factor(s) that will affect the design the most? Phrasing it differently, knowledge resides in the questions that can be

asked and the answers that can be provided [2, 3]. A sequence of inquiry characterized by a hierarchy: certain questions need to be asked and answered before other questions can be asked. There is a set procedure which constitutes the inquiry process in an epistemological context. Taxonomies of such a procedure or inquiry process have been extended to computational models [4], to the intricacy between asking and learning [5], and would also apply to the questions students ask during a class and/or tutoring session [6].

There are two classes of questions within a design context; the first is the category of questions that do have a specific answer, or a specific set of answers. Such questions are characteristic of **convergent thinking**, where the questions attempt to converge on and reveal “facts”. As such, answers to converging-type questions are expected to be truthful and verifiable. The second category of questions is diametrically opposite to the first, and is characteristic of **divergent thinking**, where multiple alternative known answers exit, regardless of being true or false. The key distinction between the two types is that **convergent** questions operate in the knowledge domain; whereas **divergent** questions operate in the concept domain [1]. This has strong implications for teaching conceptual design thinking, since concepts need not be truthful or have true value, whereas knowledge does. **Design thinking** therefore is seen as a series of transformations from the *concept domain* to the *knowledge domain*. Such questioning and thinking is the “backbone” of any design process, and the major tool by which designers add to the pool of engineering knowledge [7]. The significance of the transformations between the *concept* and *knowledge* domains is further supported by the finding that the combined incidence of deep reasoning questions and generative design has been shown to correlate positively with performance, in arriving at design solutions [8]. Therefore, any properly produced design is preceded by effective inquiry that includes both a *convergent* component (lower level and deep thinking questions) and a *divergent* component (generative design questions intended to create the concepts upon which the design is based).

The forgoing discussion raises questions relevant to teaching design in all engineering disciplines. Clearly, the *divergent* inquiry in *design thinking* is neither recognized nor included in most engineering curricula. I think the time is right to introduce the iterative *divergent-convergent* process(s) in order to develop better pedagogical approaches to engineering design.

Focusing on Design-related Education: Recently, designers, throughout the world, have helped develop an increasingly complex “built” environment that includes some major large-scale engineering projects. Simultaneously, designers have been pushing the envelope at relatively fast rate making products, systems and engineering projects increasingly more complicated as they strive to improve reliability and increase service-life by increasing number of components and their

interdependencies. Further, designers have to expand the design boundaries to include environmental factors, social impacts, and public safety issues in their designed systems and projects. The author believes that engineering designers are in need of skills and experience to help them cope with the complexity and facilitate the arrival at optimum design. Invariably, this type of: knowledge, skills, and related experience need to find its way to the classroom through curricula updating, proper counseling, mentoring, and insuring a conducive classroom environment.

There are *four* aspects of design education believed to be of relevance to acquiring and/or enabling young designers, and students in particular, to embark on the mission. The *four* are highlighted in the *subsections* to follow.

1) Thinking about a system's approach: A good designer is some one who can anticipate and deal with intended and unintended consequences resulting from interactions among the multiple factors of the system. Exposure to system analysis and system dynamics – preferably through a rigorous course(s) - would assist the designer in sorting variables, prioritizing, and managing the design process. Unfortunately, these skills are not common, do require prerequisites, and regarded by most as difficult to learn. Many different teaching methods have been proposed to improve people's abilities to grasp and retain knowledge under this category. Recognizing that there are difficulties in proper delivery of *systems analysis* and *systems dynamics* to engineering students; the fact remains that these tools are extremely useful for someone who plans to become a designer. Therefore, ways have to be found to enhance the understanding of systems' thinking, and at the same time, to develop educational experiences that could efficiently improve learning outcomes.

2) Looking at risk management and uncertainty: Engineering design is carried out relying on incomplete data, imperfect models, often with unclear objectives, and other potential problems and constraints. The effects of such uncertainties on the design of a project may have serious consequences unless proper safeguards have been undertaken based on probabilistic and statistical approaches to design and factors affecting design. Some have argued that current undergraduate curricula greatly underemphasize the theory and application of probability and statistics in engineering [9]. Research has revealed that people are generally prone to serious errors in probabilistic and statistical thinking, including neglect of prior probabilities, insensitivity to sample size, and misconceptions of regression[10]. The formal course work in probability and statistics falls terribly short of exposing engineering students to various encountered errors, e.g., systematic underestimation of uncertainty. Engineering educators are concerned, and some have been working to alleviate the difficulties by stressing conceptual understanding, emphasizing active teaching methods, and using more graphics & simulations [11]. There is a long way to go with regard to *uncertainty* and the way it ought to be handled in the classroom. Suggested improvements and changes have included the following [12]:

- offer probability and statistics courses early on in the program,
- include "*uncertainty*" and its implications in engineering analysis courses,
- consider offering technical electives, in this domain, and let "*uncertainty*" be a central theme,
- make use of modern computational tools to support probabilistic thinking.

Such curriculum changes may fall short of meeting set goals without adequate research aimed at continued improvements in probabilistic and statistical thinking for engineering in general and design component in particular.

3) Estimation: A main challenge of a project design is the number of variables and their interactions during the design process. Often, the system stretches beyond designers' capability to grasp all of the details simultaneously [1]. One strategy for coping with the many variables is to bring the system back within the limits of human mental capacity by focusing selectively on a limited number of factors, preferably the most significant ones. Designers are usually good at estimation. They are able to size up parameters, sort them out in terms of their relative importance, and neglect the ones that have less impact on the project. Today's graduates are not good at estimation [1]. This poor performance by the new graduates appears to be related to a weak conceptual understanding of basic engineering science, limited ability to form appropriate analogies, weakness in visual perception, short-term memory, and insufficient interaction with their physical surroundings. Additionally, current engineering education emphasizes sophisticated methods for precise calculation and thus may underemphasize approximation skills [13]. Attempts to rectify the situation would require research and development and eventually instigating potential changes in curricula and teaching methods

4) Physical modeling and experimentation: Unfortunately, the advent of the computer and its impact on teaching engineering has made it easy to produce computer-based models at the expense of physical models. This fact is behind a general trend of teaching applied engineering subjects with minimal students' involvement with physical set-ups including laboratory experiments. Carrying out laboratory experiments and generating experimental data, visiting a project site, and using pencil and paper to produce a schematic, are gradually fading away. These traditional tools were instrumental in developing an engineering common sense. It is argued here that generating data from physical models is potentially a great learning tool, particularly when the model is built by the students. Building a model, testing a model, generating physical data from the model, and analyzing said data, help students alternate between *inductive* and *conductive* processes, thus broadening their design vision and their understanding of the experimental approach to engineering design. There is potentially a real need to research the ways to teach engineering students how to make proper use of physical models and experiments.

The four aspects (discussed above): thinking about a systems approach, looking at risk management and uncertainty, estimation, and physical modeling and experimentation – are intended to pin point some shortcomings in design-related education that need to be addressed, using a principled approach to dealing with these issues.

DEVELOPMENT AND GROWTH OF DESIGN THINKING IN A TEAM ENVIRONMENT

All aspects of design is being recognized and taught today in most institutions as a team process with socio-technological dimensions [13]. One practical reason is that ABET general engineering criteria target the social aspects of engineering education at several levels. In addition to criterion 3(c), “an ability to design a system, component, or process to meet desired needs,” criterion 3(d) addresses the need to function on multidisciplinary teams, criterion 3(f) social and ethical responsibilities, criterion 3(g) communication skills, and criterion (h) addresses global and social impact. Constructivist theories of learning, irrespective of the subject matter, recognize that learning is a social activity, and design-based courses, including project-based courses, are regarded by most as opportunities to improve students’ ability to work in teams, as well as their communication skills. As a result, universities now incorporate many of these aspects in their design classes, ranging from first-year design courses to capstone design. In fact, many of the early researchers have emphasized that the design process requires the designer to continually raise questions, and exchange views with others over the advantages and disadvantages of alternative solutions [14]. Also, design has been defined by some as “a social process” in which teams define and negotiate decisions and each team member possesses an “ingrained” set of technical capabilities that could act as a filter during design team interactions and , consequently, the end result is an intersection—not a simple summation of participants inputs. This view of design has received the attention of many researchers, and was used by some to develop relevant pedagogies, to promote multidisciplinary discourse and constraint negotiations [15].

Several researchers investigated the role that gender plays in design education and in forming design teams [16]. The results have shown that background and technical knowledge are far more important than gender and/or ethnicity. There is also a wide body of research in design practice and design learning on the use of psychometric measurement of personality type, such as MBTI, to analyze and predict the behavior and likelihood of success of teams in general [17,18]. Such techniques have been successfully applied to forming design teams in engineering classes, particularly the use of MBTI that has shown that better outcomes are achieved with teams consisting of members with complimentary roles, a plurality of viewpoints, and a neutral team leader [19]. Much effort has been devoted to furthering the understanding of individual influences on team behavior. More insight may be gained by exploring the relationship between personality and

learning style preferences [20]. Lent et al [21] have described the effect of *collective efficacy*, a team’s beliefs about its capabilities to work together, on the cohesion and satisfaction of the team. They found that negative feelings of *collective efficacy* may limit outcome expectations, requiring remedial steps to promote effective teamwork. Clearly, more research appears needed on applying set measures to analyze team behavior and to form teams, and on furthering the understanding of the impact of individual diversity factors on team performance.

PROJECT-BASED LEARNING

Project-based learning (PBL) begins with an assignment, to one or more students, to carry out specific tasks that would eventually lead to the arrival of a final product- a design, a model, a device and/or a computer simulation. The end result is normally a written and/or an oral report highlighting the main steps undertaken to produce the product and the outcome. (Note: the acronym PBL is also used to denote problem-based learning. But it is used here to refer to project-based learning). At the initial stage, there are two approaches: either the instructor chooses the project, which helps maintain a focus on course and curriculum objectives. The second is to allow students the autonomy to choose their own project: its general objective, its formulation and strategies and their approach to it, which, most likely, tend to increase students’ motivation and self reliance. Which is best? The answer is to be decided taking into consideration students’ prior experience, their skills, and students’ abilities to use available resources. De Graaf and Kolmos [22] define three types of projects that differ in the degree of student autonomy:

- **Task project:** Student teams work on projects that have been defined by the instructor, using primarily instructor-prescribed methods. This type of project is part of traditional instruction in most curricula, and results in minimal student motivation and skill development. It falls under traditional instruction as per most engineering curricula.
- **Discipline project:** the instructor selects and defines the subject area of the projects and specifies in general terms the methods to be used (involves common methods usually deployed in the subject area and usually known to students), but the students identify the specific project and select the method/approach they decide to follow to complete the project.
- **Problem project:** In this type of project students have complete autonomy to choose their project and their approach to it from beginning to end.

The common difficulty faced by students in a PBL environment is the ability to transfer methods and skills acquired in one project to another project in a different setting or discipline. Instructors should include such transference in their course objectives and should guide students to see connections between their current project and what they have learned previously, and gradually withdrawing this support as

the students gain knowledge and become more capable of seeing the connections by themselves. The instructors should also prepare students to fill in gaps in content knowledge when the need arises, taking into account the fact that such gaps are likely to arise in PBL than in conventional lecture-based instruction [22]. In essence, PBL addresses one of the key issues in the cognitive sciences, *transfer*, which can be defined as the ability to extend what has been learned in one context to other new contexts [23]. This is an important component of engineering competency development. While the design studio has long been a centerpiece of design thinking and pedagogy outside engineering, it took the medical community to lead engineers back to thinking formally about PBL and related pedagogies. Project-based learning at the individual course level is known in engineering education, having been used almost universally in capstone design and in first-year engineering courses and in courses that engage students in consulting projects. A few European schools, including the Universities of Aalborg and Roskilde in Denmark, and others in Europe and Australia, have made PBL the focus of most of their engineering courses [24].

The use of PBL in medical schools demonstrated that the first-year students were significantly better diagnosticians, i.e., practitioners, than those taught by lecturing [25]. Today, the professions are converging; engineering, medicine, law, and business are moving toward similar project-and problem-based pedagogic frameworks. The evidence is clear: that PBL encourages & supports collaborative work, and that it improves retention and enhances design thinking. However, there remains the need to extend the results already obtained and to demonstrate as well PBL's values in increasingly authentic design scenarios that typically include participation across disciplines, as well as across geographical boundaries [1].

Introducing PBL in the First Year: The first year design-oriented courses are similar to many capstone design courses, but differ markedly in their tendency to focus more heavily on conceptual design methods and less on discipline-specific artifacts (e.g., cars in mechanical eng., chips in electrical eng.), primarily because there are now many accessible sources of information, including textbooks, and also, because most first year students can do reasonable conceptual design without the detailed technical knowledge they acquire only later in their programs. In fact, there is a strong belief that first year design-oriented courses:

- Enhance students' interest in engineering as well increase students' retention in engineering programs;
- Motivate learning in upper division engineering science courses; and
- Enhance performance in design courses in general and in capstone design courses in particular

While there are different views of the proper metric for assessing retention, there seem to be enough data to support the thesis that a design course or a course that contains design elements- including projects, teams and written and oral

communication- can produce very positive changes in engineering student retention rate [25]. In terms of other measures of potential benefits of design courses, much data is available from various institutions. Purdue's EPICS program reports that students regarded team work, communication, and time management and/or organization as "the three most valuable things learned" from the EPICS course [26].

There is strong evidence that supports the statement noted above [27] including assessment data on the impact of PBL and design courses on student' benefits, general outcome, & future career [28]. Mills and Treagust [29] reviewed published evaluations of PBL programs in engineering and concluded that students who participate in PBL early on, are more motivated, demonstrate better communication and teamwork skills, and have better understanding of professional practice and how to apply their learning to real problems; however, some may have less complete mastery of engineering fundamentals, and some may have "second thoughts" about the time and effort required by projects and the interpersonal conflicts they experienced in team work, particularly with teammates who fail to devote the time and effort required to get the job done properly. In addition, if the project work is done entirely in groups, some of the students may be less equipped to work independently.

Intertwining PBL with Problem-Based(The Hybrid Approach): Curricula with high concentration of Project Based Learning intertwined with Problem Based Learning were assessed at the University of Louvain[30]. The assessment measures included pretests and posttests of students' basic knowledge, understanding of concepts and the ability to apply them. Also, students' self-efficacy, satisfaction with the curriculum, attitudes towards team work, instructors teaching practices, and the impact of the "*hybrid*" curriculum(*project/problem-based*) on the instructional environment. The results of the Louvain assessment are extremely supportive of the "*hybrid*" (*project/problem-based*) curriculum. Students in the "hybrid" curriculum expressed their satisfaction with the new curriculum, because: they received a lot of support from the instructors, saw more connections between theory and practice became more willing to use autonomous learning strategies, and were less reliant on rote memorization relative to students in the traditional curriculum[30] The positive outcomes for the "hybrid" curriculum-taught students is attributed to two main factors: factor one, is the great support received from their instructors; factor two, students' perceptions that they should work harder than students taught traditionally. Teachers in this study saw a positive impact of the "hybrid" curriculum on student competencies in team work, transfer of knowledge, and learning; the quality of student -teacher interactions and teacher-teacher interactions; and teachers' pleasure in teaching and their willingness to change their teaching practices to make it compatible with the new system they have adopted[24, 30]. The last two outcomes were particularly strong among teachers who perceived their administration to be supportive of teaching, in general, and

valuing teaching improvement in particular. This outcome has important implications for the critical role of college administrators in attempts to reform education.

GETTING STARTED WITH DESIGN COURSES, INCLUDING: PROJECT-BASED LEARNING

Once instructors are persuaded that design and design – related pedagogies are worth attempting, they face the question of which method to use, and when is the appropriate time to embark on the selected method(s). The answer, like the answer to any real question, begins with “it depends” ; it depends specifically on the instructor’s learning objectives, his or her prior experience with learning-centered teaching methods, instructor’s teaching skills and his/her willingness to acquire new skills when the need arises, and the availability of local expertise and support for each of the selected methods. Before teaching a topic or series of lessons using design-related pedagogy, the instructor should focus on *learning objectives* that define what the students should be able to do (search, calculate, derive, analyze, design, model, critique,...) after the course and/or instruction has been concluded. The learning objectives should guide the choice of focal points, learning activities, potential changes, and assessment methods. Once *learning objectives* have been defined, a suitable instructional method(s) may be identified. When the decision regarding the adoption of a method or methods, is made, the instructor should refer to relevant texts, articles, and Web-based resources on the chosen method(s) and take full advantage of experienced colleagues and teaching center consultants who can offer advice on implementing selected method(s) and dealing with problems that may arise with its use.

There is a clear need to expand the number of faculty members interested in and capable of teaching design including *project –based design* courses. The most important recommendation is that engineers in academe, both faculty members and administrators, make enhanced design pedagogy one of their highest priorities in future resource allocation decisions. In addition, there are ways of approaching design education that can offer systematic payoffs and help in setting up a framework for continuous quality enhancement [1, 2, 13]. These include the following:

- Encourage experienced design faculty to help manage the contextualization of engineering design theory and practice. This would not only bring invaluable experience into the classrooms, but would also alleviate the shortage of faculty who want to teach design.
- Adopt the idea that engineering design courses, and related courses, should be taught across geographically dispersed, culturally diverse, international networks [1].
- Challenge all engineering faculty to incorporate the tools of *design thinking* into relevant parts of the engineering curriculum.

- Alert the administration to the cost of lost human design potential resulting from the lack of investment in design pedagogy.
- Provide forums where design practitioners, design teachers, design researchers, and experts from industry to come together to discuss and collaborate on all aspects of design teaching.

Finally, design education represents both serious challenges and great opportunities for faculty, college administrators and stakeholders. On the other hand, it is clear that incorporating the elements discussed above will raise the cost of education (smaller sections, involvement of experts, etc.), but, on a macro, or global scale, these costs are small compared to the cost of lost human talent in the engineering pipeline. Design is what engineers do, and if proper steps are taken to improve design education, both students and the instructor should soon start seeing positive outcomes.

CONCLUDING REMARKS

On the whole, the intended move towards encouraging instructors to adopt *project-based learning (PBL)* seems farfetched and difficult to accomplish, especially in the initial stage. This is because time is needed for those undertaking the task to be trained to implement and gain the experience necessary to move the process forward. Time is also needed for other stakeholders to be convinced and provide the support needed to prescribe the change. Most importantly, those promoting the change must be able to show evidence that PBL is effective for engineering education.

It is highly recommended that an “Active Learning Taskforce” be formed of experienced faculty, to initiate, infuse, and oversee the progress made. Their determination, patience, and resilience are required to successfully promote college-wide implementation of PBL. Nevertheless, with clear intention, goals and plans of action, coupled with support from the highest level of the University’s key personnel, the Taskforce and other core groups, should be able to move the process forward. Success would almost be guaranteed, when a well-coordinated College-wide implementation of PBL is underway in other departments and colleges of the University.

Department of Engineering Education
Utah State University
Logan, USA

andreas.febrian@aggiemail.usu.edu¹, olawanto@usu.edu², matthew.cromwell@aggiemail.usu.edu³

Abstract—The potential of typical, handwritten engineering design journals to advance knowledge in engineering education is diminished by technical issues (e.g., readability and interpretability), writing lens (i.e., focus on the result not the process), and the ‘freshness’ of the events recorded. The authors argue that utilization of a novel online electronic-Journal (e-Journal) can overcome these challenges and open a new avenue to learn about students’ self-regulation within the context of engineering design. Work is underway to develop a system fulfilling this need. The resulting e-Journal is designed concordant with the engineering design phases: Problem Definition, Conceptual Design, Preliminary Design, Detailed Design, and Design Communication. The e-Journal enables the act of going back and forth between phases to support the iterative nature of engineering design. The online nature of this e-Journal ensures data currency because students can report their activities concurrently with design activities or at their convenience. Analyzing rich recorded data will enable researchers to learn about student’s activities in areas such as task interpretation, project planning and execution, monitoring efforts and design goals, and management of resources, time and teamwork as individuals and teams. Additional work will focus on the way the e-Journal is utilized within a two-part mechanical engineering capstone course and will analyze the obtained results after both parts conclude.

Keywords—engineering design, electronic journal; self-regulation

I. INTRODUCTION

Engineering education researchers are able to reap benefits from the analysis of engineering design journals (or notebooks) to learn about students’ self-regulation during their design process. Studies find that students with good self-regulation skills are inclined to be successful academically [1]. In engineering areas, higher awareness of thinking processes lead to better engineering design [2]. Consciousness of the cognitive process is not innate but rather a trainable expertise which is attained by those who seeking it. Meticulous investigation of students’ design process will lead to means for teaching self-regulation skills to all engineering students, which, in the long run, can improve the quality of graduating engineers.

One major obstacle for engineering education researchers in collecting meaningful design journal data is the incongruity between the researchers’ and students’ priorities. As designers,

students are interested in various design concerns and issues, e.g., experimental results, data sets, calculations, drawings, measurements, ideas, and thoughts. On the other hand, researchers are interested in students’ process of thinking through and solving the design problem, e.g., students’ interpretation of the tasks, planning, and how they monitor progress. Providing prompts to guide students’ in writing the journal entries could resolve these differences in expectations. However, some journal entries can be hard to read due to students’ handwriting. Additionally, student’s entries are highly contextualized to their project and tasks, which yield them harder to interpret. We argue that providing an alternative journaling system in a digital form could solve these problems.

An electronic-Journal (e-Journal) is conceptually similar to a physical design journal which serves to record students’ design notes, sketches, and drawings in digital form as students engage in these tasks. With the ubiquitous presence of mobile devices connected to the Internet, this journaling method provides a high level of access to the participants of the study along with 5 additional benefits: 1) prompts to guide entries can be provided; 2) minimization of handwritten data; 3) ability to collect various types of data (e.g., pictures, drawing packages, videos, and voice notes); 4) enabling concurrent access by team members, instructors, and researchers; and 5) improving communication among them. Having multiple data points (e.g., design artifacts and planning scenarios) will ease the interpretation process of contextualized reports. These features not only will improve the quality of research, but also enhance students’ dynamics within the group.

Our work utilized an open source project management system called Redmine [3]. This system was ranked first out of 21 other potential software platforms according to our criteria for a good e-Journal: being accessible online, having secured data connection and storage options, an ability to support multiple users and projects, a file management system, milestone arrangement, task tracking, custom form, and plugin system. Redmine is a cross-platform and cross-database web-based system, coded using Ruby programming language [3], [4] with a Rails framework [3], [5] which enables us to modify or add additional functions in a fairly uncomplicated way. We customized this software by installing additional plugins (e.g., Custom Field, Finance, and Contacts) and modified the core codes to create desired functionalities. We also developed

additional plugins to enable uploading digital documents and writing design journal entries. The web-based program was then used to collect data from the first segment of a two-part capstone engineering design course at a state university in the Intermountain West of America. A capstone course encompasses the practical application of students' prior coursework [6]. Capstone courses aim to teach professionalism [7] by providing experience of working on a real design project (e.g., assessing client's needs and create design requirements).

This paper discusses our e-Journal's features, user roles, workspace, student-system interactions, system's logging characteristics, collected qualitative data, method of analysis, and future work. The work presented here puts forward a framework for a system capable of obtaining a richer level of detail from engineering design journals than is currently available. Validating the use of online journaling resources can bring about a deeper understanding of the dynamic changes occurring within the design process and provide tools to help researchers explore the self-regulated learning of students and teams as they employ these tools to address design challenges.

II. CAPSTONE ELECTRONIC-JOURNAL

The e-Journal is being developed as a project management system and data collection tool for engineering students, design instructors, and educational researchers. This section illuminates important characteristics of our e-Journal in terms of features, roles, users' workspace, and student-system interaction. From here forward, for the sake of simplicity, the term e-Journal will be used to refer to our Capstone e-Journal.

A. Features, Roles and Security

In terms of functionality, the e-Journal consists of three modules, which are Design, Communication, and Finance modules. All are crafted to help students to finish their design project in a structured manner. Each module consists of several services. Access to these services is regulated by user roles, which will be explained further at the end of this subsection, after the discussion of each module.

First, the Design module is fashioned to provide services related to design activities: planning, monitoring, and reporting. Collecting design activity reports (or design journal entries) is its main service. Users are able to submit their design progress through a form, along with additional digital documents (e.g., drawings, text documents, or images). The module stores journal entries systematically based on submitted date, design phase, category of reported activity, and work breakdown item. The e-Journal accommodates five design phases, which are Problem Definition, Conceptual Design, Preliminary Design, Detailed Design, and Design Communication; these phases are adopted from [8]. Each phase has a different overarching goal, for example the goal in Problem Definition is to "clarify client's objective and gather the information needed to develop an unambiguous statement of the client's wishes, need, and limits" (p.24), while Conceptual Design's goal is to "generate concepts or schemes of design alternative or possible acceptable designs" (p.26). Hence users' activities for each phase are also different, e.g., activities in Problem Definition are clarifying design objectives

and constraints, while activities under Conceptual Design are establishing functions and design alternatives.

A part of the planning process is to populate design tasks based on their characteristics in a hierarchical structure that makes the tasks easy to be completed and managed independently [9]; work breakdown structure is suggested for such a purpose [10]. In the e-Journal, task breakdown is merged with task assignment and both are tied to a Gantt chart. In essence, for each breakdown item, there is an identical Gantt chart item. Having these items correlated facilitates in assigning team members to each item, setting start and end dates, and monitoring their team's progress whenever they want.

Second, the Communication module is fashioned to enable rapid exchange of relevant data among team members, by means of Forum, Wiki, News, and Activity History tabs with email notifications from each. This module takes advantage of the online nature of the e-Journal: it is accessible from anywhere, at any time and multiple users may access information concurrently. Team members are able to utilize forums to discuss design issues among themselves. Every user is able to start and reply to discussions. Unlike Forum, News is designed as one-way communication. A member of the team can use News to inform the rest of the group about a major breakthrough or issue within the project. A Wiki function is designed similar to Wikipedia; which can be used as a digital notepad or manual. A Forum, News, or Wiki post is capable of containing documents, images, or videos. The e-Journal is configured to send email notifications for every new post, which enables users to monitor their project via email, without having to log into the e-Journal. Journal entries are likewise configured, enabling users to get email notification for new design reports. The last service is Activity History, which displays reported activities in sequential order.

Third, the Finance module is designed to help users in tracking their income and expenses, but does not have transaction processing features. To set up access this tool, similar in function to a bank account or check register for their project, users have to fill in an account name. It is possible to set up more than one account for each project which could help users to keep track of and plan for transactions and varying sources of funding. This module is independent from the previous two modules discussed; hence automatic cross reference checking is unsupported. This module also comes with a service for listing contact information, e.g., their own, and that of suppliers, product vendors, document editors, researchers, and clients.

Accessibility of each module by different users is not equal, but determined by role. Excluding the Administrator, there are three distinct levels of access: Researcher, Supervisor, and Student. Student level access has full use of all three modules. Supervisor and Researcher have full access to the Communication module and read access for the Design and Finance modules. In addition, the Supervisor role is able to write comments for every financial transaction and had full access to the Contact service.

With security in mind, the e-Journal is configured to back up its data (i.e., uploaded files, self-reported texts, and system

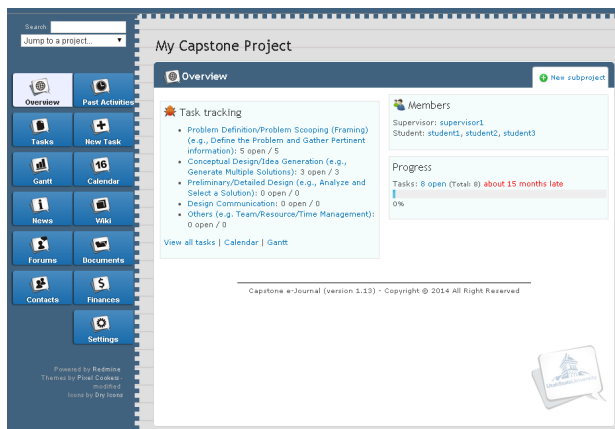

Fig. 2. The e-Journal workspace.

logs) automatically every Tuesday and Friday at 11:59 PM. Days and times were arbitrary selected. Updating is done rapidly, taking less than five minutes to export, compress, and back up e-Journal data to Cloud storage. Additionally, secure data transfer is available to those who wish to use it. Although the unlikely chance of machine and software failure exists, there were no losses of data and access to the most recent data was possible for a substantial portion of the project time frame.

B. Project Workspace

The e-Journal groups its users by project. The e-Journal system is able to host any number of projects and users. It is also possible to establish relationships within projects by partitioning it into several subprojects. A project may have more than one user working on it and a user can be assigned to more than one project or subproject. Within a project, it is possible for a user to have more than one role, but cannot be added without one. Therefore a relationship between a user and a project is a requirement of the e-Journal, otherwise user privileges cannot be assigned.

It is important to note that the e-Journal is not designed to replace the design process or help students to shortcut engineering work on their capstone project. Rather, it is designed to help them manage their project communication, document progress, finances, and collect artifacts, coordinate schedules, and manage finances, thus becoming a window through which to view traditionally internal processes. In order to use the e-Journal, students have to know their project (e.g., design statement, requirements, teammates, supervisors, and clients) prior to using it. They are able to apply for e-Journal accounts once they acquire that information. Applicants' registration will be executed as a group. They provide personal information, i.e. names, students' ID numbers, and primary email addresses. Summarily, after the administrative process of creating the associated project workspace, each applicant will receive an automatic email from the e-Journal which contains the applicant's username, password, project workspace name, and a direct link to the e-Journal.

The project workspace (Fig.1) is accessible subsequent to the login page. Users are able to access Design, Communication, and Finance modules from a panel on the left side of the interface. The number of blocks on the panel is

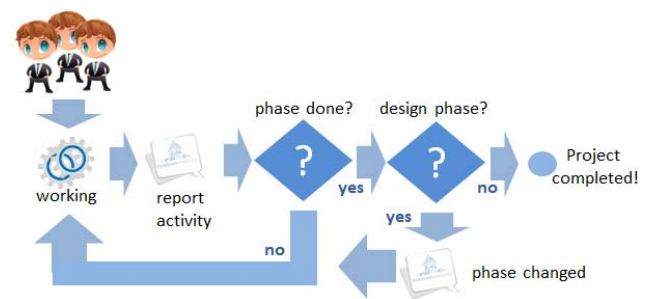

Fig. 1. Student-system's interaction flowchart.

generated based on the user's role. On the right, users can see identifying descriptions for his/her teammates, supervisors, and researchers. The process to register supervisors and researchers remains similar to students; they provide names, instructors' ID numbers, and institutional email addresses.

Although there is no specific client role, it is possible to include a client in the e-Journal. A client could be a person, a company, or even one of the faculty. A Supervisor role may also be given to him/her. However, if necessary, any new role can be added into the e-Journal. By including them, supervisors and clients are able to monitor students' progress, design and management issues, and interact with students in real time.

C. Student-System's Interaction

In this section we elaborate on routine interactions between students and the e-Journal in terms of design activities, which is illustrated in Fig. 2. Students' primary goal is to finish their project in a timely manner by working on their design tasks, either as a group, with a partner, or individually. The design tasks may be varied, including meetings, brainstorming, drawing, looking up information, calculating factors of safety, planning, or assigning group specific tasks and due dates.

Once the activity is finished, students write a journal entry about that particular activity. A reporting form with prompts is accessible by clicking the "report an activity" link on the Design module's main page. These prompts serve as guidance to write the journal entries. Six out of eight prompts are required an answer, e.g., "what did you do?", "what was the result of this activity?", and "how do you feel about the result?" Two operations are executed after the journal entry is submitted. First, the student will be returned to the Design module's main page. Second, notification emails about the new entry will be sent to all team members.

Having returned to the Design module's main page, students have a decision to make, whether they are done with their current phase (e.g., Problem Definition), or not. Suppose they choose no, their next option is to continue the working-reporting loop. However, if they decide to close their current phase (e.g., Problem Definition), they then have to complete three tasks before starting the subsequent phase (e.g., Conceptual Design). The first task is to set up carry-over access to prior documents needed for the next phase. Students are allowed to select attachments that they wish to retain access to. The second task is to confirm whether their latest results are valid. The third task is to fill out an Engineering Design Metacognitive Questionnaire (EDMQ) for that particular

phase. Lawanto, Butler, Cartier, Santoso, and Goodridge [2], [11] developed EDMQ to assess students' metacognitive strategies (e.g., task interpretation, planning strategies, and monitoring & fix up) on each phase and on overall team performance (i.e., teamwork, resources management, and time management).

Design processes are iterative in nature. In the e-Journal, iteration was accounted for by allowing students to return to any previous stage needed, e.g., a return to the Problem Definition phase, even when students have progressed to the Detailed Design phase. Reverting to an earlier phase is a regulation strategy, indubitably we required students to explain their reasoning for conducting this action. There is no instantaneous forward phase transition in the e-Journal, which means if we continue using the previous example, it is then necessary to at least pass through the Conceptual and Preliminary Design phases in order to return to the Detailed Design phase; but this is not a lengthy process.

Detailed design is not the terminal phase in the e-Journal. The final segment, rather, is the Implementation phase, which represents construction-heavy activities when the project's product is built. The activities that fall under this phase are building, testing, and improving design prototypes. Completion of this phase means that students have finished their capstone design course and are ready to deliver a finished product.

III. DATA TYPES AND METHOD OF ANALYSIS

There are three types of data collected: self-reported, system logged, and design artifact data. Each represents different aspects of students' engagement in their project and offers diverse insights into students' self-regulation. In this section, we elaborate on each data type and associated method of analysis.

A. Self-Reported Data

Self-reported data are defined as information which was consciously given by users on various e-Journal forms. There are at least nineteen self-report forms to be filled out within the e-Journal, e.g., to edit project descriptions, revert to a previous phase, and a financial transaction forms. In this subsection, we focus on two of those: the design activity report and Gantt chart forms. Both belong to the Design module (subsection II.C on page 3) and are described in subsection C on page 3.

The design activity report form is used to assess students' design activities, design results, feelings toward the results, teamwork, and an estimation of their task completion. Through data tied to specific design activities and results, researchers are able to learn about students' regulation strategies during every stage of the design process. This is important because it is plausible that students employed different strategies for each particular phase. By analyzing teamwork data, researchers are able to identify a person (or other instances) that triggered students' regulation, either their supervisors, clients, one of the team members, or a complete stranger. Conscientious analysis of a task's completion estimation will enable researchers to learn about students' ability to monitor their own progress. On a larger scale, meticulous study of design activity reports in

parallel with Gantt charts can explicate students' planning and follow up skills.

B. System Logged Data

This type of data is defined as that stemming from users interacting with the e-Journal and logged automatically. There are seven types of logged interactions, with each providing insight into different parts of students' regulation. In this subsection, we elaborate on methods of analyzing students' planning skills through system logged data.

Students' planning strategies are closely related to their Gantt chart, therefore each change made to the Gantt chart is recorded, e.g. adding tasks, deleting tasks, and revision of any other aspect of the plan. All internal system addresses that are accessed by users within the e-Journal are logged so that each user's time spent in the system is recorded. Analyzing this logged data enables researchers to describe the evolution of student planning in every stage, which illuminates students' strengths (e.g., planning or teamwork) or weaknesses (e.g., overconfidence, vague descriptions, and task breakdown that lacks in detail). By triangulating the Gantt chart log, design activity reports, and access log, researchers are better able to learn about students' planning, execution, and monitoring.

C. Design Artifacts

Design artifacts represent the design in a tangible way, either as CAD drawings, sketches, mathematical models, or tables and charts [12]. Artifacts are used as triangulation data; confirming that students are doing, or not doing, what they claim they did in the e-Journal, validating self-reported data and the research itself. In the e-Journal, students can upload their design artifacts in digital formats, either as word documents, presentations, 3D drawings, images, or calculations. Preliminary observations from the first portion of the class indicate that student use of the e-Journal yields unique data reflecting team involvement, distribution of effort and iterative actions within the design process.

IV. FUTURE WORK

Future efforts will focus on fine-tuning the way the e-Journal is utilized within a two-part Mechanical and Aerospace Engineering Capstone course and will analyze the obtained results after both parts conclude. Our goal is to improve e-Journal congruity with the class structure, dynamic and needs, which means to take user input into account, believing from a research point of view, that addressing these needs will increase data quality. We aim to make the e-Journal an integrated course tool available for validation by other users, while determining the extent to which student behavior reveals self-regulation in comparison to other methods in use.

cumming3@purdue.edu, ashafaat@purdue.edu, oakes@purdue.edu

Abstract—This exploratory study investigates design expertise through the lens of Robust Design. Robust Design is typically applied to manufacturing processes. Robust Design has the objective of minimizing the effects of uncontrollable noise factors on the output of the process or product. Designers achieve robustness through the control of design variables.

A coding scheme was developed from the conceptual framework of Robust Design, particularly investigating designers' awareness of noise factors and design variables. The dataset includes video and transcripts of working engineers in two conceptual design meetings. Protocol Analysis was employed on the transcripts of both meetings.

The Dreyfus model of expertise was applied to the observed behaviors. The designers displayed "competent designer" behavior in these meetings by identifying noise factors first and complementary design variables; this may be due to the moderator's problem framing to focus on a noise factor.

The result of problem framing and subsequent design activity can inform the development of undergraduate classroom interventions. Educational implications include 1) that instructors can advance students' design expertise by enhancing awareness of noise factors' and design variables' effects on the output and 2) that Robust Design can also be applied to cognitive design processes.

Keywords—robust design; expertise; protocol analysis

I. INTRODUCTION

Aerospace engineering as a culture seeks to reduce risk through the quantifying and reducing of uncertainty [1]. To that end, multiple design processes have been proposed in order to seek out sources of uncertainty earlier in the product's life cycle, one of which is Robust Design. Robust Design itemizes sources of variation and provides at least three methods for guaranteeing that the variations, though not eliminated, will not have disastrous impact on the product's performance, through the controlling and testing of design variables.

During the product design process, a set of the critical variables are the conditions in which the product is produced and implemented. The variation in these conditions will impact the product's performance. The essence of Robust Design is

that the product's consistency in performance will be improved by reduction of variations. Statistical quality control and optimization have formalized the concept into mathematical models. In this realm, Robust Design is defined as

"an efficient and systematic methodology that applies statistical experimental design for improving product and manufacturing process design. By making product and process performance insensitive to (robust against) hard-to-control disturbances (called noise factors), robust design improves product quality, manufacturability, and reliability at low cost" [2].

During the coevolution of the problem and solution spaces, designers are trying to meet the evolving requirements [3]. In this process, some designers may neglect variation of conditions. In other words, designers assume an ideal environment for product or process they are designing. The main reason for this negligence is lack of experience. Naïve designers fail in recognition of the variation in environment [4] since they are not familiar with the whole procedure. In contrast, competent designers' systematic outlook allows them to see the differences between the real world and the ideal one. They discern need for controlling conditions' variations. This perception of need and projected response should be assessed using a framework. Robust Design provides the framework that indicates the level of effort that designers put in defining the variation, their impact, and the control mechanisms.

What do designers recognize as sources of uncertainty? How do designers mitigate the impact of the identified sources of uncertainty? It is conjectured that as designers gain experience, they spontaneously identify and mitigate risk and uncertainty in design rather than ignoring uncertainty until externally prompted.

In this paper, we employ the concepts in Robust Design in order to understand designers' behaviors in a brainstorming meeting of working professionals. The data includes transcripts of two meetings. The Protocol Analysis includes an *a priori* coding scheme developed from Robust Design, along with a preliminary diagnosis of the entire team's level of expertise exhibited. The implications for aerospace engineering design education will be discussed.

II. CONCEPTUAL FRAMEWORKS: ROBUST DESIGN AND DREYFUS MODELS OF EXPERTISE

Two models from the literature provide lenses for understanding design and designers. First, in the aerospace engineering design context, Robust Design intends to reduce risk of failure by accounting for variations in the process or product, introduced through noise sources, through control of design variables, or items that the designer can control [5]. Second, [6] summarizes and adds to the Dreyfus model of expertise, also outlined in other work [4]. This model of design expertise identifies 7 or 8 levels of expertise along with ways of “perceiving, interpreting, structuring, and solving problems” [4]. An assumption is that a good designer would have an implicit goal to reduce risk of failure; therefore, the designer’s observable behavior would include identification of sources of noise and design variables as they affect the response of the process or product being designed.

The primary conceptual framework for this paper is Robust Design, presented as an overview and then expounded as three methods of design and experimentation [5]. The design process is presented with vocabulary oriented toward the machine, with only small reference to the user, but acknowledgement of the influence of the user is at least present. For the purposes of this work, the general understanding of Robust Design is sufficient because the data set involves only conceptual design but not experimentation or detailed mathematical modeling.

A general view of Robust Design is shown in Figure 1 below. The process or product at the center of the flowchart is the thing being designed. The response (right side) of the process should be equal to the target value (left side). The response is influenced by the design variables that the designers have control over, and influenced by the noise factors which the designers cannot control. The principle, then, is to mitigate the influence of the noise factors by adjusting the design variables and the process. Several categories of noise and examples are listed in the top left of the figure, with emphasis in this project on External Noise, such as Human Error.

A second representation of Robust Design’s concept of variation (noises) and its impact on the outputs (system performance), which the designers should control, is shown in Figure 2. This interaction (coevolution) should be controlled by the designers. With the consideration of the noises and control parameters, it is possible to create a designed product with less chance of failure and more consistent performance.

The secondary framework for this paper is Dorst’s interpretation of the Dreyfus model of expertise, as described in two different papers [4], [6]. Summarized are the two papers with 8 levels identified, though the later Dorst paper eliminates Proficient and adds Master and Visionary. Perhaps the titles of the levels are not as significant in this work as the column of Approach to Design Practice Description in Table 1 below. Key elements in this table that align with Robust Design are “makes plan” and “assesses risk” approach of the competent designer because of Robust Design’s intent to reduce risk.

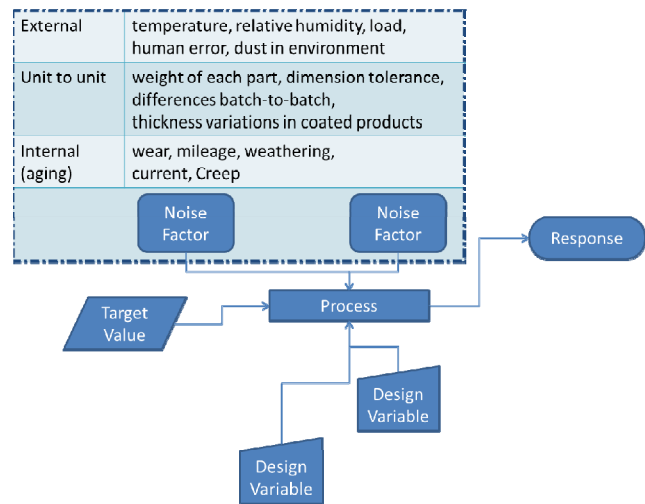

Figure 1. Overview of Robust Design, adapted from [5].

Figure 2. Objective of Robust Design, adopted from [2].

TABLE 1. ADAPTATION OF DREYFUS MODEL OF EXPERTISE [4, 6].

Level of Expertise	Approach to Design Practice	Approach to Design Practice Description
Naïve	Choice based	
Novice	Convention based	Consider objective features of situation, follow strict rules
Advanced Beginner	Situation based	Situational aspects important, sensitivity to exceptions to ‘hard rules’
Competent	Strategy based	Emotional attachment, trial-and-error, learning and reflecting, selects relevant elements, makes plan, assesses risk
(Proficient)		Immediately see most important issues, appropriate plan, reasons what to do
Expert	Experience based	Respond intuitively, perform appropriate action straightaway
Master	Create new schemata	
Visionary	Redefine field	

III. DATA

Working professionals in a company agreed to participate in a study as part of Design Thinking and Research Symposium 7. The data corpus includes 4-camera video, transcripts, and photographs of artifacts created in engineering and architecture meetings. The data set for this work includes

video, transcript, and artifacts of Engineering Meeting 1 and 2 where the design task is a thermal printing pen either as a toy or as a serious product [7]. This product is an internal TTP company project called Project Penny. The meetings take place in a conference room, with a projector as the central focus of the room, and a paper flipchart, about one fourth the size of the projection screen, to the right of the projection screen. The meetings were recorded using four cameras and they had access to flipchart, pens, and pencils.

Engineering Meeting 1 was prompted with a “homework assignment” as generated by a participant named Tony. The instructions included guiding topics: keeping print head level, protecting print head, print head activation, and print head angle. The participants were instructed to bring a product or picture of a product that glides smoothly over contours, which it appears that the participants completed. The data item here is the first 43 minutes of the 1.5 hour transcript. Early in the meeting, the focus of the meeting (as indicated by the gaze of the participants) moves from the projection screen to the flipchart, presumably because the intent of the meeting is brainstorming.

In the second meeting, a group of six engineers and one intern discussed product features, control and selection of user features, electronic architecture, and other applications. This conceptual design meeting duration was 100 minutes. The team members were discussing design of a thermal pen and its media. The pen has a small processor and memory, which can store pre-programmed patterns. At this stage, designers expressed more concern about the different applications of this product, its technical features, and possible extensions and developments.

Figure 3 shows the teammembers’ titles and their seating arrangement. Robert is doing his internship in the company and he is the project manager of the thermal pen development. He prepared some prototypes, which are not shown in the videos. The rest of the members are TTP employees. Data extracts relevant to Robust Design will be shown in the Results section of this paper.

IV. PROTOCOL ANALYSIS

Protocol Analysis is a well-established empirical research tool in studying the design process [8] [9]. A protocol is a piece of record of the time path of behaviors [10], which capture the content of the statements rather than the rationale of their occurrence [11]. Design protocols are usually in the form of recordings of designer’s behaviors, like sketches and audio-

Figure 3. Engineering Meeting Two seating.

visual recordings captured by camera [12]. This study follows the steps:

- (1) Develop the Protocol Analysis framework
- (2) Observe the design session
- (3) Code the video using the framework
- (4) Analyze the coding results to find the design trend.

The first iteration of coding the video and transcripts was inductive to “chunk” by topic of conversation. For subsequent iterations, the Robust Design codes were utilized in each chunk. The coder for Meeting 2 trained the coder for Meeting 1 and they coded independently.

The first iteration of chunking according to topic of discussion was completed using either the words of the participants or the coder’s summation of the topic. For example, Meeting 2’s lines 1 through 50 were coded as “introduction and ground rules”, whereas lines 89 through 106 were coded as “arm movement”, specifically from line 97 of the transcript. Key phrases that indicate a new topic include, such as in line 89, “the focus...at the moment... is...”, and line 158 “any other things that that sort of generated?” or line 271 “any other pictures?” These chunks are very much situated in the discussion at the moment, with concrete artifacts being examined as part of the group discussion.

The second iteration of coding included the items from Figure 1: Target Value, Noise, Response, Design Variable, and Process/Product. It is assumed that Response specifically and only refers to the resulting printed pattern of the thermal pen. The Process here is mainly the interaction of the user with the thermal pen in making a printed pattern. The Product here is mainly the thermal pen and its many analogies of existing products. These delineations and definitions of what fits into those codes only leaves Target Value, Noise, and Design Variable as the available codes for most of the transcript. A considerable amount of the transcript remains uncoded if it does not easily fit these codes, such as clarifying questions, jokes, repeats and one word interjections. The coded sections were analyzed and the exemplar findings are presented in the next section.

V. RESULTS

In Meeting 1 lines 1190 to 1268, the first topic is “controlling the printed pattern by using barcodes.” Here, designers try to evaluate the concept after they have reached a conclusion that using a barcode scanner can be helpful. They then try to expand the idea to make the tool capable of generating the entire image after scanning its barcode. It takes approximately 3 minutes for the design team to understand that the concept is not very useful. Table 2 shows the coded quotes for this topic.

The second topic is safety, a concern which was present in earlier conversations but was not discussed. It is in line 1130 that Rong-kai (approximately 1:04:30) asks about it and shows concern. From here to line 1189 (1:07), the design team discusses safety issues. It takes less than 3 minutes for them to consider what is needed to prevent the head from becoming very hot. The result of the analysis for this topic is shown in Table 3.

The third topic concerns the battery. Like safety, batteries and charging the device were concerns from the beginning of the meeting, as the terms appear in conversations in the first 30 minutes. The designers revisited this issue and started analyzing it in more depth in line 1428. However, the discussion deviated from the topic in line 1464. They again came back to the issue in line 1552 (1:23:30), with the discussion about energy ending in line 1716 (1:32:30), when Rong-kai showed concern about the device's noise. In total, these two topics are discussed for 10 minutes. The results of the analysis of this topic are shown in Table 4.

TABLE 2. EXAMPLE OF CODED TRANSCRIPT FOR THE TOPIC "CONTROLLING THE PRINTED PATTERN BY USING BARCODES".

Code	Description	Example
Target Value	Requirements that the product must satisfy like: Allows children to print a picture by scanning its barcode (Easier the better) Allows children to make their own patterns (Easier the better)	Kids would like that Course they will
Noise	Variation from the original problem space	...kids do not worry about the barcode.
Response	Performance of the product/process such as: How easy kids can use the device or How much kids love it	..for kids you can imagine designing really simple sort of click click click on the dots almost draw a picture and then generate the barcode for that
Control Variables	Reducing the variation and the variations' impact like: Using the barcode instead of complicated user interface	..put this barcode underneath the image so you know if they want it they scan it.
Product/ Process	The way the pen functions normally	..scan it with the side of the pen or something... or ...got a link to the PC but it's actually an electronic link...

TABLE 3. EXAMPLE OF CODED TRANSCRIPT FOR THE TOPIC "BURNING RISK".

Code	Description	Example
Target Value	Requirements that the product must satisfy like: Do not burn skin or papers (colder the better)	It wouldn't hurt you at all actually
Noise	Variation from the original problem space like: unexpected user behavior	Going into natural selection Or Wouldn't be any more harmful than eating a tin of whole crayons
Response	Performance of the product/process such as:	You might be able to do it erm just from the temperature of the carrier
Control Variables	Responses to the possible variation in the system., like: Having sensors or locks for turning down the device	Could you erm put some sensors... Or So some safety locks that sense when the time is wrong
Product/ Process	The way the pen functions normally	Press down to make the head-...-come out so head will come out retract and not

TABLE 4. EXAMPLE OF CODED TRANSCRIPT FOR THE TOPIC "BATTERY AND POWER SUPPLY".

Code	Description	Example
Target Value	Requirements that the product must satisfy like: Heat up the media (faster the better)	...you wanted a hundred and eighty dpi quickly
Noise	Variation from the original problem space like: Speed of the pen	...either quickly or slowly its going to heat it up
Response	Performance of the product/process such as: Cost of the pen including battery	...it will be a bit on the faint side
Control Variables	Responses to the possible variation in the system., like: Limiting the voltage in specific range so variation cannot impact the system	...because rechargeables are the worst because they're low voltage aren't they?... Or ..but if you're driving into a two amp resistor-
Product/ Process	The way the pen functions normally	() is constant it doesn't matter as you increase speed or increase (size)

In Meeting 2, the design team identified target values straight away, but without assigning numeric values: angle, grip, heat, feedback to the user, and force or pressure. The conversation in the 43 minutes of coded transcript circulates around these target values. It is no surprise that the conversation focuses on these items, especially since the moderator identifies the problem of "the wobbly arm movement of the users... five to eleven years olds" in line 97 and 98. The moderator further defines the problem as two problems "the printout needs to stay in contact with the thermal print paper to actual print" in line 101 and "printout needs to stay in the right angle to print" in line 103.

Throughout the 43 minutes coded, the design team identified a large number of design variables, or items that they could control in order to achieve the target values or account for the noise factors. For the angle of the print head, they identify the shape of the base (line 141, line 160), a universal joint or a gimbal. For the grip, they identify the relative size of the pen (line 171), a grip that feels right, or even a joystick. For the heat source, they consider a battery source, switches, and detection of heat. For feedback to the user, they identify a projected image (line 652) and a grip that feels right (line 777). For force or pressure, they identify pressure sensors and springs. For following a contour, they identify tracking capability, ball bearings, rails, and suspension. Of course, these items are not solely linked to the target value listed, but can have interacting impact.

The team identified noise factors beyond the problem of wobbly arms. They identified a difference between hand grip and using a joystick. They identified left and right handed influences (line 783). They identified intentional jerking movements. They identified overheating or going cold (line 247). They identified the desire for the user to lift up the pen to check the results (lines 672, 674). They identified holding the pen the wrong way, which may result in the pen leaning. They identified non-standard pencil-holding form of the hand (lines 719, 270).

Several things the team identified do not seem to fit well with the Robust Design coding scheme: the user giving up, the user feeling patronized by the feedback (line 697), or the user not recognizing feedback as a comforting sound or feel (line 700). However, these effects could be considered as a failure if these effects cause the potential users not to buy or use the product. Alternatively, the design team identifies the product as potentially teaching a skill, such that the user might have a sense of achievement (line 373).

VI. DISCUSSION

The items identified by the design team in the Results section shed light on their design expertise. The design team in a short time identified noise factors and then immediately identified design variables to mitigate the impact of the noise factors on the product's response. Of course, the problem framing by the moderator as a problem that needs control certainly helps the design team get into the mindset of designing in robustness. Then the team's quantity of design variables in qualitative terms is considerable. They demonstrate an awareness and mitigation of risk without excessive prompts from their moderator. They also identified not their own emotional attachment to the product, but the likely impact of the product on the user's emotions. These behaviors align with a competent designer in Table 1.

The design team basically stayed within the bounds of an electrical solution rather than a mechanical product. The design variables identified included heat source, sensors, light, noise, and feedback in the electrical domain. Mechanical elements as design variables included shaping such as finger holes for a proper grip. The constraint away from a mechanical solution, such as the rubber stamp wheel and inking pad proposed in lines 391 to 428, perhaps constrain the team from proposing something radically different, which might limit the ability to see Master and Visionary design expertise levels.

There are a few items that the team does not appear to do. First, the design team did not spend much time defining the response of the product, which is the printed pattern it should make. There is slight reference to varying a pattern, to color density, and to thickness of lines. Perhaps the team assumes that controlling the inputs is more difficult than defining and modeling outputs. Second, the team did not mathematically quantify or mathematically model much of what they discussed. There were few attempts to assign numerical values or units to heat, speed of movement of the product across the medium, battery life, or temperatures. Perhaps these behaviors are more explicitly demonstrated later in the design process.

VII. CONCLUSIONS AND IMPLICATIONS

The Robust Design framework showed significant potential for communicating uncertainty, coding the risks and mitigation process as well as for technical reasoning and iteration. In Meeting 1, three topics have been coded using the framework. The first two topics were about the operation process in which users play a significant role. Since the users' behaviors are not completely predictable, the system should be robust in order to continue performing, even under extreme conditions. The

designers' responses to this need were captured using the Robust Design framework. The third topic focused mainly on "control variables", "Product and Process", and "Response" spaces. In that portion of the meeting, designers evaluated several options by looking at the way that system would perform and what the control factors would be. Therefore, we have shown that this framework is able to code the designers' communications about variations and risks and makes the protocol capable of evaluating and then differentiating among designers based on the time and effort they spend at different spaces (noise, control, target value, response, and product/process).

We also have shown that this framework will be beneficial in coding the detailed design process because in detailed design, dimensions are clearer. In detailed design, when designers are discussing the target values, they use boundaries and when they are talking about control variables, they mention the limits using numbers or other technical language. In conceptual design, sometimes it is difficult to distinguish transitions between control and target, and between control and response. This is because they are talking about several options with different limitations and different performance levels, so they have to go back and revise the target value and change the applications of the device.

There are educational implications from this exploratory study of working professionals that can be applied in the classroom. First, ahead of the second meeting, the moderator set up a homework assignment and some ground rules for the brainstorming session, which provided the atmosphere and artifacts to elicit robust design thinking. By introducing a noise factor as the problem to solve, the design team set to thinking about items that they could and could not control, with special attention on mitigating the uncontrollable elements. Second, a team of designers instead of an individual designer brought multiple perspectives for noises and for design variables. Third, the layout of the room with the flipchart or common drawing surface being far removed from the participants probably had an effect on the mode of communicating ideas from sketching to verbal, which may be beneficial for transcription but perhaps not beneficial for collaboration.

For researchers, further studies of design meetings, using the lens of Robust Design, can enhance our understanding of Robust Design thinking as a cognitive process in addition to manufacturing processes. Researchers can continue the work of discovering cognitive processes in order to inform curriculum. This may help bridge the gap of students' transition from the classroom to industry, especially in the manufacturing processes [13].

For educators, a lesson from these meetings is to train students to collaborate respectfully by setting ground rules, to welcome multiple perspectives, even those perspectives that challenge theirs, to think ahead for planning activities of design meetings, to consider different scenarios creatively, and to communicate verbally and visually. Overall, 1) a more robust product may be developed and 2) students' design expertise can be advanced through an intentional focus on Robust Design.

ACKNOWLEDGMENT

The authors would like to thank Dr. Robin Adams for the advice, encouragement, inspiration, and data to complete this paper.

Abstract— Student designers and professionals alike have difficulty accessing appropriate analogies for design problems. Recognizing the advantages of Design-by-Analogy (DbA), the Design-Analogy Performance Parameter System (D-APPS) tool was developed to include a library of analogy entries and a matching algorithm. These components are combined into the Design Repository & Analogy Computation via Unit-Language Analysis (DRACULA) software package that maps functions across domains in order to present analogies to designers as initiated through engineering performance metrics and critical functions. Most tools developed for DbA emphasize the searching by function feature. Since analogies are based on more than function, DRACULA incorporates both performance and function for the user to identify relevant analogous solutions. Prior to exposing engineering students to this tool, we investigated their ability to use analogies when crossing domains. During this process, we identified three function concepts to be vital for students to effectively use analogies across domains: reoccurring functions, critical functions, and mapping functions. The results establish a better understanding of the information that students utilize in order to formulate appropriate and creative analogous design solutions.

Keywords— *design-by-analogy, engineering education, functional modelling, mapping functions*

I. INTRODUCTION

Through academic efforts, engineering curriculum aims to prepare students with a developed and extensive skillset in order to provide them with the means to successfully implement their knowledge in innovative and real-world applications. However, the challenge arises for the need to equip these engineers-in-training with the ability to understand both concept and application. Analogical reasoning or Design-by-Analogy (DbA) presents this opportunity for growth within the engineering domain. Amidst the complexity among the engineering domains, Design-by-Analogy offers the prospect of alleviating the barriers and potential design fixations associated with crossing domains.

In designers' attempts to tackle engineering problems, plausible solutions can be discarded or remain untouched

early in the design process. During these early stages, designers can access multiple tools that can aid in concept development and idea generation. Of the many tools that are available for designers to use, functional modelling is one that allows designers to decompose a design problem into specific functionality as per a generalized taxonomy, the functional basis [1]. This generalizable decomposition introduces and pinpoints areas of innovation. It is in these areas of functional innovation that the Design-Analogy Performance Parameter System (D-APPS) tool can offer potential analogies. Integrating the D-APPS tool with the Design Repository & Analogy Computation via Unit-Language Analysis (DRACULA) software package seeks to provide analogies of similar functionality to design engineers and to employ the use of engineering performance metrics in a quantified manner. DRACULA consists of a repository, a matching algorithm, and an interface that returns alternative solutions.

Through the initial research in developing DRACULA, three function concepts were identified: reoccurring functions, critical functions, and mapping functions. For the purposes of the paper, functions are active verbs denoting an operation in a design process. The reoccurring functions are the functions that are commonly utilized throughout the various domains. Critical functions are the functions that are crucial for solving a specified design problem and defining the functionality of the product. Mapping functions are the functions that are favorable for determining appropriate analogies when crossing domains. Prior studies sought to validate the existence of reoccurring and critical functions [2-4]. During these studies, the concept of mapping functions surfaced. The process and initial findings regarding mapping functions are presented in this paper. It is important to note that these three function concepts are not mutually exclusive. There is overlap between them. This overlap introduces opportunities in building up the DRACULA repository in such a way that magnifies the potential for students to employ analogies across domains while reducing the potential for design fixation.

II. BACKGROUND

A. Design by Analogy (DbA)

To alleviate the effects of design fixation for students, analogies can offer alternative solutions to a design problem. When solving design problems, analogies provide engineers with latent analogical solutions based on a linguistic or visual portrayal of the design problem and description. Visual analogies are also useful in increasing the innovation of the design solution for both novice and expert engineers [5]. However, experimental results show that experts employ more analogies than novices [6].

Further experimentation has focused on using analogies as a means of improving design innovations [7-9]. In seeking innovative design solutions, human reasoning utilizes analogies through adhering to the design process, where the student polls their memory for source analogues. The student designer searches his or her memory and finds analogies that are comparable to the original problem. The connection between the design problem and the analogue can be established based upon experiences and memories. The final step is to develop the final design solutions using all of the analogical inputs.

To use analogical inputs in the design process, a repository of knowledge is required. Unfortunately, student and novice engineers do not have as robust of a repository as experienced engineers have due to an expert's wealth of experience that comes through practice. However, novice engineers are more willing to utilize previously employed technologies or solutions in their designs [5]. Because novice engineers do not always realize analogies to their fullest extent, they only partially reap the benefits proffered by abstraction.

B. Functional Modeling

Innovation can be engendered by functional modelling where a product is broken down into sets of functions that comprise the final tangible solution. When approached from a systems (top-level hierarchical) methodology, the sequential grouping of requirements for certain functions or subsystems (lower-level hierarchical) can lead to the same final functionality simply encased in a different form. In particular, function structures allow for the functional representation of a product using the system concept, as demonstrated through individual function boxes and flows. Function structures allow for a level of abstraction to be incorporated into the product design. Pictorially, the function and flow combinations allow for a form-independent solution that meets the design requirements. While the design progresses, the form becomes more function-dependent, and student designers can establish the specific nuances of the product in greater detail [10].

The function structure methodology requires breaking the functionality of the product into individual purposes or sub-functions. Graphically, the individual purposes are functional boxes with flows as both input and output arrows. Each flow is a material, energy, or signal that becomes pertinent to the operation of the box as derivative-notation, in a mathematical sense.

1) Functional Basis

Otto and Wood [11] proposed a defined taxonomy that can be used across multiple engineering disciplines and applications. This taxonomy was developed and refined in an attempt to aid functional modelling methods by utilizing a generic level of specificity and synonyms, also known as functional basis [1]. In this functional basis, the verb-object combination correlates to the function-flow relationship of the individual purposes. This vocabulary can be used in conjunction with the function box diagram aforementioned.

Within functional basis, functions are verbs that necessitate a specified action at a certain point in the requirement sequence. Consequently, the functions are formulated and generalized into a hierarchy of eight classes: channel, support, connect, branch, provision, control magnitude, convert, and signal. More specific functions result from the further decomposition of these eight classes. On the other hand, flows are the noun or form that coincides with this verb. Flow taxonomies can be broken down into three levels of general abstraction: material, energy, and signal as mentioned previously. As with the functions, greater levels of specific abstraction are the result of the decomposition of these three flows.

C. Functional Classification

Through the contributions of several universities, a design repository has been initiated as the basis for this work. The synthesis of the function structures in the repository led to the concept of various function classifications external to the class structure devised by Hirtz et al. [1]. This research broke down the functional modelling utilizing functions and flow based upon functionality. This functionality was derived from specific design problems possessing the potential to provide analogies for the same functions and not just linguistic similarity. The critical functions, reoccurring functions, and mapping functions are all subsets of the functions. As such, the relationship between these three function concepts is demonstrated in Figure I. The repository for providing analogies will be populated from the intersection of the critical and reoccurring functions.

1) Reoccurring Functions

Reoccurring functions are those functions that are most commonly used to model design problems in and among multiple domains. The reoccurring functions are domain specific and do not traverse boundaries as per analogical mapping. These functions are the most frequently represented functions and do not hold any specificity to the design problem. When solving design problems, student designers will more frequently use these functions to decompose the given problem, regardless of the domain for which the students are solving the problem in. For example, a student might decompose the design of a pulley system to include the function and flow combination of "import energy". This same combination of "import energy" can be utilized in efforts to decompose the design of a lamp. The pulley is in the mechanical domain whereas the lamp is in the electrical domain. Although the pulley and lamp are in different domains, the function "import" can be commonly

incorporated into the functional decomposition of each product.

2) Critical Functions

Although reoccurring functions are commonly used in functional decomposition, this general subset of functions is not necessarily vital to the product's performance. Critical functions are those functions whose performance directly relates to a Key Performance Parameter (KPP) or over-arching purpose of the product or system as a whole. These functions are crucial in decomposing the product into appropriate subsystems that still successfully represent the overall system. The premise behind this concept is that not all functions hold the same level of importance in satisfying the KPPs. The KPPs are problem specific and are akin to the over-arching system-level black box model in functional modelling. Though critical functions can be made from reoccurring functions or mapping functions, critical functions are not explicitly defined by either reoccurring or mapping functions. Instead, the critical functions are problem specific and are the corner stone for this research.

III. MAPPING FUNCTIONS

Design-by-Analogy promotes design creativity and innovation [12, 13]. Innovations are either implicitly or explicitly considered when recognizing analogies. A formal definition of mapping functions is proffered as:

Mapping functions are the general subset of functions that are most conducive for successfully mapping analogies across domains in a specific design problem as laid out by functional modeling.

The differences and similarities between critical functions and mapping functions must carefully be addressed. Mapping functions behave differently in their use and purpose. Regarding domains, mapping functions act across domains in order to provide analogies which thereby indicates their lack of domain specificity. These functions illustrate the similarity between the original inspiring analogue and the analogous solution. On the contrary, critical functions are essential to the development and use of a product. Despite this difference, a mapping function can be a critical function for solving the design problem, as demonstrated in the overlapping region in Figure I. Therefore, for a given design problem, a mapping function may or may not be a critical function, and a critical function may or may not be a mapping function. The advent of mapping functions originates from the results of the following empirical pilot study and product study.

A. Empirical Product Study

This research corresponds with the study run by Ngo et al. [2] who conducted a pilot study to investigate patterns that designers use when mapping out functions for design analogies. Because of the coalescence between mapping functions and the study run by Ngo et al. [2], it is important to evaluate wherein lies the extraction of mapping functions through process that Ngo et al. follows. The process for the pilot study investigation follows that of an empirical product study, as shown in Figure II. By utilizing an empirical study, the research sought to investigate the claim that inventors

will focus on certain critical function to the design problem when developing analogies. Investigating this, the study aimed to compare the critical functions of a product to the critical function of the product's respective source analogy, as pertaining to the black-box functional models. Results from the pilot study instigated further experimentation in a full-scale product study, which will be addressed later in this paper. When viewing the outcomes of both studies, the analysis suggested the presence of mapping functions in design.

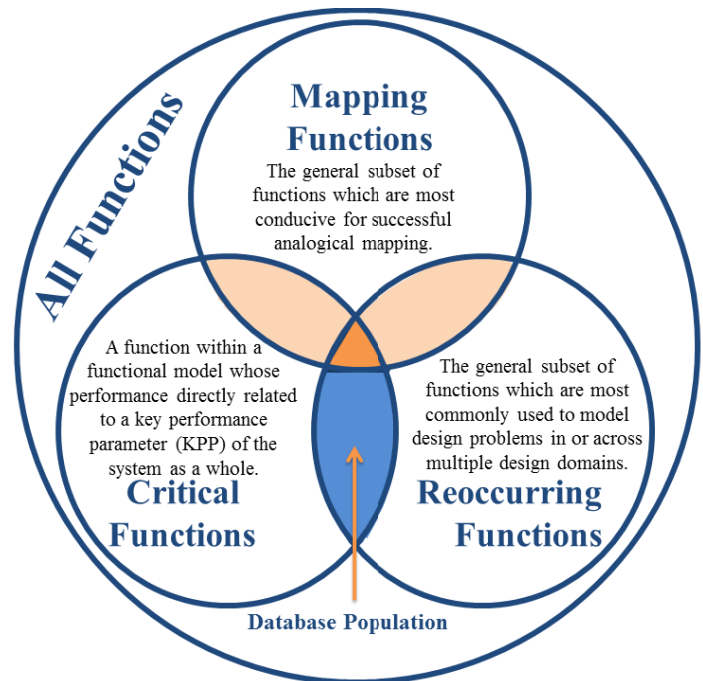

FIGURE I DESIGN SPACE FOR FUNCTIONS THAT STEM FROM FUNCTIONAL MODELING.

1) Example Collection and Screening

Prior to the pilot study commencing, the researchers searched for already existing products that were inspired by analogy. After searching through a wide range of sources, a commercial product collection was compiled to include 77 product examples. These examples were screened to ensure they were in fact inspired by analogy; as such, this resulted in removing 20 examples from the collection in order to give a total of 57 product examples that would be presented to the participants of this study. A more descriptive account on the specifics of the screening process can be found in Ngo et al.'s work [2].

2) Classification

While the pilot study primarily sought to investigate the claim that inventors focus on particular critical functions, 5 classification variables were applied to the design processes that are utilized when creating the analogy-inspired products [2]. A classification variable is a variable that depends on features of the given product, the inspiring analogy, or the design process to characterize the examples provided. The 5 classification variables used are as follows:

1. Critical Functionality and Performance:

Recalling that a critical function corresponds to the purpose of the system, the method for identifying the critical function originates from the method demonstrated by Otto et al. [11] with the Functional Basis. However, the detection of critical functions was discerned by Lucero et al. [3] as being both problem and domain specific. For each critical function, we needed to identify the system's complementary solution and performance effects. In other words, the critical function is the need, the system's solution is how the system solves that need, and the system's performance effect is the how the system's performance changes (i.e. durability, simplicity, maneuverability).

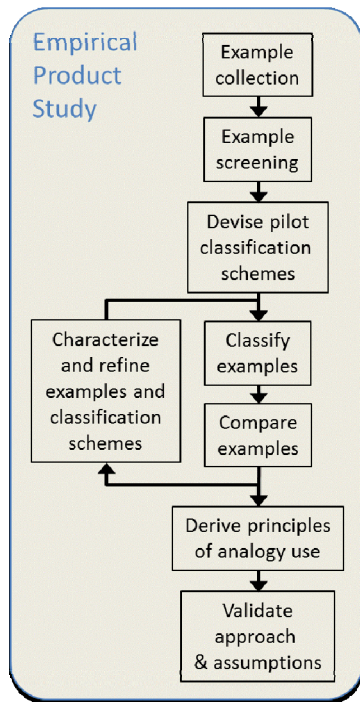

FIGURE II THE EMPIRICAL PRODUCT STUDY METHOD USED FOR PRODUCT EXAMPLES INSPIRED BY ANALOGY AS PRESENTED BY [2].

2. Main Benefit of Analogy Usage:

In design-by-analogy, the analogs inspire innovation. The main benefit of analogy usage establishes the primary contribution that an analogy inspires in an innovative product. There remain three benefits for design-by-analogy:

- **Function-benefit:** The analog inspires a new way of accomplishing a task.
- **Performance-benefit:** The analog inspires a better way of accomplishing a task.
- **User Interaction-benefit:** The analog inspires a new way of user interaction for accomplishing a task.

3. Analogy Difference Level:

Although the analogy inspires changes in the product's design, recognizable differences exist between the analogy and the product. Based on a low, medium, and high relation, these differences occur in the following areas:

- **Critical Function:** The product or analog's main purpose or function.
- **Construction:** The product or analog's physical configuration: material and geometry.
- **Operating Environment:** The product or analog's surrounding environment and conditions.

The low, medium, and high scale derives from counting the number of areas that the analogy and the product are different. When the difference is in 1 area, we assign the variable to have low-difference. With difference in 2 areas or significant difference in 1 area, we designate a medium-difference to the variable. As such, a high-difference occurs when there is difference between the product and analogy in 3 areas or significant difference in 2 areas.

4. Inventor's Primary Field of Work:

Recording the inventor's main area of work aimed to determine if their primary field of work impacted their analogy usage causing cross work domain differences to occur. The primary work fields were given as:

- **Academic:** This includes professors and students.
- **Commercial:** This includes companies and entrepreneurs.
- **Military:** This includes government affiliated laboratory researchers.

5. Analogy Origin and Driving Approach

During the design process, the context for how and why the analogy is used pertains to the driving approach. Analogies are not arbitrary used when mapping functions, but rather can be applied in two potential manners.

- **Solution-driven approach:** The designer understands a system or phenomena that can be used as an analogy, recognizes a design problem, and identifies the analogy to be the solution to the design problem.
- **Problem-driven approach:** The designer recognizes a design problem, identifies a system or phenomena to be used as an analogy the solution to the design problem,

and fully understands the analogy being used.

3) Mapping Functions in the Pilot Study's Results

In order to analyze the analogy and product features, Ngo et al. [2] counted the number of examples regarding the criteria for each categorical variable, summarized this information into a contingency table as found in Table I, and recognized existing patterns in the data. Of the patterns found through the analysis, two patterns insinuate and validate the existence of mapping functions.

1. Critical Functions: Typically, inventors duplicate one or two of the analogue system's critical functions into their products.
2. Driving Approaches: The identifiable driving approach used for analogy mapping impacts how the analogy is incorporated into the design process.

TABLE I CLASSIFICATION SUMMARY OF THE PILOT STUDY [2].

Classification variables and labels	# of examples
Critical Function Matching	
Identical - One critical function	17
Identical - Two critical functions	4
Different - Inverted	1
Different - Other	2
Total	24
Analogy Benefit	
Function	30
Performance	24
Interaction	3
Total	57
Analogy Difference Level	
Level 1 – Low-difference	47
Level 2 – Medium-difference	9
Level 3 – High-difference	1
Total	57
Inventors' Field of Work	
Academic	32
Commercial	24
Military Research	1
Total	57
Driving Approach to Analogy Mapping	
Solution-driven	9
Problem-driven	4
Total	13

4) Critical Functions

Of the 24 varying analogy examples, results demonstrated 28 identifiable product and analogue critical functions pairs. For the 25 identical critical function matching pairs, we realized that there are not only critical functions, but also functions that allow for analogue mapping to occur. Since critical functions cannot be mapped across domains, these limitations on critical functions imply that certain functions exist that surpass such limitations. As such, the presence of functions capable of being mapped between domains signifies that mapping functions are a valid conjecture.

Since the results suggest that inventors directly transfer critical functions from analogies to products, further speculation insists upon the existence of mapping functions.

To address these phenomena, we reviewed the latter portion of the content of the pilot study and designed a study to include human participation for data analysis

5) Driving Approach

From the pilot study, we re-examined the design process associated with the 13 products that had originally been investigated in efforts to determine the approach that inventors took for analogy mapping. The results of this effort can be found in Table II. As demonstrated, the solution-driven approach outnumbers that of the problem-driven approach by 9 products to 4 products. Additional results from this study indicate that: academic inventors gravitate towards solution-driven approaches whereas commercial inventors remain balanced in their approaches; problem-driven approaches tend to produce less performance beneficial analogies than function beneficial analogies whereas solution-driven approaches maintain a balance for analogy benefits; the analogy difference level does not depend on the driving approach that the inventor takes [2]. In the follow-up study performed by Ngo et al. [14], the inventor's occupation presented no correlation to the approach taken.

This analysis indicates the difference in the driving approaches influences the design process and the success of the design. In design-by-analogy, inventors travel down different avenues in their pursuit for innovation and design fabrication. In one path, the inventor already has inherent knowledge of a system or phenomena and applies their knowledge by means of an analogy in order to formulate a solution to a design problem; otherwise, this is known as a solution-driven approach. For the alternative pathway, the inventor knows of a design problem and seeks the solution through researching and applying potential analogies. This correlates to the problem-driven approach. Both approaches require mapping between domains.

TABLE II DRIVING APPROACHES VS. OTHER CHARACTERISTICS [2, 14].

Driving Approach	Field of Work		
	Academic	Commercial	Military
Solution-driven	5	4	
Problem-driven	1	3	
Driving Approach	Analogy Benefit		
	Function	Performance	User Interaction
Solution-driven	5	4	
Problem-driven	3	1	
Driving Approach	Analogy Difference Level		
	1- Low	2- Medium	3- High
Solution-driven	6	3	
Problem-driven	3	1	

In each approach, mapping functions initiate the response of the inventor. For the solution-driven approach, the inventor recognizes how certain functions within a system can be applied as functions in solving a design problem. These specific functions (aka mapping functions) allow the designer to acknowledge the similar functionalities between the product and analogue domains. As with the problem-driven approach, the inventor pursues a solution to a design problem. In their pursuit, they search to match functions of

the desired product to that of an applicable analogy. Once again, the inventor heavily relies on the ability to map functions between domains. Evidently, mapping functions are essential for the inventor's ability to successfully implement analogical mapping. The mapping functions lead the designer to recognize inherent similarities between a product and an analogy.

6) Follow-up Study

In a follow-up study, Ngo et al. [14] compiled a collection of 70 products inspired by analogies for a larger cross-sectional empirical product study and analysis. In this study, two additional classification variables were incorporated for measuring the benefits in using analogies in design: additional function and improved performance. Additional function refers to a supplementary capability that arises in the participant's analogous product and not in the original functions associated with other existing products [15]. Moreover, improved performance signifies the analogy-inspired product's ability to exceed the initial functions of similar contemporary products. Integrating these variables into the analysis, subsequent results revealed that 90% of the analogy inspired products demonstrated improved performance in shared functions and 21% utilized additional functions when compared to similar products that did not utilize design-by-analogy.

We hypothesize that a majority of student designers who use analogies in analogous mapping will produce products with improved performance. However, designers will likely refrain from instituting additional functions to their innovative product. Nevertheless, during this process of mapping across domains, these results suggest that the student designer seeks to identify certain mapping functions which will not only allow them to develop an analogy-inspired design but also a product with enhanced-performance. In utilizing mapping functions, inventors have the ability to match functions across domains while producing more successful products.

IV. STUDY

A classroom study was performed to investigate the use and identification of mapping functions by engineering students. Mechanical engineering undergraduate students in a design course at Clemson University participated in the study. In this one semester course, students were trained in the engineering design process outlined by Otto and Wood, and also taught the functional basis for functional modeling [11].

A. Method

A specific in-class assignment was employed for use in understanding how students use mapping functions in the design process. Students were each provided with a function

structure for a fruit/vegetable peeler as seen in Figure III for problem contextualization. The customer needs for the peeler product included a portable device that shields the operator from potential harm during use. Students were given different functions and a single flow type for their assignment. They were asked to provide analogies for the same action of the function on the flow. The assignment asked for any action that performed the same function to the listed flow. Directions for the assignment were given to the students as: *"You have been given three functions and a single flow type. You are to provide analogies for the same action of the function and flow. Provide any action that can do the same function to listed flow. For example, the 'Guide energy' function can be analogous to trees sucking up water through capillary action. You may use analogies from any other domain and can use your phones or other devices to look up analogies."*

The students were each provided with a table template of paired "function + flows", an "analogy" column and a "rationale" column. Students were verbally instructed that this was to be an individual assignment to be completed without the use of external sources such as mobile devices or books. The instructor emphasized the desire to have as much creativity in the responses as possible by encouraging open-ended responses. Students were told there were no "correct" answers and their assignment would be graded as a participation credit.

B. Results

Provided with the given design problem, students' responses were categorized by function and analogy in order to determine their ability to produce analogies when provided with a function. Looking at the four potential functions that the students were asked to identify analogies for, convert, dissipate, position, and regulate, demonstrate relative equality in initiating analogies within the students' responses. As shown in Table III, the students who were able to create an analogy for convert was 76%, for dissipate was 64%, for position was 61%, and for regulate was 72%. This demonstrates that 24-39% of the students were not able to successfully generate analogies using the provided functions. Students and novices clearly require more support for generating analogies. Through additional analysis, the number of ideas generated was compared with the number of analogies produced, as demonstrated in Table IV. This shows that of the ideas generated for the convert, dissipate, position, and regulate functions 69%, 55%, 51%, and 64%, respectively, were analogies. Once again, the ideas generated that were not analogies ranged from 31-49% for the provided functions. This demonstrates the students' ability to utilize mapping functions when using analogies to cross domains.

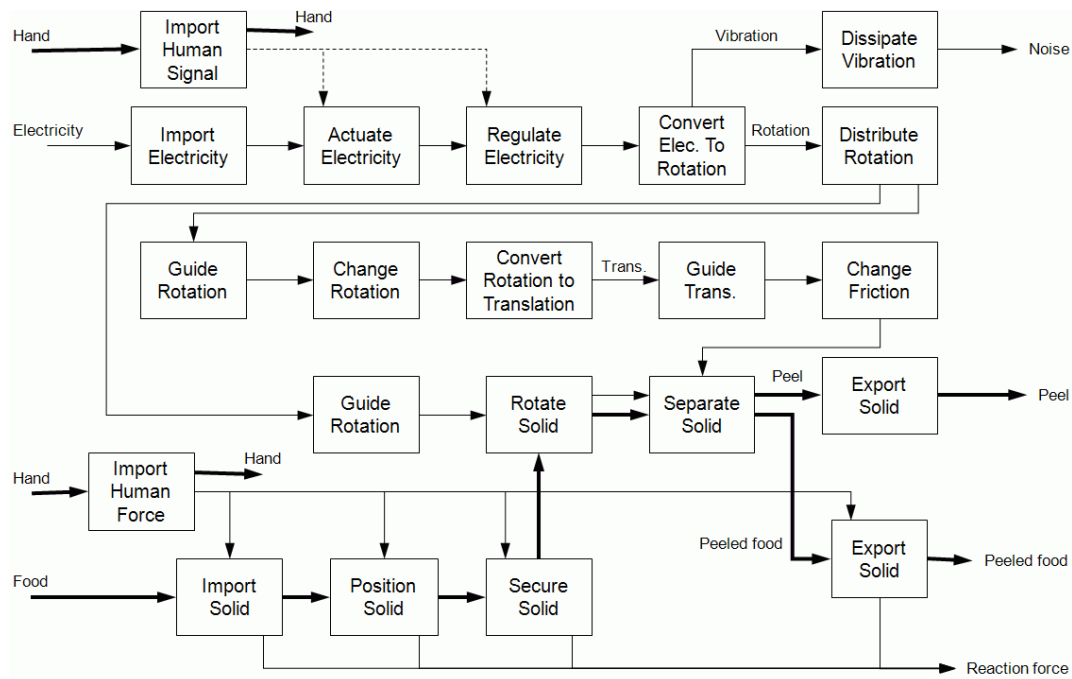

FIGURE III FUNCTION STRUCTURE FOR FRUIT/VEGETABLE PEELER FOR STUDENT ASSIGNMENT [11].

TABLE III NUMBER OF STUDENTS WHO WERE ABLE TO CREATE ANALOGIES.

Function	# of Students Who Created an Analogy	Total # of Students	% of Students Who Created an Analogy
Convert Energy	34	45	76%
Dissipate Energy	30	47	64%
Position Solid	27	44	61%
Regulate Energy	34	47	72%

TABLE IV NUMBER OF ANALOGIES FROM IDEAS GENERATED.

Function	# of Ideas Generated	# of Analogies	% of Analogies to Idea Generated
Convert Energy	80	56	70%
Dissipate Energy	77	42	55%
Position Solid	84	43	51%
Regulate Energy	84	54	64%

V. CONCLUSION

This research seeks to abate the effects of design fixations on engineering design problems when plausible solutions have been discarded too early in the design process or have yet to be found. By using functional modelling to decompose a design problem into specific functionality with a generalized taxonomy, certain areas of innovation can be pinpointed. These areas demonstrate the potential for student designers to more successfully utilize analogies across domains in order to create innovative and plausible designs.

When it comes to utilizing analogies across domains, mapping functions are the general subset of functions which are most conducive for successful analogical mapping. The mapping functions are an area of continued investigation at this time. Identified during the critical function study of Lucero et al. [3] and Ngo et al. [14], these specific sets of functions have the potential to provide more analogous

solutions than those of just the critical functions or the reoccurring functions.

The research herein identified the mapping functions as retaining function, performance or user-interaction benefits between the analogue and product. The benefits of these functions then are based upon the product critical functions, the construction, and the operating environment. The approach of the mapping functions to generate analogies is based upon either a solution or a problem approach, similar to a forward or reverse methodology. To further validate the findings, additional studies are currently in the works and will be published.

ACKNOWLEDGMENT

Support for this work was provided by the National Science Foundation Award No. CMMI-1304383 and CMMI-1234859. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation. The authors would also like to thank Dr. Joshua Summers at Clemson for assisting with data collection. This work is derived from the dissertation of Briana Lucero [4].

(480) 727-1405 and (480) 727-1063

Index Terms – Making; tinkering; engineering pathways; engineering education

SESSION GOALS

Participants in this special session will:

1. Learn about the knowledge, skills, and attitudes possessed by Makers
2. Discuss the similarities and differences between Makers and Engineers
3. Discuss how Makers fit ABET's model for engineering graduates
4. Discuss how Makers fit the Engineer of 2020 model for engineering graduates
5. Leave enlightened and informed on how the worlds of Making and Engineering could collide

SESSION DESCRIPTION

In the last 5 years, there has been increasing interest within the engineering education research community about the growing community of Makers who engage in informal engineering education and tinkering activities to create technical artifacts. A Maker is an emerging colloquial term we use to describe a group of do-it-yourself-minded individuals participating in informal communities (doing-it-with-others) that support building and prototyping technical proof-of-concept exploration and ad-hoc product development.

Novices and experts alike share an enthusiasm and appreciation for building and creation. Individuals and groups embark on projects of all sorts, led primarily by their interests and curiosities, informed by their skills or the skills they want to learn. They make creative efforts like fire-breathing robots as performance art, combining contributions from community members with electrical, mechanical and embedded systems know-how or construct intricate, wooden geometric puzzles CNC'd from exotic woods commissioned by patrons.

Makers also embolden the *Engineer of 2020* characteristics of *practical ingenuity*, *creativity*, and propensity toward *lifelong learning*, which are indispensable to future workplace innovation.

Some Makers have followed life pathways that include formal engineering education; some have not. Other Makers are professional engineers by day, others are not. Some participate in group-based informal engineering education organizations (e.g., robotics teams), while others Make alone in the privacy of their garages, supported by the growing Making ecosystem on the Internet. Makers come in all ages, demographics, professions, and interests – but are they engineers?

In this special session, we will explore the similarities and differences between Making and Engineering, guided by archetypes of Makers from our ongoing NSF-funded research on the Maker community [1,2]. These archetypes will provide a foundation for discussion in groups of questions such as, (1) *Can a Maker be considered an engineer, and vice-versa?* and (2) *Is the Engineer of 2035 a Maker?*

SESSION AGENDA

1. Introduction to Makers (5 min presentation)
2. What are Makers? What are Engineers? (15 min small group post-it brainstorming)
3. Report out (10 min)
4. Makers and Engineers: Similarities and Differences (10 min large group discussion)
5. Introduction of Panel of Archetypes (10 min presentation with handouts)
6. ABET and E2020 Ranking of Archetypes (15 min small group analysis)
7. Report out (10 min)
8. Is the Engineer of 2035 a Maker? (10 min large group discussion)
9. Resources for Lifelong Learning on Makers (5 min presentation)

PAPERS

The results of this Special Session will be submitted as a Full Paper to FIE 2016.

ANTICIPATED AUDIENCE

At our paper presentations at ASEE in 2013 and 2014 and at FIE in 2014, the rooms were packed with engineering faculty and NSF program officers on the forefront of the field. At FIE, we similarly expect a lively participatory

audience of faculty and NSF program officers interested in learning more and debating the boundaries between Making and engineering. We believe the smaller discussion-based atmosphere of FIE will make the Special Session lively and engaging for participants.

REPORTING OUTCOMES

One week after the Special Session, participants will be asked to complete a follow-up survey to identify characteristics of a Maker and an Engineer, given the discussion and time to reflect after the Special Session. Post-its generated and worksheets completed by each team will be collected and analyzed by Dr. Jordan and Dr. Lande's research group as part of ongoing NSF-funded research studies on Makers. Summary results will be electronically distributed to participants shortly after the Special Session. A full qualitative analysis will be conducted, and the results compared with results from other Maker research. The final comparison will be submitted as a full paper to FIE 2016, and will support future research by the engineering education community on Makers.

SESSION JUSTIFICATION

There is a significant interest among members of the engineering education community in the Maker movement. During our recent presentation on the background of our NSF-funded study entitled, *Should Makers be Engineers of the Future?*, we were greeted by a packed room of people with many questions about Makers and the Maker community. We ran out of time to answer the numerous questions and engage in the deeper discussions on who Makers are and what we could learn from them in the Engineering Education community. This response, paired with Alan Cheville's DiSRuPTioN special session at FIE 2013, inspired us to propose a special session on the hot topic of Makers.

Additionally, Drs. Lande and Jordan are emerging leaders in studying the Maker community. They have two NSF-funded Research in Engineering Education grants to study the knowledge, skills, attitudes, and life pathways of both Adult and Young Makers. They attend and present regularly at Maker Faires around the country, and are liaisons to build bridges between the Engineering Education and Maker communities.

Abstract— Engineering and Computer Science (E&CS) Education is an emerging discipline and is a subset of the larger field of STEM (science, technology, engineering and math) education. E&CS Education has a relatively brief history, and many individuals who are not directly involved in the discipline are often confused about its purpose. In this special session, we will use up to two background stories to frame the larger questions around E&CS Education goals and help draw the conversation from practice to philosophy while creating a safe space for open conversation addressing issues of change in our discipline.

Keywords—special session; organizational change; case study; goals of engineering and computer science education

I. INTRODUCTION

We attend FIE partly because we want to make positive change in STEM education, especially Engineering and Computer Science (E&CS) Education and, through that, in our world at large. E&CS Education is an emerging discipline with a brief history and its purpose is not always clear to individuals outside the discipline. As a consequence, the goals for the E&CS Education disciplinary community have largely been surface layer objectives provided by reports and outside groups, e.g. increase the number of students studying E&CS fields. While we need the surface layer objectives in our portfolio, we also need to have the deeper conversations within our community regarding what we want and why we exist. Without the deeper discussion, we have a limited understanding of the real impacts of the proposed objectives, intended and otherwise. This special session will create a safe space for this deeper discussion among a cross-section of the FIE community. The deeper goals of our discipline not only help us answer the larger questions of how we serve society and empower people, but they also help us evaluate the meaning, efficacy, and desirability of objectives provided to us.

In the context of working towards identifying goals of E&CS Education based on historical context and discussion, the goals of this session are:

- To open the conversation on the future goals of E&CS Education to a broader audience while providing a tool for supporting change in a local context.
- To provide structured time for contemplating academic change dilemmas and role playing potential paths towards solutions.

II. CASE STUDY APPROACH FOR THE SESSION

In this special session, we will use a case study approach to frame these larger questions and help draw the conversation from practice to philosophy while creating a safe space for open conversation. A set of background stories is a product of the Engineering Education Research NetWorkshop (NSF grant numbers 1314725 and 1314868). The NetWorkshop was a series of workshops held for engineering education researchers in conjunction with the ASEE Annual Meeting to focus on mid-career leadership, development, and community building. The NetWorkshop used the "Influencer" framework [1] to give participants tools to navigate confrontational issues. Our approach to working with the stories is based on elements of this framework. The background stories are aggregated experiences that feature issues recognizable to most individuals in our community. These experiences come from the viewpoints of individuals in roles common to E&CS faculty members and administrators. We will present tools to help participants prepare for "crucial conversations" that often arise from these background stories [2], and participants will practice the tools while role playing at least one background story. This and other similarly constructed case studies can be adapted for future use by participants.

A. Background Story 1: Managing Up to Affect Change

A discipline-based education research (DBER) faculty member is thrust into an administrative role when changes at her university result in her being the most senior faculty in her DBER department. To protect and advance DBER as a discipline, she undertakes a crash course in managing up – trying to communicate the mission of her department with the administration, and developing a strategy for survival and

The authors gratefully acknowledge the support of the National Science Foundation, award numbers EEC-1314725 and 1314868.

growth. It seems that there are two separate conversations underway (internal and external to the department) about the actual goals of DBER, and what role DBER could/should play in shaping undergraduate and graduate education at the institutional level. The struggle to reconcile these two conversations results in simultaneously advocating for more resources and asserting, with evidence, that the DBER department has successfully fulfilled its role in leading innovation in E&CS Education. This background story includes navigating the change process, the roles played by faculty, students and administrators, and the ongoing adjustment of how the mission and strategic plan for a DBER program are articulated to all involved.

B. Background Story 2: Change Among Peers and Students

Here, the chair of an engineering department finds himself having to navigate course and curricular changes that had been proposed by his predecessor. The proposed changes were developed during a faculty meeting in which all members of the department suggested ideas which were then ranked by popularity. As the chair seeks to rally support in moving from ideas to actions, he finds that underlying seemingly simple course changes are layers of unstated assumptions and beliefs which are deeply held but poorly articulated. As frustrations build faculty discover that while they all are speaking the same words—"design", "problem solving", "hands-on experiences"—their conceptions of these differ greatly from those of their colleagues.

This background story, drawn from work on curriculum theory [3], explores how differing beliefs of faculty along with the inability to clearly articulate wants and needs can paralyze a change process even when on the surface there is a clear consensus for change. During the role play, participants will discuss past experiences and potential approaches to moving forward. The case study created through role play will also discuss common mistakes in managing departmental changes including shutting down opposing views, assuming everyone draws upon the same information, and not carefully considering both potential gains and losses. The background story contrasts lived academic experiences with published change models [4], pointing out areas where these align and examples where best practices can fall short. Participants will experience applying a change model that identifies and leverages influencing factors to achieve a desirable outcome.

III. OUTCOMES AND FUTURE MOVES

The expected outcome is a broader basis for the facilitators and other interested individuals to continue discussions and

implementation of change actions in STEM education broadly and E&CS Education in particular. Ultimately, we hope to articulate how the discipline of Engineering and Computer Science Education serves society and empowers individuals and toward a better understanding of the issues facing our community as we act as change agents to achieve these goals. This workshop focuses on tools to support development as change agents.

This is the second FIE special session in the overall dialogue [5], and it builds on the participant feedback regarding the direction of the conversation that is reflected in the background stories and associated analysis. As the deeper conversation moves forward, the facilitators anticipate further discussion-based sessions/workshops summarizing the conversation so far and engaging additional members of the community, papers on the deeper goals of our DBER discipline and what the goals mean for the community, and increasing the confidence and effectiveness of our community members as change agents.

The only way to build sufficiently deep and broad goals for the E&CS research community is to involve a cross-section of community members. As a special session, this emerging discussion can move forward as a conversation that is framed by real experiences and representative stakeholders while not constrained by narrow participation.

ACKNOWLEDGMENT

The authors wish to acknowledge contributions of all members of the Engineering Education Research NetWorkshop community.

An Investigation of the Relationship between K-8 Robotics Teams' Collaborative Behaviors and Their Performance in a Robotics Tournament

Muhsin Menekse, Christian Schunn, Ross Higashi, Emily Baehr

Learning Research & Development Center
University of Pittsburgh
Pittsburgh, Pennsylvania
muhsin@pitt.edu

Abstract— This study investigated the relationship between robotics team members' collaborative behaviors, communication and coordination in particular, during hypothetical challenges and their teams' actual performance during physical robotics challenges. Dataset included robot performance, robot design, research project, core values, and collaboration quality scores for 61 K-8 Robotics teams (N = 366) that participated in a FIRST LEGO League (FLL) Championship in 2015. Our analysis primarily focused on how well the collaboration quality scores predict team performance across different categories. Results indicated that the level of collaboration quality among team members is significantly associated with the team performance in the robotics tournament.

Keywords—Robotics, Teamwork, Collaboration, Programming, Informal Learning.

I. INTRODUCTION

In recent years, robotics programs for young people have become highly popular interactive and innovative educational activities. Literature shows robotics in K-12 settings having been typically used as a learning tool to develop student's academic skills and to stimulate their curiosity and interest towards Science, Technology, Engineering, Mathematics (STEM), and computing [1]. Benitti's review study [2] showed that being a part of a robotics team has the potential to significantly influence a student's academic and social skills, by allowing learners to actively engage in critical thinking and problem solving in team settings through designing, assembling, coding, operating, and modifying robots for specific goals. In addition, its interdisciplinary nature makes robotics a valuable pedagogical resource for both formal and informal learning environments.

Robotics teams allow students to collaboratively engage in tackling problems by designing and building robots and then programming them for autonomous tasks. Successful

collaboration requires effective communication, coordination, trust, and respect among team members, as well as individual and team level responsibility and accountability to achieve certain tasks. However, some studies in learning sciences and educational psychology have shown that achieving successful collaboration is challenging, and working in small groups is not always beneficial in terms of group performance and individual learning [3, 4]. Lou and colleagues' [5] meta-analysis study showed almost 25% of the published experimental studies in collaborative learning indicated null or even unpredicted effects when compared to individual learning conditions. Dillenbourg and Hong [6] argued that the lack of the elaborated explanations, mismatch in mutual regulations of cognitive processes between group members, low quality of arguments and the nonexistence of negotiation of meanings reduces the effectiveness of collaborative learning.

Working effectively in teams is one of the most critical 21st century skills [7], and robotics team settings provide a good venue to study the effective factors on team performance for young people. However, very few studies have investigated how being a part of a robotics team influences students' collaborative skills and how the quality of collaboration effects team performance in informal robotics education. In this study, we explored the role of the collaborative behaviors on teams' performance in a robotics competition by investigating the level and quality of students' engagement during teamwork. In addition, we specifically investigated the relation between team collaboration quality and programming performance to understand how well the programming quality and efficiency predict teams' collaborative behaviors. Lastly, we examined the relation between the experience of teams and their collaborative behaviors.

The structure of the paper is as follows: Section II briefly reviews the robotics competitions, section III presents the data sources and team scores used in this study, section IV describes the conducted analyses and results. And section V

summarizes the findings and concludes this study by discussing some of the limitations and future work.

II. ROBOTICS COMPETITIONS

Robotics competitions provide unique opportunities for students and teams to engage in teamwork for a shared goal in a certain timeframe. The common goals for many competitions include the development of skills, interest, and awareness toward STEM and computing, a focus on the ability to effectively work in teams, and the development of cooperation and respect towards the other teams participating in the competitions. Robotics competitions have immensely contributed to the recognition of the educational robotics, especially in United States and other developed countries [8]. There are two main types of robotics completions, FIRST and VEX robotics. Within FIRST, there are several types of events, beginning with JFLL (Junior FIRST LEGO League), FLL (FIRST LEGO League), FTC (First Tech Challenge) and FRC (FIRST Robotic Competition), whereas VEX is comprised of VEX, VEX IQ Challenge, Botball Educational Robotics Competition, and RoboCupJunior (RCJ). The data in this study comes from an FLL Championship held in Pittsburgh, Pennsylvania, in January of 2015.

The FIRST competitions, founded in 1989 by Dean Kamen, are currently one of the most popular competitions worldwide. FIRST LEGO League (FLL) began in 1998 as a collaboration between the FIRST organization and the LEGO group to introduce robotics to students ranging in age from 9-14 years-old. According to the FLL website, there are more than 25,000 FLL teams in approximately 80 countries. To compete in FLL, teams are required to use LEGO kits (MINDSTORMS robot sets) and work on a real-world scientific topic themed challenge, with past themes including climate change, senior solutions, food safety and medicine. The challenges are announced by FLL organizers at the same time each year, after which competing teams have several months to prepare for the final Grand Championship competition, during which their performances are evaluated, based on their scores during the robot game, and their success on a research project, robot design/programming, and FLL core values.

III. METHODS

A. Data

Dataset in this study includes the 61 K-8 Robotics teams (N=366) that participated in the FIRST LEGO League Western PA Championship, with participants ranging in age from 9 to 14 years-old. Dataset included scores for actual performance (i.e., table scores), core values, project, and robot design. All 61 teams were being judged on these categories, with different groups of judges evaluated each team and their performance. Each team received three scores for core values, project, and robot design categories, with the

scores for these three categories ranging from 1 (beginning) to 4 (exemplary). Additionally, each team was assessed in terms of collaboration quality while working on a hypothetical challenge. The minimum score for collaboration quality was 1 (minimal) to 3 (substantial). All these categories are discussed in detail in the following section. Table 1 shows the means and standard deviations for all scores.

TABLE I. AVERAGE MEANS AND STANDARD DEVIATIONS OF EACH SCORE FOR ALL TEAMS.

Team Scores	Mean	Standard Deviation
Average Table Scores	99.87	63.22
Core Values	3.00	.64
Project	2.50	.98
Robot Design	2.49	.84
Collaboration Quality	2.16	.60

B. Measures

1) Table Scores:

Table scores indicated the actual robot performance on the specific challenges. Each team's robot performed for three rounds, with the best round score being used for the tournament ranking. In this study, we used the average score of the three rounds instead of the best scores for our analysis.

2) Core Values:

Core values included three sub-categories, being: inspiration, teamwork, and gracious professionalism. The inspiration was evaluated based on teams' ability to integrate the FLL values to their daily lives, their enthusiasm for team spirit, and balanced emphasis on all aspects of FLL. The teamwork score was based on teams' efficiency and effectiveness for problem solving, time management, distribution of roles and responsibilities, and team independence with minimal involvement of team coach. For gracious professionalism, teams were judged by their attitudes and respect towards their own team members and their recognition of friendly competition.

3) Project:

In addition to designing, building, and programming robots, each FLL team was also responsible for a research project, creating an innovative solution for a problem that they identified, correlating to the theme of the competition. The project scores were

evaluated based on the value and clarity of the research question, innovation and creativity of the solution, and the quality of the presentation.

4) *Robot Design:*

Robot design scores involved mechanical design, programming, and strategy & innovation subcategories. The mechanical design was evaluated based on the durability, efficiency and mechanization of robots, while the programming sub-score was assessed based on quality, efficiency, and autonomy of robots with minimal to no driver intervention. The strategy & innovation sub-score indicated the characteristic of design process, the team's game strategy, and innovative nature of the robotic features that teams developed and integrated.

5) *Collaboration Quality Scores:*

We developed a collaboration quality rubric to evaluate the collaborative behaviors of all teams (see Table 2 for more details). This rubric was used to explore joint versus individual behaviors of team members while they worked on a hypothetical challenge. The challenge had teams generate a computer program to allot for a reliable path in order for a robot to move from the start to the finish, successfully avoiding any and all obstacles (Figure 1). This challenge was novel to all teams, therefore, they did not have a chance to practice or prepare for the task beforehand. The spectrum of the collaboration quality scores ranged from minimal (score 1) to moderate (score 2), and to a substantial level of discussion (score 3). For example, teams received a score of 1 when none or only one student generated detailed statements, or when none of the team members asked why/how type questions, or discussed each other's claims. On the other hand, teams received a score of 3 when students clarified or completed their partners' statements through expanding, elaborating, or rebuttal.

TABLE II. RUBRIC FOR THE COLLABORATION QUALITY SCORE

Score 1	Score 2	Score 3
A <i>minimal</i> level of discussion.	A <i>moderate</i> level of discussion.	A <i>substantial</i> level of discussion.
None or only one student generates detailed statements.	One student's statements are mostly substantive and the other varies between detailed and shallow.	Substantive statements of each student build upon those of the other, indicating a shared line of reasoning.
Students do not	Statements are	Students clarify or

clarify or complete their partners' statements, instead voicing generic responses of agreement.	discontinuous as each student makes assertions independent from those of the other.	complete their partners' statements through expanding, elaborating, restatement or rebuttal.
One student decides what to write while the other agrees but contributes very little.	One student contributes most to what will be written while the others take a smaller, though substantive, roles.	Conclusions are jointly constructed with two or more students involved fairly equally in determining what to write.
None of the students ask why/how type questions, discuss each other's claims, or elaborate in response to questions.	Some students effectively engage in the collaboration process. A few why/how type questions are asked and discussed.	Most students effectively engage in the collaboration process. More than one why/how type questions are asked and discussed.

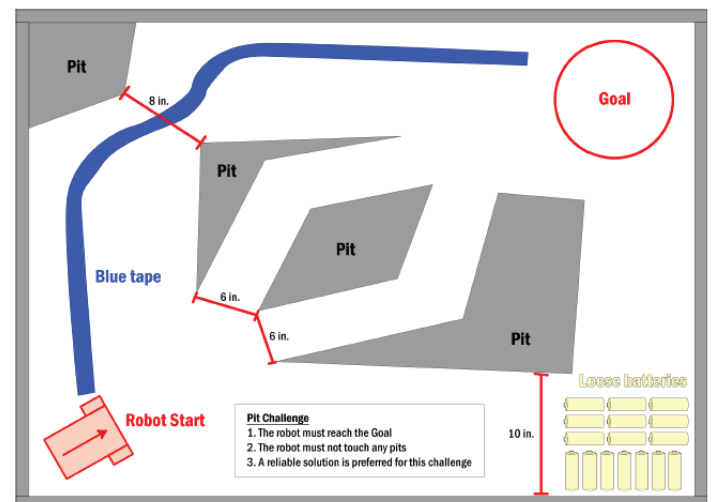

Figure 1. A sample hypothetical challenge for students to work collaboratively in order to describe the computer program for the robot to reach the goal.

IV. ANALYSIS AND RESULTS

A. *Collaboration Quality and Overall Team Performance*

Since the main goal of this study was to explore the role of the collaborative behaviors on teams' performance, our first set of analysis focused on understanding the relation between teams' collaboration quality scores and other

variables. First, we computed a set of correlation coefficients by using the Bonferroni approach to control for Type I error across four correlations, a p value of less than .0125 (.05/4 = .0125) was required for significance. The results of the correlational analyses presented in Table 3 show that all four correlations were statistically significant. The results indicate that the collaboration quality score is significantly associated with the teams' performance across different categories in the FLL robotics tournament.

TABLE III. CORRELATIONS BETWEEN THE COLLABORATION QUALITY SCORE AND OTHER MEASURES

	Average Table Score	Core Values	Project	Robot Design
Collaboration Quality	.39*	.49*	.55*	.46*

* indicates $p < .0125$

Next, we conducted a multiple linear regression analysis to evaluate how well the collaboration quality, core values, project, and robot design scores predict the average table performance of teams. The linear combination was significantly related to the average table performance, $F(4, 56) = 13.91$, $p < .01$. The sample multiple correlation coefficient was .71, indicating that 50% of the variance of the average table scores can be accounted for by the linear combination of predictors. All the bivariate correlations between the average table score and other predictors were statistically significant. However, the only significant partial correlation was between the robot design score and the average table score, indicating that the robot design score for each team is the best predictor for the average table score. Table 4 presents the bivariate and partial correlations.

TABLE IV. THE BIVARIATE AND PARTIAL CORRELATIONS OF THE PREDICTORS WITH THE AVERAGE TABLE SCORES

Predictors	Bivariate Correlation	Partial Correlation
Collaboration Quality	.39*	.14
Core Values	.30*	.01
Project	.24*	-.12
Robot Design	.70*	.63*

* indicates $p < .05$

B. Collaboration Quality and Team's Programming Performance

We were also interested in understanding the relation between the collaboration quality and teams' programming

performance. The programming score was one of the subcategories of the robot design score, and involved three components: programming efficiency, programming quality, and automatic features of robot's movement. We were interested to conduct a multiple linear regression analysis to evaluate the strength of relationship between the programming sub-scores and the collaboration quality score. However, the programming sub-scores were highly correlated to each other (all correlations were equal or greater than .70), which increase the possibility of multicollinearity. Due to this multicollinearity problem, we conducted stepwise regression and the best-fit model excluded the "programming efficiency" and the "automatic/navigation" variables. So, the final model was a bivariate linear regression with the "programming quality" variable as the sole predictor, $F(1, 54) = 11.37$, $p < .01$, with $r^2 = .17$. The regression equation for predicting the collaboration quality score was

$$\text{Predicted Collaboration Quality Score} = .50 \\ \text{Programming Quality} + 3.17$$

Please note that there were five teams with missing data for the programming sub-scores and therefore our analysis for the programming performance did not include these five teams.

C. Collaboration Quality and Team Experience

The dataset used in this study also included information for the relative experience of the attending robotics teams. The team identification number in the FLL competitions indicates that the teams with smaller numbers are more experienced robotics teams than the teams with greater numbers. In our dataset, team identification numbers ranged from two digit numbers (e.g., 30) to five digit numbers (e.g., 13000), and based on these identification numbers we divided the 61 participated teams into three categories as most experienced, experienced, and least experienced teams. Our goal was to understand to what degree the team experience was associated with the collaboration quality of teams. Table 5 indicates the means and standard deviations of collaboration quality scores for three groups.

TABLE V. THE MEANS AND STANDARD DEVIATIONS OF COLLABORATION QUALITY SCORES ACROSS THREE GROUPS BASED ON TEAM EXPERIENCE

Level of Experience	N	Mean	Standard Deviation
Most Experienced	16	2.32	.44
Experienced	26	2.30	.47
Least Experienced	19	1.84	.75

We conducted one-way analysis of variance (ANOVA) to evaluate the relationship between collaboration quality score and team experience. The ANOVA was significant, $F(2, 58) = 4.48$, $p = .01$. The strength of relationship between

team's experience and their collaboration quality score was moderate with the experience of teams accounting for 13% of the variance of the dependent variable.

Additionally, we conducted follow-up tests to evaluate the pairwise comparisons among the three groups by using Tukey HSD test. Two of three pairwise comparisons were significant; most experienced and least experienced, and experienced and least experienced. Table 6 shows the 95% confidence intervals for the pairwise comparisons.

TABLE VI. 95% CONFIDENCE INTERVALS OF PAIRWISE DIFFERENCES IN MEAN CHANGES

	<i>Experienced</i>	<i>Least Experienced</i>
<i>Most Experienced</i>	-.85 to .87	.02 to 1.86*
<i>Experienced</i>		.11 to 1.75*

* indicates that the difference in means is significant at the .05 significance.

D. Limitations of the Analysis

The results of this study are limited by a number of factors. First, since we mainly conducted correlation and linear regression analyses; these results do not imply causal relationship between collaboration quality and robotics team performance. Second, our sample size is relatively modest, since all of our analysis is at the team level. Therefore, we had a reduced chance of detecting true effect in some of our analyses. Third, there might be a validity problem with the judging scores, especially for core values and research project, due to a lack of detailed rubrics. In addition, since the judges were volunteers and a different group of judges evaluated different teams, the judging scores might be subject to reliability threat as well.

V. CONCLUSION

This study explored the relationship between collaboration quality among team members and their team's performance in a robotics competition. The results showed that collaboration quality is a good indicator for robotics teams' overall performance in a competition as well as for the core values, project, and robot design categories. We were also interested in investigating how collaboration quality is related to teams' programming performance. The stepwise regression analysis showed the programming

quality is highly associated with the collaboration quality. Moreover, the team experience was significantly related to the collaboration quality. In other words, the students in more experienced teams engaged in more substantial levels of discussion compared to the students in less experienced teams. That is interesting to note, since there were no differences in regard to attending students' age groups and their individual experience across different teams. However, the results indicated that being in a more experienced team lead to better overall performance in robotics competitions and higher level of collaboration quality.

As discussed in the section above, we are aware of the limitations in this study, but we believe that these factors do not invalidate our main conclusions. Taken as a whole, our analyses suggest that the effective collaboration skills among team members are significantly associated with robotics team performance in competitions, and further investigations, experimental studies, are needed to understand the causal links between these relationships.

Abstract—System design and development are fundamental capabilities for an engineer. The Department of Control Engineering at the National Institute of Technology, Nara College, has been offering a course called “Practical System Design,” a unique opportunity for students to experience the entire process of developing an autonomous mobile robot, to fourth-year students for about 20 years. However, in recent years, robot design and construction have become a huge challenge for these students. To address this problem, we have worked on improving the engineering program. First, we have introduced a problem-based learning (PBL) education program in all experimental engineering classes in years 1–3. Also, we require students to submit a written report after each class session. This report is intended to help improve the students’ schedule management, role-sharing, and work-tracking skills. These reports are reviewed by the relevant course teachers and assessed for logic and quantitative representation. In this paper, we discuss the approach to, achievements of, and future subjects to be taken up by this multi-stage-experience educational program, especially the effect of report-writing.

Keywords—PBL; active learning; engineering experiment; working report; evaluation method; LEGO Mindstorms; PDCA cycle

I. INTRODUCTION

Problem-solving skills are important for engineers, and they are usually honed through practical experience. In the Department of Control Engineering at the National Institute of Technology, Nara College, the course “Practical System Design” has been offered to fourth-year student for the past 20

years [1]. In this class, students study system design and development through the design and construction of autonomous mobile robots. However, for some students, it is challenging to design and construct autonomous mobile robots owing to a lack of design and construction experience. Additionally, it is difficult for students to gain problem-solving skills because of insufficient practice in schedule management, role-sharing, report-writing, etc. To address this problem, we have worked on improving the curriculum for the course and the program as a whole. First, we have introduced a problem-based learning (PBL) education program in all experimental engineering class in years 1–3. By increasing the students’ exposure to robot design and construction, we allow them to substantially improve their system design and development capabilities. Second, we have introduced a written report requirement, to be submitted after each class session. The goal of the report is to help to improve the students’ schedule management, role-sharing, and work-tracking skills.

The aim of this research is to develop a new quantitative evaluation method for the report-writing assignments. In this paper, we discuss in detail the approach that was employed, the current state of evaluation, and expected future issues.

II. APPROACHES AND METHODS

First, we give a brief outline of the multistep experience-based problem-solving program. In this program, students construct an autonomous mobile robot using LEGO Mindstorms. Thus, students have many opportunities to experience the process of robot design and construction. Figs. 1

Aim to build construction experience of real system				

Fig. 2. Contents of the multistep experience-based problem-solving program in each grade

and 2 show a schema of this program and the content of the program for each academic year. By offering the opportunity to experience the process of robot design and construction from the first year onward, students can come to understand the need to learn about special subjects such as electric circuits, control engineering, material mechanics, and engineering drawing. Moreover, the content of this program evolves as the students advance to the next year. For example, in the first year, students do their program work using GUI-based programming and attached components. In the second grade, they work on the program using control circuits that they have developed themselves, and CUI-based programming.

Second, we explain the content of the program for first-year students, which began in 2012. In this paper, we focus on last year's class. Table 1 shows the class schedule. The class consists of 10 sessions, each of which lasts for 135 min. In the class, about 40 students are divided into 8 groups (5 or 6 students per group). Students in each group design and construct an autonomous mobile robot using LEGO Mindstorms. The challenges and rules of the competition change yearly. The outline of the competition content for the last year is as follows. Students are instructed to design and construct an autonomous mobile robot using LEGO Mindstorms EV3; in the competition, students try to collect one designated block specified as a reference block and carry it back to a goal area. Fig. 3 shows the competition field. Four blocks of different colors are placed in the target block area. Thus, the robot needs to have a function for sensing and tracing the lines and blocks, and a mechanism to collect the designated block. The maximum permissible size of robot is 500 mm * 500 mm. The time limit for completing this task is 3 min. Groups gain points depending on the time to goal. The overall

10	• Second competition • Poster presentation	

Fig. 3. Competition field

ranking is determined based on the total number of points gained.

Next, we describe the report-writing process. We require students to submit a written report after each class. The goal of the report is to help improve students' schedule management, role-sharing, and work-tracking skills. In addition, it helps to increase their awareness of the PDCA cycle. The work report must include five items: (1) Objective for the week, (2) Describe your work today using a figure, (3) Describe today's achievement status in quantitative form, (4) Find and describe some helpful points from other students' work and reports, (5) Describe your approach to your next problem based on your reflections and the helpful things described above.

The reports are reviewed by subject teachers and assessed for logic and quantitative representation. Fig. 4 shows an example of a reviewed working report. Teacher comments are shown at the right-hand side of the figure. Students then go through the results of the review and resubmit corrected reports. The number of marks allocated to the report indicates the degree of (need for) modification. Thus, in this study we focus on variation in marks awarded to the reports, in order to evaluate the effect of the report-writing.

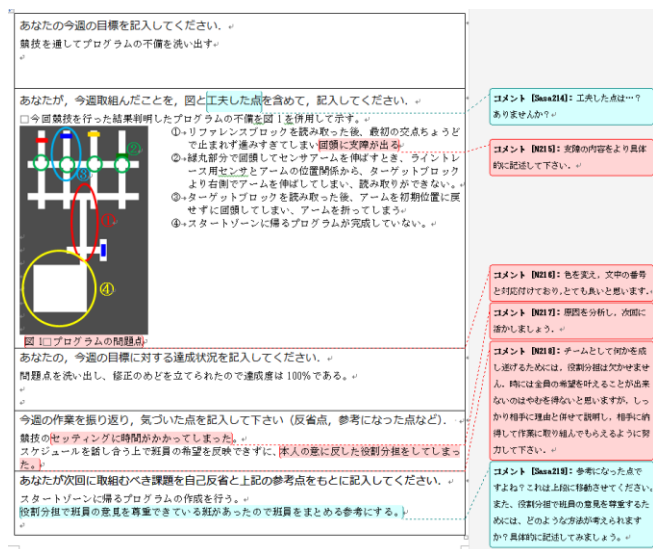

Fig. 4. Submitted and reviewed working report

Fig. 6. Variation in the categorized comments

Fig. 5. Variation in the average rankings for each group

Fig. 7. Variation in the average number of negative comments (Requests for correction) for groups A and H

III. RESULTS AND DISCUSSION

In last year's program, students were grouped into eight groups (Groups A, B, C, D, E, F, G, and H) according to the results of their first-semester midterm exams in "Mathematics α ," "Mathematics β ," "Information mathematics," and "Physics." Fig. 5 shows the variation in average rankings for each group. The abscissa is each periodic exam and the ordinate is the average rankings for these subjects. Thus, the grades of students in group A are higher than those of students in group H. Also, since there is no inversion of ranking, we see that the effect caused by this program on classroom lectures is small.

To evaluate the effect of the report-writing, we classify the teachers' comments added to the work reports into three categories depending on content. Comments that contain the

words "unnecessary," "correction," "quantitative," or "specific" are categorized as "Request for correction." Comments that contain question marks are categorized as "Ambiguous description." And comments that contain the word "good" are categorized as "Glowing comments." Fig. 6 shows the variation in proportions of comments by category, and the variation in the total number of comments. The abscissa is the number of the working report, the left ordinate is the proportion of overall comments accounted for by each comment category, and the right ordinate is the total number of comments. As you can see in Fig. 6, the total number of comments decreases with repeated report-writing. On the other hand, the proportion of comments categorized "Request for correction" increases, and the fractions categorized "Ambiguous description" and "Glowing comments" are almost constant. Although the share of each comment category does not decrease, the total number of comments does decrease. Thus, we consider that report-writing in the multistep

experience-based problem-solving program helps improve students' writing capabilities, especially with regard to the logic and quantitative representation.

Next, we focus on variation in the number of comments within each group. Fig. 7 shows the variation of the average number of negative comments (Requests for correction) for Groups A and H. The abscissa corresponds to the number of the working report and the ordinate corresponds to the average number of comments categorized as "Request for correction." The average number of comments is obtained by dividing total "Requests for correction" by the number of students in Group A or Group H (respectively). From Fig. 7, we see that the variation for Group H is large compared to the variation for Group A, and that the total number of comments categorized "Request for correction" is 98 for Group A, consisting of high-achieving students, and 169 for Group H, consisting of low achievers. Therefore, we consider that the effects of report-writing and reviewing by the subject teachers correlate with the academic results of students.

IV. CONCLUSIONS

To improve the problem-solving skills of engineering students, we have introduced a multistep experience-based problem-solving program for first- to third-year students. This program promotes seamless transition to the "Practical System Design" class, which is offered in the fourth year. Further, we designed the content of this program such that it evolves as students advance from year to year. We also introduced a written report that we require students to submit after each class. As a new quantitative evaluation method for the reports, we focus on variation in the number of marks assigned to the reports. By categorizing the comments by content, we find that although the proportions of positive, neutral, and negative

comments do not change with repeating report-writing, the total number of comments does decrease. Additionally, we can see that the variation in the average number of comments categorized as "Requests for correction" depends on the academic results of students. Therefore, we take it as confirmed that report-writing by students and review of reports by subject teachers helped to improve the students' work-tracking skills, and that this effect correlates with the academic grades of students.

There are some further subjects that remain for future investigation, such as the optimal review framework and improvement of our method for evaluating the whole process. In particular, we consider that "Glowing comments" are important as well as comments requesting corrections, and deserve further attention. Also, to reduce the large variation in number of comments, structured rules for review are needed.

Abstract—This work-in-progress paper describes our experience in introduction of a Project-Based Learning environment in teaching of undergraduate students in the field of electrical engineering at Sogn og Fjordane University College in Norway. In the scope of this work, a robot capable of playing the tic-tac-toe game with a human and an additional laboratory exercise in robotic manipulation with computer vision has been developed. In this lab, the students integrated the robotic manipulator with computer vision in order to prepare a fully autonomous robot navigation using a prepared library that provides the functions for robot control and image processing. The project can be an interesting tool for learning some advanced topics such as robot vision, robot mechanics and autonomous robot navigation. The results show that students with strong motivation start to carry out an advanced project without any theoretical background in robotics and image processing. Another advantage is that the students can test in practice the influence of all stages of image processing on final robot navigation and understand that we may control robotic manipulators by using the vision information.

I. INTRODUCTION

Robotics is one of the most important and exciting fields of technological advancements of our age. The first industrial robots have been introduced to the factories in early 1960s and we still observe the strong growth of new applications in recent years. The evolution of the technical needs of society and the technological advances achieved cause that robots are widely used in many areas such as agriculture, surgery assistance, rehabilitation, automatic refueling, automotive assembly line, etc. [1]–[3].

Robotic arms are one of the most important industrial robots, but they are typically designed to repeat tasks. Integration of the robot with the information coming from the camera can extend the functionality of their in automatic industrial process [4], [5]. However, in order to ensure the continued development and meet the future challenges in service robotics, it is important to train engineers, who will cover those necessities.

In recent years, an increased interest in robotics is also observed from the industry in the Sogn og Fjordane region in Norway. In order to respond to demands for skillful engineers Sogn og Fjordane University College (SFUC) cooperates with the regional industries in the realization of bachelor's projects. Within this cooperation almost all projects are conducted in such a way that the students receive the fragments of tasks

that should be implemented under supervision of teachers from SFUC and employers. The result of this work is a bachelor's thesis connected with real-world problem and an industrial deployment of a technology. This work is the only way to conduct the projects connected with robotics. However, due to the fact that there are no courses as introduction to the robotics and image processing in the undergraduate curriculum, the students avoid the topics related to computer vision and robotics.

During a three-month visit of one of the authors (KR) under Erasmus internship program to SFUC, there appeared an idea to design an advanced application that can be presented as a spectacular demo of the robot's capabilities for visitors of the university and encourage the students to choose the robot-related tasks. As the result of this internship, a robot capable of playing the tic-tac-toe game was developed.

The laboratory in SFUC is equipped with Universal Robots UR5 and KUKA KR3 robot manipulators, but in this work we will focus on the UR5 robot, as we received many positives opinions from Norwegian companies, which successfully deployed this robot in their business. This robot was also used in many research projects [3], [6]. The UR5 robot with the control panel is presented in Fig. 1.

Fig. 1. The UR5 robot from Universal Robots.

The second idea under this internship was to design and introduce an optional laboratory exercise that would give the students an opportunity to design, develop, evaluate, integrate and manage projects, in which they will use a robotic arm and computer vision algorithms in real-life applications. However, due to the fact that this internship took place during summer vacation, there was no possibility carrying this laboratory with the students and the laboratory stand was prepared to control it via Internet. To achieve this goal for all devices the public IP addresses were assigned, the web-camera was mounted near the robot and a free app TeamViewer for remote access to the system was used. The final workshops with the students were conducted by both authors, but one of the authors (KR) supervised the work of the students via Skype and TeamViewer applications.

This laboratory was designed in the form of Project-Based Learning (PBL) [7], because many researchers note the positive influence of PBL on education process [8]–[12]. The main idea of PBL approach is to engage students in learning and stimulate their thinking by solving a real-world problems instead of traditionally lecture-based learning [13].

The aim of this exercise was to illustrate how to localize a simple objects using computer vision methods for preparation of an autonomous robot navigation and check if further one-semester course in robotics can be conducted without lectures in robotics and image processing as PBL.

To accomplish it, we developed a basic application, in which the students need to change a small part of code to solve two proposed problems: removing all predefined objects from the table and adjusting the proper values of thresholds to recognize other types of the items on the table.

In this work-in-progress paper, we present the preliminary results of applying the PBL approach in teaching programming of robots and integrating it with computer vision and designed environments. The main idea was to introduce an additional laboratory project for the undergraduate students of electrical engineering at SFUC in Norway and show the students that they are able in an easy way to control the robotic arm using the ready-made algorithms. The next Section provides a brief description of the developed laboratory stand and prepared applications. In Section 3 we discuss the results and the impact of the deployed robot on the learning process and finally we conclude the paper.

II. LABORATORY STAND DESCRIPTION

The most challenging part of this work was to find an alternative way to motivate and capture the interest of students to obtain programming skills for solving robotic tasks. To realize it, we prepared two applications containing ready-made algorithms for robot motion planning using computer vision algorithms.

The first application is an implementation of a robot capable of playing tic-tac-toe (or Noughts and crosses) game that has been presented on student university open days, when the robot played with students and visitors to show the possibility of using robot. The tic-tac-toe is a simple and short game, in

which two players take turns marking the spaces in a 3×3 grid. The player who succeeds in placing three respective marks in a horizontal, vertical, or diagonal row wins the game. Typically, it is a paper-and-pencil game, but in our solution, we used basic geometric figures (red rectangles and blue circles) as pawns in the game.

In order to find the optimal move in the tic-tac-toe game for the robot a Minimax algorithm has been applied [14]. The Minimax algorithm is simple recursive algorithm that performs a deep search strategy checking the possible game states and allows to select the best move for the robot. A similar robot capable of playing the tic-tac-toe game was developed by a group of engineering students at São Paulo State University in Brazil [15].

A robot is able to play with a human by analyzing the position of the pawns on the table and the free fields of the game board using the visual information gathered by the Basler Ace GigE camera mounted at the end-effector of the robot. The scheme of the laboratory stand has been presented in Fig. 2. To communicate with the camera, we used SDK of Basler camera, to control the UR5 robot, we used a Python urx library developed by Olivier Roulet-Dubonnet [16], OpenCV library [17] for image processing purposes and GUI has been developed in using Qt library [18]. The communications between the camera, the robotic arm and the PC was performed via TCP/IP protocol.

Fig. 2. A scheme of developed Tic-tac-toe playing UR5 robot manipulator.

The second application illustrates how to localize simple objects (blue circles and red squares) on the table and move them to other locations. This application was used in an additional laboratory course, in which students needed to change some part of code and modify a basic image processing algorithm in order to teach a robot to recognize new items.

Similarly to the work [19], our software was divided into separate classes:

- class *Robot* for communication between the robot and the PC,
- class *FrameCapture* for images acquisition,
- class *ObjectDetection* for objects detection within the captured images,
- class *TableInterpreter* for transformation of visual information to appropriate robot's movements.
- class *MainWindow*, in which a user GUI was developed.

Within class *TableInterpreter* the functions were developed for automatic calibration of the distance between the robot's gripper and the table, the angle between camera and the robot coordinate system. Two different coordinate systems for the robot and the camera sensor are presented in Fig. 3.

Fig. 3. A scheme of coordinate system of the camera and the robots.

In the proposed course there are not any advanced computer vision algorithms what allows for easy understanding of the whole objects detection process for the student with limited previous knowledge in image processing. In the applied algorithms all objects are detected based on the color properties of the objects using HSV color space by setting the proper thresholds. Then, morphological post-processing was applied to remove artifacts, which may have appear in the previous step and connected-component labeling was used to detect connected regions in obtained binary image. Finally, for each detected object the mass center has been calculated in order to move the robot arm through the desired position. The flow chart of the developed object localization method is presented in Fig. 4.

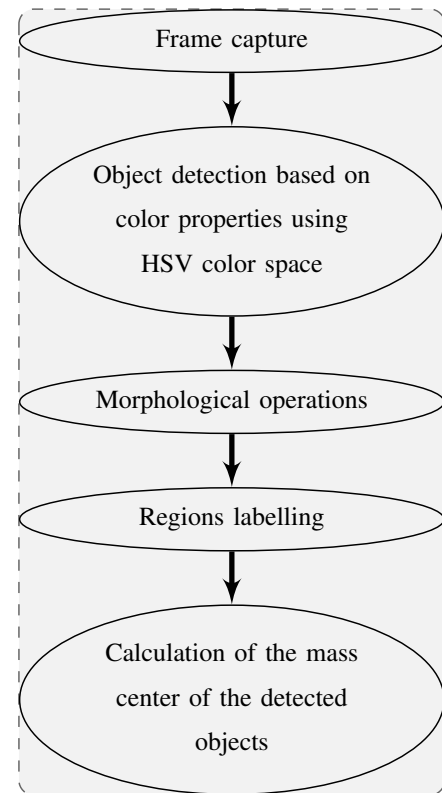

Fig. 4. Flow chart of the vision module used for object detection.

III. EVALUATION OF THE EDUCATIONAL EFFECT

The primary objective of this study was to evaluate if an obligatory course in robotics with computer vision planned in the future can be conducted in the form of PBL without traditional lectures in this field. This is due to the fact that there is limited possibility to add novel courses in image processing and robotics to the current undergraduate curriculum in electrical engineering at SFUC.

For this laboratory we prepared two simple tasks, the first connected with planning the movement of the robot arm and the second focused on image processing problem. The first task required from students a modification of the function **PickCircleObject()** that picks up a single blue circle from the table and places all the circles detected by the function **DetectCircles()** on the line. The second task was to write a function to detect the black nails based on the HSV color space using the code of the function **DetectCircles()**. In this task a short introduction to the HSV color space was conducted and an additional function with the trackbar sliders that visualize the results of image thresholding in HSV color space.

In order to evaluate educational effects and determine the degree of interest, we observed students' attitude and reactions during the laboratory. In addition, in order to avoid subjective bias, we also prepared an anonymous questionnaire before and after exercise with questions about students' motivation, interests and expectations. 60% of students of the third year participated in this optional laboratory. We divided them in

three groups.

Generally, all students in the survey reported that their knowledge about robotics and computer vision is minimal. Most students before the exercise expected to see the robot in action and acquire knowledge about the robotic arm programming and programming environment. Three persons were especially interested in the topic of workshop, because they would like to use this knowledge in their bachelor's project.

Due to the lack of earlier experience, most of the students considered computer vision and robotics as difficult and they thought that they would not even be able to start the project related to robotics. Almost half of the students noticed that they did not know that the camera sensor systems can extend the functionality of a robotic arm.

The answers from the questionnaire after exercise showed that 30% of the students were interested in both robotic arm programming and integration of the robot with camera sensors and application of image processing methods for autonomous robotic manipulation. On the other hand 40% of students were interested only in robotics without using computer vision.

The questionnaires also showed that the biggest problem for the students was the use of HSV color space, because they never heard about the Hue-Saturation-Value (HSV) color model. They were only familiar with RGB and CMYK color model and they were able to work with this novel color space only after a detailed explanation of the necessities of applying different color spaces. Another difficulty was caused by the different coordinate system for the robot and the camera and the fact that the robot axes were not directed perpendicular to the table with the items. Therefore, most students would like to receive learning materials and an instruction before the laboratory in order to prepare better for the upcoming exercise. These difficulties show that even in realization of PBL a detailed instruction is always required and it is not possible to treat the robot movement functions as "black boxes".

Contrary to our expectations, the students did not see any difficulties in conducting the laboratory exercise remotely using English by one of the lecturer. However, some concepts had to be explained by local lecturer in Norwegian language. Furthermore, all students have completed the tasks and they were satisfied with the exercise. This exercise was planned for 2-3 hours, but the students wanted an opportunity to learn for a longer period of time. Half of them outlined also the necessities of learning of some novel programming languages as they had only programming course in Java. All students will also recommend the participation in this laboratory to the other students.

IV. CONCLUSIONS AND FUTURE WORK

In this work-in-progress paper, we provide a detailed description of prepared applications, especially our robot capable of playing the tic-tac-toe game and show preliminary results and experience in conduct of a small PBL workshop related to programming robotic arm and integrating it with computer vision for autonomous robotic manipulation. The students participation in this optional exercise gave us positive feedback

on this activity and confirmed that they would like to take part in an obligatory course realized in this form.

Based on this experience, we are planning to introduce in the future an obligatory course of robotics with elements of computer vision for the students of electrical engineering at SFUC in the form of PBL.

Abstract—The Cyber Innovation Center’s Cyber Science curriculum is an interdisciplinary approach to educate high school students to become better cyber-citizens. Through Cyber Science, students learn applicable fundamental concepts from political sciences, history, and law as well as science, technology, engineering, and mathematics (STEM) disciplines as they relate to cyber. In particular, the curriculum includes basic programming and structures; advanced computer science topics; and the concepts of security and privacy in relation to cyberspace. The project-driven nature of the curriculum enables students to refine their computational problem-solving abilities through challenging and engaging programming problems. Mirroring the engineering design process, the Cyber Science curriculum introduces an iterative software development process to give students a structured procedure to approach and solve programming problems. This work in progress will address the purpose for developing the Programming Design Process (PDP), define the model used to create the process, and provide an example of a programming problem guided by the PDP.

Keywords—Cyber, Design, Programming, Robotics

I. INTRODUCTION

Careers in STEM and cyber are growing exponentially. However, the number of available positions is greater than the number of qualified professionals able to fill those jobs. One career website stated, “in 2013 there were 209,749 postings for cybersecurity-related jobs nationally.” Additionally, they pointed out that these jobs are difficult to fill due to lack of qualified talent [1]. A report by the Bureau of Labor Statistics projects there will be a 22% increase in computer and mathematics occupations by 2020 [2].

To help build a workforce for these fields, it is evident that an emphasis needs to be placed on these disciplines at the K-12 level. The students of today will be the workforce of tomorrow; if they are introduced to the possibilities of careers in STEM and cyber, then they are more likely to pursue the fields in college [3]. A deficit of U.S. STEM professionals is a major motivating factor for the development of engaging K-12 curricula that fosters excitement in STEM. The introduction of programming through simple and easy-to-use applications and platforms has become an increasingly popular method for

getting K-12 students excited about STEM and cyber. One such curriculum is Cyber Science [4], an interdisciplinary course designed by the National Integrated Cyber Education Research Center (NICERC), the education division of the Cyber Innovation Center (CIC). The CIC is a 501-3c not-for-profit organization set up as an economic development engine in Northern Louisiana (LA). Through NICERC, the CIC is able to bring engaging curricula to not only LA, but the nation as well. The CIC defines cyber as the integration of STEM and liberal arts disciplines, wrapped in a societal context with a technology underpinning. With this definition at the forefront, Cyber Science was developed to teach high school students applicable and fundamental concepts from political science, history, law, computer science, and STEM disciplines as they relate to cyber. Students are presented with various cyber-related programming activities that are both challenging and engaging.

Although curricula and programs that use programming have shown positive results toward engaging students in STEM fields [5-7], the process of programming can be difficult for some students to understand [8, 9]. The algorithmic thinking and analytical problem solving that is required to solve programming problems can be challenging for many students. To enhance step-by-step logical thinking by allowing students to organize their thoughts as they develop programs, a subject matter expert (SME) in computer science developed a process to guide students through programming problems from start to finish. The Programming Design Process (PDP) is a five-step iterative software development process that requires students to: 1) identify the goal, 2) design a solution, 3) implement the solution, 4) run and evaluate the program, and 5) customize the program.

In the rest of this paper, we provide an overview of the Cyber Science curriculum and the incorporation of the PDP, present and discuss each step of the PDP, and illustrate the implementation of the PDP with an example of a programming problem featured in the Cyber Science curriculum.

II. CYBER SCIENCE

The CIC quickly understood that in order to grow the cyber workforce, cyber education should be introduced in K-12

schools. NICERC was established and partnerships were formed with universities and K-12 school systems to grow and build opportunities to engage and challenge students in the field of cyber. For instance, the Cyber Discovery program [10] is a project that was developed at Louisiana Tech University (LA TECH) by faculty from diverse disciplines including engineering, mathematics, computer science, history, political science, architecture, and others. Cyber Discovery provides both professional development for K-12 teachers and an engaging summer experience for students. After the teachers attend two professional development workshops designed to give them the knowledge and pedagogical techniques to teach cyber concepts, the teachers mentor their students in the residential summer program. The summer program challenges students to compete with other schools in robotics competitions, solve a cryptographic treasure hunt, write thought-provoking essays, and build architectural structures; all activities and challenges are inter-related and are centered around cyber. The overwhelmingly positive student and teacher feedback from Cyber Discovery prompted the CIC with the following question: *How can the CIC keep students engaged throughout the school year?*

The CIC collaborated with SMEs and LA TECH faculty to create a year-long curriculum for high schools such that all students can experience, learn, and be challenged by cyber. Paralleling the Cyber Discovery curriculum, the Cyber Science curriculum was created with the intent of integrating liberal arts, computer science, and engineering. The course is composed of five major cyber-themes to provide a holistic view of cyber: programming basics, foundations of computer science, networking and security, artificial intelligence, and ethics and societal issues. Specifically, the curriculum includes basic programming structures (variables, algorithms, searching, sorting, etc.); advanced computer science topics (networking, security, cryptography, problem complexity); basic electrical engineering (parallel and series circuits, sensors); and the concepts of security and privacy in relation to cyberspace.

Cyber Science is taught at the high school level as an elective course. It was first piloted with a small group of regional schools in 2011 and has grown nationally with 100 high school teachers and administrators having access and having been trained to teach the curriculum; training is provided through a week-long immersive professional development workshop conducted by CIC SMEs.

III. THE PROGRAMMING DESIGN PROCESS

The engineering design process is a well-defined guide used as a problem-solving mechanism [11]. The process provides structure for students to methodically work through design ideas and challenges while also encouraging creativity [3]. Although at their core, programming problems are engineering problems that can be solved with the engineering design process, the algorithmic (step-by-step) nature of programming is not explicitly present in the process. Thus, mirroring the engineering design process, the Cyber Science curriculum introduces a simple iterative development process to give students a structured procedure to approach and solve programming problems. Figure 1 depicts the overall structure

Fig. 1. Programming Design Process

of the PDP; the following sections will discuss each step of the process.

A. Step 1: Identify the goal

The PDP begins when a student is given a prompt, problem statement, or project overview for a programming task; typically, programming problems are presented in an abstract manner. Thus, one of the most important skills a student should possess is the ability to analyze a problem statement and deduce the requirements of the program. The ultimate question that a student should answer in this step is: "What is the goal of the program?" A concise statement that details the desired functionality of the program should be written before proceeding on to the next step of the project.

B. Step 2: Design a solution

Again, only after an end goal has been established should a student attempt this step. This step requires a student to create a plan to solve the problem. As the Cyber Science course progresses and students gain more experience using the PDP, it will become clear that the best designs are those that are in the form of a sequence of steps. Using step-by-step designs make the programming implementation easier, because they model the sequential behavior of a program; however, no programming should be done during this step. The questions to address in this step include:

- 1) What steps are needed to reach the goal?
- 2) Which variables and types, if any are necessary to reach the goal?
- 3) Will any decisions need to be made to reach the goal?
- 4) Should or can any of the steps be repeated?

In particular, the solution should be designed on paper (or a computer) using English prose, pseudocode, or a flowchart. As

soon as the student is satisfied with their design, they can continue to step 3.

C. Step 3: Implement the solution

Depending on the solution design in step 2, the completion of this step should be relatively easy. If the design included a step-by-step plan to achieve the goal, the hardest part is determining what are the instructions used to convert each step into code. For example, if a step in the solution is to make a robot move forward, the students need to figure out exactly how to tell it to move forward in a language the robot can understand (lines of code). A good thing to keep in mind is the exact coding commands to implement a solution vary by programming language, and within a programming language there may be multiple ways to reach the same result.

D. Step 4: Run and evaluate the program

As the programmer, the student has the power to run, or execute, their programs. When a program is run it is checked for syntax errors. If the code is error-free, each line of code is executed. When the program execution is complete, the student should decide if the desired functionality was achieved. Essentially, did the program accomplish the goal? If so, they can move on to step 5. If the goal was not met, the students must backtrack to step 2.

E. Step 5: Customize the program

This is an optional step, but if the student has time, they can customize their program as desired as long as they have already produced the correct functionality.

IV. IMPLEMENTATION: PDP

All of the programming problems in the Cyber Science curriculum require students to program a Parallax Boe-Bot robot [13], where implementation is written with the PBASIC programming language. The advantages for teaching students to program through PBASIC include: PBASIC contains special commands for monitoring and controlling circuits; program execution is one single process to make it easy to understand and follow; the syntax of the language is simple and is not case-sensitive.

This section will present an example of a programming problem and the guided use of the PDP to program a Boe-Bot to make a left turn.

A. Left Turn: Identify the goal

The prompt for this program is simple so determining the goal of the program is straight-forward. After reading the prompt, the student is required to write a concise statement:

Goal – Move forward and then make a sharp left turn.

B. Left Turn: Design a solution

Again, in this step the student should design a general procedure that satisfies the goal; to do so, the student may choose from English prose, pseudocode, or a flowchart. In this example, we will choose pseudocode:

- Move forward
- the left tire should spin counterclockwise

```

counter  VAR Word

' Full Speed Forward
FOR counter = 1 TO 122
  PULSOUT 13, 850
  PULSOUT 12, 650
  PAUSE 20
NEXT

' Sharp Left Turn
FOR counter = 1 TO 122
  PULSOUT 13, 650
  PULSOUT 12, 650
  PAUSE 20
NEXT

```

Fig. 2. Left Turn: PBASIC Implementation. The PULSOUT command sends a pulse signal to a servo with a specified duration. In this example the servos are connected to pins 12 and 13 of the Boe-Bot, and the durations of 650 and 850 represent the spinning in clockwise and counterclockwise directions, respectively. The PBASIC syntax does not require curly braces or semicolons; the green text represent comments.

→ the right tire should spin clockwise

→ pause between pulses

→ Sharply turn left

→ the left tire should spin clockwise

→ the left tire should spin clockwise

→ pause between pulses

The goal is the driving factor for the pseudocode design, and hints that there are two phases of the program: moving forward and turning left. However, the student should reflect about the engineering and behaviors that cause the Boe-Bot to move forward and turn left. In particular, the Boe-Bot is designed in such a way that the servos controlling the tires are mounted opposite each other; in order for them to collaboratively produce a forward motion, both servos need to spin in different directions. Thus, in order to turn left, the servos should spin in the same direction.

C. Left Turn: Implement the solution

Once the pseudocode has been designed, the conversion from pseudocode into the PBASIC language is relatively simple. Figure 2 shows the implementation of the design in PBASIC code. The hardest part of this step is determining the equivalent PBASIC commands for each line of pseudocode, and understanding the PBASIC syntax.

D. Left Turn: Run and evaluate the program

After writing the program, the student should test the code to make sure that behavior of the Boe-Bot corresponds to the goal. If the Boe-Bot successfully moved forward and then turned left, the student may continue to the next step. Else, they should revisit their design in step 2 and revise their pseudocode if necessary. If the design is correct, then there may have been an implementation error that should be fixed in step 3. This iterative process should continue until the Boe-Bot is programmed to follow the correct functionality specified by the goal.

E. Left Turn: Customization

At this point, the student has the opportunity to customize the program. Specific to this problem, the student can experiment and make changes to the speed of the robot, the sharpness of the left turn, add code to move in other directions etc.

V. CONCLUSION AND FUTURE WORK

Establishing the PDP was the first step in creating the foundation for future research on the effectiveness of a methodical structure to help guide students to better understand programming and achieve goals. The PDP was developed in summer 2014, and was first introduced into the Cyber Science curriculum during the fall 2014 school year with a small set of teachers to pilot the process. During the professional development training over the summer 2015, an emphasis will be placed on the PDP to educate K-12 teachers on the effective implementation of the process within the Cyber Science curriculum. At the workshop, surveys will be provided to teachers to collect their feedback about the PDP. Similar surveys will be given to the students during the school year. At the end of the year, the feedback from teachers and students will be collected and analyzed to determine the value that the PDP brings to the curricula, as well as the process' ability to help students attain programming goals.

To help familiarize teachers with the PDP at the summer workshops, a fill-in-the-blank style template sheet was provided to simplify the learning and completion of each step in the process. These PDP template sheets help to build the teachers' confidence in programming as well as provide a useful supplemental resource to the PDP that help the teachers implement it in their classrooms. Thus far, in workshops where the PDP and PDP template page have been used, the teachers have shown greater confidence in programming and teaching programming than when they have not been used. Preliminary data taken from surveys at the workshops show a positive response to the PDP. However, more data will be collected over the course of the summer and upcoming school year. Current data has not been formally analyzed as this paper is a work in progress. Future plans are to use the data collected to assess the effectiveness of the PDP in both teaching and building confidence in programming for K-12 teachers and students.

NICERC has also added the PDP to other curricula that feature programming components. Specifically, at the high school level, Cyber Physics and Cyber Literacy are two NICERC courses that utilize the structure provided by the PDP to help students solve programming problems relevant to the course; both courses also use the Parallax Boe-Bot platform. Additionally, NICERC's middle school curriculum, STEM

Explore, Discover, Apply, contains coding modules where the PDP is used to guide the students through programming a Lego EV3 [14] and creating a game using the Scratch programming language [15]. These additional implementations of the PDP show the flexibility and applicability of the process to programming problems in different domains and will provide a larger test bed for assessing its effectiveness.

ACKNOWLEDGMENT

The research presented has been supported by the U.S. Department of Homeland Security under Grant Award Number, 2013-PD-127-000001, Modification #2.

Abstract— The objective of this paper is to instill in students motivation and interest for what they are studying a little bit further of the theory they learn in classroom. Sometimes students prefer more interactive classes and want to know why the material given in class is helpful in their career. Do we have a solution for this? Autonomous Robotic Vehicle (ARV) projects can be the solution to this problem. This type of project are interdisciplinary and offer students varieties of challenges, while involving different areas of interest like programming, design, assembling and testing. One of the best ARV project is the Micromouse. The Micromouse is a small robot that solves mazes. The basic idea is that the student makes his own Micromouse from scratch using knowledge acquired from different classes and the research done. This project also helps the student to develop teamwork skills and creativity to complete the different challenges and objectives that appear when building a Micromouse. The student learns the importance of working with students from other engineering concentrations, which allows him to experience how a career in engineer will be.

Keywords— Undergraduate Research, Education, STEM, Micromouse, Autonomous Robot Vehicle

I. INTRODUCTION

In this century the courses should be appealing to students. Why is this important? Because when the professors have the student's attention the lesson imparted is better received and the student is able to recall more of the knowledge acquired in the classroom [1]. Some studies reveal that 60% of students feel bored in half of their classes, while other 30% said they feel bored in all classes. Even in this recent research some "hands-on practical sessions achieved the highest boredom ratings". The author of this research attributes the results of these hand-on session to the fact that experiments were controlled exercises were the students already knew the results [2]. The difference between those hands-on experiences and the Micromouse project is that they lack diversity of results, outcomes and challenges, while the Micromouse does not. When the student finds an obstacle there is no instructor or manual to tell him what to do next, the student doesn't know beforehand what the outcome will be.

In today's world efficient and effective communication is essential in any career. This is especially true for engineers, since many of the projects that they are involved in include people from different areas and problems in communication

could end up in fatalities like the Space Shuttle Challenger Accident [3]. While the student learns the theory in the classroom and practices it in the laboratory, there is lack of a place where to integrate the knowledge acquired from different classes and where to interact with people from other majors. The Autonomous Robotic System (ARV) Micromouse Project is ideal to give the students the opportunity to expand their knowledge to these different areas. To achieve this objective, the integration of three different major was considered: Mechanical, Computer and Electrical Engineering.

The integration of these three majors adds diversity and variety to the project giving the students the opportunity to have the experience of working with people from different majors, to learn by social interaction and to develop social and communications skills. Through this Project students design and build a land robot able to travel across a maze. In others words, students get the opportunity to improve their skills by

II. WHY A MICROMOUSE?

This year a team was created for the research project: *The Quadcopter and the Micromouse: A Cooperative Robotic System* presented to Industrial Affiliates Program (IAP) at the University of Puerto Rico, Mayagüez (UPRM). The objective of this project was to engage two autonomous vehicles: an aerial vehicle (quadcopter) and a land vehicle (Micromouse), to work simultaneously to complete the mission of solving an unknown maze. This paper focuses on the Micromouse related part of the project. The Micromouse group consists of 4 students, 1 of 4th year and 3 in 5th year. One of the students is from Computer Engineering, 2 from Electrical Engineering and 1 from Mechanical Engineering.

III. APPROACH OF DESIGN

The students from the three majors worked together to design a working Micromouse prototype as seen in Fig. 1. Since the micromouse is a relatively complex robot there are mechanical, electrical and programing aspects that should be considered before building the robot.

Fig. 1. UPRM's M_{inds}^2 CREATE Micromouse Prototype

A. Mechanical Engineering Approach

A mechanical engineering student learns to work, not only with mechanical systems, but also to design thinking about where and how the other students will place the various circuits and sensors. The student must take into account the needs of his peers to make an effective design. The student also has to communicate the mechanical constraints to the others so that these are taken into account. When the students learn to communicate effectively with each other the result is a design that integrates all the mechanical and electronic system in the best possible way.

Besides improving technical communication tools of the students, the Micromouse project allows the integration of knowledge acquired in different classes, and furthermore, it allows the student to go from theory to practice. It is true that laboratories can implement the concepts learned in class, but there are many classes that don't have laboratories, and the practices and laboratory experiments are limited to issues of the class to which they belong.

In this project the mechanical engineering student puts into practice knowledge acquired in design, static and dynamic classes. When designing the vehicle it is necessary to take into account the weight of the various static elements and where those components will be placed because if the weight distribution on the robot is not the desired, the movement of the vehicle will be affected for worse. The knowledge acquired in design classes is extremely important for the student of mechanical engineering that belongs to the Micromouse project. In Fig. 2 can be seen the design consideration for positioning the infrared sensors and in Fig. 3 a possible design of a modular version of the Micromouse [4].

Fig. 2. Top view of sensors with angles

Fig. 3. Next Generation Prototype

The main difference between the design process used for the Micromouse and designs done in class is that for the Micromouse, apart from considering other systems, the student must take into account the availability of tools and the skills the students have to build the robot and the time available to do it. Now the student has to take into account factors that were previously irrelevant. Finally the Micromouse project provides mechanical engineer students a close experience to what could be found in the workplace, closer than classes and laboratories ever will.

B. Electrical Engineering Approach

Electrical Engineer students did a research of which components were needed to design and build a Micromouse considering the limitations and constraints of the maze. Student's research parted from the different components that were be available at the laboratory with the intention of making this Micromouse a modular and economic attraction [5].

1) DC Motors and H-Bridge

There are several types of motors (stepper, servo and DC) which could be used for this project; DC motors were the chosen ones because they have higher revolutions per minute. Because we are using a microcontroller we needed a way to control the motors. An H-Bridge, which allows to control the DC motors with the microcontroller, was used. Thanks to the H-Bridge the rpms of the motors can be controlled with the PWM (Pulse with modulation) pins of the microcontroller, which means that now the DC motors can go at different speeds, as desired.

2) Encoder

An encoder is a sensor of mechanical motion that generates digital signals in response to mechanical motion. There are available magnetic and optical encoders [6]. The two types are linear which responds to motion along a path and rotary that responds to rotational motion. The encoder is able to provide information concerning position, velocity and direction.

In this design rotary magnetic encoders were used, due to their efficiency and they avoid three major vulnerabilities that optical encoders have, which are: seal failures, bearing failures and shattering due to vibrations. There are many methods of detecting magnetic field changes, but the two primary types used in magnetic encoders are the Hall Effect

and magneto resistive. The Hall Effect detects a change in voltage by magnetic deflection of electrons and magneto resistive detects a change in resistance caused by a magnetic field.

Rotary magnetic encoders use two main components to provide position feedback shown in Fig. 4. The first component is the rotor which is magnetized with north and south poles that are lined around the perimeter of the disk. The second component is the sensor. The CPR stands for counts per revolution of the motor shaft.

3) IR-Sensors And Microcontroller

Students found a variety of sensors for the Micromouse. The sensor chosen was the IR-LED distance Sensor (SHARP), because it could provide distance measures and students were already familiar with this sensor. As it was mentioned before one of the future works interest is making a modular Micromouse, so it was decided by the students to use of an Arduino Pro mini. Arduino Pro mini offers a plug and play option with small dimensions, ideal for our design.

4) Printed Circuit Board Design

One of the jobs in this research project was working with Printed Circuit Board (PCB) design. This design is achieved based on a computer program (software) together with a special machine to make these designs called PCB Controlled Numerical Control (CNC) router. The program used to design the PCB was Eagle 6.1.1 and the program that the CNC works is called Mach 3, this is the program that gets the g-code generated by Eagle and converts in to coordinates for the CNC machine to draw the PCB. This part of the project is interesting because there is no electrical engineering class that teaches how to do a PCB design and how to use a CNC machine. In Fig. 5 you can see our design using Eagle.

C. Computer Engineering Approach

The students of computer engineering have the responsibility to understand the different components of the Micromouse. It is important that students doing both mechanical and electrical design provide the students programming how the components work and their limitations. Also computer engineering students should know is the task that the Micromouse should do. In our project we were building a land robot able to travel through a maze. The computer students, knowing this, programmed the Micromouse to be able to travel in straight line and to take turns. To move in straight line the Micromouse was programed to measure the distance between the IR sensors and the walls, if the distances are constant the robot is moving straight if the distances change then the Micromouse has to correct its course. With this information the microcontroller sends more voltage through the H-Bridge to the motor that is moving less to correct the trajectory. When the Micromouse is going to take a corner it uses the encoders to determine how much the wheels are rotating and the IR-sensors to give distance to the walls, as feedback, to know how much it has turned.

Fig. 4. Rotary Magnetic Encoder [8]

Fig. 5 Eagle Design of the Micromouse

IV. EDUCATIONAL THEORIES FOUND IN THE MICROMOUSE PROJECT

In the field of education there can be found a lot of theories describing what should be the correct method and approach to teach and give the lessons to students. One of the most used in our times is learn by doing. The most influent person in this kind of approach to student education was John Dewey. Learn by doing consist in students using the theory learned in classes to do hands-on activities [7]. An example is that the student is assigned to achieve an objective (build a Micromouse capable of navigating through a maze) and doing it with all the information learned in class and research (Micromouse navigating through maze). This hands-on activity gives the opportunity to the student to apply the lesson received in class to a real life problem with different levels of difficulty and types challenges. Learn by doing provides the student interactions with materials and equipment used for the construction of the Micromouse, often not known from previous university courses.

This project also provides the students the opportunity to interact and work with students from others majors such as Mechanical Electrical and Computer Engineering. Here is another of the theories found; learning by social interaction. When in the group there is a more skillful peer the others students learn in a faster way. Also by this social interaction students are able to share their knowledge acquired in their respective areas of studies and they learn how to simplify it for others to understand their work [8]. By doing this, students develop social and communication skills which are very important in STEM careers. Students here get the closest experience to a career job in engineering and begin to understand the importance of diversity in a project.

V. SKILLS DEVELOPED

The students were able to develop a variety of skills during this research. The skills that students developed can be easily demonstrated with *Criterion 3. Students Outcome* used by Accreditation Board for Engineering and Technology (ABET) [9]. During the academic year the students made progress reports where they mentioned the research done and the objectives achieved.

- Ability to apply knowledge of mathematics, science, and engineering – This can be seen through all the process of the construction of the Micromouse.
- Ability to design and conduct experiments, as well as to analyze and interpret data - Students conducted various experiments with encoders and sensors. Also they interpreted the data received by encoders and sensors and programmed based on that data.
- Ability to design a system, or process to meet desired needs within realistic constraints such as economic and manufacturability.
- Ability to function on multidisciplinary teams - The group was composed of three different mayor Electrical, Mechanical and Computer engineering.
- Ability to identify, formulate, and solve engineering problems
- Understanding of professional and ethical responsibility
- Ability to communicate effectively - To achieve the project's objective students needed to communicate efficiently to get the work done.
- Ability to use the techniques, skills, and modern engineering tools necessary for engineering practice

VI. SUGGESTED COURSES

For this research is expected that students have taken several courses before working on the Micromouse project. In Table I, there are some courses that the student should take, or is expected to have some knowledge before taking part in the design and development of the Micromouse project. Since this project is multidisciplinary, the table will have courses from the three majors involved in the project. Some of this courses have been suggested to other undergraduate research experiences at UPRM [10], [11].

TABLE I. Suggested Courses [12].

Course	Course Description
INEL 3105 Basic Circuit Analysis	Analysis of direct current and alternating current linear electric circuits; laws and concepts that characterize their behavior
INEL 4102 Intermediate Circuit Analysis	Networks functions; Circuit analysis by Laplace Transforms and Fourier series; Two-port Networks; Butterworth and Chebyshev Filters; Computer aided Analysis of these System.
INGE 3016 Algorithms and Computer Programming	Development of algorithms and their implementation in a structured high level language. Programming techniques applied to the solution of engineering and mathematical problems.
INEL 4505 Introduction to Control Systems	Analysis of Control Systems and their mathematical models; analysis and design of Control Systems for single input plants; Computer solution of problems will be emphasized.
INEL 4201 Basic Electronics Circuits Analysis	Semiconductor device characteristics: Semiconductor, Diodes, Bipolar Junction Transistors and Field Effect Transistors; analysis of basic digital circuits; analysis and design considerations of Transistor Amplifier Introduction to Integrated Circuits.

VII. FUTURE WORK

During the process of research and design it was known to the students that using the IR Sensors would require a bigger Micromouse. For further works it is planned to use smaller IR Sensors so the design would be smaller. Also it is planned the implementation of a maze's solving algorithm to this new version of the Micromouse so it can solve the maze autonomously. The research group noticed that it was needed a modular Micromouse for this kind of activities that is way the robot presented in this paper have some parts and components considered for our next design.

VIII. CONCLUSION

The students in this research were able to design and build a Micromouse capable of navigating through a maze. They were able to identify problems in design and overcome them with different approaches. At the end the Micromouse responded to the commands send via Bluetooth. This kind of research takes the students to a whole new level of experience and challenge. They can acquire knowledge with the interaction of students from different majors. While they interact they develop team work and oral skills. The experience working in the lab with the different programs and design tools gives the student a close approach of what a STEM career will be.

Abstract—First-year students are often not well equipped with the base competencies that are a necessary precondition for effectively acquiring complex new knowledge. Among others, these base competencies comprise self-organization, analytical thinking, or communication skills. Shortcomings in these competencies often lead to problems in the study process. To solve these problems, we need to investigate the students' initial competencies, in order to become aware of possible deficits, find ways to deal with them, and thus to enable students to reach their goals. Therefore, we developed a self-assessment on base competencies, an accompanying knowledge test and a questionnaire on personal information. The data collected by these tools was analyzed, searching for competence characteristics which influence whether our students persevere and participate in the final exam, or drop out early. The results of our data analysis support the assumption that both non-technical and technical competencies are crucial to study successfully. Correlation analysis has identified several characteristics which distinguish the students that participate in the exam from those who do not. Based on these results, we suggest ways to optimize university courses, teaching methods, and the support of first-year students to meet their needs.

I. INTRODUCTION

Over the last years, computer science industry has been growing. This trend is likely to continue, as computer science becomes more and more important for both everyday life and business. As a consequence, industry requires a growing work force of well educated software engineers. Correspondingly, universities denote an increasing number of students that enroll in computer science and related topics. Nevertheless, computer industry still faces a shortage in well educated engineers [1, p. 7], [2, p. 37] and [3, p. 58]. In Germany, one reason for this situation is a high drop out rate of over 30% in STEM (Science, Technology, Engineering, and Mathematics) subjects [1, p. 8], [4, Tab.2.5.78c] and [5, p. 60].

Our observations identified two main factors for this high drop out rate. The first one is the diversity of our first-year students' academic skills, caused by Germany's heterogeneous system of secondary schools, which lead to a variety of different entrance qualifications for higher education. Thus,

lecturers have difficulties in identifying the ideal knowledge baseline from which they start their class, trying to challenge their students neither too little nor too much. As a second factor, many of our first-year students experience their first term at university as a tough challenge, having to adapt to a new way of learning and teaching. In computer science, especially, they must deal with a highly abstract manner of thinking, which differs from what most of them are used to from school or everyday life.

A. Problem Statement

The CS department of Munich University of Applied Sciences offers three different bachelor programs. In all of them, the mandatory course on software development is the major hurdle that freshmen have to face. More than five years of statistical observations indicate that each year, a total of approximately 70 percent of our freshmen students pass the final exam of this class with a rather poor grade (3.3 or worse, on a scale from 1.0—excellent to 5—fail, with 4.0 being the last passing grade), fail the exam (grade 5), or postpone taking the exam to some later semester. As software development skills are the fundamental basis for many of the more advanced courses in later semesters, students who were unable to cope with study requirements right from the beginning only have a very small chance to study successfully later on.

From past teaching experience, lecturers strongly suspect that in many cases, the observed difficulties in acquiring new CS knowledge are caused by significant deficiencies in certain base competencies (i.e. self, practical/cognitive and social competencies). Moreover, past teaching experience shows that whenever lecturers identified gaping holes in the base competencies of individual students, and were able to close these gaps by specific coaching and tutoring, these students were enabled to study successfully. So far, this detection and mending of base competency deficiencies has mainly been guided by the lecturers' gut feeling, and focused only on a small subset of students. To increase the impact of this approach, it has been evolved into a more systematic set of tools consisting of a

self-assessment of base competencies and a knowledge test [6]. These two tests have been taken by all of the first-year students at Munich University of Applied Sciences at the Faculty of Computer Science in winter semesters 2013/14 and 2014/15.

B. Current state of our project

To measure the initial competencies of freshmen students, two tests were developed. A self-assessment [6] focuses on base competencies that are crucial to study computer science or related topics successfully. An accompanying knowledge test addresses fundamental academic skills, such as German and English reading comprehension, fundamental maths, basic computer skills and abstract thinking. A supplementary questionnaire provides personal information, such as the students' migrational background and type of their university entrance qualification.

To gain insight into our students' biography at university, we developed a third questionnaire focusing motivation and current attitude towards their studies, which we assessed in November 2013 and 2014. Finally, we identified via aliases which students participated in the final exam of the mandatory course on software development.

C. Research Objective

Lecturers cannot influence the base competencies and knowledge that students acquired before enrolling at university. However, lecturers need to be aware of the first-year students' competencies to pick them up where they are. Therefore, as a first step we identified competencies that are success factors for studying computer science or related topics [7].

Based on the data we gained by several test-instruments, which are described in detail later on, we want to identify attributes of our first-year students that enable us to detect early on those students who might be in danger of not taking their first semester exam in software development, and thus are at risk of falling behind and never catching up. Identifying the group of students which is insufficiently prepared provides the basis for a portfolio of interventions that help these students to improve their insufficient base competencies. Thus, we want to reduce drop-out rates in our first-year programs of computer science and related topics.

To achieve this, we analyze the data gathered by our tools (tests and questionnaires), using a combination of visualization as well as statistical and data mining methods. Furthermore, lecturers want to gain insight into their cohorts' competencies and deficits, to be able to guide them effectively through their student entry phase. Lecturers will coach students in their attempts to close their gaps, to enable them to complete their studies successfully. Thus, known teaching methods need to be investigated and maybe adapted, if necessary, or even new methods need to be developed.

II. RELATED WORK

High drop-out rates in engineering and computer science are an internationally observed phenomenon [1, p. 8], [4, Tab.2.5.78c] and [5, p. 60].

French et al. [8] find high school ranks and SAT scores to be the most reliable predictors of engineering students'

retention and academic performance. The study acknowledges, though, that the results may not be representative of academic achievement and persistence of minority and/or international students. Furthermore, much variance remains to be accounted for.

Carnegie et al. [9] confirm that high school grades in specific subjects may, with some restrictions, be used to predict academic success of students in "digital" engineering programs including computer science.

A number of studies points to other factors that influence students' retention and academic success in computer science and engineering [10], [11], [12], [13]. They show that students are not attracted to or leave the fields because of perceived culture, perceived inadequate teaching and lack of opportunities to engage.

In [7], we considered many studies on competencies and success factors while identifying competencies that are relevant for studying computer science and related topics successfully. Based on this research, we developed a set of tools to assess the students' initial competences and knowledge [6].

Sharabiani [14] described an approach to use data mining methods to build a model for predicting students' academic performance. When using several data mining methods with different parameters, an enhanced bayesian network provided the highest accuracy. Thus, we adopt this approach for our data analysis. In addition, we employ statistical methods to identify characteristics among our students.

III. INSTRUMENT DESIGN

Every year, an extremely heterogeneous group of students enrolls at Munich University of Applied Sciences, Faculty of Computer Science and Mathematics. Students differ regarding their cultural, educational and professional background. As not all incoming students are well equipped with base competencies or knowledge to study successfully, paper-based questionnaires have been developed to gain insights into students' initial level of competencies, knowledge and personal background.

In total, there are six data sources: Self-assessment, knowledge test, personal information (e.g. work experience and migration background), presence in a lecture in November, participation in the final exam (yes/no) and additional information (e.g. degree program, study group). Students fill out these tests during their first year of studies. The data sources can be correlated by means of an individual anonymous alias.

A. Self-Assessment

The self-assessment used to assess competencies has already been published in [6] and presented at EDUCON2014. We will give a short overview of this instrument in this section.

Our self-assessment focuses on base competencies necessary for the study process in general, and on base competencies that are specifically needed for acquiring knowledge in computer science [7]. Examples are self organization, thinking in an abstract way, or thinking logically. All in all, the self-assessment consists of 36 competencies. Two positive

competencies were matched into complementary pairs of competencies and are depicted on a bipolar scale. In order to avoid misunderstandings, each competence is explained in a short sentence. Normally, it is very difficult to decide for only one of two positive competencies on the bipolar scale as competencies are not always located at exactly one position. Usually a combination of the competencies is necessary to achieve a perfect result. To reflect this, students were asked to consider each pair of competencies in two different modes: *normally* and *easily adoptable*. In *normal* mode, students have to decide which competence fits their normal behavior. The range in which students can easily move between two complementary competencies, is the mode *easily adoptable*. In this mode, students have to tick several check-boxes in a row, which represents the range [6]. An example of two complementary competencies from the self-assessment and how the question has to be filled in correctly is depicted in figure 1.

To evaluate the self-assessment tests the research team designed a *Model Student* based on the results of interviews with lecturers [6]. From these results a level for each base competence has been calculated. These levels can be seen in the radar chart in figure 2.

In order to validate the feasibility of our self-assessment, we did a pilot study. We successively tested the instrument on small groups of students. Based on their feedback and first results, we improved the assessment design and introductory usage instructions again and again [6].

Furthermore, we met the following current standards [15] that are well-known for assessment execution, while carrying out our self-assessment.

B. Knowledge Test

The knowledge test contains questions on: German and English reading comprehension, fundamental maths, basic computer skills and methodical competencies, like logical and analytical thinking. Amongst others, the math section contained questions about reducing a fraction, solving equations or probability theory and statistics. To test methodical competencies, we used tasks, like finding the odd graphic out of five, doing some modeling in order to find a solution, understanding an issue shown in a given graphic, or extracting a rule set based on given examples and transferring it to another situation. This test evaluates students' current knowledge at school level, not at university level.

Some tasks were deliberately designed in a way that they assess selected competencies in the self-assessment. For example, in the self-assessment we ask students about their reading skills, the ability to understand graphics or how distinctive their ability to think logically is. Adjusted to the crucial competencies, we included questions focussing these competencies [6].

A concrete example would be finding a rule set based on given examples of combinations of X and O that can be transferred to code consisting of a, b, c, i, x and o. Afterwards, students need to transfer this rules to another combination of X and O to find the correct code (cf. figure 3) [16]. Thereby, we gain insight into how adequately students are able to assess their own skills [6].

X	X	O	O	O	X	X	bxcobx
X	O	O	O	O	O	X	axeoaax
O	O	I	I	I	I	O	???
X	O	X	I	X	O	X	axaoaxiaxaoax
X	X	O	O	O	X	X	bxcobx

Fig. 3. Example question from the 'Informatik Biber' [16]

C. Personal Information

To complete our data, we developed a questionnaire focusing on personal information, like university entrance qualifications, migration background, family environment, work experience and current employment, as well as, details of the school background.

The questionnaire used in winter semester 2013/14 often contained questions with free text answers. In the second run in winter semester 2014/15 we changed all answer possibilities to multiple choice, in order to allow an automatic import to a computer system. Based on the answers given in 2013/14, the multiple choice answer possibilities were chosen.

D. Limitations

In the first run, data was transferred manually from paper-based questionnaires to a computer program. This can imply mistakes and can lead to wrong data if not done with the necessary attention and accuracy. Thus, this process should be automated. This approach has been implemented in winter semester 2014/15. All questionnaires are created and scanned with EvaSys©, which is a survey automation suite.

IV. EXECUTION

Data collection started in winter semester 2013/14. During an introductory day we successively assessed the students to not overcharge or bore them. The day started with a game where students get to know each other. Subsequently, we started with the self-assessment, followed by some team-building exercises. After the knowledge test, which also contained the questionnaire on personal information, the day ended with another action to promote team-building.

In the winter semester 2014/15 we also had such an introductory day containing all activities and tests with minor changes.

A. Population

At the beginning of the winter semester 2013/14 we asked all first-year students of computer science, scientific computing, information systems and management as well as geotelematics and navigation at Munich University of Applied Science, Faculty of Computer Science and Mathematics to complete three questionnaires. All in all we assessed about 320 first-year students. In the following winter semester 2014/15 we again assessed about 315 first-year students.

B. Test Execution

All first-year students in winter semester 2013/14 and 2014/15 completed the same paper-based self-assessment and

	obstinate	self-contained				team-oriented				over dependent

Fig. 1. Filled example of a pair of complementary competencies [6].

Fig. 2. Expectations towards students at the beginning of the first semester (Model Student). Defined with help of lecturers of different Universities of Applied Sciences.

knowledge test at the same time and place within one hour each. We shortly introduced our project and the benefits of the self-assessment, in order to motivate students to fill in the questionnaires. Additionally, we handed out a manual summing up the usage instructions for the self-assessment. Furthermore, we insured that all assessment results will be processed anonymously and privacy issues will be observed at all time. Students were requested to fill out the instruments on their own. They were able to ask questions that might occur, while working on the questionnaires [6].

C. Tracking During the Semester

In November 2013 and 2014, thus after 2.5 months of studying, students were asked to fill a short questionnaire about their motivation and current attitude towards their studies. We think this is a good point in time to evaluate this, as most of the students are still attending classes and they already obtained some experience about the study contents as well as the study process. Hence, they are able provide a first

assessment. This questionnaire also asked for the alias, to track students presence in the lecture.

Additionally, just before the beginning of the final exam on Software Development, students were asked to provide their alias on an anonymous sheet, so we can keep track of the individual attendance.

V. ANALYSIS OF THE DATA

Based on the test results, we analyze if there are competence characteristics among our first semester students that distinguish the students that attend lectures regularly or participate in the final exam of Software Development from those who do not. Furthermore, we provide lecturers with an idea of the initial skills of their particular cohorts and an overview of all first semester students. As well, we gain information on the heterogeneity of our students. During the analysis, we focus on technical as well as non-technical competencies. For analysis we used both data mining methods and classical statistical methods.

A. Analytic Process

In order to develop a predictive model from the given data, it is necessary to prepare and select attributes as well as to train and validate the model in the end [17].

After data has been collected, new attributes can be generated based on existing ones in the *preparation* step. Furthermore, values are normalized and transformed if they have variable ranges in this step. Subsequently, data is selected (*selection*), both relevant instances and attributes. In the *analysis* step, data can be visualized, for example, which is often very effective. Correlation can be used to find relationships between attributes. When classifying instances, classifiers are used. We use supervised learning methods to create classifiers that are based on labeled instances. This enables us to predict the classes of new instances, i.e. whether a new student is likely to pass or drop out. Finally, in *evaluation*, results of the analysis must be interpreted, documented and evaluated whether they are significant or not [17].

B. Data Preparation

In the first step all information from the different data sources are merged. We ended up with about 180 attributes per instance.

Furthermore, attributes are transformed and combined to create new ones as well as discretized. This is common practice in data mining to try to improve the success of the methods [18, p. 305]. The goal is to automatically or at least semi-automatically discover meaningful pattern in electronic data [18, p. 4–5]. An example is that buying patterns are different on weekdays and weekends. This can only be seen, if an attribute weekend (yes / no) is present in the data. Otherwise, it can be created based on the invoice date.

SELF-ASSESSMENT

Filling out the self-assessment [6] is not simple. Some students did not understand the concept of modes or did not fill in all check-boxes of the questionnaire consequently. Most of the time this happened in the mode *easily adoptable*. Students just ticked the most left and right check-box to indicate their range (cf. figure 1). In this section, we give several examples for the data preparation we did.

Missing check-boxes in a row, especially in *easily adoptable* mode, were filled automatically. In more detail, all check-boxes between the most left and right check-boxes were ticked if not done by the students themselves. Whether students understood how to fill the questionnaire or not, was investigated manually by the research team. Questionnaires where students obviously did not understand the process, were deleted from the data set.

The data set is enriched by the maximum value of all competencies in normal and easy mode. Furthermore, the minimum value of all competencies in easy mode has been added. As students in normal mode have to position themselves on one side of a bipolar scale, the minimum value is always zero. In addition, the overall media and average for normal as well as easy mode is calculated.

KNOWLEDGE TEST

Answers of the knowledge test can be easily corrected, whether

they are right or wrong. To reduce the number of attributes, results of topics are grouped. For example the knowledge test contains German and English reading comprehension as two separate topics. The number of correct answers of each topic is summarized to form a new attribute. Moreover, an attribute is introduced that states whether students exceed the predefined threshold of this topic or not. The same approach is applied to subtopics in mathematics like: fractions, functions, statistics, stochastics and problems formulated in text form.

Thresholds for each topic or subtopic are defined in consultation with lecturers. They represent the expectations towards first-year students on their first day.

Furthermore, we had questions focusing different competences on three different levels (easy, medium, difficult). Based on the number of correct answers given per level, we calculated a number that can be compared with the self-assessment of this competence. Subsequently, we can compute, whether a student overestimated, underestimated him or her self, or if the self-assessment was correct.

PERSONAL INFORMATION

Most of the questions in this questionnaire contain free text answers. This creates many different response formats. One example is the last math grade. In Germany there are usually grades from 1 (best) to 6 (worst) with a step size of 1 at school. In more advanced years there are grades from 15 points (best) to 0 points (worst). It is possible to transfer grades from one system into the other. However, some students did not clearly specify which system they use. Hence, there occurs the problem that it is not clear, if they had 1 to 5 points or grade 1 to 5. Points were transferred to the benefit of the students into grades, though.

Furthermore, students noted how long their last math class dates back. These data is clustered into three classes: less than 6 month, between 6 month and one year, more than a year.

Some of the students completed a vocational training before starting their studies. This is also asked in the questionnaire. Students also state, which job they were trained on. With help of these two information snippets a new attribute “type of apprenticeship” has been generated. It has the following characteristics: IT apprenticeship, non-IT apprenticeship, no apprenticeship.

C. Data Selection

After all data has been revised, transformed and new attributes have been generated the impact of each attribute towards building the prediction model can be identified. This can improve the performance of the data mining methods [18, p. 305]. Thereby, a reduced set of attributes is generated. Additionally, only complete instances (data per student) are considered for further analysis.

INSTANCE SELECTION

For some students at the Faculty of Computer Science and Mathematics their studies started with an introductory day. They had to fill in one questionnaire, two tests and socializing games took place between the tests. All other students just filled in the questionnaire as well as the two tests during a lesson.

As some students were late or left earlier, there is not always an accompanying knowledge test for each self-assessment or vice versa. For analysis, only a complete instance of a student is considered. An instance consists at least of: self-assessment, knowledge test and personal information. Consequently, incomplete instances are deleted from the data set. After this process, 228 instances were left ($n=228$).

Subsequently, the data set was partitioned into two sets:

- Computer Science, Scientific Computing and Geotelematics and Navigation
- Information Systems and Management

This was done, as these two groups had a different amount of lecturers on software development per week as well as a different curriculum. All ongoing steps, like attribute selection, are executed on both data sets in parallel.

ATTRIBUTE SELECTION

Attribute selection is an important part of the data mining process, as irrelevant attributes can confuse the algorithms.

As a first step all possible *linear correlations* between two attributes are calculated. In case the correlation is high, one attribute can predict the other. Hence, one is irrelevant for data analysis and can be deleted. However, no linear correlations exist in the data. Hence, we additionally use standard attribute selection methods from Weka© to extract attributes that are influence the prediction. These methods to find relevant attributes are successful for our data.

D. Data Analysis

After the attribute selection data can be analyzed. The aim is to create a classifier that predicts, whether a student participates in the exam or not. Furthermore, the competencies or their combinations which are different among this two classes of students should be discovered. Thereby, competencies that are relevant for successful studies can be identified. Moreover, lecturers can help students to close their individual gaping holes, so they can study successfully.

As we do not know what patterns exist in the data and we do not want to assume one, we use methods from the field of data mining, rather than classical statistics [19]. We chose Decision Trees as the result is easily understandable for people and it can be visualized. Hence, a profile of students participating in the exam or not can be simply constructed from the visualized tree. k-Nearest Neighbor is a promising method, because different distance measures can be used. Other distance measures than euclidean distance might fit the data much better. All methods were used several times with different settings to find the classification model that is as accurate as possible. To evaluate the models, a 10-fold cross validation is applied.

E. Validation

In order to validate the classifier, *10-fold cross-validation* is used. This method partitions the data into 10 approximately equal-sized subsets. One of the subsets is used for testing the model, the remaining $k - 1$ subsets are used for training the classifier. The process of training and testing is repeated ten times. Mean- while, each of the subsets is used once to validate

the model. Afterwards, the results are averaged or combined to come up with a single classifier. One advantage of this method is, that all instances are used for training as well as testing [18].

F. Correlations

Another tool for analyzing data that is often very effective, is visualization. Standard methods for visualization are plots [17]. A possibility to basically analyze data are pivot tables combined with pivot diagrams. They can be easily generated and interpreted. In order to find interesting attributes that influence the exam participation (attribute with occurrence yes or no) we use pivot tables and diagrams in Microsoft Excel 2013© to quickly generate contingency tables and diagrams. This helps to get an overview of the data and to identify interesting correlations. Furthermore, we calculated frequencies of different attribute combinations. For highly interesting correlations, we additionally compute the p-value with help of Fisher's exact test [20].

VI. FIRST RESULTS

In the following, we show first results from the tool set conducted at Munich University of Applied Sciences, Faculty of Computer Science in winter-semester 2013/14 and 2014/15. Students filled in these tests as part of an introductory day. The most interesting attributes and their possible values can be found in table I.

TABLE I. OVERVIEW OF THE MOST INTERESTING ATTRIBUTES AND ATTRIBUTES WITH A HIGH IMPACT ON THE PREDICTIVE MODEL.

Attribute	Values
exam participation	yes, no
lecture attendance (lecture in November)	yes, no
specialization at school	social, technology, economy, no answer
abstract thinking (self-assessment, knowledge test)	0 – 5
comparison (self-assessment and knowledge test)	correct, over, under (estimated)
apprenticeship	no, IT, non-IT, no answer

All other practical and cognitive competencies, like thinking concretely or logical thinking have no impact on the exam participation or lecture attendance.

A. Details about the Study Population

In winter semester 2014/15, 262 of 312 students stated their gender. About 75% were male and 25% were female. This is a distribution we usually have among our students at the Faculty of Computer Science and Mathematics. Furthermore, 33% of our first-year students participated in the final exam of Software Development, after the first semester.

About 34% of the first semester students in 2013/14 made an apprenticeship before starting their studies. Approximately 14% of the apprenticeships were related to computer science. The other 20% accomplished a vocational training in other fields, like media, welfare, science, technology, engineering, and mathematics (STEM), business administration or finance.

In 2014/15 we had a similar distribution of: 22% non-IT apprenticeships and 15% IT apprenticeships. Figure 4 shows the corresponding diagram for the distribution.

Fig. 4. Distribution of students (2014/15) according to whether they made an apprenticeship before starting their studies or not. (n=148)

B. Data Mining Results

It is important to test different data mining methods and divers parameter values to see which works best [18, p. 305]. This empirical testing of various attribute selection methods combined with different classifiers has shown that the data set of 2013/14 has a certain relevance. It is possible to predict the exam participation for more than 70% of the students correctly using k-nearest neighbor. A value of correctly classified instances greater than 70% using 10-fold cross validation is a good result for both data sets. Hence, the questionnaires have a relevance for predicting the exam participation.

A restriction to relevant competencies is possible. Weka's GainRatioAttributeEval [21] reduced the number of attributes to four respectively nine relevant attributes, namely:

- 1) Information systems and management students
 - Self confident
 - Abstract thinking
 - Logical thinking above/below our predefined threshold
 - Specialization at school
- 2) Computer science, Scientific computing and Geotelematics students
 - Serenity
 - Analytical thinking
 - PC theory
 - PC practice
 - Knowledge test overall above/below our predefined threshold
 - 3 concrete specialized questions

These results support the assumption that the tests and the questionnaire ask the right questions to get information that are necessary to forecast students' exam participation. Furthermore, the classifier refers to non-technical as well as professional base competencies. This indicates that there are base competencies and technical competencies that are crucial to study successfully. Results are promising, so more time should be spent on manually choosing attributes and applying more advanced data mining methods.

C. Correlations

Correlation analysis has shown that there exist several attributes that distinguish students who participate in the exam or attend lectures regularly, from those who do not.

If students of Computer Science, Scientific Computing and Geotelematics and Navigation exceed the defined threshold for the number of correct answers in the knowledge test, there is probably no influence on the exam participation. However, if

students failed to exceed the threshold, they supposedly do not participate in the exam on Software Development I. Table II shows the corresponding calculation.

TABLE II. FREQUENCY OF THE STUDENTS' PARTICIPATION IN THE FINAL EXAM COMBINED WITH THE THRESHOLD OF THE KNOWLEDGE TEST FOR STUDENTS OF COMPUTER SCIENCE, SCIENTIFIC COMPUTING AND GEOTELEMATICS AND NAVIGATION (DATA OF 2013/14).

Exam participation	Threshold passed	Threshold failed	Overall
yes	44.44%	18.46%	34.15%
no	55.56%	81.54%	65.85%

Applying classical test theory (Fisher's exact test [20]) we get significant results in the sense that the null hypothesis *The participation in the end of term exam in Software Development is independent from passing the knowledge test* can be refused with error probability less than 10^{-3} .

Experiences at our institution show, that students with an apprenticeship often manage the study process better than students without. This assumption is confirmed by the data of 2013/14 (cf. table III). Students with relevant work experience additionally benefit from there already existing professional knowledge in some subjects, especially in introductory courses like Software Development I or Introduction to Databases. Thus, they can focus on dealing with the study process itself. Again high significance for the correlation between the exam participation and whether students did an apprenticeship before their studies or not.

TABLE III. OVERVIEW OF THE STUDENTS' PARTICIPATION IN THE FINAL EXAM REGARDING THEIR PREVIOUS VOCATIONAL TRAINING.

Exam participation	IT	non-IT	no apprenticeship
yes	60.47%	42.37%	32.66%
no	39.53%	57.63%	67.34%

Furthermore, it is very interesting that in all degree programs, students that specialized on social topics at school, did not participate in the exam. Table IV shows, that the frequency of students who participate in the exam for the group 'Social' is 0%. Whereas the frequency for 'Economics' is 20.59% and for 'Technology' is 40.63%. Among all students participating in the exam of winter semester 2013/14 the frequency was 29.46%.

TABLE IV. FREQUENCY OF THE STUDENTS' PARTICIPATION IN THE FINAL EXAM REGARDING THEIR SPECIALIZATION AT SCHOOL (DATA OF 2013/14).

Exam participation	Social	Technology	Economics	Overall
yes	0.00%	40.63%	20.59%	29.46%
no	100.00%	59.38%	79.41%	70.54%

Beside the exam participation, we also want to examine the attendance at lectures. Therefore, we tracked students in November, after two month of studying. Thereby, we want to find characteristics of students who skip lectures at an early point.

For example, students who attended the lecture in November, where we tracked their attendance, tend to underestimate their competence of abstract thinking at the beginning of their studies (cf. table V). If we additionally look at the students

who underestimated themselves, we see in table VI that these students achieved a high level in the knowledge test compared to other students. That good students underestimate themselves also applies to logical and analytical thinking. However, when looking at this two competencies, the impact on the attendance is not that high.

TABLE V. FREQUENCY OF THE COMPARISON OF SELF-ASSESSMENT AND KNOWLEDGE TEST REGARDING ABSTRACT THINKING COMBINED WITH THE LEVEL STUDENTS ACHIEVED IN THE KNOWLEDGE TEST (DATA OF 2014/15).

Attendance	Comparison self-assessment and knowledge test			Overall
	Correct	Over	Under	
present	53.45%	56.38%	65.98%	59.44%
not present	46.55%	43.62%	34.02%	40.56%

TABLE VI. FREQUENCY OF THE COMPARISON OF SELF-ASSESSMENT AND KNOWLEDGE TEST REGARDING ABSTRACT THINKING COMBINED WITH THE LEVEL STUDENTS ACHIEVED IN THE KNOWLEDGE TEST (DATA OF 2014/15).

Self-assessment	Level of abstract thinking (knowledge test)				Overall
	0	1	2	3	
correct	9.38%	24.62%	30.43%	24.81%	23.29%
overestimated	90.63%	66.15%	43.15%	9.30%	37.75%
underestimated	0.00%	9.23%	26.09%	65.89%	38.96%

This indicates, that abstract thinking is an important competence in computer science and related topics and can not be easily learned beside the studies. Whereas, it seems that logical and analytical thinking can be trained with help of the usual assignments.

Moreover, it shows that good students tend to underestimate themselves. From past teaching experiences, we suspect that self-critical and reflected students perform better than other. Good students still see room for improvement and actively call for feedback during the practical sessions. This assumption is supported by this data.

VII. CONCLUSION AND FUTURE WORK

Experience shows that students in computer science or related topics often encounter problems at the beginning of their studies, due to deficits in those base competencies that are required for dealing with the study process itself, as well as for acquiring complex new knowledge. To pick students up where they are, lecturers need to be aware of their competencies and deficits.

Our first goal was to gain an overview of the students. Thus, each lecturer received a short report containing statistics on personal information, results of the knowledge test and a summary of the cohort's non-technical competencies, compared to the *Model Student*. These cohort-specific reports comprised details similar to those shown in this paper for all the first-year students at Munich University of Applied Sciences in 2013/14 and 2014/15.

Secondly, we wanted to identify similarities and differences among the students with respect to their attendance at one specific lecture as well as the participation in the final exam on Software Development. Correlation analysis using plots, contingency tables and frequencies show that there exist several

attributes that distinguish students who participate in the exam from those who do not. Some of these results were surprising, while others were expected. For instance, it was quite obvious that students who completed a vocational training in the field of computer science prior to their studies would perform better than others that are new in the field. However, an alarming result was that none of the students who specialized on social topics at school participates in the final exam. This evidence suggests that there are certain crucial qualifications which are neither taught to students who focus on social topics at school, nor recapitulated during the first term at university.

After we gained these new insights into our cohorts, we started to include reflection phases into the practical lab sessions. Here, students correct each other's assignments and give hints to improve solutions. Afterwards, each student has to give a short feedback whether he or she accepts the suggestion or not, and why. This enhances the abilities of being self-critical or reflected as well as the ability to scrutinize.

In a next step, we want to analyze the differences of the specializations at school as students who focused on social topics apparently come along with some deficits and knowledge gaps. Subsequently, we can for example design a bridging course or directly address the students' deficits and knowledge gaps in the lectures. Furthermore, we will focus on abstract thinking during our practical sessions, as this skill (or its lack) seems to have a strong impact on the lecture attendance and maybe on the exam participation, too.

The third goal was to build a classifier to forecast the participation in the final exam on Software Development. The data allows us to correctly predict the participation of more than 70% of the students (2013/14). Thus, the tests and questionnaires developed by the research team have a significance for predicting the exam participation. The process of assessing students and analyzing their results indicates which students are at risk not to participate in the final exam.

Furthermore, an alternative to the automatic attribute selection methods of data mining is to select the relevant attributes manually. In this process, decisions are based on a deep understanding of the data. This might increase the accuracy of the prediction model.

All in all we want to continue collecting and analyzing data in the next semesters in order to enrich our data set, to confirm our findings and to reveal new relationships. Concurrently, a portfolio of appropriate interventions can be developed to support students who are at risk of falling behind and never catching up. These interventions should help students to overcome their deficits and to reduce drop-outs. A first evidence is to fortify students' identities and professional skills as engineers [22], [23]. Subsequently, we want to develop an integrated approach to increase retention in our first-year programs, as students are well equipped with those base competencies they need to study successfully.

ACKNOWLEDGMENT

This work was supported by the German Federal Ministry of Education and Research (BMBF), grant no. 01PL11025, as part of the "Qualitätspakt Lehre" ("Teaching Quality Initiative") program. Thank you for your support.

What is the Effect of Establishing Programs that Address Sense of Belonging on Undergraduate Engineering Retention?

Abstract - Research ascribes that a variety of factors (e.g. course load, poor instruction, financial restraints) contribute to students' decisions to change majors and to drop out of college. Less well understood, however, is the influence of a sense of belonging on student persistence, particularly within engineering. Several studies have connected sense of belonging with retention, but few have focused on the relationship between specific programs and longitudinal retention among engineering students. In this study, researchers examined the long-term effects of a suite of strategies designed to enhance a sense of belonging of engineering students.

To evaluate these reforms, an interrupted time series approach was utilized. Fourteen annual cohorts were examined from 1998 through 2013. Trends were first evaluated among the engineering students as a whole, and then by gender and ethnicity. Overall, the rate of retention increased at an average rate of 1.1% per year. Prior to reforms, retention was on the upswing but only at a rate of 0.9% per year. Following the new strategies, this rate nearly doubled to 1.6% per year. Finally, it is noted that the increase in retention occurred alongside an increase in the overall size of the engineering student body.

Keywords – retention, persistence, sense of belonging, co-curricular, student support programs

BACKGROUND/RATIONALE

Recent research has shown that engineering students tend to leave their majors at a rate comparable to other students enrolled in the

humanities, business, and education. Students who are changing majors, however, are then far less likely to select engineering as their next career choice [1]. This relative outflow without a balanced influx has created a high degree of attrition within engineering schools across the country. Possibly, administrators keep this imbalance in mind as universities enroll far more students in their freshman engineering courses than will ever graduate from these programs.

Despite this, nearly all future projections call for an increase in the number of students trained in the STEM (Science, Technology, Engineering, and Mathematics) fields, particularly engineering. Even with this growing spotlight, however, some studies have still shown how the number of students entering college as STEM majors has actually declined in recent years [2]. This issue of low matriculation combined with growing national attention highlights a need to place a higher priority on the retention of enrolled engineering students.

Attrition issues are often ascribed to a variety of factors, including problems with course load, poor instruction in introductory courses, and a student's sense of belonging within the discipline [3,4]. The theoretical works of Spady and Tinto are particularly useful for integrating the idea of a "sense of belonging" and its impact on retention for college-level students [5]. Tinto's model indicates that there are multiple points at which students may "depart," and deselect themselves from a major. This framework highlights that

student retention is related not only to academic integration (e.g., identification as a student, enjoying the subject) but also to social integration (e.g., personal contact with faculty, friends in the major). In this framework, the depth of integration is related to both goal commitment (motivation to earn a selected degree) and institutional commitment (motivation to graduate from a particular institution) [6,7].

Tinto's work further points out how institutional adaptations can promote retention by directly addressing students' academic and social integration. Several studies have connected sense of belonging with retention, but few have focused on the connection between a deliberate development of programs and longitudinal retention among engineering students. And while there exists some prior research into these ideas, most current literature addresses only general retention and fails to be specific enough to examine issues particular to engineering. Relying upon these general trends thus fails to explain why engineering as a discipline experiences this greater level of attrition when compared to other fields. To fill this gap in knowledge the following study focused on the concept of a student's sense of belonging within engineering, as that has been shown to often be one of the best indicators for future success [8,9]. More specifically, it examines whether certain programs designed to promote students' belonging has an effect upon retention within the Ira A. Fulton Schools of Engineering at Arizona State University.

Starting in the late 1990s, the Fulton Schools instituted a variety of strategies with the goal of better addressing the attrition of its engineering students. Examples of these changes included formalizing tutoring opportunities, elucidating programs of study, and adjusting advising procedures. In 2003, the college implemented a significant change by revising the graduation requirements for its programs from 128 credit hours to 120 credit hours. This helped afford students a reduced workload and greater flexibility in their scheduling, making it more feasible for students to graduate within the four-, five-, or six-year tracks. This can be seen in that

(while both figures have risen over time), since 2003 the percentage of students graduating in four years has risen far more dramatically than the percentage of students graduating in six years (Table 1). These reforms were not always implemented simultaneously across the different disciplines, but the college still experienced a substantial growth in its retention rates.

Beginning in 2007, however, a much more concerted effort was made toward advancing retention rates. Prior to this most reforms implemented were programmatic, and were not designed to target a student's sense of belonging. To rectify this, the college instituted a large series of systemic changes to address students' feelings of displacement as first- and second-year engineering students. This new suite of strategies can be further broken down as *Co-Curricular Experiences*, *Course Curricular Experiences*, and *Student Support Programs*.

- *Co-Curricular Experiences* include undergraduate research opportunities, engineering summer camps for freshmen, and professional student societies (often specific to a student's major). The goal of these programs is to have students bond with one another and with faculty outside of the classroom, all the while honing their research and professional skills.
- *Course Curricular Experiences* refer to two mandatory courses all engineering students in the college must take. The first is a student success course taken by all entering university students focused on time-management and study skills. The second is a revised introduction to engineering course designed for first-year students, geared toward problem-solving and team-building tasks.
- *Student Support Programs* are many-fold and include upper-division engineering students serving as peer mentors and undergraduate teaching assistants (UGTAs), supplemental instruction made available through an engineering-specific tutoring center, and a student residential

community wherein all freshmen engineers live together in a centralized, on-campus complex. Together these policies provide physical support and role models for students who may be struggling while also promoting the development of close-knit, supportive cohorts within the greater engineering community.

These different strategies and programs were made available to all Fulton engineering students, across the different degree programs. As was described above, however, many of the strategies specifically targeted underclassmen engineers. This was done in the hopes of reinforcing these students' early sense of belonging within the engineering community, thereby encouraging their retention.

METHODS

An interrupted time series approach was utilized to evaluate the effects of this suite of strategies implemented during the 2007-08 academic year. Both enrollment status and retention data for the entire engineering college were available from 1998 through 2013. A quasi-experimental design was then employed comparing the retention of incoming freshmen engineers from their first semester through to the beginning of their junior year. As a result, in this study being 'retained' was operationally defined as a student who entered into an engineering program and then remained in that program at the two-year mark.

This cutoff was chosen because, at this particular institution history shows that a student who remains in their engineering program for the first two years is then likely to graduate from the college within six years (Table 1). For example, only 50% of the freshmen from the 2007 cohort were retained (still enrolled) in their engineering majors by the fall of 2009. Within this subset that stayed, however, 83.6% (41.8% of the original

class) went on to graduate from the college within six years. The largest drop off in student retention thus occurs early on, making the two-year mark a good testing point for a student's likelihood to persist through to graduation.

This cutoff thus yielded a set of nine pre-intervention two-year cohorts (the 1998 – 2006 freshman classes) that were then compared to five post-intervention cohorts (the 2007 – 2011 freshman classes). Retention trends were first examined for the entire engineering student body. Following this first look, the results were then disaggregated and analyzed by both gender and ethnicity to determine whether these reforms had additional effects on any particular sub-groups.

In order to efficiently address ethnicity, two aggregate ethnic categories were created. The first was comprised of students identifying themselves as either White or Asian/Asian-American. The other category was then comprised of traditionally underrepresented minorities (URMs) within the field of engineering, namely American Indian, Black, and Hispanic students [10]. These categories thus encompass the five groups historically addressed within American higher education research (i.e., Asian, American Indian, Black, Hispanic, and White). While we acknowledge that the experiences of each of these lumped minority groups would be distinct, their small sizes prevent them from being analyzed individually. This classification also filtered out students who did not provide ethnic identification, identified as multiracial, or were listed as international students.

In all cases, retention rate was the relevant measurement. Finally, mean retention rates (i.e., slope) of the different groups were compared and evaluated to determine if change, such as abrupt change or delayed change, had occurred [11].

Table 1: Percent of Student Retained Compared with Percent Graduating in Four and Six Years

Entry Year as Freshmen	Percent of Students Retained at Two Years	Percent of Students Graduating within Four Years	Percent of Students Graduating within Six Years
1998	44.9%	11.0%	34.4%
1999	46.2	9.5	33.6
2000	46.8	11.0	32.7
2001	47.5	9.9	31.6
2002	42.2	12.4	29.8
2003	46.3	11.8	33.8
2004	50.7	18.2	37.9
2005	50.7	15.9	37.6
2006	53.9	24.6	42.5
2007	50.0	26.3	41.8
2008	55.2	31.0	N/A
2009	57.4	32.4	N/A

Table 2: Percent of Students Retained in Engineering Freshmen through Junior Year

Cohort	Overall	Gender		Ethnicity	
		Women	Men	URM	Asian & White
1998-2000	44.9%	39.5%	46.5%	38.5%	46.1%
1999-2001	46.2	48.0	45.6	46.8	45.4
2000-2002	46.8	52.2	45.3	30.2	50.2
2001-2003	47.5	52.8	46.1	42.9	47.2
2002-2004	42.2	40.1	42.6	36.6	42.3
2003-2005	46.3	49.3	45.7	41.8	46.3
2004-2006	50.7	53.7	50.0	45.1	50.4
2005-2007	50.7	46.5	51.7	43.6	51.4
2006-2008	53.9	49.6	54.9	48.5	55.4
2007-2009	50.0	54.2	49.0	37.8	52.7
2008-2010	55.2	53.5	55.6	49.8	56.0
2009-2011	57.4	55.9	57.8	48.0	59.8
2010-2012	57.5	58.9	57.2	53.1	57.1
2011-2013	56.9	54.5	57.5	42.7	58.9

RESULTS

There was a clear, overall 14-year upward trend in the proportion of freshmen engineering students who persisted in their program through to the start of their junior year (Table 2). Interestingly, this growth is found both before and after the introduction of the new strategies in 2007.

Over the 14 year period, retention rate (as modeled by linear regression) increased at an average rate of 1.1% per year (Figure 1). Breaking apart of the timeline, however, produces some more interesting results. Prior to the new wave of reforms, for example, this increase in freshmen persisting until their junior year was only 0.9% per year (Figure 2). With the addition of the new programs, however, the average retention increase then jumps to 1.6% per year (Figure 3). This jump occurred while the incoming freshman class simultaneously increased from an average of 774 to 957 students. Part of this observed increase, however, can also be attributed to a drop in the retention of the 2007 cohort (50.0%), allowing the trend line to slope higher for the subsequent years as it jumped back up. Overall though, these new strategies appear to be successful in helping to retain a growing percentage of a growing number of students.

Figure 1: Overall Percent of Engineering Freshman Retained

Figure 2: Percent Retained Pre-2007

Figure 3: Percent Retained Post-2007

Examination of data based on gender indicates that overall retention rates similarly rose over time for both male and female students (Figures 4 & 5). Examining before and after, however, reveals that these strategies seem to have affected the two groups differently. There is a noticeable jump in the rate of retention of male students following the introduction of these new programs – 1.0% to 1.9% per year. The strategies, however, seem to have had minimal effect on furthering a retention rate increase for female students, as that trend remained level at 0.6% per year.

Figure 4: Percent of Men and Women Retained Pre-2007

Figure 5: Percent of Men and Women Retained Post-2007

Similarly, the retention rates for URMs (underrepresented minorities) along with Asian and White students continued to exhibit an overall upward trend (Figures 6 & 7). Both of these categories saw incremental jumps in their retention rates following 2007 – from 1.0% to 1.3% for URMs and from 0.9% to 1.4% for Asian and White students. Despite this, it is also worth

noting that the retention rate for Asian and White students was almost universally higher than that of URM students (the 1999 cohort presents the only exception). This consistent gap (not found in the gender breakdown) highlights the need to develop further programs that will target the retention of specific groups of students, in order to better balance retention of the different groups.

Figure 6. Percent of Ethnic Groups Retained Pre-2007

Figure 7. Percent of Ethnic Groups Retained Post-2007

CONCLUSIONS

In reviewing the results of the program, it's important to bear in mind that these new strategies were not created to address a lagging retention rate. On the contrary, these reforms targeting students' belonging were launched while retention rates had already been experiencing an overall steady increase for nearly a decade. Instead, the concern expressed from the Fulton schools was centered on the fear that retention would soon reach a ceiling, if not decline. Keeping this idea in mind then, a linear progression toward 100% retention was not the goal of these new strategies. Instead, the objective was to maintain momentum in retention by

promoting and supporting students' belonging as engineering students.

As a result, analysis of these data is somewhat inconclusive. While we can say that the retention rates did experience substantial change overall, the initiation year of the interventions (i.e., 2007) did not result in a clear spline, knot, or polynomial transition for all of the various subgroups. Instead, results are mixed across the different populations, notably seeming to have had a larger positive impact on the retention of males than it did for females. These new strategies also failed to bridge the retention gap observed between White and Asian students and URM students, though it's important to note that doing so

was not the purpose of these reforms. Overall then, this study highlights the overall success of the integration of these new strategies. At the same time, however, it also opens the door into possible future research topics further investigating the differentiated effects among subgroups.

Abstract— Studies suggest that students' attitudes toward engineering courses may determine whether they persist in engineering, rather than academic performance alone. We take a mixed-methods approach to explore gritty attitudes and to confirm whether previous research on grit can be applied to undergraduate engineering students. We address two main research questions: (1) Does the grit scale predict retention among first-year undergraduate engineering students? (2) What does grit specifically look like for engineering students? To answer the first question, we invited all first-year engineering students at one university to complete the grit scale during Fall 2014. We will check whether the scores on the grit scale correlate positively with retention in engineering. To answer the second question, we invited all students who were persisting in engineering after having earned a D or an F grade in a required technical course to participate in a semi-structured interview. We hope to capture how these engineering students respond to academic setbacks and what they believe about effort, perseverance, and academic success.

Keywords—grit; retention; mindsets; academic motivation

I. INTRODUCTION

In the United States, engineering programs suffer high rates of attrition. Among students who start as freshmen in engineering, only 57% complete baccalaureate degrees in engineering [1]. Numerous studies (for example, see [2]) have identified reasons for attrition from engineering. These studies suggest that students' attitudes toward engineering courses may determine whether they persist, rather than academic performance alone. In this study, we explore how gritty attitudes play a role in the retention of engineering students. Grit is defined as the perseverance and passion for long-term goals [3]. To measure grit, Duckworth et al. [3] devised a grit scale, which was revised by Duckworth and Quinn [4]. Each item is scored on a 5-point Likert scale, then all items are summed and divided by the number of items to produce the grit score. Therefore, a grit score of 5 would describe a very gritty person while a grit score of 1 would describe a person as not gritty at all. The grit scale predicted the retention of freshmen cadets at the U.S. Military Academy (West Point) better than a combination of admission scores, including GPA [3][4].

We address two main research questions: (1) Does the grit scale predict retention among first-year undergraduate engineering students? (2) What does grit specifically look like for engineering students? The results of this study will determine whether previous findings about the grit concept and the grit scale can be applied to engineering students in college,

who differ significantly from previous populations with which the scale has been tested. The results may also help identify engineering students who may be more likely to drop out and inform the ways in which educators can advise at-risk students.

II. ADMINISTERING THE GRIT SCALE

A. Participants

In the middle of the Fall 2014 semester, all engineering freshmen at a public university in the Midwest were invited to complete the grit scale [3] through an online survey, including demographic information. The invitation email was sent through the engineering orientation course that all first-year engineering students were required to take. No form of compensation was offered for completing the grit survey.

B. Preliminary Results

Out of roughly 1600 first-year engineering students, 310 students completed the survey, a response rate of about 19%. Table I compares the demographic characteristics of the survey respondents with the demographics of the undergraduate engineering population. Female and domestic students were slightly overrepresented among survey respondents.

The results of the grit scores are shown in Table II. Students were given the option not to disclose their ethnicity. Non-Hispanic Whites seemed to have the highest average grit score at 3.49, while Asians or Asian Americans had the lowest

TABLE I. DEMOGRAPHIC COMPARISON

<i>Demographic Category</i>	<i>Survey Results</i>	<i>Undergraduates in Engineering</i>
Male	69%	83%
Female	30%	17%
Domestic	83%	76%
International	17%	24%
Non-Hispanic White	60%	58%
Asian or Asian American	24%	28%
Black or African American	1%	2%
Hispanic or Latino American	5%	7%
Other or Mixed	5%	4%
Undisclosed Ethnicity	5%	1%

TABLE II. GRIT SCORE RESULTS

<i>Demographic Category</i>	<i>Sample Size</i>	<i>Mean</i>	<i>Standard Deviation</i>
Total	310	3.42	0.52
Male	214	3.40	0.52
Female	93	3.47	0.50
Domestic	257	3.43	0.53
International	53	3.39	0.44
Non-Hispanic White	155	3.49	0.50
Asian or Asian American	61	3.31	0.55
Black or African American	3	3.44	0.27
Hispanic or Latino American	12	3.41	0.65
Other or Mixed	14	3.48	0.54
Undisclosed Ethnicity	12	3.10	0.64

average grit score at 3.31. Our total average grit score of 3.42 was a bit lower than the engineering freshmen cohort at Northeastern University [5], whose average grit score was 3.55. However, the student population at Northeastern was very different from our study's population. At the end of the academic year, we will collect retention data and correlate grit scores with retention, using binary logistic regression. We expect to see a positive correlation similar to the results for the freshmen cadets at West Point [3].

C. Preliminary Statistical Analysis

Using the statistical software package R, we determined that the following categories did not pass the Shapiro-Wilks test for normality: Total, Male, Domestic, and Non-Hispanic White. As a result, we used non-parametric tests to compare grit scores. We chose the standard 0.05 threshold for statistical significance. According to the Mann-Whitney-Wilcoxon test, there was no significant difference between Male and Female populations ($p = 0.49$) nor between Domestic and International populations ($p = 0.44$), but amongst the ethnicities, there was a significant difference between Non-Hispanic Whites and Asian or Asian Americans ($U = 3750$, $p = 0.018$, rank-biserial correlation = 0.21). The Kruskal-Wallis test showed that there was no significance difference between ethnicities as a whole ($\chi^2(4) = 5.479$, $p = 0.24$). No tests were conducted using the Undisclosed Ethnicity category.

III. CONDUCTING SEMI-STRUCTURED INTERVIEWS

A. Purpose

Duckworth [3] describes gritty behavior as “working strenuously toward challenges, maintaining effort and interest over years despite failure, adversity, and plateaus in progress.” As engineering is a challenging major, many students often find themselves having difficulty in college even when they had performed well in high school. Some students respond better to poor academic performance than others. We used semi-structured interviews to explore this gritty phenomenon and focused on engineering students persisting in their major.

B. Participants and Procedure

In the Spring 2015 semester, all undergraduate engineering students at a public Midwestern university were invited to participate in a one-hour, semi-structured interview. The recruitment email specifically invited students who were persisting in engineering after having earned a D or an F grade in a required physics, math, computer science, or engineering course. We thought that this particular population would be information rich in helping us understand the variety of ways students dealt with poor performance in a required course.

The interview questions asked students how they responded to poor exam grades or failing a class, what strategies they would take to succeed in challenging classes, and how they defined success and failure. The questions were designed to understand failure from the student's point of view and see how their interpretations of failure helped them persist.

There were 26 interview participants total, from freshmen to seniors, ranging in years and majors. The interview data are still being analyzed. Our analysis of the interview data will use Dweck's theory of growth and fixed mindsets because interventions designed to change students' mindsets seem to promote gritty behavior [6]. Through our analysis, we want to see how these mindsets align with gritty students. We will use phenomenography to describe the variety of ways engineering students respond to failure. We chose phenomenography because the ways in which students respond to academic setbacks vary and we were interested in how students' perception of their failures influence their realities [7]. We will follow the standard thematic analysis methodology to construct categories of students' responses to failure based on mindsets, attitudes, and success strategies. We will use the results to inform interventions aimed at improving retention by motivating undergraduate engineering students to succeed even after experiencing academic failures.

Measuring Student Integration and Institutional Support

Walter C. Lee & Holly M. Matusovich

Department of Engineering Education

Virginia Tech

Blacksburg, VA, United States

walterl@vt.edu, matushm@vt.edu

Abstract—Engineering is a demanding discipline and otherwise qualified students often take their talents elsewhere—either before earning a Bachelor’s degree or shortly thereafter. As a result, engineering educators must provide students with adequate support to increase the chances of students successfully integrating into the field of engineering. However, little is known about the relationship between *Institutional Support* and *Student Integration* or how each construct influences the retention or early-career decision-making of engineering students. Drawing on the Model of Co-curricular Support, the purpose of this paper is to describe current efforts to develop survey instruments that can be used to investigate how undergraduate engineering students rate themselves on *Institutional Support* and *Student Integration*, paying close attention to gender and race/ethnicity. Survey instruments that are valid and reliable within this context would be useful for assessing the impact of student interventions.

Keywords—retention; student support; diversity; integration

I. INTRODUCTION

Engineering is a demanding discipline and otherwise qualified students often take their talents elsewhere—either before earning a Bachelor’s degree or shortly thereafter. As a result, engineering educators must provide undergraduate students with adequate institutional support to increase the chances of students successfully integrating into the field of engineering. Towards this effort, considerable resources have been allocated to institutional practices intended to support undergraduate engineering students, particularly those from underrepresented population. However, little is known about the relationship between *Institutional Support* and *Student Integration* or how each construct influences the retention or early-career decision-making of engineering students. Grounded in the recently developed Model of Co-curricular Support (MCCS) [1], this research posits that students who receive sufficient *Institutional Support* and achieve *Student Integration* may be more readily retained and more likely to pursue engineering-related careers. We selected these constructs because they represent the outputs—or student experiences—associated with co-curricular interventions from the perspective of student-support practitioners (*Institutional Support*) and the medium-term outcomes associated with students who receive said support (*Student Integration*). While developed on the foundation of Tinto’s Model of Institutional Departure [2], the predictive/explanatory power of the MCCS has not yet been explored and, thus, the development

of survey instruments that can be administered to undergraduate engineering students are necessary. The specific changes made to Tinto’s Model are detailed elsewhere [1]. At a high level overview, changes included expanding the model to incorporate the broader intentions of student-support practitioners, subtracting constructs from Tinto’s Model that were not appropriate for this particular application, and aligning the longitudinal sequence of Tinto’s Model with the naming convention of logic models.

The purpose of this work-in-progress is to describe our current efforts to develop survey instruments to be administered to undergraduate engineering students that can be used to investigate the level of *Institutional Support* and *Student Integration* received and achieved by undergraduate engineering students, paying close attention to gender and race/ethnicity. While *Institutional Support* and *Student Integration* are easily understood in abstraction, little, if any, consistency exists in the current literature with regard to operationalizing these constructs in the context of undergraduate engineering education. Understanding the influence that these constructs have on student retention and early-career decision-making will assist the engineering education community with ensuring that all undergraduate students are sufficiently supported and increasing the likelihood of them selecting engineering-related careers after successful matriculation. To address this purpose, our work is guided by the following research question: What aspects of the undergraduate experience should be included in instruments to measure *Institutional Support* and *Student Integration* in the context of undergraduate engineering? Answering this question will enable us to develop instruments that are valid and reliable within the context of engineering to measure *Institutional Support* and *Student Integration*. Such instruments will be useful in assessing current and developing future support interventions aimed at promoting integration.

Through this research, we will develop measurable definitions of four integration constructs: (1) *Academic Integration*, (2) *Social Integration*, (3) *Professional Integration*, and (4) *University Integration*. We will also provide definitions of six support constructs: (1) *Academic Performance*, (2) *Faculty/Staff Interactions*, (3) *Extracurricular Involvement*, (4) *Peer-group Interactions*, (5) *Professional Development*, and (6) *Additional Circumstances*. Clearly defining each construct is an

important first step in evaluating current efforts geared towards supporting students. Since there has been minimal research in engineering education regarding the measurement of these constructs, this research fills a notable gap by examining the impact support provided by engineering colleges can have on students, particularly those from underrepresented populations. This work is a part of the lead author's long-term research plans, and it is directly geared towards student-support practitioners, administrators, and engineering education researchers interested in inclusion, retention, and diversity in engineering.

II. OVERALL RESEARCH PROJECT

This work-in-progress is a part of a larger study exploring the appropriateness of Tinto's Model of Institutional Departure [2] with regard to co-curricular support in engineering. By examining six Engineering Student Support Centers (ESSCs) of varying classifications, the larger study investigated whether or not each construct outlined in Tinto's Model encompasses the components of integration considered in undergraduate engineering education and the areas of institutional support commonly provided alongside undergraduate engineering programs. So far this larger project has yielded the Model of Co-curricular Support [1], which is a repurposed version of Tinto's Longitudinal Model of Institutional Departure [2] that was developed throughout the phases of the overall research project. The Model of Co-curricular Support posits that students who receive more comprehensive institutional support will more thoroughly integrate and subsequently are more likely to be successful undergraduate engineering students.

We are currently using a subset of the data from the larger study to develop survey instruments that can be used to measure levels of *Institutional Support* and *Student Integration*. The development of the survey instruments will be carried out in seven steps, following best practices as defined by Gall et al [3]:

1. *Clearly define the construct of interest.*
2. *Define the target population.*
3. *Review related surveys to generate ideas regarding format and validity.*
4. *Develop the prototype of the survey instrument.*
5. *Evaluate the prototype.*
6. *Revise test based on suggestions.*
7. *Collect data to determine test validity and reliability.*

The developed survey instruments will be grounded in the Model of Co-curricular Support [1].

III. METHODOLOGY

The methods described in this work-in-progress were completed to clearly define *Institutional Support* and *Student Integration* and to collect data to generate items that could be used to develop the prototype of the survey instruments to measure these constructs. This involved analyzing interviews conducted with student-support

practitioners tasked with serving these populations and open-ended surveys completed by undergraduate engineering students.

During the overall research project, we interviewed 17 student-support practitioners across six student support centers housed at four institutions to identify and categorize existing institutional practices for providing undergraduate students (particularly those from groups traditionally underrepresented in engineering) with co-curricular support. We used semi-structured interviews [4] to ask these practitioners about the programs, activities, and services provided by their respective support system. We reviewed the particulars of each intervention in search of underlying themes that would provide insight with regard to *Institutional Support* and *Student Integration*. To analyze the interviews, we used a priori codes [4] grounded in Tinto's Model to categorize the outputs of the institutional efforts in distinct areas (e.g., *Academic Performance*) and open codes [4] to identify emergent themes (i.e., categories) within each of the areas (e.g., the *Academic Performance* areas contains *Academic Information*, *Academic Resources*, *Academic Monitoring*, *Transferrable Student Skills*, and *Course Preparation*). We completed this process to modify Tinto's Model in a way that encompasses the retention-related institutional practices used in undergraduate engineering education and to operationalize the subsequent constructs. Tinto's Model provided four areas in which we anticipated finding outputs geared towards: (1) *Academic Performance*, (2) *Faculty/Staff Interactions*, (3) *Extracurricular Involvement*, and (4) *Peer-group Interaction*. In developing the MCCS, we confirmed the inclusion of these areas and expanded the model to also include (5) *Professional Development* and (6) *Additional Circumstances*. Open coding was used to identify emergent themes within each of these six areas.

We also distributed open-ended surveys to students to solicit feedback with regard to the isolated experiences of students served by each support system. We asked students to indicate whether the support system at their institution had positively, negatively, or not influenced them with regard to each of the following: (1) interactions with engineering faculty and staff; (2) interactions with other students; (3) academic performance; (4) participation in extracurricular activities; and (5) professional development. To analyze the open-ended responses, we reduced the data through the process of unitizing; this involved dividing data chunks into single concept coding units that could be further analyzed and compared [5]. The process of unitizing included dividing multi-concept original responses into multiple unitized statements and combining single-concept original responses that included the same concept into a single representative unitized statement. In instances where a single-concept original statement was unique, the response was reduced to a single unitized statement as well. In total, this process resulted in a list of unitized statements that represented the original responses provided by students across ESSCs. Some examples are shown in Table 1. We

completed this process to triangulate the data collected from practitioners with the student perspective and to develop single-concept statements that could potentially be used to develop prototypes of the survey instruments to measure the constructs of interest. Specifically, triangulation included using the emergent themes within five of the six a priori categories to map each unitized statement to emergent themes previously identified. We did not use *Additional Circumstances* because this output area/theme was emergent and students were not asked specifically about this area in the open-ended survey.

Table 1 - Unitizing Example

Original Response	Unitized Statements
“[ESSC] helps me study because I have study partners. It helps me understand concepts because of the wealth of upperclassman knowledge.”	I had an easier time forming study groups and finding people to work with academically.
	I had access to students whom I could ask for academic assistance.
“The [learning community] academic events definitely had a positive influence on my grades last semester.”	“I received academic assistance at the help sessions I attended.”
“The exam reviews are helpful.”	

IV. CURRENT STATUS/PRELIMINARY FINDINGS

The results from clearly defining the constructs of interest are below. In total, we divided *Student Integration* into four constructs, each with a specific definition that is listed in Table 2. We divided *Institutional Support* into six constructs, each with a specific definition that is listed in Table 3. In addition to the constructs outlined in Table 2 and Table 3, we developed a list of unitized statements for each of the constructs except *university integration* and *additional circumstances*, which emerged following the open-ended survey being deployed and as a result were not included during the initial phases of the larger study. Examples of these statements are listed in Tables 4-5.

Table 2 - Student Integration Constructs

Construct	Definition
Academic Integration	Student having a positive perception with regard to intellectual fit (i.e., access and support) and sufficient interactions within the formal and informal academic systems of an engineering college and is most directly impacted by their academic performance and faculty/staff interactions.
Social Integration	Student having a positive perception with regard to social fit (i.e., access and support) and sufficient interactions within the formal and informal social systems of an engineering college and is most directly impacted by their extracurricular involvement and peer-group interactions.
Professional Integration	Student having a positive perception with regard to professional fit (i.e., access, support, and characteristics) and sufficient interactions within the formal and informal professional systems of an engineering college and is most directly impacted by their professional development.
University Integration	Student having a positive perception with regard to institutional fit (i.e., access, support) and sufficient interactions within the formal and informal university systems surrounding an engineering college and is most directly impacted by their personal and financial experiences at the university level.

Table 3 - Institutional Support Constructs

Construct	Definition
Academic Performance	Institutional support geared towards disseminating information related to improving academic performance or circumstances, providing access to resources that support academic performance, monitoring academic performance or development, or contributing to the development of content-independent and content-dependent skills that contribute to academic performance.
Faculty/Staff Interactions	Institutional support geared towards disseminating information related to interacting with faculty or staff, increasing the quantity of interactions students have with faculty or staff, and helping student establish informal or formal relationships with faculty or staff.
Extracurricular Involvement	Institutional support geared towards disseminating information related to improving or increasing extracurricular involvement and providing students with extracurricular opportunities.
Peer-group Interactions	Institutional support geared towards disseminating information related to students interacting with other students, increasing the quantity of interactions that students have with other students outside of the classroom, or grouping students based on some part of their identity or academic circumstances.
Professional Development	Institutional support geared towards developing industry-independent skills that contribute to obtaining employment or admittance; disseminating information related to career opportunities via an undergraduate degree in engineering; providing work experience that contributes to the professional development of students via employment; providing access to role models along different career trajectories; or developing industry-independent skills that contribute to successful professional performance.
Additional Circumstances	Institutional support geared towards acclimating students into the university environment; facilitating access to financial assistance; publically acknowledging the successes of students; or discussing life as an underrepresented engineering student.

Table 4 - Student Integration Statement Examples

Construct	Unitized Statements
Academic Integration	I can effectively approach engineering problems.
	I can manage the academic workload.
	I can effectively prepare for engineering exams.
Social Integration	I can actively participate in a student organization.
	I can positively interact with other engineering students.
	I understand the importance of extracurricular activities.
Professional Integration	I can communicate in a professional manner.
	I can network professionally.
	I have leadership skills that will be useful as an engineer.

Table 5 - Institutional Support Statement Examples

Construct	Unitized Statements
Academic Performance	I received academic assistance from tutors/mentors.
	I had access to a positive learning environment.
	I received advice on how to manage my time better.
Faculty/Staff Interactions	I was encouraged to interact with engineering faculty.
	I had the opportunity to network with engr. faculty.
	I have become more familiar with engr. professors.
Extracurricular Involvement	I was encouraged to become involved in the community.
	I had the opportunity to be involved in many activities.
	I was more aware of the opportunities at the university.
Peer-group Interactions	I had the opportunity to develop social skills.
	I met engineering students that shared my interest.
	I met upper-class engineering students in my major.
Professional Development	I received assistance with developing a resume.
	I talked to engineers about their career paths.
	I receive professional guidance/advice.

V. FUTURE WORK

Our preliminary findings provide clear definitions for the constructs of interest, define the target population, and lay the foundation for developing prototypes of the survey instruments. In the next phase of this process, we are developing surveys to be evaluated and revised. The surveys will include questions geared towards each of the constructs previously discussed. Once the survey is revised, we will collect data to determine validity and reliability.

Recruiting, retaining and transitioning computing undergraduates the STAIRSTEP way

Peggy Doerschuk

Judith Mann

Lamar University

Beaumont, Texas

Abstract— Lamar University's Students Advancing through Involvement in Research Student Talent Expansion Program is designed to recruit, retain and transition undergraduates in five Science, Technology, Engineering and Mathematics disciplines. The program was supported by a five-year grant from the National Science Foundation that started in 2009 and is currently supported by the university. This paper focuses on the computer science arm of the program. During the five years of National Science Foundation support, 100 percent of participants in STAIRSTEP Computer Science were retained as majors. Their grades in major courses were consistently higher and drop rates consistently lower than cohorts of students from the five-year period prior to inception of the program. Incoming enrollments in the Computer Science Department grew dramatically, as did undergraduate majors and degrees awarded. This paper briefly describes the strategies used in the STAIRSTEP model and describes in detail how activities supporting the strategies were implemented in the Computer Science Department. A formal assessment documents the positive impact that the program has had on the department and its students. The paper includes suggestions for others who may want to adopt these methods and discusses successes and challenges in sustaining the program in the absence of external support.

Keywords—broadening participation, retention, undergraduate research

I. INTRODUCTION

Lamar University's Students Advancing through Involvement in Research Student Talent Expansion Program (STAIRSTEP) is designed to recruit, retain and transition undergraduates in computer science and four other Science, Technology, Engineering and Mathematics (STEM) disciplines. The program was supported by a five-year grant from the National Science Foundation that started in 2009 and is currently supported by the university. Over its five-year span, the STAIRSTEP disciplines as a whole experienced a dramatic increase in the number of undergraduate majors and incoming students, and the program has been very successful in helping students to make the transition to the STEM workforce or graduate study. It received a 2013 Star Award from the Texas Higher Education Coordinating Board for exceptional contributions to closing the gaps in higher education in Texas.

An earlier paper described the STAIRSTEP model and the accomplishments of the program as a whole. [1]. This paper focuses on the computer science arm of the project, which has exceeded all of the program goals. Section II describes the need for this type of program in computer science. Section III briefly describes the model, its goals and strategies. Section IV describes how activities supporting the strategies were implemented in the Computer Science Department. Section V presents the results of a formal assessment that documents the positive impact that the program has had on the department and its students. Section VI presents suggestions for others who may want to adopt these methods in their institution. Section VII discusses successes and challenges in sustaining the program in the absence of external support.

II. MOTIVATION

The United States President's Council of Advisors on Science and Technology 2012 Report [2] indicates a need to produce a million more college graduates in STEM fields in general by 2022 and notes that fewer than 40% of students who enter as majors in STEM fields complete a degree in STEM. There is also a shortage in STEM professionals in other countries, including the UK, Germany, Austria, Belgium and Poland [3].

It is especially important to produce more Computer Science graduates because computing careers are predicted to be among the fastest growing in the next decade, while current degree production is much lower than it was a decade ago. Between 2012 and 2022, U.S. jobs for software developers are predicted to grow by 22%; computer systems analyst positions by 25%; and positions in information security will increase by 37% [4]. The 2014 National Science Board's Science and Engineering Indicators [5] shows that the number of bachelor's degrees granted in computer sciences dropped dramatically from 2004 to 2009, rose in 2010 and 2011 but still has not reached its 2004 level.

III. THE STAIRSTEP MODEL, GOALS, STRATEGIES

STAIRSTEP implements best practices for increasing participation in STEM in an innovative way. The program engages undergraduates in an enriched team research experience that includes faculty and peer mentoring, tutoring and other support. Small teams of undergraduates are paid a competitive stipend to participate in team research, outreach

and transitioning activities for an average of 10 hours a week under the direction of a faculty mentor in their discipline. Teams can include students from all levels, freshmen through seniors. Graduate students can help lead the teams. The more advanced students mentor, tutor and train the less experienced students.

STAIRSTEP targets talented ‘at risk’ students, including low income, first generation, and/or underrepresented students who face social and economic challenges that can make it difficult for them to progress to graduation. Students apply to participate and are selected based on their grades, income, first generation status, race, ethnicity, letter of interest, and letters of reference. Students can participate for multiple years, as long as they participate fully and maintain at least a B average in their major courses and a 2.5/4.0 overall grade point average (GPA). Faculty mentors receive one course release time for each long semester of participation.

STAIRSTEP’s innovation lies in the scope of students served (freshmen through senior), the breadth of activities (research, outreach and transitioning) and the multidisciplinary approach (computer science and four other STEM disciplines targeted). More details can be found in [1].

The program’s goals are as follows:

1. Retaining students: at least 70% of program participants will be retained in their STEM major.
2. Transitioning students: at least 80% of graduating student participants will be transitioned to careers or advanced study in STEM within 6 months of graduation.
3. Recruiting students: incoming freshmen will increase by 5% a year starting in year 2; and incoming community college transfers will increase by 20% starting in year 2.

The program uses the following strategies for retaining and transitioning students.

- Engage students in team research with tutoring, mentoring, and peer support.
- Dispel misconceptions that discourage participation in STEM.
- Use institutional relationships to help students bridge to the next level.

The program’s strategy for increasing incoming students is as follows:

- Engage STAIRSTEP undergraduates in team outreach to high school, community college and university students

This paper focuses on how activities supporting these strategies were implemented and results achieved in the Computer Science arm of STAIRSTEP. STAIRSTEP CS activities are similar to the Students & Technology in Academics, Research and Service (STARS) program at the University of North Carolina at Charlotte, a broadening participation in computing project that offers a wide range of student support, engaging students in selected research outreach or service activities [6]. STAIRSTEP students are

engaged in both outreach and research activities, as well as peer tutoring and mentoring and transitioning activities. This range of services is broader than that offered by STARS and helps students develop a wider range of professional and interpersonal skills that are needed throughout the continuum from entry to career transition.

IV. IMPLEMENTATION OF STAIRSTEP STRATEGIES IN COMPUTER SCIENCE

A. *Engage students in team research with tutoring, mentoring, and peer support*

STAIRSTEP engages undergraduates in research that is beneficial, engaging, and accessible while building upon the expertise of the faculty mentor. The first author is the faculty mentor for the Computer Science team. The team engages in research in computer science education, robotics, and machine learning. Students who enter the program as freshmen typically start in computer science education research and can progress to research in either robotics or machine learning.

Computer science education research involves developing engaging instructional materials that can be used to increase high school students’ computing knowledge and interest. Even first semester freshmen can engage in this research. Participation in this research strengthens the understanding and skills of the undergraduate researchers, who must learn to articulate their knowledge correctly and clearly. The materials are used in hands-on workshops with students from local schools, and formal assessments document the effectiveness of the approach. The undergraduates are instructors in the hands-on workshops, which increases their communication and teaching skills. These events also improve the students’ organizational and teamwork skills. The undergraduates present their research at local and regional conferences. Two teams have won awards for their research presentations [7, 8].

The robotics research centers on developing autonomous robots. Robots are attractive to students, and research in robotics reinforces concepts in software engineering, artificial intelligence, computer networks, architecture, operating systems, and other areas. Past work includes designing and implementing a system that allows a resource limited robot to use the services of a remotely located planner. This work won third place in an international student research competition [9]. Current work centers on using machine learning techniques to enable a robot to learn its tasks [10].

The machine learning research centers on improving the performance of various learning algorithms. Machine learning is a very popular research area because students know that it is being used by big firms like Google, Microsoft, IBM, Disney, and others and is being applied in search engines, recommender systems, games, and many areas that affect our everyday lives. Typically, participating juniors and seniors who have taken coursework in machine learning can select to engage in this research. Because the machine learning course was introduced in 2013, relatively little has been done thus far [11]. The undergraduates work with graduate students who are performing theses in this area under the direction of the faculty

mentor. Current work focuses on improving the performance of a neural network learning algorithm [12].

Teamwork and peer instruction are critical to this research. In many cases, students are exposed to concepts in the lab that they have not yet encountered in the classroom. The more experienced students help train and lead the less experienced. This reduces the burden on the faculty mentor, who would otherwise have to teach each member individually. Over time the students progress from team member to team leader as they grow in experience and confidence. This also gives all the students valuable experience in communication and teamwork, critical skills that are highly valued by computing employers. Working in teams toward common goals also helps develop a sense of community and belonging among the members.

The faculty mentor not only leads the team in STAIRSTEP research but also encourages eligible members to participate in other research programs both on and off campus. Several of our undergraduates have participated in the McNair Scholars program, which is designed to encourage underrepresented low income students to progress to graduate school; and the ASCENT program, which provides support for juniors and seniors to enable them to complete their degrees in a timely fashion. One team member participated in a Research Experience for Undergraduates (REU) in robotics at Texas A&M.

Team members tutor each other in computing and other courses, and the students often form study groups. Team members also tutor other Computer Science majors in computing courses, and typically one or two STAIRSTEP undergraduates help students in the hands-on programming labs in the first two introductory programming classes. Their involvement in these freshman labs has helped to increase the program's visibility and recruit new students into the program.

The Computer Science STAIRSTEP teams have ranged in size from 3 to 8 students. During the five years and eight months of NSF support, eighteen percent of CS STAIRSTEP participants had overall GPAs 3.5 or above (on a scale of 4.0). Fifty-eight percent had a GPA between 3.0 and 3.49. Twenty-four percent had GPAs between 2.5 and 2.9. Most started as freshmen or sophomores. This sets STAIRSTEP research apart from other undergraduate research programs, which typically target juniors and seniors with high grade point averages [13].

Computer Science STAIRSTEP participants include freshmen through seniors and graduate students. This facilitates the peer instruction model and provides peer mentoring, tutoring and community building to undergraduates at each level. This model provides a way to include undergraduates in research during their freshman and sophomore years, when retention is most at risk; and to broaden the base of undergraduate researchers to include students whose grades are not the highest.

B. Dispel misconceptions that discourage participation

Females and underrepresented minorities are in general underrepresented in STEM. Computer science degrees awarded to women has seen a decline in recent years, with only 11.7% of degrees awarded to women in 2010-2011 [14]. Of the

2012 entering freshman population, only 1.4% of females, 3.2% of African Americans, 2.9% of Hispanics/Latinos, and 0.8% of American Indians or Alaska Natives indicated an intention to major in computer science [15]. The lack of role models and the stereotype of the computer scientist with no social skills who works alone with his machine create the misconception that computing is a non-inclusive and socially isolating field, which makes it unappealing to women and minorities.

To help dispel these misconceptions, STAIRSTEP hosts Research Seminars and Career Forums. Research Seminars bring renowned researchers to campus and expose students to current STEM research and successful STEM researchers. Career Forums host successful practicing professionals and expose students to career opportunities in STEM. Wherever possible we include as our guest speakers females and underrepresented minorities and give our students face time with these successful role models. During its first three years, STAIRSTEP CS partnered with Lamar University's Increasing Student Participation in Research Development (INSPIRED) Program in co-hosting its Research Seminars and Career Forums. INSPIRED was a National Science Foundation Broadening Participation in Computing project that was directed by the first author [16].

The Computer Science arm of STAIRSTEP has hosted or co-hosted one or more Research Seminars each year. Some of our more notable speakers include the following, some of whom are pictured in Fig. 1:

- Professor Juan Gilbert, Clemson University, who was named one of the nation's top African-American Scholars by Diverse Issues in Higher Education and a national role model by Minority Access Inc.;
- Professor Nancy Amato, Texas A&M, who is a member of the Computing Research Association's Committee on the Status of Women in Computing Research (CRA-W) and the Coalition to Diversity Computing (CDC) and codirects the CRA-W/CDC Distributed Research Experiences for Undergraduates Program and the CRA-W/CDC Distinguished Lecture Series;
- Professor Valerie Taylor, Texas A&M, who has received numerous awards for distinguished research and leadership, including the Tapia Achievement Award for Scientific Scholarship, Civic Science, and Diversifying Computing; and
- Professor Robin Murphy, Texas A&M, who was awarded the Al Aube Outstanding Contributor award by the AUVSI Foundation for founding the field of rescue robotics and was named one of the Most Influential Women in Technology by Fast Company and an Alpha Geek by WIRED Magazine.

STAIRSTEP CS has hosted one or more Career Forums each year. Forums have ranged from one guest speaker to a dozen. Panelists include alumni, representatives from local companies who hire our students, members of the department's Industrial Advisory Board, and members and associates of the Association for Women in Computing Houston organization.

Fig. 1. Research Seminar Speakers Gilbert, Taylor, and Amato (left to right)

The panelists have spanned a broad spectrum of industries and organizations, including IBM, DuPont, JP Morgan Chase, SYSCO Foods, Accudata Systems, Southwest Research Institute, Rice University, Schlumberger Information Solutions, and Giddings Independent School District. These forums expose students to a wide array of careers and give them advice on job search and on what types of knowledge, skills and experience are in demand.

C. *Use institutional relationships to help students bridge to the next level*

STAIRSTEP CS partners with several organizations across campus to help students bridge to either advanced study or careers in STEM. This includes the university's McNair Scholars Program and ASCENT program, described below, the university's Career Center, and the Computer Science student professional societies.

The Lamar University McNair Scholars Program encourages juniors and seniors who are first generation and low-income students, or who are from a group underrepresented at the doctoral level, to pursue graduate studies by providing opportunities to define goals and to engage in research. STAIRSTEP partners with the Lamar University McNair Scholars Program to help increase the rate of graduate school progression among STAIRSTEP students. STAIRSTEP encourages its eligible students to participate in this program. Thus far three of the Computer Science STAIRSTEP undergraduates have participated as McNair Scholars.

ASCENT provides scholarships for eligible juniors and seniors majoring in computer science or mathematics to help students progress to graduation within two years. STAIRSTEP Computer Science partners with the ASCENT program to help our juniors and seniors progress to a timely graduation. Thus far five STAIRSTEP CS students have participated in ASCENT.

STAIRSTEP partners with the university's Career Center by encouraging students to participate in a wide variety of center-sponsored events, including job fairs, speed interviewing events, networking events, seminars on interviewing techniques, and workshops on LinkedIn. The faculty mentor makes students aware of the center's database of jobs and internships and encourages them to post their resumes in the center's online database. Several Computer Science STAIRSTEP students have received internships and jobs as a result of this participation.

STAIRSTEP CS students must be active members of the student Association for Computing Machinery (ACM) professional society. This has breathed new life into the society, whose membership had dwindled. We also partner with the student ACM to bring to campus guest speakers for the ACM's spring banquet and the CS STAIRSTEP Research Seminars. Since the program started, most of the officers of the student ACM society have been STAIRSTEP members. Many STAIRSTEP students have also served as officers in the Computer Science student honor society. These societies have initiated free tutoring and mentoring programs for students.

D. *Engage STAIRSTEP undergraduates in team outreach to high school, community college and university students*

A key STAIRSTEP strategy is to transform undergraduates into a powerful source for attracting others to STEM. Through their participation in the program, the undergraduates become strong and enthusiastic advocates and role models who demonstrate that computer science is not just for white males.

STAIRSTEP Computer Science students participate in a wide variety of outreach events to students in K-14. This is a much more extensive program than the 'road shows' pioneered by Carnegie Mellon University [17]. Examples of selected activities are included here.

1) *Computing academies for middle and high school students*

Computing academies embody our most formal, intensive and impactful outreach activity. Computer Science undergraduates participate in the design, implementation, testing and assessment of these academies.

STAIRSTEP students participated in eight Computing Academies for middle school students and three Computing Academies for high school students in 2009, 2010, and 2011. The academies were hosted by Lamar University's INSPIRED Program, described in Section IV B. The 2009 and 2010 academies taught programming concepts to high school students in a week-long series of hands-on labs in robot programming and web page creation. The 2011 academy used game programming instead of robotics. The middle school academies exposed kids to programming concepts in one-day programs with hands-on labs in programming Lego robots, creating animations with Scratch and webpage creation. A total of 193 middle school and 59 high school students participated in these academies. Formal assessments showed that the participants experienced a significant increase in interest and knowledge of computing [18, 19]. During these years, STAIRSTEP partnered with INSPIRED. INSPIRED students taught the academies, and STAIRSTEP students gave hands-on help to the middle and high school participants during the labs and helped with other organizational tasks.

In 2012, STAIRSTEP Computer Science hosted a computing academy as part of the Lamar Achievement in Mathematics Program (LAMP), a two-week residential program. The STAIRSTEP undergraduates taught computing concepts to 24 high school participants in a series of hands-on labs using the game programming materials. Formal assessment found that the participants experienced a significant increase in knowledge; 71% of participants reported an

increase in interest in computing, and 62% said they were more likely to take computing courses in the future.

2) *On-campus visits by local high school students*

STAIRSTEP hosts day-long visits by students from local high schools. The typical visit includes a campus orientation and tour, an on-campus lunch, and visits to each of the STAIRSTEP disciplines. During the visits with Computer Science, the CS STAIRSTEP team makes presentations on careers in computing and engages the students in fun hands-on activities that expose them to computing. The team is currently developing one-hour hands-on labs that expose students to basic programming concepts using Snap! [7]. Materials have been designed, created and pilot tested by current STAIRSTEP CS team members during an on campus visit by 52 local high school students in spring of 2015. These materials will be used and formally assessed during a series of on-campus high school visits that STAIRSTEP plans to host in fall of 2015.

3) *Road shows to local high schools*

The CS team routinely participates in visits to several local high schools. During the visits, the undergraduates talk to the high school students about the field of computer science, careers in computing, computer science programs at Lamar University, life on campus, the STAIRSTEP program, their research, and other topics of interest. Some of the road shows include more formal presentations and demonstrations.

4) *Road shows, on campus visits with community colleges*

For several years, STAIRSTEP CS students have made visits to computing classrooms of local community colleges. These visits are typically informal talks about the benefits of going on to pursue a 4-year degree after the associate's degree is completed, degree programs, research, scholarships and other opportunities at Lamar University. STAIRSTEP CS hosts similar visits for prospective community college transfer students who are escorted to our campus by an alumnus who teaches computing courses at a local community college.

5) *Formal presentations*

The Computer Science students made a formal presentation on their research to about 50 students and teachers at a spring 2015 talk sponsored by the Lamar University Office of Undergraduate Research.

6) *Computing workshops for K-12 teachers*

For the past four years, STAIRSTEP CS students have participated each summer in Lamar University's National Science Foundation sponsored Computing Institute for K-12 Teachers [20], providing hands-on help to local K-12 teachers in a week-long workshop designed to teach them computer science fundamentals and programming for classroom use.

7) *Manning booths at New Student Orientation and Open House*

STAIRSTEP undergraduates participate in these and other similar events on campus, talking one-on-one with prospective students about computing as a discipline, a major, and a career.

V. ASSESSMENT

The second author is Director of STAIRSTEP Assessment. The assessment plan includes both formative and summative

elements. The STAIRSTEP Program has three major goals: (1) retain and develop at risk students majoring in STAIRSTEP disciplines through an enriched research experience that includes mentoring, tutoring, and other support, and activities that are designed to dispel some of the misconceptions that make these fields unattractive; (2) help transition these students to graduate study or careers in science; and (3) attract more students to the fields through targeted recruiting functions. The goals/expected outcomes and evaluation methods are summarized in Table 1.

The Computer Science faculty mentor worked with the STAIRSTEP Director of Assessment to develop and fine-tune two instruments for assessing the program. Studies were conducted to establish the validity and reliability of the instruments.

The Learning Outcomes Questionnaire (LOQ) attempts to measure students' progress towards attaining the learning objectives of their discipline that prepare them for the transition to graduate school or careers in STEM; and the degree to which STAIRSTEP has contributed to this progress. Each STAIRSTEP discipline has its own LOQ because the learning objectives of each are different. During the program's first year, a high number of advanced students participated in STAIRSTEP. These students started the program at an advanced level of preparedness, so growth was limited. This appeared to have functioned as a confounding variable in the measurement of program effectiveness. For this reason, revisions to the LOQ instruments were made in Spring 2010. The revised questionnaires ask students to rate their progress towards each of the learning objectives of the discipline's undergraduate program on a scale of 1 (lowest) to 10 (highest) and to similarly rate the impact that participation in STAIRSTEP has had on their attainment of each learning objective.

The Self-Assessment Questionnaire (SAQ) asks students to rate their own interests and abilities in seven different areas: (1) ability to work in a team; (2) ability to write technical reports/papers; (3) ability to make a technical presentation; (4) interest in their STAIRSTEP discipline as a field of study; (5) interest in obtaining an advanced degree in their STAIRSTEP discipline or a related field; (6) knowledge of job search/interviewing techniques; (7) interest in pursuing a career in their STAIRSTEP discipline; (8) organizational skills; and (9) leadership ability. Students rate their abilities with the use of a rubric on a scale of 1 to 5 and the impact of the STAIRSTEP program on their abilities on a scale of 1 to 10. All STAIRSTEP disciplines use a common SAQ instrument.

Assessment is performed at the end of the spring semester of each academic year of participation. In addition to analysis of the student responses on the two assessment instruments, the assessment compares retention rates, grades, and drop rates of STAIRSTEP participants with those of cohorts of students from five years prior to start of the program. It also measures enrollments, majors and degrees granted in the discipline.

A. Assessment Results

This section reports the cumulative findings from the inception of the program on 1/1/2009 through the end of NSF

TABLE I. EVALUATION METHODS

Goals/Expected Outcomes	Evaluation Methods
At least 70% of STAIRSTEP participants will complete their degrees in STEM	<ul style="list-style-type: none"> Retention rate comparison Grade and drop rate comparison Self-Assessment Questionnaire
The STAIRSTEP experience will help students attain their department's targeted learning outcomes, preparing them for advanced study or careers in science.	<ul style="list-style-type: none"> Learning Outcome Questionnaire
At least 80% of STAIRSTEP students who complete the program will make the transition to advanced study or careers in science within six months of graduation.	<ul style="list-style-type: none"> Structured Exit Interview
FTIC enrollments in STAIRSTEP disciplines will increase by 5% or more starting in Year 2, Community College transfers to STAIRSTEP departments will increase by 20% starting in Year 2.	<ul style="list-style-type: none"> Student enrollments

support on 8/31/2014. A total of 21 undergraduates participated in the Computer Science arm of STAIRSTEP during this period.

1) Retention

The goal of retaining 70% of STAIRSTEP participants in their Computer Science major was exceeded, with 100% retained as CS majors. Cumulative statistics show that since inception STAIRSTEP CS participants have consistently made higher grades (3.45 GPA vs. 2.62) and lower drop rates (1.99% vs. 12.5%) in their major courses than cohorts of students from prior years. The cumulative STAIRSTEP student responses (all disciplines) on the Self-Assessment Questionnaire suggest significant perceptions of growth ($t=6.66$, $p<0.000$). A p score of 0.05 or less is considered significant. Students perceive STAIRSTEP as having a significant impact on their growth ($t=14.25$, $p<0.000$).

2) Graduation/field Placement (Transitioning)

The goal that at least 80% of STAIRSTEP students will transition into advanced studies or careers in STEM within six months of graduation was exceeded, with 90% of STAIRSTEP CS graduates that had been graduated for six months having transitioned into either graduate school or STEM employment. Ten STAIRSTEP CS students had graduated by 8/31/2014. All but one (10%) successfully transitioned into either graduate studies programs or STEM related employment.

An analysis of the students' responses on the Learning Outcomes Questionnaire is summarized in Table II. The results of the LOQ reported by the CS students cumulatively since the improved form was implemented in Spring 2010 suggest significant growth towards readiness within the Learning Outcomes necessary for their discipline. Students also report that this perceived growth within their discipline was attributed to participation in the STAIRSTEP program to a significant level. The results for the last year indicate that the perceived growth and impact were continuing to improve.

TABLE II. LEARNING OUTCOMES QUESTIONNAIRE RESULTS

Period	Learning Outcome Progress		STAIRSTEP Impact on Growth	
	<i>t score</i>	<i>p value</i>	<i>t score</i>	<i>p value</i>
Cumulative Spring 2010 – Spring 2014	6.08	0.000 ^a	7.54	0.000 ^a
Fall 2013 and Spring 2014	7.5	0.000 ^a	10.97	0.000 ^a

^a A p score < 0.05 is considered significant.

Fig. 2. Incoming First Time in College freshmen, community college transfers, and majors in Computer Science grew dramatically during the five years of NSF support.

3) Attracting Students

The goal of increasing enrollment of First Time in College (FTIC) freshmen by 5% starting in Year 2 was exceeded. Since STAIRSTEP started, CS enrollments and majors have increased dramatically, as shown in Fig. 2. The number of FTIC freshmen enrolling in CS increased from 25 in the fall of 2008 before STAIRSTEP started to 51 in the fall of 2013, an increase of 104%, despite two increases in entrance requirements (Fall, 2009 and Fall 2011). This compares to a 21% decrease seen in the university's non-STEM disciplines during the same period. Undergraduate majors in CS grew from 114 to 202, an increase of 77%. This compares to a decrease of 1 % in the university's non-STEM disciplines during the same period.

The goal of increasing community college transfers into CS was likewise exceeded. As of Fall 2013, the number of community college transfer students in CS was the highest it has been in the past 6 years, and is four times as high as the Fall 2008 pre-STAIRSTEP number.

B. Comments from Students

Included here are selected comments from CS STAIRSTEP participants with respect to various components of the program:

- Research: “<STAIRSTEP> gives the students valuable research experience which places the student at a higher level when applying for a Masters or Doctorate program or when applying for internships and REU programs at other universities.”
- Research Seminars: “We got to hear Dr. Murphy talk about the challenges that robots experience when trying to rescue people who've been involved in disasters. I really

appreciated the view into that world. She also told us things that we'd need to know if we planned to pursue graduate studies, some I already knew, but other things I did not."

- Career Forums: *"She made me think that I could make it in a computer science career."*
- A computing workshop for high school students: *"It felt wonderful to teach the students useful skills and concepts in my field of study and doubly so after I saw their faces light up while they began to create and experiment."*
- A visit to a local community college: *"I think one of my favorite parts of this program is the outreach. Our talks <with students in a community college class> were seemingly enjoyed by the class and several students said they would see us here at Lamar in the fall."*
- A visit to a local high school: *"These visits to ... local high schools help to provide information about the program to students at critical points in their lives, and help them to consider a degree in Computer Science."*

The following are excerpts from selected student testimonials:

- an African American male who participated in STAIRSTEP for 3 years, starting while taking freshman level CS courses, completing the BSCS/MBA program in December, 2014: *"As a typical student before STAIRSTEP, I would attend class, go home and have no involvement in the Computer Science Department. After joining STAIRSTEP my GPA increased, I became more involved with the department, and was able to fine tune my personal and career goals....The relationships and the experience gained from working as a team ... allowed for me to create and grow in a manner that is not possible while working alone....All of the extra-curricular activities have developed and honed skills that would not be there otherwise. These are not only resume material, but they are character building."*
- a Caucasian female who joined STAIRSTEP while taking freshman level courses and has participated for 1.5 years: *"When I started my first Computer Programming class ... I had no programming knowledge... After I was assigned any homework I knew that someone would always be in the <STAIRSTEP>lab to help me <with free tutoring>. I decided that I really wanted to be a part of STAIRSTEP so I could help others the way the older students helped me. Being able to participate in STAIRSTEP has been an amazing opportunity. The STAIRSTEP team has kept me motivated to make good grades. The research aspect of STAIRSTEP has helped further my knowledge about the Computer Science world and opportunities... I have learned to work in a team and collaborate my work with others. With the outreach programs we have I think we can really affect others, making an impact on student's lives and future career paths."*

VI. SUGGESTIONS

The following advice is offered to those who wish to adopt these practices in their programs.

The importance of a formal assessment plan directed by an independent evaluator cannot be stressed enough. The independent assessment provides evidence that the program is succeeding and can help identify problem areas. The former is a requirement for publication and recognition of the program. The latter is essential for program improvement.

Wherever possible partner with others who have similar goals. Partnerships can help broaden the program's base of support and increase its impact. The partnership with the Career Center has helped achieve the common goal of preparing students for the workforce. The partnership with the student professional organizations has helped develop students' professional and social networks and helped bring distinguished researchers to camps. The partnerships with other research and outreach programs on campus have helped extend and strengthen the impact of each.

Make use of professional organizations. The ACM's Distinguished Speakers Program is a good source for guest research speakers. Organizations like the local Association for Women in Computing can help provide speakers for career forums and help develop the students' professional network. The department's Industrial Advisory Board can likewise be a good source for career forum speakers.

Wherever possible include graduate students in the team. They can help lead the undergraduates in research, serve as role models for the undergraduates, and provide advice to them on applying for and succeeding in graduate school.

Promote the program ceaselessly. Publish in professional settings, give informal talks on and off campus. Work with the university's public relations department to help publicize the program. Work with the marketing department to develop promotional brochures. This will increase visibility of the program and help promote its success.

VII. SUSTAINING THE PROGRAM IN THE ABSENCE OF EXTERNAL SUPPORT

Some components of our program have been sustained without external support, while some remain a challenge.

The Research Seminars are now institutionalized in the Computer Science Department. The speakers often are provided by the ACM Distinguished Speakers program. The department pays for local travel expenses. Likewise, the Career Forums have been adopted by the department. Speakers are representatives from local firms that hire our students, members of the department's Industrial Advisory Board, and members and associates of the Association for Women in Computing, Houston. These speakers have generously given of their time and do not request reimbursement for travel.

Participation of undergraduates in on-campus and off-campus recruiting events has been adopted by the department. Students now routinely volunteer to participate in Open House and other on-campus events, and have also accompanied the department chair on visits to local high schools.

Partnerships with the McNair Program, ASCENT program, and Career Center continue and need no external support. Partnerships with local K-14 schools are continuing and

growing. Some of our past STAIRSTEP participants who are now teaching STEM classes in local high schools and community colleges are facilitating these partnerships.

The CS STAIRSTEP program has fostered a sense of community among our students, who have learned to help each other rather than to remain isolated or compete with each other. It has also helped to develop a culture of undergraduate research that will continue, with support from the university's recently established Office of Undergraduate Research (OUR).

Going forward, the proposed plan is that a number of STAIRSTEP teams will be supported each year, depending on available funding. The teams can come from the five original STAIRSTEP disciplines (Chemistry, Computer Science, Earth and Space Sciences, Mathematics, and Physics) and from other STEM disciplines. Interested faculty can apply to participate each academic year. From the pool of applicants, participating faculty mentors will be selected by a steering committee. The proposed budget includes faculty release time/stipends, student stipends, and support for supplies and research related travel.

Lamar University has agreed to provide limited support for STAIRSTEP teams in Computer Science, Mathematics and Physics for two years, during which time the faculty mentors in those three disciplines must secure external support to sustain the program. STAIRSTEP and its budget have been placed under the umbrella of the OUR, with additional duties in support of the OUR entailed. The faculty mentors are working with University Advancement, the Career Center, the Sponsored Programs Office, the local Workforce Development Board, and others to find sources of external support. The Beaumont area industry is largely petrochemical. There is currently no critical mass of employers of computer scientists in this area. That makes it difficult to secure adequate funding from local industry. The search is ongoing.

ACKNOWLEDGMENT

STAIRSTEP was supported by the National Science Foundation under Grant No. 0757057 from January 1, 2009 through August 31, 2014, and is currently supported by Lamar University's Office of Undergraduate Research, Computer Science Department and College of Arts and Sciences. INSPIRED was supported by Lamar University, a Broadening Participation Grant from the National Science Foundation (NSF) under Grant No. 0634288, and ExxonMobil grants.

Abstract— The importance of innovation and entrepreneurship has grown significantly over the past decade. Institutions of higher education have recognized the increasing level of importance being placed globally on producing college graduates with the skills to innovate new products and services, and many are rising to the occasion. Recently, Texas A&M University has established a small business accelerator available to all students. In addition, the University has supported the development of a new course where junior and senior students across the University can interact and learn about ideation, innovative product development, and entrepreneurship. Looking across the literature, most institutions are moving in a direction of fostering entrepreneurship through interdisciplinary courses either within engineering, business or through partnerships between both. This new course is novel in that, in addition to integrating product development with entrepreneurship, it also incorporates the ideation and innovation processes through involvement of the College of Architecture. By embedding architecture students into the teams of engineering and business students, expertise in these areas is added to the teams. Finally, the course exposes all students to new tools such as the lean startup method and Launchpad Central.

Keywords—*entrepreneurship; innovation; interdisciplinary; product development; lean startup*

I. INTRODUCTION

It is widely recognized that it is not enough for today's engineer to be technically competent, they also need an innovative and entrepreneurial mindset. Not only does education in the area of entrepreneurship give students the engineering and business sense to create new products that are marketable and have the potential for profit, it is also one of the fastest growing subjects in undergraduate education over the past thirty years [1]. In fact, according to the US Department of Commerce, as of 2013 there were over 450 institutions of

higher learning with programs in entrepreneurship [2]. From the standpoint of engineering education, these programs take on many forms. A study performed by the National Collegiate Inventors and Innovators Alliance (now known as VentureWell) determined that technology entrepreneurship programs are typically driven by engineering (53%), business (26%) or as a partnership between the two (13%) [3]. One example of these partnerships is an interdisciplinary course developed at Villanova as a joint engineering-business venture in the area of pharmaceuticals [4].

While partnerships between business and engineering make sense because of the need for both technical and business expertise when creating a technology-based startup, Texas A&M University has been looking at a key component that is often insufficiently addressed: ideation and innovation thought processes. Through the College of Architecture, Texas A&M has been offering courses in this area for many years to students across all disciplines. Now, by creating a new three-way partnership, the university seeks to create entrepreneurial teams that have a technology background, business acumen, and formal processes for innovation. This paper describes a new University-level course in Innovative Product Design that formalizes this teaming approach.

II. BACKGROUND

Although entrepreneurship, business startup and product development have been topics of interest across the Texas A&M campus for many years, there has been no integrated effort available to support all of these areas for undergraduates. However, pockets of experiential learning exists in a number of the colleges together with a growing interest in pursuing such an interdisciplinary educational initiative.

For example, the College of Architecture offers coursework to a wide range of students in innovation and ideation. These

courses focus on creativity and outside the box thinking as it pertains to new product and services. The School of Business provides a number of business-oriented courses focused on small venture startups and operation. In addition, the School has established the Center for New Ventures and Entrepreneurship (CNVE) that promotes and supports activities and competitions geared to recognizing intra- and entrepreneurial efforts and successes within the “Aggie family.” Both Architecture and Business had significant interests in expanding their undergraduate educational activities to include product-based models. Within the Look College of Engineering, some departments have created courses to include innovation and entrepreneurship. For example, the Electronic Systems Engineering Technology program recently refocused its curriculum on the design, development, documentation, and delivery of working prototypes that meet private and public sector sponsors’ problems or ideas [5]. The ESET program also established its Product Innovation Cellar as an electronic, embedded software and mechanical maker space to support multidisciplinary teams undertaking projects that created prototypes with commercialization potential [6].

A new initiative fostered by the University’s VP of Research provided an opportunity for representatives from all three colleges to interact. Known as Startup Aggieland [7], the facility had the tasking and ability to unify undergraduate entrepreneurial activities across the university. Because Startup Aggieland was open to everyone at Texas A&M and was not affiliated with any one college, department, or program, all students and faculty felt welcome to participate in its activities. An outcome of this type of interaction and engagement was the creation of a new interdisciplinary undergraduate course and laboratory for innovative product and systems development. Unlike other courses developed and offered by one department or college and taken by students in other departments or colleges, two faculty members from each of the three colleges planned and delivered the Innovative Product Design course for the first time in Spring 2014.

III. COURSE OVERVIEW

The new Innovative Product Design course has been taught for three semesters; Spring 2014, Fall 2014, and Spring 2015. The enrollment for each offering was limited to twenty-four junior/senior students (six teams of four) with approximately eight from each college. The format of the course includes:

- faculty and guest presentations on innovation/ideation, engineering aspects of product development, and business concepts related to new business startups,
- a flipped classroom approach to teaching lean startup methodologies and the business model canvas,
- a course project where interdisciplinary teams create a startup and experience ideation, customer interviews and pivots.

Table I lists the topics covered in both the presentations and in the flipped course videos. The presentations are provided by core faculty and entrepreneurs associated with either Engineering (ENGR), Architecture (ARCH) or Business

TABLE I. INNOVATIVE PRODUCT DESIGN COURSE OUTLINE

Week	Presentations		Flipped Videos
	Topics	College	
1	Team Formation Creativity and Global Trends	ARCH	Startups
2	Divergent and Convergent Thinking Ideation and Elevator Pitches	ARCH	Business Models/ Customers
3	Introduction to Launch Pad Videos Customer Meetings, Team Ideas	ARCH	
4	Intellectual Property (Law School)	BUSI	Value Proposition
5	Quality Function Deployment	ENGR	Customer Segments
6	House of Quality	ENGR	Channels
7	Reverse Engineering	ENGR	Customer Relations
8	New Product Development Process, Support and Sustainability	ENGR	Revenue Models
9	Startups in Regulated Industries	ENGR	
10	Intellectual Property II Patent Searches	BUSI	Partners
11	Financials for Startups	BUSI	Resources Activities Costs
12	Financing New Ventures	BUSI	
13	Developing High Performance Organizations, Managing Creativity, IDEO	ARCH	
14	Presentation skills, Being memorable	BUSI	
15	Final Presentations	ALL	

(BUSI) while the videos are taken from the Udacity course, “How to Build a Startup,” by Steve Blank [8]. Over the past three semesters, the course has evolved from a three-hour lecture/laboratory course to a three-hour lecture-only course. Currently, the course meets twice a week for seventy-five minutes each (a 50 minute lecture equals one credit hour) where one meeting time is reserved for presentations and interactive experiences by the participating colleges and the other meeting time is used in a flipped format where students and instructors discuss the lean startup videos and the individual team projects.

IV. ENGINEERING

In addition to the ideation and lean startup approach to new business startup, the course was designed to have a third of its content clearly focused on the engineering aspects of new product design and development. Each three-person team of students participate in a series of creativity exercises to identify potential products and services they can develop as a startup company. With an idea in mind, the teams will use the lean startup process taught by the business faculty using the videos available on the LaunchPad website [9]. Once these elements are in place, the teams begin to collect customer interview information and pivot on their new product/service idea based on feedback and observations they make. At this point, the engineering faculty members bring a number of technical aspects to the course. The five weeks of engineering product development concepts include: 1) Entrepreneur vs Intra-

preneur roles, 2) Understanding new product development processes and how product innovation happens within companies, 3) The House of Quality (HoQ) approach, 4) Reverse engineering process, and 5) Special needs of regulated industries. Two of these five concepts will be further defined as examples of the engineering content of the course.

Using the HoQ, teams are able to analyze the information collected from the interviews they conduct as part of the lean startup process. These narratives (or verbatims) are first assessed using a Verbatim Analysis and Sorting Table or Affinity Diagram to ferret out the customer root wants. The root wants are then used as inputs to the HoQ. Following this engineering process, the teams will produce a single diagram that translates the root wants of the customer to requirements and specifications that engineering will use to guide the prototype and product develop efforts. Each team is required to create, present and discuss the HoQ for their product.

Another important concept is reverse engineering. Engineering faculty presentations include principles of both white box and black box reverse engineering processes and how reverse engineering has been used as part of the new product development process. As part of the lab assignment on this topic, the teams select inexpensive electro-mechanical devices and perform both a white box and a black box reverse engineering analysis of the product to determine how it works and their recommendations for improvement. For this exercise, commercial products including toys, appliances, and quality of life devices are given to the student groups. Examples include remote control cars, toasters and bathroom scales. Fig. 1 shows interdisciplinary groups of students reverse engineering commercial products.

V. INNOVATION

The College of Architecture is the most unique aspect of this course. While many schools are developing partnerships between their business and engineering programs, it is Architecture at Texas A&M that brings a key ingredient necessary for the successful entrepreneur. Specifically, Architecture is responsible for developing the students' capabilities in creativity and innovation. To this end, they deliver presentations on team formation, ideation through convergent and divergent thinking, global innovation trends, creativity and flow, and innovation in high performance organizations.

Fig. 1. Reverse Engineering Experience

For example, in order to get the student teams into a mindset for developing their initial product concepts, architecture faculty deliver a lecture on global innovation trends as well as methodologies for creating new ideas. They then lead the student teams through multiple exercises that break down barriers to group innovation, encourage teams to rapidly develop multiple product concepts, and then converge on that single winning idea that seeds their startup experience.

VI. BUSINESS

Of the three colleges, the Mays Business School has the most experience in incorporating entrepreneurship into education. Through the CNVE, they have been fostering the entrepreneurial mindset through: idea and business plan competitions; a student organization focused on entrepreneurship; a graduate student-led consulting firm; and, most recently, the organization of the university-level Startup Aggieland incubator. Their interest in the Innovative Product Design course was as a creative outlet to involve their students in more product-based startups as opposed to the more typical service-based ideas that had been traditionally created by business-only teams.

In addition to leading the course project (discussed below), the business faculty offer approximately one third of the focused course presentations as well. The topics include intellectual property, finance principles for new startups, new venture funding, and new customer/investor presentation skills. For example, through their relationship with Texas A&M's new law school, the business faculty bring in guest speakers from the law school's Center for Law and Intellectual Property to introduce the concepts of patents, trade secrets, copyright, and trademarks. In addition, the business faculty host a workshop at the library on patent searching.

As a second example, each semester the business school brings in a successful former engineering student and entrepreneur who is CEO of his own company to discuss new startup financial concepts including how to understand cash flow, profit and loss, and balance sheets. To do this, the guest speaker has developed an interactive tool with an integrated cash flow statement, profit and loss statement and balance sheet. Through interactive scenarios, the class investigates how different real-world situations impact each of these statements and, ultimately, the bottom line of their company.

VII. COURSE PROJECT: MINIMUM VIABLE PRODUCT

A key aspect of the new Innovative Product Design course is experiential learning. This is accomplished through a semester-long project where students are broken into interdisciplinary groups, must develop the idea for a new product, and then use the lean startup method to create a Minimum Viable Product (MVP) and validate a new startup company in the form of a business model canvas as shown in Fig. 2. Project deliverables include:

- Document 100+ customer interviews as well as resulting pivots
- Create a full business model canvas to communicate their startup and business model

- Develop an MVP and build a physical, costed prototype or proof-of-concept

The project begins in the first week of the semester when students use speed dating to identify team members with similar interests. One constraint placed on the students is that they must form interdisciplinary teams, partnering with students from multiple colleges. The newly formed teams then use ideation concepts presented over the next two weeks to quickly define a product. In the interim, they have also started watching the lean startup video series by Steve Blank and so begin to develop their business model canvas. To assist in keeping track of their customer interviews and the development of their canvas, teams are required to use the Launchpad Central web environment.

Through multiple customer interviews each week, the teams learn to refine their idea through pivots, often changing their entire vision multiple times until they converge on that one winning idea around which to form their company. Through weekly team presentations, they receive feedback from other teams and from faculty to help them learn how to interpret customer feedback.

As each team's product becomes more well defined, they are encouraged to bring in other concepts from the in-class lectures such as using reverse engineering of competing products to refine their ideas, using the HoQ to translate customer verbatims into root wants and quantifiable product specifications, performing patent searches to make sure they have an original idea, and developing a financial model for their new startup.

Finally, in the last week of the semester, each team presents their customer discovery story to faculty and industry. Their presentation must include a history starting with their initial idea through the current concept including pivots as well as a complete discussion of their business model canvas. Finally, teams must make a go-nogo decision as to proceeding with their startup. As an incentive to help interested teams move their ideas forward, top teams are encouraged to apply for a space in Startup Aggeland. Of the first twelve teams in the course, three teams have been part of Startup Aggeland and one team went on to raise funding from Seed Sumo (a local private accelerator).

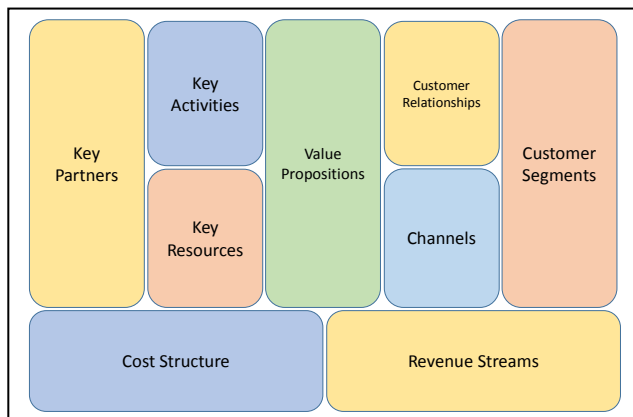

Fig. 2. Business Model Canvas

VIII. LESSONS LEARNED AND FUTURE WORK

So far, the new university-level product development course has been taught three times by faculty across three different colleges and has impacted approximately seventy-two architecture, engineering, liberal arts, and the business school students (while liberal arts does not participate in teaching the course, their students are welcome to enroll). From this experience, several lessons have been learned. First, the development of a single course by faculty with very different views on curriculum, teaching, and course development requires a team that has the patience and ability to work through contentious issues in a systemic way. To this end, it was agreed early on that "majority rules." This methodology allowed the group to avoid deadlock and move forward with the development of the course on multiple occasions.

Second, the group needs to focus on sustainable delivery strategies to ensure that the course could be offered on a permanent basis. For example, the initial offering had a three hour laboratory component. This created issues in terms of faculty availability and student schedules. Thus, the laboratory component was replaced with in-class interactive exercises and an increased expectation that student teams would meet and work outside of a regularly scheduled lab time. This flexibility has actually resulted in teams being more successful as evidenced by the increased number of customer interviews in the second and third course offerings. Other sustainability issues that are currently still being addressed include faculty loading, curriculum continuity as the faculty team loses and gains team members, and the recruiting of quality students for the course.

Third, the faculty need to develop strategies for helping student teams identify realistic product concepts. To date, anecdotal evidence indicates that about two-thirds of the teams are successful at developing creative and potentially viable products. The issue with the remaining third seems to stem from the beginning of the course where they have to quickly develop multiple products concepts and then down select. To help in the process, future offerings of the course will include a list of seed ideas from faculty and industry to help those teams who are having difficulty in getting started. It is anticipated that this will help those teams struggling to find initial ideas while not impacting teams that are self-starting.

As the Innovative Product Design course moves forward, there are multiple ideas for course improvement. For example, the faculty will perform a qualitative and quantitative assessment of student learning and team success. While anecdotal evidence shows that so far four of twelve teams have actually moved forward with their startup, the faculty need data in order to maximize the probability of teams actually creating a viable startup company. Second, the faculty team needs to find methodologies for scalability including the ability to accommodate more students per semester as the course becomes more popular and the ability to have teams interact with students from other institutions with similar interests in entrepreneurship. Finally, innovative methodologies for incentivizing students to take the idea of actually creating a new startup more seriously, perhaps through stipends and graduate degree programs.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of Startup Aggieland, the Dwight Look College of Engineering, the Mays Business School, the College of Architecture, the A&M Law School and the private companies that have assisted through seminars, lectures and laboratories especially Mike and Sandy Wilkinson of Paragon Innovations.

Assessing Idea Fluency through the Student Design Process

Molly Hathaway Goldstein, Şenay Purzer, Camilo Vieira Mejia, Mitch Zielinski, K. Anna Douglas

School of Engineering Education
Purdue University,
West Lafayette, IN
goldstm@purdue.edu, spurzer@purdue.edu

Abstract—Engineering design is a complex activity for students to undertake and for instructors to assess. This research uses large learner data sets collected through automatic, unobtrusive logging of student actions in a CAD platform to address this difficulty in observing design behavior. We used a computer-aided design software that captured student design activities to investigate patterns of student design behaviors that are associated with idea fluency. We show how micro-level process data can be used to validate observations made from viewing the student design process through design replays. Students who engaged in high idea fluency showed evidence of fluency in both process data and design replays. Similar patterns were observed for low idea fluency students. There is great potential to investigate student design learning through system-collected data. Yet, how to justify the inferences made about students based on their process data is largely unexplored. Our results demonstrate how traditional forms of assessment data can be used to validate inferences made by process data. Implications of this work would be highly relevant to engineering educators as well as researchers who are interested in understanding the relationship between learner analytics and student learning.

Keywords—engineering design; idea fluency; creativity; assessment; clickstream data, process data

I. INTRODUCTION

Assessing student learning behaviors has garnered new options through advances in learning analytics [1]. In this article we discuss examples of using learning analytics to assess student idea fluency in the context of design.

II. LITERATURE REVIEW & THEORETICAL FRAMEWORK

A. Informed Design and the Iterative Designer

The Informed Design Teaching and Learning Matrix [2], herein referred to as “the Matrix,” provides a way to think about nine key design strategies employed by expert designers as compared to beginning student designers. The Matrix deconstructs the design process in order to better connect novice learning to expert literature in order to better support informed teaching with engineering design activities [2].

One design strategy discussed in the Matrix, idea fluency, is an important strategy as students work with multiple ideas in order to avoid fixation and to experience a range of design options. When generating ideas, expert designers work with a multitude of ideas by practicing design activities such as divergent thinking, and brainstorming. To become a more

informed or advanced designer, the Matrix encourages teaching strategies to focus on brainstorming and related techniques to achieve idea fluency. However, artificial attempts requiring student idea fluency have been shown to result in superficial efforts without the promise of transformation to informed design [2].

Although idea fluency is an important informed design behavior, it can be hard to identify in student design activities. Often educators do not see the realm of all design possibilities a student considers before landing on a few select options. Because idea fluency is linked to both creativity and reflective design [3], methods, illuminating a lack of student idea fluency early would allow these teachers to offer interventions that could encourage greater ideation and could lead to greater creativity.

B. Learning analytics & Process Data

Learning analytics is an emerging area of research [4][5] and “offers the possibility of implementing real-time assessment and feedback systems” to optimize learning environments [1]. Siemens [4] defined learning analytics as “the measurement, collection, analysis and reporting of data about learners and their contexts, for purposes of understanding and optimizing learning and the environments in which it occurs.” Some [1] posit that using such data analytics is imperative to improving teaching and learning by gleaning a better understanding of the student learning process from a large learner data perspective while at the same time improving individual student progress.

Next Generation Learning Challenges (NGLC) as well as the National Academy of Engineering (NAE) through partnership with the National Science Foundation (NSF) have funded efforts to scale learning analytics solutions through “Big Data.” The thought is that by understanding what students are doing, educators can offer better interventions.

Process data, sometimes known as clickstream data, is of particular interest in the application of learning analytics. Process data is essentially a log of user actions with the corresponding time stamp of each action. Analyzing this process data in an educational context can provide rich insight regarding student learning with hands-on technology. Using process data in conjunction with other more traditional methods of analyzing student design processes allows researchers to more fully understand student design behaviors.

While process data may not meet the “Big Data” criteria level for some, having learners’ clickstream data is certainly a more in-depth observation of learning that what is typical in educational assessment research. Machine generated data requires analytics beyond typical assessment methodologies and analysis.

III. BACKGROUND

This research was conducted with a free, open-source computer-aided design platform, Energy3D (<http://energy.concord.org/energy3d/>), to design and build energy efficient buildings. This software is very user-friendly and was developed with educational research purposes in mind. Energy3D collects large amounts of data in the background as students design. Among this data collected were process data and a logger of student actions allowing reconstruction of the entire student design process.

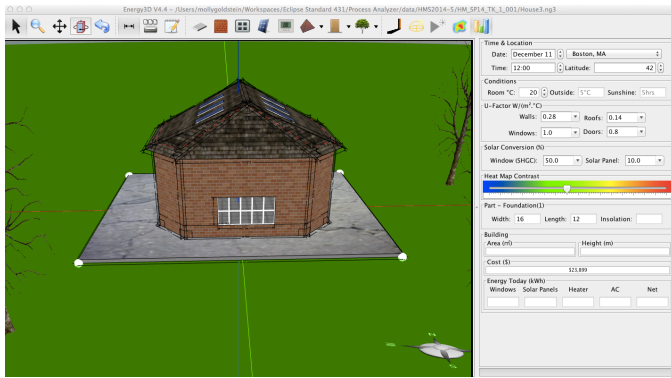

Fig. 1. Example student design in Energy3d

The design challenges that students undertake as they use Energy3D to design address the following engineering principles (i.e., design knowledge) outlined in the Next Generation Science Standards (NGSS) [8].

- HS-PS3-3. Design, build, and refine a device that works within given constraints to convert one form of energy into another form of energy.
- HS-ETS1-1 Analyze a major global challenge to specify qualitative and quantitative criteria and constraints for solutions that account for societal needs and wants.
- HS-ETS1-3 Evaluate a solution to a complex real-world problem based on prioritized criteria and trade-offs that account for a range of constraints, including cost, safety, reliability, and aesthetics as well as possible social, cultural, and environmental impacts.
- HS-ETS1-4 Use a computer simulation to model the impact of proposed solutions to a complex real-world problem with numerous criteria and constraints on interactions within and between systems relevant to the problem.

IV. RESEARCH DESIGN

This research sought to determine if idea fluency was evident from watching the student design process and if learning analytics corroborated the initial qualitative data analysis. Two student cases are presented in greater detail as they designed energy-efficient buildings using a computer-aided software system: (1) a student who exhibited a great degree of idea fluency; and (2) a student who exhibited a lesser degree of idea fluency.

A. Research Participants

This pilot study investigated eight (8) students in an AP Chemistry class at a large urban high school during the 2014 spring semester.

B. Design Challenge

The design problem presented to the students, named the Solar House Design Challenge, is set in 2020 where legislation dictates new homes must consume nearly zero energy. To that end, the challenge encourages students to consider solar energy in designing an energy efficient model house that maintains a comfortable interior temperature in both summer and winter. Design criteria are presented in Table 1.

TABLE I. SOLAR HOUSE DESIGN CHALLENGE CRITERIA

Criteria	Description
Energy	Minimize energy needed to keep the building comfortable on a sunny day or a cold night. Consume less than 8,000 kWh of energy per year.
Cost	Minimize total cost of the building. Cost cannot exceed \$50,000 in building materials.
Size	Comfortably fit a 4-person family (approximately 185.8 m ²). The house’s platform must not exceed the 28 x 36 m platform provided in the software.
Attractiveness	Has attractive exterior or “curb appeal”

C. Data sources – Design replays

The Energy3D software records every action of the students. In addition to having accessible process data, these logs of students’ actions such as sketching buildings, conducting experiments, collecting data using simulations, etc. can be used to reconstruct the entire student design process. This reconstructed process, a design replay, is similar to time-lapse photography in that the entire student design process can be sped up to provide a compressed view of the process in a shortened amount of time. In addition, if students took electronic notes while designing, these notes present were replayed synchronously to the students’ design actions.

D. Analysis

The design replays were viewed by two researchers looking for idea fluency. The researchers developed a codebook of idea fluency for student design actions, shown in Table II.

Two researchers then independently viewed all design replays coding for idea fluency. Differences in coding were noted and discussed before coming to a consensus on each student. An idea fluency score for each student was calculated by

summing the total idea fluency for each of these areas, where an individual student could have a total maximum score of 10. This scoring system allowed the researchers to identify a student who exhibited a high degree of idea fluency and a student who exhibited a lower level of idea fluency. Then, process data for these two students was analyzed to better understand if idea fluency that was visible through the design process was also evident from the process data.

TABLE II. IDEA FLUENCY CODING PROTOCOL

Strategy	Level of Idea fluency		
	Low (0)	Medium (1)	High (2)
Build/Modify Walls	Maintained same basic shape of house through all design iterations.	Experimented with 2 or fewer variations on the original house shape.	Made 3 or more variations on the house shape (height, overall shape, footprint, etc.)
Build/Modify Roof	Kept same roof throughout design.	Made one change in roof type (pyramid, hip, gable)	Made two or more changes in the roof type (pyramid, hip, gable)
Build/Modify Windows	Minimal change in window placement, size, or shape.	Evidence of changing 2 of the following: the size, shape and position of windows	Evidence of changing more than 2 of the following: the size, shape and position of windows
Add/Modify Solar Panels	No use of solar panels.	Explore either position of or quantity of solar panels.	Explore both position of and quantity of solar panels.
Add/Modify Trees	Added trees at the end of a design without modifying placement or type.	Explore either: position of type of, or quantity of trees.	Explore 2 -3: position of type of, or quantity of trees.

V. RESULTS

Table III presents the number of students within level of idea fluency for each of the design areas.

TABLE III. DISTRIBUTION OF STUDENT IDEA FLUENCY

Strategy	Level of Idea Fluency		
	0	1	2
Build/Modify Walls	1	7	0
Build/Modify Roof	4	4	0
Build/Modify Windows	0	6	2
Add/Modify Solar Panels	1	6	1
Add/Modify Trees	5	2	1

Fig. 2. Total idea fluency score per student

Design replays were reviewed and coded for all students in the class. Figure 2 shows the total idea fluency score for each of the students out of a possible 10. The cases of Emily and Eric are presented to illustrate difference in high idea fluency and low idea fluency.

The first student to be discussed, Emily, was among the most idea fluent students in the class. Through the design replays, researchers noted her use of idea fluency in particular in building and modifying the windows and solar panels in order to achieve better solar performance of the building. In the design replays, Emily changed the size, shape and position of windows in order to have a higher functioning home with lower energy usage requirements. Emily also explored many positions and quantities of solar panels as seen in the design replays. Her total idea fluency score of 5 reflects a level 1 in walls, 0 in roof, 2 in both windows and solar panels, and a 0 in trees (See Table IV).

TABLE IV. EMILY'S IDEA FLUENCY IN DESIGN

Strategy & Level	Detail of Idea fluency Level
Build/Modify Walls Medium Level	Experimented with 2 or fewer variations on the original house shape.
Build/Modify Roof Low Level	Kept same roof throughout design.
Build/Modify Windows High Level	Evidence of changing more than 2 of the following: the size, shape and position of windows
Add/Modify Solar Panels High Level	Explore both position of and quantity of solar panels.
Add/Modify Trees Low Level	Added trees at the end of a design without modifying placement or type.

The second student, Eric, practices a lower level of idea fluency. While he did modify the windows and solar panels in his design, he did not explore a wide range of options. His total idea fluency score of 3 reflects a level 1 in walls, 0 in

roof, 1 in both windows and solar panels, and a 0 in trees (See Table V).

TABLE V. ERICS’S IDEA FLUENCY IN DESIGN	
Strategy & Level	Detail of Idea fluency Level
Build/Modify Walls Medium Level	Experimented with 2 or fewer variations on the original house shape.
Build/Modify Roof Low Level	Kept same roof throughout design.
Build/Modify Windows Medium Level	Evidence of changing 2 of the following: the size, shape and position of windows
Add/Modify Solar Panels Medium Level	Explore either position of or quantity of solar panels.
Add/Modify Trees Low Level	Added trees at the end of a design without modifying placement or type.

Using process data we can also see similar trends. The following two sets of figures show more detail about the design actions for Emily and Eric. The top left graphic in both Figure 3 and Figure 4 is a combination of all design actions (build/modify walls, build/modify roof, build/modify windows, build/modify solar panels, build/modify trees).

Recall Emily’s high idea fluency in window and solar panel design. When comparing the window design actions it is clear that Emily practiced a higher degree of idea fluency in window modification. In the design replays, Emily’s idea fluency is seen comparative to Eric’s through the qualitative coding schema. This observation from the design replays is also apparent in the process data as shown in comparing Figure 3 to Figure 4. Through her total design, Emily practiced more design actions and was more fluent in her ideas as seen from the total height of the top figure. Her idea fluency with window design is very apparent when comparing to Eric. However, both students were showed low levels of idea fluency when designing with trees as evidenced from the design replays. The process data also corroborates this claim.

Fig. 3. Emily: Number of design actions from process data

Fig. 4. Eric: Number of design actions from process data

VI. CONCLUSION & FUTURE WORK

Through the case of two students, we demonstrated how micro-level process data can be used to validate observations made from viewing the student design process through design replays. High idea fluency was evident in both design replays as well as in the process data. Similar patterns were observed for the low idea fluency student.

Our results demonstrate how traditional forms of assessment data can be used to validate inferences made by process data. Future work will compare students who are focused on idea fluency and students who practice a high degree of tradeoff analysis and will start to explore differences in developing creativity and science learning from design.

VII. LIMITATIONS

This study investigated eight (8) students in an AP Chemistry class at a large urban high school during the 2014 spring semester. While this sample size is in fact small, the AP Chemistry class represents a differentiated group of students who exhibit greater degrees of academic motivation and are of particular interest to explore design behaviors. Our goal for this pilot study was to sample few students from a very homogenous group. Although the data set may seem small, we believe that the validation process will have to start with small data as we move into large data.

VIII. ACKNOWLEDGMENT

Abstract—This article discusses students' self- and co-regulation during their engagement in a senior design project. The specific focus of this study was to understand how participants monitor their design process and manage their projects with their teammates. Fourteen students working in four different teams participated in the study, each of which were in their senior year of Biological Engineering courses. The study attempts to answer two research questions: (1) How did students individually monitor the progress of their team-based design project?; and (2) How did their teamwork factor into the completion of the design project? Quantitative and qualitative data associated with student regulation on design process and teamwork were collected from our Engineering Design Metacognitive Questionnaire (EDMQ) survey instrument, an innovative e-journal, students' journey maps, design artifacts, and interviews. The preliminary findings suggest that (1) despite distinctive challenges in managing their team, each found ways to adapt to their team's unique dynamic; (2) teams that believed in a "fair share" task division seemed to utilize better team monitoring strategies; and (3) a design evaluation checklist to refine the number of possible design solutions was not widely used during the problem framing phase.

Keywords—*self-regulation; co-regulation; engineering design; teamwork*

I. INTRODUCTION

Design, a central part of engineering education, helps students develop problem-solving ability, critical thinking, and creativity. According to Jonassen [1], design problems range from well- to ill-structured. The latter are more difficult to solve because they require more cognitive operations than simpler, well-defined ones. Reitman [2] and Simon [3] classified design problems as ill-structured when they have ambiguous goals, no predetermined solution path, or require the integration of multiple knowledge domains. Design may have numerous solution pathways and be bound by constraints, which are not always presented with the problem. In engineering education practices, students are often required to work on their design projects with a team.

Although teamwork has been recognized as one of the major skills practiced in the workplace, in educational practices it is often perceived by many students as challenging and adding to the complexity of their design tasks [4]. In engineering programs, students are expected to be able to work in teams and this expectation is even prescribed in one of the student outcomes endorsed by Accreditation Board for

Engineering and Technology (ABET) [5]. Development of the skill of teamwork management is often only found in limited situations such as homework and lab activities, which differ from the ill-structured environment of design/build.

Working on a design project in a team requires effective self- and co-regulations. Research has found that self-regulation may be generalized to individuals in teams and teams as well [6] and in many situations, random assignment being one, social interactions may negatively impact individual and team self-regulation [7]. Conversely, it is well known that good quality teams have the ability to synergize, thus achieving a level of performance beyond which the individual team members could attain.

This article presents a study that is currently being conducted to understand student self- and co-regulation processes during a senior design project. The specific focus of this study was to understand how participants monitor their design process and manage their projects with their teammates. Some preliminary findings are included in this article.

II. RELEVANT LITERATURE

A. Engineering Design

The National Academy of Engineering suggested that engineering education was deficient if it did not include the global perspective in engineering design [8, 9], which views design from a systems level rather than from an isolated modular perspective. Not only do open-ended, system-type problems more accurately reflect industry practices, they also provide students more flexibility and choices [10].

Dym and Little [11] contended that the design process consists of five phases: problem definition, conceptual design, preliminary design, detailed design, and design communication. Similar models were proposed by Christiaans [12] and Cross [13]. These design phases are considered as high-level overall views of design processes. They involve a sequence of actions or strategies that are self-contained cognitive approaches and relate to the current state of the design process. For example, during the problem definition phase, students analyze the design problem. It may be divided into several functional subsets. Students frequently consider understanding of the problem to be the most important engineering design activity [14]. After clearly understanding the problem, they may be ready to propose a solution, analyze it, and decide whether to use it or find alternatives. Seniors

found identifying constraints and iterating more important than did first-year students.

Senior capstone design projects were selected to be the context of this research because they represent ubiquitous, complex, and ill-structured problems which prepare students for post-baccalaureate work by immersing them in industrially-based projects. This study will use Dym and Little's [11] five-stage prescriptive model to categorize and code cognitive engineering design strategies and evaluate students' metacognitive activities during the five design phases. This design model was selected for two reasons. First, it categorizes the design process into five 7 main phases (i.e., problem definition, conceptual design, preliminary design, detailed design, and design communication) with specific cognitive strategies in each phase. Second, the model offers clear coding categories for student cognitive strategies in engineering design.

B. Project Management

Kerzner (2013) [15] defines project management as an approach for finding internal solutions to resource control issues and requires, "methods of restructuring management and adapting special management techniques, with the purpose of obtaining better control and use of existing resources" (p. 2). Working in a team is not just about working together with peers sharing the same space and tasks to work on, but also balancing power and responsibility as they seek to control the path their team takes to meet its mission. Numerous studies have suggested that group learning offers a basis for social comparison and social learning [16] and teamwork quality and team diversity impact the effectiveness and quality of the task completion [17].

In the context of engineering senior design projects, the project mission is accomplished as students manage the demands of tasks and assignments from clients (someone who funds the design project), the instructor and each other. In academic environments, there may be a leader assigned to a particular group, yet members of the team are generally peers and the assignment of leadership may be arbitrary and loosely distributed as in social contexts the students may be more familiar with. Thus, the distribution of power and responsibility is subject to the unique dynamics of each group. Project management in this work is comprised of three components: Team Management, Resources Management and Time Management.

Team management includes the interpersonal dynamics of group planning, distribution of tasks, and utilization of each team member. Resource management is seen as the group allocation, tracking and use of funding. Time management is considered on an individual basis, as students prioritize work on their particular project tasks and coordinate with teammates to meet their pre-determined deadlines for delivering portions of the deliverables.

C. Self-Regulation and Co-Regulation

Research on self-regulated learning (SRL), which in this proposal is defined broadly as a complex repository of knowledge and skills for planning, implementing, monitoring, evaluating, and continually improving the learning process,

shows that enhancement of these abilities strengthens learning skills [18] and improves academic success [19-23]. Coutinho [24], along with Otero and Campanario [25], found that students with good SRL skills are more likely to achieve academic success and a high GPA. According to Zimmerman [26], self-regulated learners are "metacognitively, motivationally, and behaviorally active participants in their own learning process" (p. 329); therefore, self-regulated learners are skilled in goal-setting, self-monitoring, self-instruction, and self-reinforcement [27] and build "habits of mind" and commitment to the ideals of reflective thinking, assessment, and learning as an ongoing, lifelong process. When students are working in a team, team interaction may affect student's self-regulation with some interactions being especially difficult, such as when individuals are grouped together by assignment [7]. A student uses good SRL processes to oversee his or her learning process, plan and monitor ongoing cognitive activities, and compare cognitive outcomes with internal or external standards [28].

In this study, regulation in contexts of the model by Butler and Cartier [29, 30, 31] was used to assess the dynamic and iterative interplay between metacognitive and cognitive activity which characterizes SRL as a complex, dynamic, and situated learning process [28]. This model involves six central features that interact with each other: (1) layers of context; (2) what individuals bring; (3) mediating variables; (4) task interpretation and personal objectives; (5) self-regulating strategies; and (6) cognitive strategies.

Co-regulation, on the other hand, is a transitional process of interaction between two or more peers that acquire self-regulation in a common problem-solving plane [32, 33]. This co-regulation is a temporary support for each other's SRL and peers are required to be aware of one another's goals and progress and consider those in relation to the shared task [34]. In the co-regulation process, one of the peers is usually a more regulated peer that assumes responsibility for regulating a less regulated peer. Research suggests that students are benefited to succeed in learning as a result of participating in the co-regulation process [32].

In an engineering design educational context, the layers of contexts may include learning expectations in engineering as a field of study, the nature of engineering design tasks, and the expectations of particular instructors in different settings. The second feature of what individual brings include students' strengths, challenges, interests, and preferences. The mediating variables include students' knowledge, perceptions about competence and control over learning, and perceptions about design activities and tasks. Task interpretation is the heart of the SRL process. Students draw upon information available in the environment, and knowledge, concepts, and perceptions derived from prior learning experiences to interpret the demands of their design tasks. Students set personal objectives such as achieving task expectations in order to direct their engagement in learning. Fifth, students manage their engagement in academic work by using a variety of self-regulating strategies: planning, monitoring, evaluating, adjusting approaches to learning, and managing motivation and emotions. The sixth SRL feature is the cognitive actions or

strategies selected to realize their design and project management plans.

III. THE STUDY

The objective of this study was to learn about students' self-regulation during their engagement in a senior design project. The specific focus of this study was to understand how participants understand the tasks they are working on, make relevant planning strategies and monitor their design process and teamwork.

A. Research Questions

Two research questions were constructed to guide the study:

- 1) How did students individually monitor the progress of their team-based design project?
- 2) How did their teamwork factor into the completion of the design project?

B. Student Participants and Design Projects

Fourteen students working in four different teams participated in the study, each of which were in their senior year of Biological Engineering courses. Five among those 14 students were female. All had a GPA between 3.0 and 4.0 on a 4 point scale.

The first project was tasked with the development of a hernia mesh derived from synthetic spider silk with the ultimate objective to create an alternative hernia repair mesh using synthetic spider silk. The second project was to develop a drug delivery system using human serum albumin (HSA) as a carrier for anti-inflammatory, antibiotic, antiviral, and antioxidant drugs for kidney and/or liver failure patients. The third project was the production and purification of antimicrobial peptides in *Escherichia coli*. The objective of this project was to work towards optimizing a design to produce four different antimicrobial peptides by studying the effect that some different variables have on yield, activity, and purity and deciding which methods produce the best results. The fourth project was to design and optimize a process for the production of green fluorescent protein (GFP) secreted from recombinant strains of *Pichia pastoris* grown in bioreactors. Each group had to complete their project within two (spring and fall 2014) semesters.

C. Data Collection and Analyses

Students' self-regulation in the design process and project management were collected through Engineering Design Metacognitive Questionnaires (EDMQ) survey instrument, an innovative e-journal, students' journey maps and interviews.

1) *Quantitative Data*: Quantitative data were collected through EDMQ. The instrument development is grounded in Butler and Cartier's self-regulated learning (SRL) model which describes the interplay between motivation, cognition, and metacognition in a design activity. A rubric matrix combined Butler and Cartier's SRL features (i.e., task interpretation, planning strategies, cognitive strategies, monitoring/fixed-up, and criteria of success), as well as Dym and Little's design process and project management

components were used in the instrument development. Dym and Little contended that the design process consists of five phases: problem definition, conceptual design, preliminary design, detailed design, and design communication. The project management activities include students' teamwork, time and resource management. Individual performance on student self-regulation during the design process and how they managed their project were assessed using this survey instrument.

2) *Qualitative Data*: Qualitative data were collected through interview, Electronic Journal (eJ), design journey map and artifacts. Coding of interviews will follow the main categories in the Butler and Cartier model. Specific attention will focus on how students describe task demands in all phases of a project (to complement EDMQ data on task understanding), and interview probes will be used to ask for explanations of observed activities. Common themes are expected that may facilitate knowledge about students' understanding of design tasks, why they elect certain design strategies, how the strategies relate to task understanding, and how the strategies change during the course of a design project. The e-Journal was designed concordant with the engineering design phases: Problem Definition, Conceptual Design, Preliminary Design, Detailed Design, and Design Communication. The online characteristic of the eJ ensure the 'freshness' of the data because students can report their activities concurrently with design activities or at their convenience. The e-Journal enables the act of going back and forth between phases to support the iterative nature of engineering design. A form with prompts is available for the students to enter reports of their activities and upload related documents pertinent to each design phase. The reports also serve as a communication means among the team member in the group, or between the group with instructors, clients, supervisors or researchers. Students were required to attach files that comprised student's design deliverables. The design artifacts were evaluated to confirm what they said they would do and what they actually did. Approaching the end of the project time, participating students were asked to describe their cognitive (including metacognitive) actions and emotions as a journey map while working on their design project. These sort of pictorial descriptions tell a host of stories that cannot be captured by survey instruments.

3) *Analyses*: Students' design journal entries were coded to identify SRL features and engineering design strategies. Possible links between planning activities and engineering design strategies will be made in order to identify accomplishments, adjustments, or the abandonment of strategies. The accuracy of the information collected from the eJ will be judged through design artifacts. The measure of agreement between student reports from the eJ and other sources recording design progress will be validated and evaluated. An index score of EDMQ indicates the level of balance among domains of SRL activities. An Index Score was defined as the score associated with each of these

domains and helps shape this study's interpretation of student self-regulation effect. As such, the relationship was modeled using a magnitude from the EDMQ answers given, and a weighting factor that scales the applied SRL effect of each team member. As teams scores are found and normalized over the number of team participants, a corresponding efficiency of the team's SRL is obtained that corresponds very closely to the information being obtained about team dynamics from other sources. Thus it appears that team dynamics may have a powerful effect on SRL or vice versa. This effect is a prime area for more study.

IV. PRELIMINARY FINDINGS

The analyses are currently in progress and are not yet completed. In this work-in-progress paper, three preliminary findings are presented in this article:

1) Despite distinctive challenges in managing their team, each found ways to adapt to their team's unique dynamic. While adaptive methods may be generally viewed as positive, in these teams, it was apparent that there were various degrees and qualities of adaptation. Some adaptive behavior shown is highly self-regulated in nature, for example, taking over where someone leaves work undone, or in helping a struggling teammate. Conversely, examples have been shown where teams allowed roles to shift and stopped long range planning activities. What we are seeing is adaptive behavior over time that can either strengthen or weaken team efforts to continue SRL. Continued inquiry into this area of project based team behavior is needed.

2) Teams that believed in a "fair share" task division seemed to utilize better team monitoring strategies. They tended to stay on task, check each other's status more often and had more open communications with each other about the project. Teams with relatively higher composite TI/PS Effect scores showed an efficiency characterized by their members completing their design tasks or cooperative efforts to stay on track. In light of the other forms of data collected (eJ, interviews, journey maps) the self-reported characterizations of SRL effect correlate very strongly to the flavor of team dynamics encountered. For example, the team with the highest normalized TI/PS effect score over project management issues seemed to be composed of members more effectively implementing SRL, individuals were more team oriented than ego-centric, had better planning, strategies, more open communications, and a shared sense of responsibility and power. On the other hand, teams with lower normalized TI/PS scores on project management issue seemed to struggle with project management efforts regarding teamwork, time management, and resources management generally. Compelling evidence for these findings is qualitatively reflected from student interview and design journey map.

3) A design evaluation checklist to refine the number of possible design solutions was not widely used during the problem framing phase. This finding was indicated by the consistent lower self-regulation EDMQ scores on task-interpretation, planning and monitoring strategies associated with developing an evaluation checklist during problem-definition design phase.

V. NEXT STEPS

Further analyses are currently being conducted to understand our data and triangulate it from those multiple sources identified as providing input to answer the two research questions within this study. A novel approach to compare teams via composite index scores is currently being validated that may show relations across various SRL constructs. The results of this study are also being further analyzed in light of additional design artifacts. These have further information to provide that can inform studies of SRL among students design teams.

Abstract—Global conditions are changing at such a rate that foreseeing trends in technological development, economic fluctuations and climatic conditions is ever more difficult. When developing technologies, there is one constant factor that practitioners and researchers should be aware of, and that is people. This is not to say that people, culture and social conditions remain stagnant, for these too evolve with the surrounding circumstances. Rather, appropriate tools and capabilities for investigating people, their lives and life situations, are integral to understanding what people need in terms of technology, how these technologies will be used, and more importantly how they will be valued in the scheme of a person's life. This paper describes the process and outcomes of a course in Cognitive Science focused on developing the tools needed for Life-Based Service Design (LBSD). The course is implemented via problem-based learning (PBL), and students are guided through the process by charting an explanatory method adhering to the Life-Based Design (LBD) ontology. This ontology comprises: 1) Form-of-life analysis; 2) service concept and requirements; 3) fit-for-life analysis; and 4) innovation design. Results show heightened awareness and sensitivity of life conditions, values and needs, revealing design concept strengths and weaknesses in the pre-development phase.

Keywords—*life-based design; problem-based learning; cognitive science; service design; interaction design*

I. INTRODUCTION

In the world of education there has been much discussion on the need to train students in 21st century skills [1] [2] [3]. Despite attempts to establish frameworks [2], the term 21st century skills often remains vague as a concept, especially in terms of substance. There is no prescribed set of skills that will prepare individuals for the 21st century [1]. However, Trilling and Fadel [2] identify that the century will require several skill sets. These include: 1) learning and innovation skills – critical thinking and problem solving, communication and collaboration, creativity and innovation; 2) digital literacy skills – information, media and ICT literacies; and 3) career and life skills – flexibility and adaptability, initiative and self-

direction, social and cross-cultural interaction, productivity and accountability, as well as leadership and responsibility.

While we are pointed to the direction of what types of skills need to be instilled and developed, the exact skills and tools needed remain vague. This vagueness lies in our inability to adequately predict the vast changes that are expected to occur over the next 20 to 30 years in relation to climate, technology, social, economic, cultural and other conditions that await. In fact, the dependence of our livelihood and wellbeing, physically, socially, psychologically and financially on radically developing technological conditions, means that we are quite often only able to rely on the state of things *today*, rather than count on what comes *tomorrow*.

For this reason, in the Cognitive Science education program, the university has introduced the Life-Based Service Design course. While we cannot fully imagine the possibilities of tomorrow on the basis of technology, we can direct students towards the source of these developments – people. People are diverse, not only amongst one another, but also within themselves. Due to continual physical and psychological life processes of cell generation and cell death, learning and experiencing, human beings are never the same entity from one moment to the next [4] [5]. This is why overlooking people and focusing on aspects such as technology, and other designed systems, leaves us prone to a lack of understanding regarding how these systems develop and operate.

In this paper we describe the Life-Based Design (LBD) methodology, and how it serves to gauge the nuances of human cognition from the perspective of life circumstances, or as termed in LBD, Forms of Life (FoLs) [6]. We then go on to describe problem-based learning (PBL) and how it is integrated into LBD as not only an approach to design practice, but also as a method for learning about human cognition, its relationship to physical reality, and how this impacts (or should impact) the way practitioners approach

service and system design. The paper moves on to describe how the LBSD course has been implemented over the past two years (2013 and 2014), what processes students undergo, how they choose topics, gain mentoring, and reflect these learning processes. The learning outcomes of the course are then described in terms of subsequent projects students have endeavored as well as resulting services. In the conclusion we discuss the effectiveness of the course, and directions for future LBSD problem-based learning.

II. LIFE-BASED DESIGN METHODOLOGY

The main tenet of LBD is that services and technology should exist for the benefit of life quality [6] [7] [8]. The four main phases of LBD methodology are: Form-of-life (FoL) analysis, concept design, fit-for-life design (FfL), as well as innovation design [8]. LBD differs from other human-technology interaction (HTI) design paradigms, which include human factors, usability engineering, and ergonomics in that these paradigms focus on the systems and services themselves. That is, according to Leikas et al. [8] they are devoted to establishing seamless and unproblematic interactions between people and systems, yet from a technological perspective [9] [10] [11] [12] [13] [14]. Thus, the study of people in these paradigms is focused on the HTI, and how well systems operate in light of the user.

LBD on the other hand, starts from human beings and their life conditions (i.e., family, career, age, gender, socio-economic, cultural, ethnic, religious, disabilities etc.) and identifies the areas which may be assisted and enhanced by particular technological solutions, in order to improve life quality. The components of LBD can be seen in Figure 1, which illustrates the relationship between FoLs, Rule-following actions (RFAs) and Technology-supported actions.

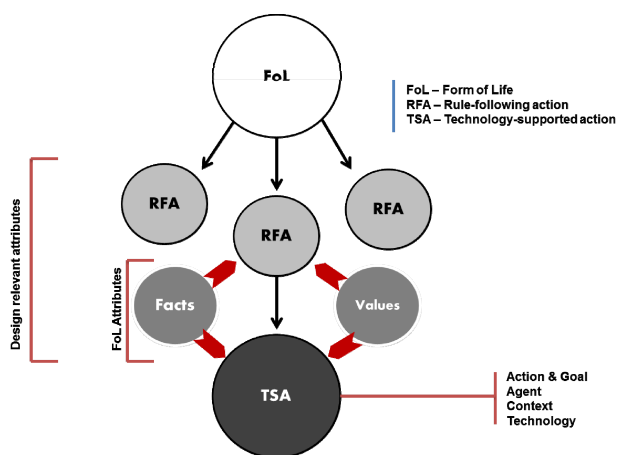

Fig. 1. Components of design leadership according to LBD, adapted from Leikas [6], p. 6.

As stated above, central to the service design process in LBD is the person and their FoL, or life circumstances (physiological, psychological, social, economic, information,

etc.). Everyone in their FoL engages in RFAs. That is, similar to routines, people fall into pattern of actions and behavior. These patterns may begin from a necessity, i.e., waking up early to go to work, and then continue even when the actions are no longer necessary (e.g. retirement or while on vacation). Thus, the *facts* are elements which are inherent to the FoL, such as the need to arrive at work on time, while the *values* (and norms) possess the meaning of action – why people behave the way they do. Then, the design relevant attributes inform the designer when making specific design decisions for people experiencing the FoL in question. This in turn affects the technology-supported action (TSA), which in itself is the dynamic interaction of action and goal, agent, context, and technology or service. [6]

III. PROBLEM-BASED LEARNING

Problem-based learning, or PBL, is a constructivist approach to learning that engages students through the presentation of problems, relevant to the desired learning outcomes in question [15]. It was originally developed by Howard Barrows and colleagues at the McMaster Medical School in 1969, not as a pedagogically or psychologically tried and proven method for learning, but instead as a way of making the learning of medicine fun [15]. While there are many forms and adaptations of PBL, some of the core principles behind the method are: 1) PBL is student-centered; 2) it generally takes place in small groups or teams; 3) learning is active, whereby learners actively seek answers themselves; 4) cases or problems are utilized as stimuli for learning; 5) and learning takes place during independent study time, which is usually significant [16] [17].

PBL has been defined in terms of learning objectives and goals, teaching philosophy, in addition to pedagogical attitudes and values [18]. PBL has even been identified as a 7-step process by authors such as Henk G Schmidt [19] who isolated the seven steps as being: 1) the clarification and agreement of ‘definitions in progress’ of terms and concepts which are as yet, still unclear; 2) identification of the problem(s) in question and agreement of issues and phenomena which need further explanation; 3) the analysis of effects of various components (via e.g. brainstorming) and explanations in order to form a rough hypothesis; 4) the discussion, arrangement and evaluation of likely reasoning facilitating the working hypothesis; 5) creating and ranking learning objectives; 6) undertaking independent research to develop a deeper understanding of these objectives between tutorials or seminars; and 7) the reporting of findings at tutorials and seminars, which thus aids in the establishment of plausible explanations and reapplication of these explanations to new information and problems.

PBL has been characterized in terms of its strengths and weaknesses. In terms of positive cognitive attributes, PBL is noted as promoting better memory retention of material learned during problem-based processes. The applied way in which knowledge is acquired means that this knowledge is more readily recalled and utilized in solving other similar

problems. Pattern recognition is enhanced and encouraged through knowledge acquisition that occurs over time via real life examples. Further, PBL promotes the activation of prior knowledge which enables efficient processing of new information. Knowledge, or pieces of information, are readily explained and contextualized during moments of learning. Then finally, the attachment of context to knowledge acquisition eases future recall. [15] [20]

The negative aspects of PBL have been characterized as mainly placing too much load on working memory. This is noted by Kirschner, Sweller and Clark [21] as being problematic in that the working memory is incapable of simultaneously problem-solving and learning. In other words, its capacity is said to only enable one of these actions per time. Additionally, Kirschner et al. [21] highlight that processes of learning how to practice in a field of knowledge such as medicine and the processes of actually practicing cognitively differ. We argue that by implementing PBL in the Life-based service design course we not only promote the learning of user-centered design (UCD) modalities in a fun way, but the processes of PBL and the LBD approach to UCD are complimentary, and can be used to reinforce one another.

This is due to the explicit stages of LBD ontology examination and definition which sit neatly with Schmidt's [19] outline of the 7-step approach to problem-based learning. Learners are encouraged to consciously reflect on the learning process, not simply in terms of the LBD methodology itself, but also of the designer's process in coming to understand other individuals (people in various FoLs) and in particular, their cognition. More will be explained about this mutually complimentary process in sections V and VII.

IV. PBL IN DESIGN AND ENGINEERING EDUCATION

In their article "Engineering education – is problem-based or project-based learning the answer?" Julie Mills and David Treagust [22] criticize the *then* dominance of "chalk and talk" (p. 2) education. Mills and Treagust highlight the importance of keeping pace with the rapidly changing technological conditions engineers in today's world face. They additionally emphasize the significance of developing skills such as flexibility, adaptability, and most importantly people skills. In particular, they stress research findings which suggest that engineers should possess effective teamwork and communication skills [23] [24]. On this note, Helen Beetham and Rhona Sharpe [25] see PBL as a means of gaining and strengthening 21st century skills precisely for its qualities in supporting collaborative learning and requiring that learners seek the answers themselves – without the guidance of a teacher or tutor. Their argument is that conditions the students find themselves in, such as their technological landscape, should guide the process. With this said, they emphasize that the technology should lead the learning process, rather than traditional teaching and learning methods, limiting the advantages of the technologies.

PBL is noted as being favored among students in that it prepares students for the eventuality that the worlds of engineering and design are problem-based environments [22] [26] [27]. Thus, allowing students to practice problem-solving in the safety of their learning contexts. This is critical when considering the design and engineering professions as solving everyday problems [28]. Furthermore, PBL is quite similar to project-based learning, in that they both require group work and collaboration as well as self-directed learning. Furthermore, both modes are noted for their interdisciplinary natures. However, the difference between the two is that project-based learning is focused on *applying* knowledge, while PBL is focused on *acquiring* it [29]. This is where LBD as a method differs from pure PBL in that it requires both acquiring and application during the research process, and in the reporting phase. With PBL as a methodological back drop, the following describes the application of LBD as an extension and practical application of this type of self-directed group approach to learning.

V. LIFE-BASED SERVICE DESIGN COURSE – IMPLEMENTATION AND LEARNING PROCESSES

The Life-based service design (LBSD) course has been offered as a course through cognitive science for the past two years. It is an advanced learning module, taught at a master's degree level with the possibilities to continue research cases from differing aspects in other courses held in the program. Due to the time and work demands of lecturers as the result of numerous supervision sessions (or tutorials) during the course, student numbers are kept to a minimum. The course is open to a maximum of 25 students per time, meaning that there are essentially five to ten groups, and thus, cases. While four group members are the maximum, ideally two to three member groups are the optimum size.

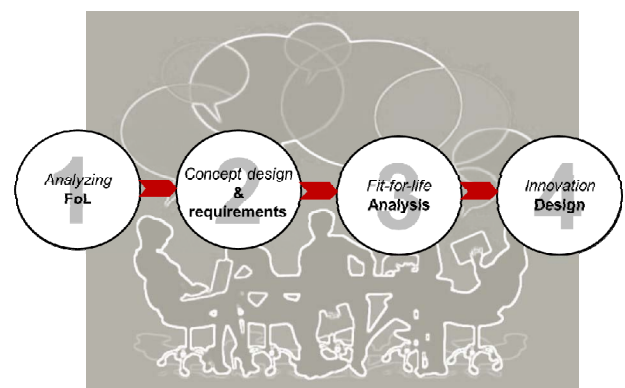

Fig. 2. Stages of the LBSD ontology (see [6])

At the beginning of the course students are provided with information about LBD in the form of two lectures. LBD is introduced firstly as a concept, and then as a design and engineering methodology. The concept is introduced in relation to research which has been undertaken relating to

technology generations, or gerontechnology [30] [31] [32]. It highlights the fact that in order to become genuinely engaged in UCD, and to essentially truly design for people and their diversity – differing requirements and desires for differing life circumstances – designers and engineers must become familiar with technology and service users on a *day-in-the-life* basis.

The methodology is explained at the same time as the assignment guidelines are distributed to the group. These guidelines are labeled ‘LBSD ontologies’, following the ontologies of LBD [8] and comprise four steps: 1) Analyzing forms-of-life; 2) the concept (design) and requirements; 3) Fit-for-life analysis; and 4) innovation design. These steps of the methodology are instrumentally used to break down the assignment task of the course. Each step is outlined as follows. Figure 2 illustrates the stages of the LBSD ontology.

A. LBSD ontologies and learning stages

1) Analysing forms of life (FoL)

For this step students, and ultimately designers/engineers, are guided to define the problem area and explore the nature of the FoL (life circumstances) of the service’s target users. Through contextualizing and identifying the problem area and human elements involved in the problem, the students are then able to establish a design problem, for example the lack of high speed internet connection for a particular digital learning application at an elementary school in some part of the world. Additionally, what is included in the ‘form-of-life analysis’ is the discovery of ‘Rule following actions’ (RFAs). These are typically known as habits which have formed through years of repeated actions, possibly for specific reasons. In an educational context this may be the practice of taking notes in lectures. Although these days students have access to lecture material via online learning platforms such as Moodle, Blackboard and other spaces, for more mature students, the practice of note-taking is upheld, and in many cases assists cognition through the kinetic processing of information [33]. These RFAs are particularly important when not only trying to understand users and potential users, but also when anticipating the use and potential use of the service in question.

Further, logically the actors, or users (teachers, administrators, learners and possibly parents), need to be identified even before commencing the journey of exploring life circumstances and RFAs. These actors need to be identified in terms of age, gender, skills, culture, social-economic circumstances, educational level, field, subject and other relevant information.

Then, the typical use contexts need to be established and explored. Information that is required of the context includes social, psychological, physical and technical factors. For instance, when designing digital learning services for mature aged students, designers must be aware of conditions such as technophobia, and possible social stigma surrounding technology such as computers, the internet and distance

learning that may be held by a particular group of learners. There are possibilities to overcome these issues via the technical design which may also be enhanced in the way the services are implemented – i.e. via a combination of face-to-face and online meetings.

Finally, as a tangible starting point for the service design, students are required to define the design theme and purpose of use. The purpose of use may have been the trigger for the service project, however, through FoL analysis other, previously unforeseen uses may arise, which could be critical to the success of the service.

2) The concept (design) and requirements

This step, which is quite similar to Schmidt’s step 2 in PBL, where the problem in question is determined, focuses on establishing what type of service design concept is to be developed in addition to the user requirements. Yet, rather than concentrating on the service itself, students are encouraged to explore the FoL in relation to RFAs in order to derive what types of technologies are appropriate and have the potential for enhancing quality of life. Thus, RFAs are examined for possible technology and service-supported actions. For example, telephone answering services have been developed with the idea in mind that in certain situations such as meetings, while driving and in other cases people cannot answer the phone. Yet, it is more convenient for the caller to leave a voice message than to independently type an SMS message. Similarly, online shopping – particularly grocery and even fast food ordering – have been developed for people who prefer to avoid crowds or do not have time to pick up goods in person.

At this stage students, and LBSD designers, investigate the possible alternative solution ideas. This is achieved by brainstorming – also prominent in PBL in steps 3 and 4 in particular. During these brainstorms attention is placed on elaborating various solution models – types of services or technologies, and what is required. The interaction between users and services is explored in terms of user-interface prototypes (fast or paper prototypes) and through further discussion.

Ideas and prototypes are tested with real users from the relevant FoLs (target groups). This is achieved both in terms of the conceptual model, and possibly even regarding more specific issues such as usability if the user interface prototype is at such a level of completion that usage can be simulated and/or evaluated. These investigations lead to a more precise definition of the technical solution concept. Thus, the design for development is known by now, and students can set their sights on gauging whether or not the service will suit the FoLs and RFAs in question.

3) Fit-for-life analysis

The *Fit-for-life analysis*, or FfL analysis, stage looks at how the FoL may be improved by the inclusion of the service

in development. This is somewhat of a departure from traditional product and service design in which a market is located through identification of possible uses [34]. Here, focus is placed specifically on how the innovation may potentially improve life quality of those who use it. Thus, emphasis is on the intangible value of the research and design work. This is quite similar to the hypothesis development occurring in PBL (Schmidt). Reflecting the design concept back onto real life situations and pairing the concept and its prototypes with target users' practical everyday life and values students (and designers/ engineers) can re-evaluate as to whether or not the concept is the best solution for the design problem in question.

During the FFL analysis meanings are explored, particularly in terms of what the service design concept means for the FoL under investigation. Meaning is especially pinned to the idea of improving life quality, whether this is in terms of making daily living (actions and chores) easier, or by encouraging *happiness* through social interactions with peers and loved ones. When considering life-long learning and its increasing popularity, digital and online learning solutions may be a key to improving life quality by enabling learners to become more actively involved in their learning. However, the learning solutions need to match the technologies and capabilities possessed by many mature-aged users.

Finally, during this stage special consideration needs to be given towards ethical questions regarding the user, usage, user context, and of course the service concept design being developed [35]. The service needs to be observed from an ecosystemic perspective which gauges the elements, not simply as separate elements, but as interacting actors, which change in meaning and therefore consequences depending on their combinations.

4) Innovation design

The final stage of the LBSD and learning process is the innovation design component. It is at this point that the actuality of the service design is considered. Here, matters such as infrastructure and use culture creation are examined. Distribution and sales are strategized in terms of marketing and implementation. Other problems or issues which need to be tackled by the students are for instance maintenance plans (particularly of online services) and the expected life-span.

B. How it works

The course is structured as to give students a brief introduction to the terms and concepts of the course. They are then initiated into the group assignment via the presentation of FoLs and their associated problems, in addition to already formed cases. For instance, one FoL may be young elderly people (55-75+) who have received an early diagnosis of memory impairment. Another may be mothers of young children seeking activities and play friends for their children. Groups are formed based on the students' interests, i.e.,

students choose a FoL and work with others who have also chosen the topic.

The instructions, in the form of the ontology, are made available for the students (both in their online learning platform and on paper) and students are given a week after the first meeting to begin structuring their research plan and approach to the FoL and subsequent LBSD process. The groups then present their ideas and preliminary plans to the group. During this research plan session questions are asked and feedback is given by both the students' peers as well as lecturers and tutors. After this presentation session all other meetings take place during supervision times arranged by the students with the teachers and tutors. In the two month course students are required to meet with teachers and tutors at least twice for guidance.

The supervision sessions are designed to provide the groups with advice regarding means of approach towards investigating the FoLs as well as in terms of theory. The theoretical direction of this supervision exists on three levels: 1) relating to the course subject – life-based service design – its philosophies and methodologies; 2) regarding the FoL in question, particularly in relation to issues of cognition and human-technology interaction (HTI); and 3) relating to design itself – students are required to investigate past and state-of-the-art services to discover possibilities and any present flaws in these services. There are no limits to how many times groups can arrange supervision, however the average amount of meetings is three. Generally, the amount of supervision sessions also rests on the level of challenge presented by the FoL and design problem in focus.

The groups present their projects at the final seminar of the course. Presentations take place according to the structure of ontology instructions, being with an introduction to the FoL stating simple facts about the group and then moving into previous scientific research regarding the FoL and specific everyday problems relating to this group of people. More previous research (if any) is presented regarding attempts to solve this problem. Then the students' own empirical component is explained. The empirical component consists of data collection from people experiencing this FoL via methods ranging from ethnography, to interviews and questionnaires, and even experiments in some cases. Based on the results of the empirical FoL material, the service design concept is either formulated or modified. The important aspect for students to remember in this process is that the research is not about discovering how to fit services into people's lives. Instead, it is about discovering how the services would naturally fit into their everyday lives.

The groups present their findings and following these they outline either the service design concept developed as a consequence of the research, or prototypes. In some cases groups have also managed to not only present prototypes, but also second or third iterations which have been influenced by

user or usability studies with people from the FoLs in question. Approximately one month after the completion of the course, students are required to submit reports of the project and design process. There are no set page requirements for this, however on average groups submit around 25 page reports, some even 50 pages – depending on the design challenge and level of motivation.

VI. OUTCOMES OF THE COURSE

Although LBSD is offered as a stand-alone course, its philosophies and the LBD methodology are present throughout the Cognitive Science Master's degree program. Therefore, continuation of projects initiated during the course is encouraged and supported. Since 2013, 49 students have taken part in the course. Of these, 24 were female and 25 were male. This equal representation of gender is already an achievement given that the course is held in the Faculty of Information Technology, which is dominated by male students. The age distribution of students is broad, the youngest being 23 years of age and the oldest being 58 - the average age being 31 years of age.

Besides the cognitive science students, students undertaking the course also come from disciplines such as information systems, computer science and software engineering. Students also come from diverse backgrounds, many already having vast professional experience either in the fields in question or in other fields. For this reason LBSD course and the LBD methodology, in light of the constructivist approach to learning that PBL affords, is highly advantageous for these types of student groups.

Since beginning the course 17 projects have been undertaken. The FoLs have included: young children (childcare and pre-school) learning about nature; families with children (young children and youth); foreign students seeking accommodation; people with memory impairment (institutionalized elderly and young elderly with early diagnosis); healthcare professionals providing services for elderly still living at home; tertiary students with Asperger's syndrome; tertiary students with vision impairment; foreign students with vision impairment; and organizational leaders seeking innovation management systems to name some.

The types of service concept designs which have derived from the studies have included: scheduling services; social media directly for the FoL in question; accommodation matchmaking; information systems enabling more fluent home healthcare options; affective toys; daily audio assistants; innovation management services; and augmented reality for educational application. Of these 17 projects, seven (41%) have continued after course completion. Some of these have been continued in other subjects offered by cognitive science such as User Research, Usability Analysis and Interaction Design. Four of the projects have been used as platforms for service business ideas, and two (an innovation management

service and an augmented reality educational application) have received national innovation funding to be developed further on a much larger scale. These funded projects in themselves are substantial achievements.

Numerous advantages have been noticed in adapting LBD as an educational approach and philosophy in the cognitive science program. Here is a list of the strengths of the method:

- It provides a fun and active introduction into human cognition placing real life situations at the foreground
- Theory is readily integrated into practical problems both relating to the FoLs as well as design issues
- Learning takes place on three levels: 1) LBD methodology and theory; 2) FoL familiarization; and 3) design theory, practice and state-of-the-art innovations
- Contextual, social, psychological and physical aspects affecting HTI are emphasized as central figures rather than the designs themselves
- Through consistency and support among staff (and faculty) LBSD course provides continuation to projects, supporting deeper learning
- Continuation and possibilities for greater achievements provide students with motivation for learning

During the course's history there has, however, been criticism towards this methodology, which can be seen as a side-effect of this independent, or self-guided (while in a group) constructivist approach. This relates to the minimal amount of lectures, an argument which contradicts the problems seen in the work of Mills and Treagust [22] who note the prominence of pen and paper engineering education, which sacrifices student motivation and engagement for the safety of traditional teaching implementation. Another problem rests in the group work itself and the distribution of responsibility between group members. Students have complained about final grades in light of some group members not producing as much as others.

Despite these short-comings, as the result of the consistency, adaptability and multiplicity of the course method, strengths rest not only in its effectiveness in relation to student learning, but its ability to construct firm collaborative relationships. These relationships occur within the student groups, between students, teachers and tutors, and between the teaching staff themselves. There is the atmosphere of constructing something larger in terms of understanding users, and possibly creating new innovations which will improve life quality. On this note, relationships between students and people in the FoLs themselves are also forged.

VII. LBSD COURSE APPROACH AS EXPLICIT PBL REINFORCEMENT

There are many overlaps between PBL and the LBSD course approach. However, as cited in relation to the comparison between PBL and project-based learning, LBSD is not only driven towards students acquiring information, it also requires them to apply it. Thus, through beginning with the empirical – FoLs – moving soon to the theoretical (both regarding the FoLs as well as design), and then back into practical application within the concept design (see Figure 3), LBSD can be seen as a combination of the two, plus more.

Fig. 3. LBSD methodological learning

The more comes into question when considering the holistic nature in which the LBSD course is delivered. That is, the projects that begin in the LBSD course do not simply stop there. If the students desire, they may continue their research and development projects throughout the cognitive science program, building on their knowledge and expertise of issues relating to cognition and HTI in relation to the FoL, and strengthening their skills as service designers. This may be continued into thesis work, and as seen in several of the projects so far, may even go on to develop into business ideas and/or attract national innovation project funding.

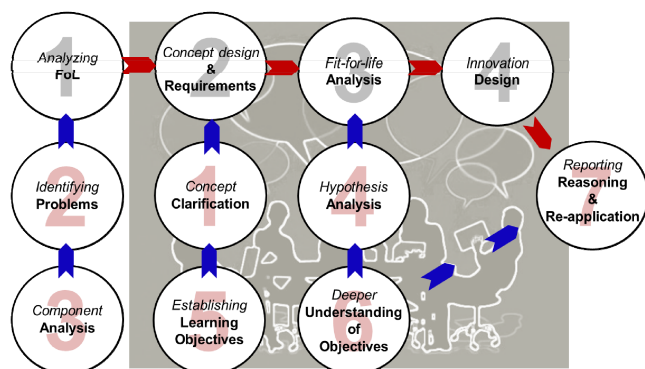

Fig. 4. Relationship between LBSD and PBL according to Schmidt's [20] 7-steps

There are four major stages in the LBD ontologies that students follow as a part of the LBSD course. While there are only four, they are intensive as three of the stages comprise at least six of the seven PBL steps Schmidt [20] outlines (see Figure 4). The LBD stages and the seven PBL steps are related in a non-linear way. As seen in the diagram, it may be noted that stage one, Analyzing FoL, entails the identification of problems and component analysis. Stage two, Concept design and requirements, includes the clarification of concepts and also the establishment of learning objectives (three fold – LBD, FoL and design possibilities). Stage three, FfL analysis, comprises hypothesis analysis – are the means of rationalizing the FoL and their needs and desires accurate? It additionally requires that students dig deeper and strengthen their understanding of the learning goals and objectives. Stage four, the innovation design component resembles part of the concretization phase of project-learning. Subsequently, at the end of the LBSD course, groups report their projects and reason their findings. Finally, there is the hope with this methodology that the learning does not end there, but continues with re-application and continual research – keeping abreast of the developments and changes which are occurring in our rapidly moving societies.

IX. CONCLUSION

This paper has focused on explaining the application of a design methodology, Life-based design, for the purposes of gaining a deeper understanding of people and their daily lives in the fields of service and technology development. As a point of departure, the paper has used PBL as an anchor in order to demonstrate the stages and components of the learning process when using a methodology such as this in a cognitive science program. This paper has highlighted criticism towards “chalk and talk” modes of teaching in engineering education, and emphasized the mode of learning in the LBSD course as that which is guided by real life. Design issues and problems are contextualized in social, physical, psychological, economic and even information (access to) factors. The contextualization forms motivation for delving into the theoretical, to find out how the FoL has been characterized, what the typical problems are, what has been done, and where the gaps lie for what can be done. This knowledge is then applied to the development of concept service designs, and even in some cases, prototypes and working prototypes.

The UCD process is iterative, and by following the LBD method, people from relevant FoLs not only inform the concept design but test the concepts and prototypes in terms of usability, usefulness and overall desirability of the products. Questions asked within the LBD methodological process do not purely pertain to whether or not the design would be useful or usable. Instead, the questions concern how the designs, technologies and services in general fit into the lives of these people, and whether or not, the services and technologies to be developed will improve their life quality.

Pressure is on educators to equip students with the much discussed “21st century skills”. While qualities such as self-

direction, communication and collaborative team skills have been emphasized, there is still something more that we as educators and (educational) designers may hope for. The term “designing for happiness” is not unfamiliar to developers of the LBD methodology [6] [7] [8]. And, given the versatile and uncertain conditions the students as future designers and engineers face, designing for happiness for people of all walks of life in diverse situations seems a noble goal strive for.

ACKNOWLEDGMENT

We would like to thank the University of Jyväskylä for the opportunity to push our exploration of pedagogical methodologies in cognitive science, design and engineering, as well as for the opportunity to write this paper. Many thanks also goes to VTT for supporting this research.

A Spiral Curriculum in Design and Project Management

Chris Venters, John Reis, Hayden Griffin, and Gene Dixon

Department of Engineering
East Carolina University
Greenville, North Carolina, USA
ventersc@ecu.edu

Abstract—This paper documents the design and implementation of a four year, five-course sequence in design and project management within a general engineering program at a large public institution. The design of the curriculum was inspired by the “spiral curriculum” concept, and as a result, seeks to build knowledge and skills related to engineering design and project management during each of the four years. Course descriptions and examples of the ways that knowledge is spiraled through each are provided. The first cohort to progress through the entire spiral graduated in Spring 2015; next steps will continue to monitor the effectiveness of the spiral through continued program assessment.

Keywords—*design education; project management; curriculum development; spiral curriculum*

I. INTRODUCTION

At a large institution with a small engineering program, the engineering department was formally established in 2004 and has since offered a BS degree in engineering. The engineering program has a rigorous assessment plan that monitors fulfillment of ABET outcomes and provides a means for continuous improvement. In following this process, two program shortcomings related to design and project management were identified by the faculty.

The first shortcoming was observed at the outcome level when the outcome c (design) coordinator rated the satisfaction of that outcome a level 2 out of 5 for two consecutive assessment cycles during academic years 2008-2010. This prompted the formation of a committee charged with examining the current curriculum and identifying ways that design instruction may be improved. At the time, the sophomore year lacked a design-related course, and it was suggested that continuously building design knowledge throughout the curriculum might be a better approach. In fall 2010, the process of creating a revised curriculum, more strongly emphasizing engineering design and project management, began.

The second shortcoming was identified at the course level. During academic years 2010-2012, based on ongoing faculty assessment of design knowledge among students in ENGR 4010 (Senior Capstone Design Project I), it was concluded that there was a deficit in the readiness of seniors to begin capstone work. The deficit was characterized as a lack of competence

with some basic engineering design and project management knowledge. Although students were able to successfully complete capstone, too much time was being spent reviewing design and project management knowledge. It was believed that the existing three-credit hour project management course, ENGR 3500, was no longer successful in its attempts to provide junior-level students with adequate design and project management skills prior to entering capstone. Anecdotal data collected during exit interviews with students supported this finding.

A solution to simultaneously address both shortcomings was developed and implemented in the form of a four-year, five-course sequence.

II. CURRICULAR APPROACHES TO TEACHING ENGINEERING DESIGN

As Atman, et al. note in the *Cambridge Handbook of Engineering Education Research*, approaches to engineering design education typically align with one of three primary models: the capstone-only model, the cornerstone-capstone model, or the integrated model [1]. They also note a general shift among engineering programs toward more integrated approaches, in which design learning occurs throughout the curriculum, as the other models are being identified as insufficient.

Many examples of integrated approaches to teaching engineering design have been presented in recent years. Faculty at the University Park campus of The Pennsylvania State University developed a coordinated sequence of design courses, respectively featuring design tools and project management content in the second and third years, in preparation for a semester-long capstone during the senior year [2, 3]. At Queen’s University, the curriculum was redesigned to implement a four-year “spine” that sought to integrate technical and professional skills throughout as a solution for meeting newly required accreditation standards without a loss of traditional technical skills [4]. The general engineering program at James Madison University features a six-course, ten credit-hour design sequence in which students complete a year-long design project during their sophomore year and a two-year capstone project [5, 6].

While our approach to teaching design shares many of the characteristics of the integrated approaches mentioned here, we have attempted to structure our design and project management courses using the spiral curriculum model described by Bruner [7]. In the model, the “basic ideas” of a discipline are taught and continually revisited as instruction progresses throughout the student’s time in school. Bruner wrote of the spiral curriculum model in the context of K-12 education, arguing for the spiraling of topics as the developmental level of the child increases. Bruner’s view that students, regardless of age or discipline, could and should be taught in a realistic way that reinforces the principle ideas and structure of the discipline.

While not used specifically for design, the spiral approach has been used within engineering education previously in cases ranging from first-year curricula [8] to entire program curricula [9, 10]. Using this approach, we have attempted to integrate project management and design into all four undergraduate years of our curriculum, utilizing the principal ideas and structure of the engineering design process: problem framing, ideation, selection, implementation, and project management. We situate this within actual design practice using a series of small projects, each year increasing in duration, scope, and complexity.

III. IMPLEMENTATION

As mentioned previously, a solution to simultaneously address the identified design shortcomings was developed and implemented in the form of a four-year, five-course spiral. ENGR 3500, identified as no longer being effective, was eliminated and replaced with two new courses. The resulting course sequence is as follows:

- ENGR 1016, Introduction to Engineering Design, an existing two credit hour course.
- ENGR 2000, Engineering Design and Project Management I, a new one credit hour course.
- ENGR 3000, Engineering Design and Project Management II, a new two credit hour course.
- ENGR 4010, Engineering Capstone Design Project I, an existing two credit hour course.
- ENGR 4020, Engineering Capstone Design Project II, an existing two credit hour course.

This course sequence is mandatory for all graduates of the engineering department although transfer students may receive credit for some of these based on prior coursework. To better accommodate incoming transfer students who have not received credit elsewhere, a hybrid of ENGR 1016 and ENGR 2000 is taught as a separate three credit hour course. The following section will provide a general description of each of the primary courses listed above.

A. Course Descriptions

1) ENGR 1016 – Introduction to Engineering Design

ENGR 1016 is a two credit-hour course taken by most students during the second semester of their first year in the engineering program. The course provides a hands-on

introduction to conceptual engineering design through four team-based design projects, each culminating in a design product. The course follows a similar “practice-then-apply” scaffolding structure as that presented by Carberry, Johnson, and Henderson [11]. The first three projects are faculty-defined and each places a stronger emphasis on a different element of the design process (namely, problem framing, solution ideation, and solution selection). The final project is open-ended and allows teams to apply their accumulated design skills to a problem of their choice all the way from problem identification through solution selection and construction of a working prototype.

The course benefits from a relatively low student to faculty ratio. Each section is capped at 18 students and has a faculty member and undergraduate teaching assistant who facilitate the course. The course is also supported by two college lab supervisors.

2) ENGR 2000 – Engineering Design and Project Management I

ENGR 2000 is a one credit-hour course taken by virtually all students during the first semester of their second year in the engineering program. The course provides a more advanced experience with specific stages of engineering design through three team-based design projects: two culminating in a paper design and one in a physical realization. The first two projects are faculty-defined, with the first focusing on a project design and the second on a process design. The design foci vary each semester. The third design project is for students to select, design, and manufacture a prototype toy given cost constraints. All projects repetitively reinforce the key design processes of problem framing (problem statement), solution ideation, solution selection, and project completion. Both analytical and intuitive processes for ideation and selection are introduced. The selection processes include both a feasibility assessment (compliance with constraints and physical possibility) and selection processes for the remaining feasible processes. The feasibility assessment includes identifying the specific reasons for being infeasible (if it is) and then identifying modifications that may make it feasible. Both project framing and ideation topics begin with individual assignments before working as a team to limit production blocking commonly found in brainstorming. Project management skills from ENGR 1016 (problem framing, task identification, task scheduling, and project completion/implementation) are reviewed, but not expanded upon. The focus is on strengthening design skills. Both written reports and oral presentations by the teams are required. Cost assessment (materials and labor) are included in the analysis, but not the time-value of money.

This course does not use a TA and the course size is limited to 30 students with one faculty member.

3) ENGR 3000 – Engineering Design and Project Management II

ENGR 3000 is a two credit-hour course taken by most students during the second semester of their junior year. The course introduces more advanced project management knowledge and skills, specifically focusing on the integration of project management into the engineering design process. Students are given a semester-long design project, sometimes

recycled and de-scoped capstone or other example projects, to apply their design and project management skills toward solving through the conceptual phase. Engineering design knowledge from ENGR 2000 and 1016 is utilized and documented in project design reports but otherwise not expanded upon. Practical design fundamentals related to jointery, electrical and mechanical power transmission, pump theory, piping and tubing, manufacturing, and fabrication are also presented. Other topics to prepare students for capstone include literature searches and intellectual property considerations, engineering standards, Design for X, prototype testing, and written/oral presentation skill development.

The course size is approximately 30 students with one faculty member assigned to each section.

4) ENGR 4010/4020 – Engineering Capstone Design I and II

ENGR 4010/4020 is a two-semester capstone design course in which students are assigned to teams of 3-4 and tasked with designing a solution to an open-ended problem. The projects are typically sponsored by an industry partner. Ideally, ENGR 4010 culminates with a project proposal, which is then further designed, built, and tested during 4020. Designs are required to be detailed enough for implementation; some designs go through prototyping while others go through construction and testing. Skill extension from previous courses is required and new skill development is often expected.

While student teams largely work independently, they consult with an assigned faculty advisor and a liaison from their industry sponsor. The department's capstone coordinator also serves as an advisor.

B. Spiraling of Topics

The design and project management spiral curriculum seeks to revisit the areas of: problem framing, ideation, selection, implementation, and project management in each course. Examples to illustrate how some of these are spiraled throughout the course sequence are given below.

1) Problem Framing

With respect to problem framing, ENGR 1016 emphasizes the identification of a problem or need as a first step in the engineering design process. Differences between solution objectives and solution constraints are also highlighted, as is the construction of written problem statements. During the project specifically focused on problem framing, students practice interviewing a fictional client to assist in determining the objectives and constraints of a solution.

In ENGR 2000, students are asked to consider the problem from different perspectives. For example, a product design can be considered from the perspective of a purchaser, the company legal department, top management, etc. They then individually write a series of problem statements based on the perceived needs and desires of each of those groups. Based on that assessment, they work as a team to write a comprehensive problem statement for future use.

By ENGR 3000, students are expected to apply their problem framing skills to an open-ended project (sometimes a

recycled, de-scoped capstone project). In addition to identifying constraints and customer requirements, students must also use this information to determine a project scope. The requirements identified are based on interpretation of the information directly provided by the client(s) and other stakeholders, as well as substantive research conducted by the design team in the form of literature reviews and patent searches. Emphasis is placed on developing a clear chain of reasoning to support the inclusion of the chosen requirements.

During capstone, students in ENGR 4010 go through the problem framing phase for a new, open-ended design problem from their industry sponsor. In addition to the methods used in ENGR 3000, students must perform site visits, conduct interviews, investigate related codes and regulations, and perform more extensive research to define the problem. Students are expected to develop engineering design specifications that provide performance criteria for their design. Additionally, human factors and ergonomics are considered.

2) Solution Ideation

In ENGR 1016, students are encouraged to brainstorm individually and in groups as a means of expanding the design space. The basics of functional decomposition and research on existing designs are introduced and paired with brainstorming to generate novel solutions.

In ENGR 2000, students continue to generate ideas by looking at related solutions, modifying existing solutions, conducting internet searches, and brainstorming. They also use morph charts to identify key attributes of the problem and then mathematically combine all permutations of these attributes. They work individually through a round of ideation with the intent of generating a large number of potential solutions. Most teams generate hundreds of options and variations. The emphasis of ideation is to not judge: quantity is more important than quality. The quantity is judged both on the total number of ideas generated (ideational fluency) and on the total number of categories of ideas generated (ideational flexibility).

Solution ideation methods from the previous courses are practiced and applied to larger scope projects in ENGR 3000.

In ENGR 4010, student teams build on their previous ideation knowledge and skills by interacting with a broader range of creativity models such as: facilitated creativity, Phases of Creative Thought, value-focused thinking, biomimicry, painstorming, skit exercises, and others. The emphasis is on creativity and stretch.

3) Solution Selection

In ENGR 1016, students receive an introduction to using the decision matrix design tool and ensuring constraint satisfaction. Students are expected to demonstrate basic principles of creating and presenting a decision matrix, including qualitative and/or rudimentary quantitative justification of assigned ratings. During the project specifically focused on solution selection, students conduct an analysis of team-collected experimental data to argue for the preferred sensor option for use in their design.

The selection process becomes slightly more formalized and nuanced in ENGR 2000, as it is separated into two steps. The first step is a determination of each of the solution alternatives (or solution categories) for feasibility. A solution is feasible if it satisfies the constraints listed in the problem statement and if it is possible for the solution to be implemented. Each of the potential alternatives are assessed for feasibility. If an alternative (or category of alternatives) is deemed feasible, it is carried forward. If it is not, specific reasons for it not being feasible are identified and potential modifications that would make it feasible are developed. These modified alternatives, if they are feasible, are added to the list of alternatives to be considered further. The second step in the selection process is to develop both qualitative and quantitative metrics to compare the alternatives using a decision matrix. Students then use either or both types of metrics in the final selection of their alternative.

In ENGR 3000, the same design reduction methods from ENGR 2000 are employed and documented in project design reports. Students, however, are expected to utilize knowledge from relevant engineering analysis courses to create appropriate metrics – and assign scores using those metrics – in order to evaluate solution alternatives that have been considered feasible.

In ENGR 4010, students use their accumulated knowledge related to solution selection to present a proposal that they wish to develop during ENGR 4020. Students must identify and technically support engineering judgements that play a role in the selection process, particularly with regard to meeting their established performance requirements. Feasibility analysis is required from both technical and economic points of view. During detailed design, material selections and manufacturing process selections are discussed, along with Design for X considerations and robustness.

4) *Solution Implementation*

Projects in ENGR 1016 typically reach the initial prototype stage. Students have in-lab access to CAD software, desktop 3D printers, and simple construction materials such as foam board. Within the context of the second two projects, students are introduced to the basics of programming and learn how to incorporate sensors, actuators, and other mechanical, electrical, and pneumatic components into their designs. The final, open-ended projects typically incorporate many of these resources.

In ENGR 2000, the third project requires the creation of multiple copies of the toy prototype they design (one for each team member to keep and one to give to the instructor). A detailed cost analysis must also be made, including materials and labor, for the manufacture of a large number of the toys (typically 1000).

Since projects in ENGR 3000 are conceptual in nature, there is no direct implementation. However, other practical design fundamentals related to jointery, electrical and mechanical power transmission, pump theory, piping and tubing, manufacturing, and fabrication are presented.

In ENGR 4010/4020, the scope of the project is much larger than in previous courses. Designs are required to be detailed enough for implementation, and some designs go

through prototyping while others go through construction and testing.

5) *Project Management*

An introduction to constructing and utilizing work breakdown structures and Gantt charts is provided in ENGR 1016. Basic Gantt charts are constructed using spreadsheet software, and emphasis is placed on correct activity sequencing, determining slack time, and identifying the critical path of the project.

Work breakdown structures and Gantt charts are reviewed in ENGR 2000, and students are expected to provide these for their final project. In this case, little new material is presented, and the main course focus is on developing design skills.

Project management is once again revisited in more detail in ENGR 3000. In this course, students begin utilizing more specialized project management software programs like Microsoft Project® to construct Gantt charts, Network diagrams, and resource charts. They also discuss, in more detail, how to estimate project time and costs, precedent-successor relationships, and project oversight. Students are asked to apply these project management techniques to their semester project. Other relevant topics, like managing project risk, project leadership, and resource management, are also discussed.

In ENGR 4010/4020, students are evaluated on their ability to use project management tools in directing and executing project activities. Development of a full project management plan is required, including detailed documentation of the project schedule, resources, responsibilities. Students submit individual time sheets reporting project activity hours and weekly activity reports.

IV. SUMMARY AND CONCLUSION

Implementation of the design and project management course spiral to date has taken nearly four years. With the creation of the new courses, ENGR 2000 and ENGR 3000, we feel that our students are better prepared for capstone than in previous years. While each course currently contributes to students learning design knowledge and skills, there is still improvement needed on synthesizing the content of each course into a more cohesive spiral. Most of this is not a problem of content, so much as a problem of context. Currently, the different courses – and even different instructors teaching the same course – sometimes use different terminology to express the same phenomenon, or worse, the same terminology to express different phenomenon. Understandably, this inconsistency leads to confusion among students, who find it difficult to integrate new knowledge within their prior knowledge gained from earlier design courses. From a program assessment standpoint, it also presents difficulty in using an integrated assessment instrument, since some faculty might interpret the assessment instruments differently; this has been evidenced in the ABET assessment reports for some of the design (outcome c) courses in recent years.

The first cohort to completely progress through the new spiral graduated in Spring 2015. Based on ABET assessment

data collected during their time in ENGR 4010, we feel that they are more prepared to enter into capstone than their predecessors. Assessment data from this past year's ENGR 4020 course will be used to verify the observations from the 4010 data, and we will continue to monitor the effectiveness of the design and project management spiral in the coming years.

Abstract— Hackathons bring developers, artists and designers together around a shared challenge: ideate, plan and create an application in a highly constrained time frame. A way to socialize, solve problems, and strengthen soft and hard skills, hackathons have grown tremendously in popularity in the last half decade. Despite this growth, it has been noted that females do not participate in hackathons with the same frequency as males. Some theorize that the hackathon culture is intimidating, does not appeal to women, or that it acts to amplify pre-existing cultural biases in computing. In this paper we introduce an alternative format for hackathons to address these issues. Think Global Hack Local (TGHL) is a non-competitive, community-based hackathon that connects non-profit organizations with student developers. Students donate a weekend to solve problems that these organizations otherwise lack the resources to solve. To date, there have been two TGHL hackathons, and we have observed many interesting divergences within the culture of TGHL in comparison to other hackathons. Response has been positive, and nearly all of them indicate that they would do it again. By adopting some of these ideas, we believe that hackathons can become an environment that is more inclusive and fun for all.

Keywords—hackathon gender issues; community engagement; community-based projects; service learning

I. INTRODUCTION

For student participants, hackathons offer many promises: improving or acquiring programming skills, spending a brief but fun and immersive time with like-minded people, taking a non-trivial project from beginning to completion in a short time, competition and prizes (though many events are non-competitive), an agile prototyping environment and direct contact with potential employers. Despite what many may perceive as positive attributes, hackathons also elicit strong negative reactions from others: they can foster a competitive, male-oriented programming culture, they can encourage poor software development practices, and they can reinforce the

"nerd" stereotype. This paper explores both sides of the discussion and describes a hackathon format (Think Global Hack Local), which retains most of the positive attributes while attempting to minimize the negatives by focusing on community-based projects. From participant responses to post-event surveys, we have an understanding of what motivated these students to attend this event and what aspects they felt were positives about the event. Participants tell us that the community focus was important to them and that, as previously reported by others, the social aspects of the event have a big influence on their initial interest in participation and their willingness to come back.

II. BACKGROUND

Hackathons, hacking (or coding) marathons, have seen a surge in popularity in recent years. Now considered a staple of the technology community, such events grew primarily out of companies looking for ways to innovate within their business, but have since grown into the public domain and academia as a way to build things, advance new ideas, and improve skills. Some have become so large and garnered so much attention that many students participate as a way to help them with job search [1].

Like hackathons, game jams have grown in popularity evolving their own culture that is similar, yet slightly different than the hackathon model. Jams have been noted to focus on experimentation and innovation, rather than polished products [2]. One of the earliest jams was *Indie Game Jam 0* that took place in 2002 with 14 experimental games created over four days [3].

In [2], we see game jams characterized as ludic craft, a constructive form of play. The authors characterize them as focused on creativity, playfulness, and “gamefulness”, providing a focus on generating ideas and creating, not always on finished and polished products. This may not be a true picture of the difference between the two however, as many

hackathons do not produce finished or polished products either. However, it is important to note that many feel a jam has a different focus, or at least had a different impetus when they first began appearing on the technology scene.

We also see [2] focus time in discussion about the community that exists during a jam, emerging both from the structure of the event as well as the people participating. This is called out as an important factor in the jams. The authors conclude that the jams that tended towards playfulness facilitated more innovation.

Of the largest game jams, *Global Game Jam* (GGJ) [4] started in 2009 with concurrent game jams in 23 countries. Continuing yearly, the 2015 GGJ had 28,837 people registered for 518 jam sites in 78 countries. There were 5438 games produced [5].

A. For the Social Good

As jams and hackathons have grown in popularity, we have seen the emergence of such events around specific causes commonly associated with social good, sometimes referred to as civic hacking [6].

These events can be focused around themes. One such series of events, given the title “Game Jam 4: X”, centers around three primary themes for X: health, diversity, and research [7]. In a related effort, [8] describes a series of three hackathons in India to solve social problems sustainably; [9] describes a hackathon designed to create technologies for the homeless. The *CDC Games for Health* game jam provided a way for participants to jam on health-related issues [10]. During a recent *Global Game Jam*, Scott, Ghinea, and Hamilton [11] promoted designing games for inclusiveness (for sensory, motor, or cognitive impairments) at their jam site.

The products that come from civic hackathons can be viewed as secondary. As claimed in [12], the more interesting by-product is the versions of the civic imaginary and can transform the way people view themselves as citizens. The *CDC Games for Health* organizers saw that participant interest and awareness of health-related issues and careers increased [10]. After the focused GGJ that Scott, Ghinea, and Hamilton ran, a survey was administered showing participants were more likely to consider issues of inclusiveness in games in their future development [11].

Computing with the community in mind is not a new idea to the computer-science education community. There are many examples of projects and entire courses at all levels of the curriculum that have service learning components and/or community-based projects [13] [14] [15] [16] [17] [18] [19].

B. Academic Hacking

The popularity of hackathons and game jams has made its way into the broader academic community, with a particular rise of these events as part of conference programs. At SIGCHI 2013, a game jam was organized to allow members of the CHI community to participate and explore this model of creation as a way to focus on interacting with digital play [20]. At SIGCHI 2014, there were two hackathons, one dealing with big data and privacy issues [21], and the second using a game

jam to focus on a research question in HCI [22]. *OCDData Hackathon @ CSCW 2014* was a hackathon that focused on online communities [23]. At Group 2014, a hackathon was organized centering on online co-production systems (systems where many people are contributing to the system) [24].

Another area of academic focus when it comes to hackathons and jams is as a resource for academic study. As Fowler, Khosmood, and Arya point out in [25], given the large number of participants across the world, the GGJ provides a learning opportunity and a research platform for many [26], and has spawned several workshops around this idea [27][28][29].

Of particular academic interest is the impact of the participation on those involved in these activities. Such research shows that participants can gain skills in prototyping and collaboration [30], can have a positive correlation with academic performance [31], and can improve confidence of participants [32]. Reng, Schoenau-Fog, and Kofoed [33], discuss the importance of the social aspect of the jam as highly important to the participants.

C. Criticism of Hackathons

Even with the surge in popularity and massive amounts of participation and success stories, there remain some points of concern around hackathons. Guzdial laments that these types of events help to propel the “geek” stereotype and promote poor software design practices [34]. Given the amount of literature devoted to techniques for software development and the countless methodologies that exist for creating good software, some question if a 24-, 36-, 48-hour development cycle helps to promote those practices. In [35], we are presented with a way hackathons were used by a software company focused on security software to help improve their business. They recognize one challenge in turning the prototypes created into products that are of real business value.

That aside, the “geek” stereotype as a turnoff to women has garnered more attention. For the 2013 *Global Game Jam*, a survey was administered to participants. Of those that filled out the survey, 85.97% identified as male while only 12.54% identified as female [36].

A post on Quora gives some perspective on why women may feel out of place at hackathons, including the way they are treated by male participants (calling to mind the ongoing #gamergate scandal [37]), false perceptions of the general format (e.g. having to stay up the entire time, no showers, eating junk food), and not having a community of friends that participates [38].

Johnson’s article [39] adds onto [38] by providing suggestions for how to make hackathons more female-friendly. These include a pre-registration period just for women (though we note a high risk of making matters worse by creating a reinforced sense of exclusion by adding another layer of separation), avoiding competition, ensuring a clean and welcoming environment, broadening recruiting (such as through women’s groups on campus), watching for use of non-welcoming language in advertising, working to make beginners feel welcome, and advertising events in a gender-neutral

manner, avoiding strictly male stereotypes and images of males participating, and publishing attendees list so that women can see ahead of time that women attend (though we add privacy concerns must be kept in mind).

In an effort to address these issues, several hackathons specifically targeted at women have emerged [40] [41], including the International Women's Hackathon sponsored by Microsoft [42]. However, as with the women-only pre-registration period, such segregation arguably increases the sense of separation and distracts from the real issue of creating an inclusive, safe environment, regardless of gender.

To this end, others have taken a different approach. Instead of creating events specifically for women, they have instead focused on changing events to be more welcoming and by extension appeal to women. Spotify's hackathon had an impressive 50% female participation rate. This was achieved by specifically calling out the culture as mostly male-oriented and working to increase diversity. They reached out in advertising to women, served healthier food and removed the prizes, creating an atmosphere that was more like a science fair [43]. Brown University changed the focus of their event towards beginners, paying special attention to use of language (create and build instead of hack) [44].

StitchFest [45] adds elements to a traditional hackathon to try to appeal to a more diverse audience, such as the use of LilyPad Arduinos to design wearables. This portion of a larger hackathon saw 33% female participation, as opposed to the entire event (PennApps [46]), which had only 14.8% female participation [47].

In response to Guzdial's original post [34], Krishnamurthy brings up a correlation between hackathons/jams and the film industry's 48-hour film competitions. He refers to [48], which makes a strong case for why these competitions are important to film, many of which can be equally applied to computing like "actually starting and finishing...", "honing your craft", "it's fun". The article also focuses on the human aspect of the competition, something we see echoed in the discussion of the computing equivalents.

Similarly, we acknowledge that while there are tradeoffs, it is important to note that jams and hackathons provide unprecedented opportunities to practice agility, iteration and scoping. Many companies use such events as a way of testing students' capabilities to iterate quickly and scope effectively. Typically any such projects are thought of as proofs-of-concept, not finished products. The expectation is that development will continue after the event. Furthermore, unlike many traditional computer-science programs, jams and hackathons provide an opportunity for students to learn to work with artists and designers, an invaluable skillset that is often missing as our students graduate.

III. THINK GLOBAL HACK LOCAL

Think Global Hack Local (TGHL) [49] and its structure were inspired by industry practice and community need. Hackathons and jams are popular events for local industries in partnership with universities. At the University of British Columbia (UBC), this has been the case for some time.

Companies frequently request running hackathons on campus to allow them to put their product/service/software in the hands of students. It is both an opportunity to inspire innovation around their product and a chance to preview students for potential future hires.

A strong connection with community grew out of the UBC's CPSC 319 course entitled, "Software Engineering Project". In this course, students work throughout the term (13 weeks) on small teams (6 students) to create software for a real-world client. These projects have been solicited from the community (both the university community and beyond) for many years. Occasionally, one of the clients for the course would propose something that would be useful for them, but was not enough work to keep a team of 6 developers busy and engaged for 13 weeks, so the need went, unfortunately, unfulfilled.

Given the existing highly engaged student sub-community of hackers and jammers (Vancouver's Global Game Jam site at the UBC had over 350 participants in 2014 [50]), and given the ever-present need for software-related help in the non-profit sector, it seemed a natural next step to plan a jam around such civic need.

When designing the TGHL hackathon, a conscious decision was made to be non-competitive, and to find ways to amplify collaboration even more. The assumption was not only that students were capable of filling the needs present in the community and open to the challenge, but that the students would be intrinsically motivated to help the community.

Clients were recruited through past clients for the CPSC 319 course as well as UBC's Centre for Community Engaged Learning [51], which actively promotes efforts that put UBC students and faculty to work for the greater community good. The Centre was able to provide potential clients for this event. Students were recruited through advertisement within the Computer Science Department (posters in building, email, etc.) and asked to attend an information session, which provided food and drink along with information about the event.

A. Event Structure

TGHL follows the "typical" hackathon structure of a weekend (48-hour) time period starting on Friday evening and ending late Sunday afternoon.

On Friday evening, participants gathered for an overview of the event, any rules and regulations, and themes and goals for the weekend. Teams would be formed for each of the clients with no project overlap between teams. It was made clear that there was no competition involved—the "prize" was to create products to fulfill the needs of the clients. The introduction was followed by short pitches from the clients describing their problem and their ideas about what the solution might be.

After brief introductions, dinner was served and the participants were able to discuss the projects in greater depth with each of the clients. Students were then given an opportunity to choose a project. In order to ensure that each project had sufficient staff, organizers would ask students to move when participation was low. In almost all cases, students were willing to switch teams if needed after discussion.

After the teams were formed and requirements elicitation was completed in its initial phase, the clients left and teams were left to plan the rest of their weekend.

Saturday was a day of solid work, interrupted by meals, provided by TGHL. Most of the clients dropped by at some point during this day to chat with their teams, answer questions, and check on progress.

Sunday morning and early afternoon was working to finish up the projects. For the last two hours (starting around 4pm), the teams would demo what they had accomplished and the clients were given the floor once again to talk about their experience in the process and products.

Throughout the event mentors (typically graduate students from the Centre of Digital Media, other students, or local industry professionals) would drop by to help students design and plan their solutions, debug code, and address software and design architecture issues—a key element given concerns around fostering an educational environment and practical, best software practices.

IV. RESULTS AND OBSERVATIONS

To date, there have been two Think Global Hack Local hackathon events, one in March 2013 (TGHL 1) and one in October 2013 (TGHL 2), both with the same format. A third is planned for summer 2015. In this section, we present our observations about the participants, the events, and some of the responses from the surveys administered after the events took place.

Table I gives some demographic information about participation in these events. For TGHL 1, there were 5 projects from 5 distinct clients. The clients were: Burnaby School Board, BC Cancer Agency, SelfDesign/PCRS/PeerNetBC, PeerNetBC, and Delta Youth Orchestra. For TGHL 2, there were 8 projects from 7 distinct clients. There were no repeating clients from TGHL 1 to TGHL 2. The clients for TGHL 2 were: BC Centre for Employment Excellence, Neil Squire Society, BC Association of Family Resource Programs, Sunshine Coast Botanical Garden Society, UBC Department of Medicine, Writer's Exchange and Climb and Conquer Society Canada.

There were 35 participants in TGHL 1 (35% females) and 65 participants in TGHL 2 (30% females). Although demographic information was not collected on major systematically, the majority of the participants were observed to be computer science majors. At this time, the UBC Computer Science undergraduate program was made up of 25% women.

TABLE I. DEMOGRAPHICS OF PARTICIPATION

	TGHL 1	TGHL 2
Number of clients	5	7
Number of projects	5	8
Number of participants	35	65
Number of survey responses	32 (91%)	47 (72%)

A. Observations

Overall, the events were judged a success by the organizers and clients. The atmosphere was fun, excited and energized. A positive and collegial mood remained through the entire event.

Plenty of collaboration was observed during the events. Teams were actively encouraged to help each other and as such no competitive behaviors were observed during the events. As an example, the following was observed:

If a team had an issue with PHP, for example, they might yell out "is anyone here a PHP guru?" and someone from another team would leave their project for a bit and help with the other project.

The structure and expectations for the event led to an atmosphere that did not put an onus on the students to stay up and cram and build the entire time. Students were instead mentored around scope and realistic planning for the weekend. In fact, on the first night after project teams were created, many participants chose to go home and get a good night's sleep and return the next morning to start work.

B. Participant Feedback

Participants were asked to fill out a short survey about their experiences with TGHL at the end of the event. In this section, we will present the feedback collected from those surveys. Participation in the survey as a whole was voluntary and no questions on the survey required a response. Therefore, the number of responses varies from question to question.

Table II shows the responses to the question "Was this your first hackathon?" For both events, the number of first-time hackathon participants was greater than veteran hackathon attendees. Response rate and percentages of total are shown.

Table III summarizes some of the main reasons that were given to the free response question "What made you decide to attend?" This was a question on the survey that directly followed the first-timer question. The percentages given in the table are percentages based off of all responses to the survey (32 and 47). The categories that were tracked were responses that dealt with the following:

- Student desire to learn, gain experience, try new things
- Student desire to help non-profits, do something good for the community, work on "impactful" projects, solve real-world problems
- Student desire to be part of the social group either because friends encouraged them to attend, friends were attending, or to come to know their peers better

TABLE II. FIRST TIMERS

	Was this your first hackathon?		
	Yes	No	Did not answer
TGHL 1	23 (71%)	6 (18%)	3 (1%)
TGHL 2	40 (85%)	7 (15%)	0 (0%)

TABLE III. REASONS FOR ATTENDING

	<i>What made you decide to attend?</i>		
	<i>Learning</i>	<i>Civics</i>	<i>Social</i>
TGHL 1	6 (18%)	9 (28%)	6 (18%)
TGHL 2	19 (40%)	9 (19%)	12 (25%)

TABLE IV. LIKELIHOOD TO REPEAT

	<i>How likely are you to attend another community hackathon?</i>					
	<i>Def</i>	<i>Very Likely</i>	<i>Likely</i>	<i>Likely but not for a while</i>	<i>Not Likely</i>	<i>Did Not Ans</i>
TGHL 1 First Timer	7	1	10	1	2	2
TGHL 1 Veteran	3	3	0	0	0	0
TGHL 2 First Timer	21	1	15	0	1	2
TGHL 2 Veteran	4	0	3	0	0	0

The students could have indicated more than one of these items in their response and several did. The responses were then categorized in multiple categories. Also noted was the number of veteran and first-timer responses in each category across the two events. For veterans, learning came up in 2 responses, working with the non-profits in 4 responses, and social aspects in 3 responses.

Table IV gives the results of the question “How likely are you to attend another community hackathon?” broken down by response to the veteran question. This question was a Likert scale question with the responses being: *Definitely*, *Very Likely*, *Likely*, *Likely but not for a while*, and *Unlikely*. Placing these on a numerical scale with 5 being definitely will attend again and 1 being unlikely to attend again, first timers averaged 3.48, while veterans averaged 4 for the first event. In the second event, first timers averaged 4.08, while veterans averaged 4.14.

When looking at the response to the survey question, “What aspect of this hackathon do you like the most?” two categories of answers stood out. The first were responses that dealt with the personal and social aspect of the events, which included one’s team as well as the others at the events. The second were responses that dealt with the real world projects and community aspect of the events. Table V summarizes the number of responses in the two categories for both events.

TABLE V. MOST LIKED ASPECTS

	<i>Which aspect of this hackathon do you like most?</i>	
	<i>Social</i>	<i>Community</i>
TGHL 1	11 (34%)	12 (38%)
TGHL 2	20 (43%)	8 (17%)

Since this question was free response, participants could have mentioned both aspects in their response and would be counted in both groups in the table.

Some of the comments that stand out from this question (about most liked aspects) included:

- *Collaborating with and learning from each other*
- *Connect with the organization and put their idea to some real products*
- *Getting lots done, realizing I know more about web dev than I thought*
- *The non-competitive positive environment*
- *Meeting new people with similar interests and learning from one another*
- *Learned a lot. Also feel really fulfilled when finally done (especially it's for the community)*
- *Developing something for a client*
- *Working on a problem that has real world applications*
- *Coding with awesome people and learning new stuff*

C. Client Feedback

Clients were also asked to fill out a similar survey as the participants about their experiences with the events. Again, participation was voluntary, but the response rate from the clients was 100% for both events.

All of the clients at both events were first-time participants in a hackathon. Their reasons for participation varied, but centered on the idea of reaching out and working with the community as well as opportunities to work with the students. Many of the clients indicated that they had a specific need and this opportunity came along and it was a fit for them to attend.

For TGHL1, all of the clients indicated that they would definitely be likely to participate in a community hackathon again. For TGHL 2, 6 of the 8 clients indicated they would definitely be likely to participate again, while two indicated that they were simply likely to participate.

When asked why they were likely to participate again, 7 out of the 13 clients (54%) indicated in some form that they felt it was a good opportunity to support the students and to work with them. A few samples of those responses are:

- *Wonderful opportunity to support student learning and community partners*
- *The students are amazing to work with*
- *Really fun, great team building exercise, good cause connecting with young, smart people*
- *Great fun. Great students. Reminds me of my misspent youth*
- *How amazing all of these people were*

The clients also pointed out in 3 out of 13 responses (23%) the community partnerships that were built because of the event.

In terms of client satisfaction, the survey responses give us a snapshot of how they were feeling after the event.

- *The team really went above and beyond in taking my ideas and running with them. They were able*

to create and visualize something that has only existed in my head as a concept.

- *From our community, we will involve more. This is fantastic; we got more results than we expected! Well done.*
- *I am really happy with what my team accomplished.*

V. DISCUSSION

Many issues are brought out by the structure and nature of this hackathon. Some of the suggestions for improvement given in [38] and [39] are put into place with the TGHL structure. Further, TGHL provides another aspect to participants that has been noted by Dahlberg et al. [52] as valued by women and minority students, the social relevance of computing. In [52], the authors argue for more civic engagement and community service into outreach programs to appeal to these groups. An event of this type, while not outreach per se, provides these elements to students. This may have resulted in the higher percentage of participation of women in the events than in the general population of students enrolled in computer science as a whole.

Student reasons for attending the hackathon varied, but the number of responses in key categories was encouraging. Students (18% and 40%) viewed the opportunity as a learning experience and were attracted by the cause and helping the community (28% and 19%) as well as the social aspects (18% and 25%) of participation in the event.

The response to returning to a community hackathon can be viewed as positive by both veterans and first timers due both to the average response (in numerical form) being above 3 (neutral), as well as the actual responses being more positive than negative. In fact, only 3 total participants indicated that they were not likely to attend a future hackathon.

It is hard to tell from the data that was collected how many participants from the first event attended the second. The question was not asked specifically about the TGHL event, but rather hackathons in general. However, it is encouraging that the event is drawing so many new participants and from the free response question on motivation, it appears that the community involvement aspect is a draw for at least some of the participants. The social aspect and having friends participating was also called out by participants as a reason for attendance, all of which point back to the sense of community around these events that has been noted previously.

The participants' views on the most liked aspects of this hackathon don't differ much from the general view of this event as a social experience of value for the participants. Comments echo the value of working with the team and the great experience they had working with their team. They call out the learning experience that they had, both learning about each other and the team as well as new technologies and the exchange of ideas.

Participants also called out the community/real work aspect of these events as a positive. This was acknowledged in 38% and 19% of the comments about the positive aspect of these events. This mirrors the similar response to reasons the

students chose to come to the events (28% and 19% were because of the community aspect). There was an increase in recognition of that fact in the first event, but not the second. However, none of the students called out the community or real-world aspect as a negative at any point in the survey responses.

From the clients' perspective, they seem to indicate benefit from the experience. It is important to note that one of the most often cited things about the event was the students. The community partners were genuinely impressed with the students and their abilities and how much they were able to accomplish against the goals of the client. The growing recognition by the community of the products of the university is a valuable contribution of this type of event.

VI. CONCLUSION

Overall, we are very pleased with the success of these two events. The students arrived seemingly interested and excited to help the community, and they were seemingly very successful. In reverse, the community (clients) anecdotally "fell in love with the students". These outcomes will keep us investing in these events for the future.

Perhaps most interesting to reflect on while looking forward to our next event is what the participants and clients asked for in terms of improvements. There was a survey question that asked them for feedback for the next event.

While responses varied, several that stuck out that are on our radar for consideration are suggestions for some pre-planning from the participants. The participants mentioned wanting to put together teams beforehand to try to help balance expertise. They asked for some basic descriptions of the projects that will be worked on and also some information about the technologies that will be used.

While not possible in all cases, and requiring teams to be put together beforehand could be discouraging to newcomers, the ideas about publishing the projects could have the potential to bring people in that might not have otherwise participated. Given that some students also mentioned attending the information session in the surveys (n=5), this may be a good time to present some of the projects.

One comment from this section stands out for us:

Do not kill this program. This has to happen every year!! This is what students should be doing with their time. Solving real problems of the real world.

Two particular future challenges we are food and the "post-hackathon problem". Food is an interesting challenge—in order to keep people nourished for the weekend, food must ideally be provided. In fact, across the 79 responses to the post-hackathon survey, food was mentioned in 50 of them (63%). Some of the comments were favorable, but some complained about food choices and food quantity. Making sure that the participants are fed in an appropriate way is an expensive and interesting challenge.

The second challenge is one of follow-through. Engaging students through the event does not guarantee that students

will continue to be involved after the event ends. This can be a problem when further development remains, changes are needed, or simply clients require help with installation (many were not technically inclined). Students certainly seem passionate about the project for the weekend's event, but how can we maintain that level of passion to help students maintain a relationship with these same community partners after the event comes to a formal close?

We are committed to constantly re-assess our procedure and the event to make sure we are improving the experience and not falling into the traps criticized by others. We want to ensure that our events remain inclusive and friendly to all and that both parties (participants and clients) get out of the event what they hoped. We are facing these challenges head-on for our next event.

ACKNOWLEDGMENT

We are thankful for support from Facebook, UBC's Centre for Community Engaged Learning, UBC's Faculty of Science, the Centre for Digital Media, and UBC's Department of Computer Science. We are especially thankful for Michele Ng's support in organizing these two events.

Characteristics of Engineering Faculty Engaged in the Scholarship of Teaching and Learning

Angela R. Bielefeldt

Dept. Civil, Environmental, & Architectural Engineering
University of Colorado Boulder
Boulder, CO, USA
Angela.Bielefeldt@colorado.edu

Abstract—This research hypothesized that differences in the culture of engineering education as it is practiced a whole, as compared to the Scholarship of Teaching and Learning (SoTL) in engineering education, would manifest themselves through the characteristics of the faculty engaging in these activities. The research question examined was: To what extent are the faculty who engage in different areas of SoTL research within engineering similar to or different than the engineering faculty at U.S. institutions overall? The research utilized a data mining approach, assuming that the authors of the American Society for Engineering Education (ASEE) Annual Conference papers would characterize engineering faculty engaged in SoTL. The demographic characteristics of the authors of ASEE papers published in 2012-2014 on the topics of Learning Through Service (LTS), engineering ethics, and design were determined, as well as the authors of papers in the civil engineering, environmental engineering, and electrical & computer engineering divisions. The demographic characteristics of engineering faculty nationally were mined from ASEE data sources. The primary differences between engineering faculty active in SoTL compared to overall U.S. engineering faculty were: a higher percentage of assistant professors, a lower percentage of full professors, a higher percentage of women, a higher percentage employed at Baccalaureate or Master's institutions, and a smaller percentage from institutions with very high research activity. Between different engineering education topics, the primary differences were in the engineering disciplines represented, the percentage of women among the authors, and collaboration patterns evident among the paper co-authors. These data indicate the ways in which engineering faculty active in SoTL are different than their engineering faculty peers overall, and also highlights differences among engineering education topics. Further exploration is needed to determine the extent to which these differences are the result of different cultural values within each group.

Keywords—*engineering faculty; demographics; disciplines; service-learning; ethics; design; culture*

I. INTRODUCTION

Culture is defined as the beliefs, values, norms, attitudes, behaviors, and other characteristics common to the members of a particular group. Culture determines what is important to a group and can shape the members of a group to embrace dominant norms via the processes of enculturation or socialization [1,2,3]. Engineering culture has been variously

characterized as individualistic, expert, masculine, quantified, and technophilic [4,5]. It is unclear whether the current, predominant culture of engineering higher education is best situated to educate engineers who are able to address the complex challenges facing our world [6,7]. For example, Cech [8] characterized engineering as encouraging a culture of disengagement from public welfare concerns. She linked this disengagement to three cultural norms of engineering education: depoliticization, technical/social dualism, and meritocracy. The predominant engineering culture has also been criticized for limiting the ability of engineering to reflect the diversity of individuals in society [5,9-13]. Godfrey [5,14] noted differences between the cultures of different engineering disciplines. Based on a qualitative study at a single institution, electrical engineering was found to have the most masculine culture versus chemical and materials engineering which was more inclusive of both feminine and masculine characteristics; these cultural differences were reflected in the gender of the students enrolled in these disciplines. Differences between the culture of engineering in practice and the culture of engineering within higher education may also be significant; for example, education is more focused on theory, science, math, and design while practice relies more heavily on professional skills, tolerance for uncertainty, etc. [15-17].

While some topics are viewed to reside at the core of the culture of engineering education, such as calculus and design, others are perceived as “unacceptable” including “[a]bstract, philosophical concepts, such as ethics” [5, p. 441]. This is interesting given the long-standing commitment of engineering to codes of professional ethics, many of which date back to 1911-1914 [18-19]. But clearly some topics live at the periphery of engineering education, despite the fact that some faculty believe those same topics to be of critical importance.

There are signs that cultural changes within engineering education may be occurring, such as the growth in Learning Through Service (LTS) activities (i.e. service-learning, human-centered design, and co-curricular programs such as Engineers Without Borders (EWB)) [20-22]. The culture of these activities reflects caring and compassion to a greater extent than is typical for engineering [23-24]. It is unclear whether these activities are the result of systemic cultural changes in engineering education, or represent a unique sub-culture. What is known is that participant demographics in these activities are

more diverse than engineering education as a whole [25].

Within higher education the Scholarship of Teaching and Learning (SoTL) as a movement traces its origins to 1990 [26]. SoTL involves the rigorous and systematic study of teaching and/or learning in one's own course or context, and the public sharing of such work through publications and/or presentations with the intention of improving student learning and the overall educational experience beyond a single course or program [27, 28]. Does the emergence of SoTL represent a change in the culture of higher education? Or is it a distinct sub-culture? SoTL has been characterized as having a "unique (and often marginal) position within university cultures" [29]. Further, given that higher education in engineering is often perceived to have a culture that rewards specialized, disciplinary research significantly more than teaching activity [30], it is unclear if individuals focused on SoTL fit this predominant culture or represent their own sub-culture. Chalmers notes "there is little evidence that [SoTL has] contributed to any substantial change in the culture and substance of rewarding and recognizing the status of teaching relative to research" [31].

Culture is hard to directly measure, but it is believed to manifest itself in visible attributes [2]. Therefore, if there are differences in the demographic characteristics of the faculty who engage in engineering education SoTL compared to engineering faculty as a whole, this may lead us to infer that there are cultural differences. However, the demographic characteristics of the engineering faculty who engage in SoTL have not been well characterized.

The first research question explored in this research was: How do the demographic characteristics of engineering faculty active in SoTL compare to average U.S. engineering faculty? The second research question was: Are there differences in the characteristics of engineering faculty active in SoTL related to different engineering education topics or disciplines? For the purposes of the research, the characteristics of interest were defined as individual demographics (rank, gender); institutional characteristics (Carnegie classifications); and co-authoring characteristics. The methods used to explore these research questions are described in more detail below.

II. METHODS

The primary method used for this research involved data mining. Individuals active in engineering education SoTL were identified on the basis of authoring papers that were presented at the American Society for Engineering Education (ASEE) Annual Conference in 2012, 2013, and 2014. These papers may also encompass educational research (EER), but were nonetheless included. There are many similarities between SoTL and education research; distinguishing factors of EER typically include that the researcher is not the instructor, the subject of research is more than a single course or program, and that the research is informed by theory [32-34]. At the ASEE conference, the Educational Research and Methods (ERM) division includes primarily research studies while other divisions include a mixture of SoTL and engineering education research. Authors of all papers on the topics of interest were included, irrespective of whether the paper represented SoTL or EER.

The search function on the ASEE conference proceedings website was used to identify papers on selected topics [35]. These searches were conducted in October and November 2014, and February 2015. Three different topics cross-cutting engineering education were explored: design, ethics, and Learning Through Service (LTS). Design is considered a quintessential engineering activity, and as such should represent a dominant culture for engineering. Ethics is very important for the engineering profession, but is often relegated to the outskirts of engineering education. LTS focuses on people and helping, topics which are not generally widely associated with engineering but are rapidly gaining popularity among students. Three representative engineering disciplines were also explored: electrical and computer (ECE), civil, and environmental engineering. These disciplines were selected because they represent a wide range in the percentage of females among the tenured/tenure-track (T/TT) engineering faculty (11.6%, 15.4%, and 23.9% [38]). The ECE and environmental divisions might also be thought to represent different engineering cultures – "thing" centric versus "nature/people" centric [36].

For design and the three engineering disciplines, papers presented within the sessions organized by the division of interest were explored. For the LTS topic, papers were identified via search terms of interest (service learning, community service, EWB, community engagement), as well as including all papers presented in the Community Engagement in Engineering Education division. For ethics, a search approach was also used, including ethics as a search term as well as including all of the papers presented in the engineering ethics division. From among the LTS and ethics search results, the abstract of each paper was examined to determine if the main focus of the paper involved the appropriate topic. In some cases, for example, service learning was mentioned in the biography of one of the authors but was not the focus of the paper.

Once the paper was confirmed to be focused on the desired topic, the title and authors of the paper were recorded in a database (spreadsheet). The total number of authors for each paper were noted. Next, the biography of the authors that was provided with the ASEE paper was examined. This generally provided information on institutional affiliation, discipline, gender (based on the pronouns used), academic rank, and additional administrative roles (department chair or head, head, program director). The biographies also sometimes stated if the individual was a licensed Professional Engineer (P.E.) or had significant industry experience. Any degrees from international institutions were noted, as well as non-engineering related degrees, when provided. In cases where a biography for an author was not provided, an online search was conducted to locate the information. Online CVs were often found, such that the academic rank and other factors could be determined for the individual in the year of interest. Next, each paper was classified as to whether or not it met each the following criteria: authors from different engineering departmental affiliations (multi-disciplinary engineering); authors included individuals from non-engineering departments such as education (interdisciplinary); authors from different institutions; and if there were graduate or undergraduate

student co-authors. Finally, the institutional classifications by the Carnegie Foundation were determined [37].

After the relevant parameters were populated in the spreadsheet, counts were conducted on the parameters of interest. Initially, overall counts across all authors were conducted. Then the counts were redone to look only at faculty, since some papers had students, post-docs, non-faculty center directors, and other individuals as co-authors. Faculty included assistant, associate, and full professors, as well as instructors, lecturers, clinical professors, and adjunct members. It was considered that lecturers, adjunct, clinical, professors of practice, and research faculty positions were non tenure/tenure-track. Individuals who held faculty rank but had primarily moved into administrative roles (such as Dean or Provost) were still counted as faculty. The counts were then conducted specifically for unique engineering faculty, since in a number of cases the same individual might author multiple publications on the same topic across the three years of interest. Engineering faculty included individuals with degrees in engineering, engineering technology, construction management, physics, and/or architecture. To determine if there were differences in the characteristics of the engineering faculty engaged in different SoTL topics, chi-square tests were conducted in Excel.

Additional data were gathered as benchmarks for U.S. engineering faculty overall from the ASEE profiles, and more specific information from the ASEE Engineering Data Management System [38]. This provided information on the ranks of engineering faculty for the institutions with engineering degrees around the U.S. When combined with information from the Carnegie Classifications, the distribution of engineering faculty across different types of institutions (public, private, Master's, Bachelor's, etc.) could be determined. Data on the number of ASEE members in different divisions were gathered from the ASEE online member search.

III. RESULTS AND DISCUSSION

A. Ranks of SoTL Faculty

The ranks of the unique engineering faculty who authored ASEE conference papers between 2012 and 2014 on different topics are summarized in Table I; the data from the ASEE engineering faculty profiles are also shown for comparison. If an individual published in multiple years, the highest rank was counted. The results show that the ranks of the engineering faculty were similar in all of the SoTL topic areas (chi-square $p=0.14$). There were generally increasing percentages of engineering SoTL faculty at the non-T/TT (12-21%), assistant (21-28%), associate (22-33%), and full professor ranks (26-39%). Although statistically non-significant, one trend in the data was that design papers had the highest percentage of engineering faculty from non-T/TT ranks; future research might find that these individuals may have industry experience and/or less research focus and therefore are not in T/TT ranks.

TABLE I. PERCENTAGE OF ENGINEERING FACULTY AT DIFFERENT RANKS

Faculty Group	# faculty	% non-T/TT	% assistant	% associate	% full + emeritus
Design	279	21	26	26	27
Ethics	90	14	21	26	39
LTS	133	17	28	23	32
Civil Eng	185	14	27	33	26
ECE	268	16	24	24	37
Environm.	82	12	27	22	39
6 SoTL topics combined	1037	17	26	26	32
ASEE profile [38]	31038	17	18	24	41 ^a

^a. ASEE profile does not include emeritus professors

There was a significant difference between the ranks of engineering SoTL faculty and engineering faculty overall (chi-square $p < 0.001$). There were more assistant professors and fewer full professors among SoTL faculty compared to engineering faculty overall. This may indicate that younger faculty hold greater value for teaching compared to more senior faculty; over time this may help shift the culture of higher education in engineering to more balance between disciplinary research and teaching and/or education research. If this trend continues, over time as more senior faculty retire and if these younger SoTL-active faculty move into tenured and full professor ranks, the culture of engineering education may shift to place greater value on SoTL activity. There are signs that this movement may already be occurring [40].

B. Disciplines of SoTL Faculty

The disciplines of the unique engineering SoTL faculty authors on different engineering education topics are summarized in Table II. There were statistically significant differences in the engineering disciplines of the faculty who engaged in research on different SoTL topics (chi-square $p=0.0003$). Note that many individuals were associated with multiple disciplines, making accurate counts difficult. Therefore, closely related disciplines were combined: electrical and computer; civil and environmental. Mechanical engineering was over-represented among the authors of ASEE papers on LTS and in the design division. The representation of ECE faculty among SoTL authors is fairly similar to their national faculty percentage. Within the ethics papers the authors are almost twice as likely to be ECE faculty compared to mechanical faculty. Civil engineering faculty were over-represented among the authors of LTS and ethics papers, at almost twice the national faculty percentage. Chemical engineers appear under-represented among LTS authors, although the percentages are small. The results seem to indicate that particular engineering education topics are more popular within specific engineering disciplines. Design appears central to mechanical engineering. Service to society is at the core of civil engineering, compared to other engineering disciplines that tend to be more customer oriented or "business-centric". These results may indicate that there is a greater role for particular topics within the culture of different engineering disciplines, and that discipline-specific faculty are unaware of this opportunity.

The number of unique engineering faculty who authored 2012-2014 ASEE papers in the ECE, civil, and environmental divisions (268, 185, and 82, respectively) were compared with the number of ASEE members in these divisions from the directory search (881, 606, and 340, respectively); this revealed 24-31% of the division members were authors. Comparing the number of authors to the number of T/TT faculty (5811 ECE, 2511+765 civil+civil/env, 159+765 environmental+civ/env [39]), it appeared that SoTL within ECE (4.6%) was similar to civil engineering (5.6%), but somewhat higher in environmental engineering (8.9%). This may indicate differential value of SoTL among these disciplines.

TABLE II. DISCIPLINES OF ENGINEERING SoTL FACULTY

Faculty Group	# faculty	% mechanical	% ECE	% civil + environ.	% chemical
Design	279	44	22	11	5
Ethics	90	16	29	21	6
LTS	133	32	20	19	3
ASEE profile [38]	25,628	18	23	10	8

C. Gender of SoTL and Engineering Faculty

The percentage of females among the authors of ASEE papers are given in Table III. In all topics there was a decrease in the percentage of women among all paper authors, faculty authors, unique engineering faculty authors, and T/TT engineering faculty authors. Thus, there was a higher percentage of women among the individuals who collaborate with engineering SoTL faculty than among the engineering faculty themselves. For example, among the papers in the design division there were 112 student co-authors; 44% of these students were female – compared to 20% females among the faculty authors. There were also 31 unique non-engineering faculty members who co-authored design papers; among these, 52% were female.

TABLE III. GENDER OF INDIVIDUALS INVOLVED IN DIFFERENT AREAS OF ENGINEERING EDUCATION SoTL

SoTL Topic or Division	# authors			% females among authors:			
	all	faculty	engrg faculty	all	faculty	engrg faculty	engineering T/TT faculty
Design	560	411	279	30	25	20	20
Ethics	198	142	90	41	40	30	25
LTS	410	257	176	43	42	38	35
Civil	364	285	179	24	21	21	19
ECE	454	342	268	23	22	20	19
Environ.	139	108	82	48	44	46	45

There were differences in the percentage of women between the SoTL topics among all authors, faculty authors, engineering faculty authors, and T/TT engineering faculty authors (chi-square p values <0.001). The LTS and Environmental Engineering Division papers had the highest percentage of women among the authors, faculty authors, and engineering faculty authors; these topics are approaching gender parity. Future research should determine whether this parity is a result of the culture in these areas being less masculine. There was also nearly gender parity (41%) among all authors of the ASEE papers about ethics, although a number

of these co-authors were students, staff, and faculty from non-engineering disciplines; only 25% of the T/TT engineering faculty authors of these ethics papers were women.

There was a much higher percentage of women among the engineering T/TT faculty who authored ASEE papers compared to the percentage in engineering overall; ASEE reported 14.5% of all engineering T/TT faculty were women in 2013, including 23.9% women in environmental engineering, 15.4% women in civil engineering, and 11.6% women in ECE [39]. Thus, it appears that the culture within engineering education SoTL may be less masculine than engineering education overall. For example, SoTL may be associated with caring for students and their learning, and care is typically characterized as a feminine trait.

There were also differences between SoTL topics in the representation of women among engineering faculty of different ranks (Table IV). There was a similar percentage of women among the assistant, associate, and full professors in engineering among the authors of papers in the Environmental Division (44-45%). For papers on LTS, the percentage of females among the engineering faculty authors at the three T/TT ranks was also fairly similar, although highest among full professors. In contrast, the percentage of women among the full professors in engineering who authored papers on the other topics (ethics, design, ECE, and Civil Engineering; 6-17%) was much lower than the percentage of women among the engineering faculty at the lower T/TT ranks (assistant or associate professors) or non-T/TT faculty.

TABLE IV. PERCENTAGE OF WOMEN AMONG ENGINEERING FACULTY AT DIFFERENT RANKS

Faculty Group	Non-T/TT	Assistant	Associate	full + emeritus
Design	23	28	28	14
Ethics	62	21	39	17
LTS	17	28	23	32
Civil Eng	35	33	17	6
ECE	26	27	27	9
Environm	50	45	44	44
ASEE profile [39]	Not Rep.	22.8	17.0	9.4*

It is unclear if the lower percentage of women among engineering full professors is due to insufficient time for women faculty active in engineering education SoTL to advance to full professor, so-called demographic inertia [41]. Alternatively, female faculty active in engineering education SoTL may be advancing more slowly to full professor than their male peers. This could be due to in part to investing time in SoTL which is not highly valued in the predominant culture of engineering in higher education.

D. Institutions Where Faculty Employed

The institutional characteristics represented by the engineering faculty active in different SoTL topics are compared in Table V. There were similar percentages of faculty from public and private institutions among the SoTL topics (chi-square p=0.97) and as compared to engineering faculty overall (chi-square p=0.85); 70-78% at public

institutions and 22-30% at private insitutions. However, a significantly lower percentage of the SoTL faculty were employed at research institutions with very high research activity (Carnegie classification RU/VH) and a higher percentage at Baccalaureate (Bac.) or Master's (MS) institutions, as compared to engineering faculty overall (chi-square $p<0.001$, $p<0.001$). These differences likely reflect cultural differences among the institutions, where teaching and SoTL is more valued at Baccalaureate or Master's institutions and disciplinary research is a higher priority and emphasis at the RU/VH institutions. In addition, faculty teaching at Baccalaureate and Master's institutions often teach more courses per year, and as such have more opportunities to engage in SoTL activities. RU/VH institutions perhaps place little value on SoTL, resulting in lower participation of faculty from these institutions on SoTL activities.

TABLE V. INSTITUTIONAL CHARACTERISTICS OF ENGINEERING FACULTY

Faculty Group	# unique institutions	% faculty at publics	% faculty at privates	% faculty at RU/VH	% faculty at Bac. or MS
Design	133	70	30	30	36
Ethics	57	78	22	27	39
LTS	68	71	29	26	38
Civil Eng	82	75	25	20	56
ECE	126	73	27	25	40
Environm.	48	71	29	20	52
<i>ASEE profile [39]</i>	<i>351</i>	<i>74</i>	<i>26</i>	<i>54</i>	<i>16</i>

Among SoTL topics, there were not significant differences in the faculty employed at RU/VH institutions (chi-square $p=0.36$), but there were differences in the percentages of faculty working at Baccalaureate or Master's institutions (chi-square $p=0.017$). The authors of papers from the design division had the greatest similarity to overall faculty demographics, which is not unexpected given that design is at the core of traditional engineering culture. In the civil engineering and environmental engineering divisions, more than half of the engineering faculty authors were employed at Baccalaureate of Master's institutions; this implies that SoTL is not particularly common among faculty in these disciplines at doctoral and RU/VH institutions.

E. Other Characteristics of Engineering SoTL Faculty

There were five additional characteristics of the engineering SoTL faculty that were compiled: international degrees, additional administrative roles, additional non-engineering degrees, industry experience prior to academia, and Professional Engineering (P.E.) licenses; this information is summarized in Table VI.

There were differences in the percentage of engineering faculty with international degrees between the different SoTL topics (chi-square $p<0.001$). Among the authors of ASEE papers in the civil engineering division and the three cross-cutting engineering education themes, 16-20% of the engineering faculty possessed international degrees; the ECE division had the highest percentage of international degree holders among its engineering faculty authors. India and

China were the most common countries where international degrees were earned. This information might indicate that the culture in ECE departments is more inclusive of diverse backgrounds; alternatively, it may be that U.S. ECE departments simply hire many qualified individuals that hold one or more international degrees. In that case, it is unclear the extent to which those individuals are being enculturated into the traditional U.S. engineering culture, versus impacting the culture through acculturation.

TABLE VI. CHARACTERISTICS OF ENGINEERING FACULTY ACTIVE IN SoTL

SoTL topic or division	% with inter-national degrees	% with additional admin. role(s)	% with additional non engrg degrees	% with industry experience	% P.E.
Design	20	23	8	25	8
Ethics	17	28	4	21	27
LTS	16	28	4	15	16
Civil Eng	17	25	5	17	54
ECE	38	24	4	20	6
Environm	25	26	5	17	26

A high percentage (23-28%) of all of the engineering faculty authors across all topics and divisions held administrative roles, in addition to standard faculty positions. There were not significant differences between SoTL topics (chi-square $p=0.93$). These roles are often indicative of interest and time invested beyond narrow disciplinary research, such as positions as associate chairs or deans for education. It is unclear the extent to which this would also be the case for engineering faculty not involved in SoTL activities. It is a positive sign that administrators are engaged in SoTL and/or engineering research; these individuals would be in positions to make informed decisions that could improve engineering education at their institutions.

Only a small percentage of the engineering SoTL faculty appear to hold additional non-engineering degrees (4-8%); this did not differ significantly across the different SoTL topics (chi-square $p=0.37$). These were most often degrees in education or business (such as an MBA). It is unclear how this percentage compares to engineering faculty overall. However, if the culture of engineering does not place value on these degrees, they may have been under-reported in the biographies written by the authors of the ASEE papers.

The percentage of engineering SoTL faculty with known industry experience (based on the biography supplied with their ASEE paper or an online CV for individuals without an ASEE biography) ranged from 15-25% across the various engineering education topics and ASEE divisions; there were not significant differences between SoTL topics (chi-square $p=0.27$). Not surprisingly, the highest percentage of faculty with industry experience was found among the authors of papers in the ASEE design division. Design skills are likely best gained in practice, so industry experience is particularly valued among those who teach design. In contrast, at research intensive universities a number of the faculty have had no industry experience, but only academic training through degrees and post-doctoral positions. Industry experience is often not valued in hiring.

The percentages of engineering faculty with previous industry experience could not be found for comparison to the information on engineering faculty engaged in SoTL. The best data available were from a 1988 study [42] which indicated that 34% of engineering faculty had previous industry experience among those who had received their highest degree less than ten years earlier; this was significantly lower than the 68% of engineering faculty with industry experience among those who earned their highest degree more than 25 years earlier. Assuming that this trend continued, today we would expect far less than 34% of the engineering faculty would possess industry experience. More recent papers only make vague references to the percentage of engineering faculty with industry experience being “so small” [43].

Finally, there were significant differences in the percentages of the engineering faculty that were licensed P.E.s across different SoTL topics and disciplines (chi-square $p < 0.001$), ranging from 6% in ECE to 54% in Civil Engineering. This may under-represent actual P.E.s among engineering SoTL faculty, but it is likely that the cultural differences in how P.E. licenses are valued is reflected in these differences. If individuals perceive that their P.E. license are not valued within the discipline or topic, they are less likely to include it in their biography. Therefore, it appears that the culture within Civil Engineering highly values P.E. licensure, while this holds little value within the culture of ECE. In a 2009 study, 44% of the civil engineering faculty were found to have P.E. licenses [44]. Environmental Engineering and ethics also appear to hold more value for P.E. licensure than design or LTS. The fairly low percentage of engineering faculty authors of the design papers who indicated they held a P.E. license is somewhat surprising in the case of design, since in practice engineering designs must be signed off by P.E.s in order to be built or constructed. Further, seven of the program criteria under ABET (including civil and environmental engineering) specify that “faculty teaching courses that are primarily design in content are qualified to teach the subject matter by virtue of professional licensure or” similar experience; 21 disciplines do not indicate this requirement [45]. Among the engineering faculty who authored the papers in the design division, 44% were mechanical engineering; so perhaps the low percentage of the design authors with P.E. licenses reflects the culture within mechanical engineering.

F. Collaborations Among SoTL Faculty

A comparison of the co-authoring characteristics among different SoTL topics is shown in Table VI. There were differences between the SoTL topics in the number of co-authors per paper, and the percentage of papers with authors from multiple engineering disciplines, non-engineering disciplines, and student co-authors (chi-test p -values 0.04, 0.0007, 0.002, respectively). The number of authors for the ASEE conference papers ranged from 1 to 10, with an average of around 3 people. The percentages of papers authored by single individuals were 16% in the design division, 18% in the ECE Division and papers about LTS, 20% in the Environmental Engineering Division, and 23% in the Civil Engineering Division and papers about ethics. This is reflective of the individualized culture in engineering. On

average, there were more authors per paper on LTS topics compared to the other topics (chi-square $p=0.04$).

Papers with co-authors from multiple engineering disciplines were the most common among papers about LTS. This reflects the interdisciplinary nature of many LTS programs such as EWB, EPICS [46], and SLICE [47]. Nearly a third of the papers on design, ethics, and from the Environmental Division also included authors representing multiple engineering disciplines. In contrast, but perhaps not surprising, fewer than 17% of the papers from the ECE and Civil Engineering Divisions included authors from multiple engineering disciplines.

Authors from non-engineering disciplines were the most common among papers about engineering ethics followed by LTS, significantly higher compared to design papers and the papers from the disciplinary divisions. Almost half of the ethics papers included authors from non-engineering disciplines, most typically from faculty from philosophy, communication, or business. Thus, the culture of different SoTL topics appears to differentially recognize the value of collaborating with individuals having expertise outside of engineering.

Collaborations across multiple institutions did not vary significantly between different SoTL topics (chi-square $p=0.44$). Interestingly, a very low percentage of the LTS papers included authors from multiple institutions (16%), about half the multiple-institution collaborations evident among the papers on ethics (30%). The lower cross-institutional collaboration may be due to local LTS efforts that are specific to a given institution. Another potential reason may be the “newer” nature of LTS as a division (in 2012 the constituent committee formed and first offered sessions at the ASEE Annual Conference) and therefore less opportunity for LTS faculty to network and form collaborative groups as compared to the other topics.

TABLE VII. COLLABORATIONS AMONG ENGINEERING EDUCATION SoTL AUTHORS

SoTL topic	# papers	Avg # authors / paper	% papers with co-authors from:			
			multiple engineering disciplines	non-engineering disciplines	multiple institutions	student ranks
Design	179	3.1	28	24	20	39
Ethics	69	2.9	28	46	30	28
LTS	121	3.4	36	39	16	48
Civil	133	2.7	12	21	23	19
ECE	159	2.9	17	14	19	31
Enviro	45	3.1	33	29	22	44

Finally, the percentage of ASEE papers that included student co-authors varied between different topics (chi-square $p=0.002$). Nearly half of the ASEE papers on LTS had student co-authors, the highest among the SoTL topics. This reflects the integral role of students in LTS, which is focused on collaborative learning and creating learning for the benefit of students. Student voices may be the most important to reflect the affective outcomes of the experience, in addition to the diverse learning outcomes. Including students as co-authors of papers rather than treating them merely as the “subjects” of

assessment and evaluation efforts reflects a culture that values students as co-creators of their learning experiences. In contrast, the low percentage of student co-authors among civil engineering papers (19%) may reflect more of a “top down” or hierarchical culture of conveying knowledge to students. The percentage of undergraduates among the students also showed differences: 9% in ethics; 18-20% in civil and ECE; 27-33% in design, LTS, and environmental topics.

IV. LIMITATIONS AND FUTURE WORK

The primary limitation of the study is the assumption that the faculty who co-authored papers presented at the ASEE annual conference were representative of engineering faculty active in SoTL. There are a number of additional individuals who are SoTL-active but publish or present in other venues (ASEE regional conferences, FIE, journals, or local institutions). Further, strict distinctions were not made between engineering education research and SoTL; both activities are likely represented among the authors of the ASEE papers. In addition, only the authors across a three-year period were examined. However, it is hoped that these authors are representative of the larger group of engineering SoTL faculty. Future work could expand to a larger number of years (such as a decade) and additional published sources. Because culture changes slowly, this larger time range should not be an issue. In addition, indicators of culture within the papers themselves will be explored, including ideas of quantification, power distance, uncertainty avoidance, etc.

At present, a limited number of engineering disciplines and engineering education topics have been explored. Additional, timely topics within engineering education that seem to reflect emerging cultural changes could be explored. For example, the emergence of new divisions within ASEE is often driven by a critical mass of individuals with a particular concern. Exploring these could reflect cultural changes within engineering education. Other disciplines within engineering could also be examined. Mechanical engineering has experienced explosive growth in student numbers within the past 10 years [39, 48]; perhaps an attribute of the culture within mechanical engineering resonates with today’s generation of college students. Further, newer disciplines such as biomedical engineering may have unique cultures, since they are less constrained by historical precedents.

Another key consideration is to explore the number of cultures that are intersecting in these contexts. This includes the culture of engineering, the culture of higher education, cultures within particular engineering disciplines, the culture of SoTL (beyond just engineering education), institutional cultures, and cultures within specific departments. Additional and more extensive methods should be used to assess these cultures, how they interact, and which seem to dominate in particular situations (such as promotion and tenure). Individuals may feel that they are part of the dominant culture, or feel part of a sub-culture. There are also the processes of enculturation, acculturation, and cultural changes over time to consider. As SoTL grows within engineering education, will it remain a sub-culture or will it begin to infuse its values into mainstream engineering education?

V. SUMMARY AND CONCLUSIONS

The research results indicated that there were significant differences between the engineering faculty involved in SoTL as compared to U.S. engineering faculty overall in the following characteristics: distribution of faculty between T/TT ranks (faculty engaged in SoTL a higher percentage of assistant professors and fewer full professors); representation of engineering disciplines; percentage of women overall and at different T/TT ranks (higher among faculty engaged in SoTL); employment at RU/VH and Baccalaureate / Master’s institutions (lower and higher among faculty engaged in SoTL, respectively). Given the large number of differences, it appears likely that engineering faculty active in SoTL represent a distinct sub-culture within engineering higher education as a whole. This culture is perhaps more collaborative, less masculine, and less hierarchical. The specific cultural attributes that manifested in the differential predominance of faculty demographic characteristics requires further exploration.

The research also found that there were significant differences in the characteristics of the engineering faculty engaged in SoTL focused around different topics and disciplines within engineering education. These differences included: which engineering disciplines were active in selected engineering education topics; the representation of women; employment at Baccalaureate and Master’s institutions; P.E. licensure; and collaborations in SoTL with individuals from other engineering disciplines, non-engineering disciplines, and students. Thus, differences in culture in regards to the collaborative and gendered attributes appear evident. Learning through service and environmental engineering appear the least gendered or masculine, perhaps because these are more recently emergent areas of engineering education that did not carry historical male-dominance upon formation of their culture. Further research is needed to explore what specific cultural differences have led to these differences that were observed in the characteristics of the faculty who engage in engineering education SoTL.

ACKNOWLEDGMENT

The author thanks Daniel Knight, Chris Swan, Dave Kazmer, and Olga Pierrakos for helpful comments on this research and the manuscript.

Abstract— Engineering design is understood to be a social activity, and requires collaboration and negotiation with diverse groups of people. Group communication literature suggests that team member interactions and communication have a major impact on a team's decision-making abilities. Furthermore, these interactions and decision-making processes are impacted by the diversity makeup of the team. In this study, we examine the ways in which communication and social processes relate to ethical issues and decisions, which we envision as interwoven throughout the design process and arise on a day-to-day basis in engineering design. Thus, this work-in-progress paper describes preliminary results about how diversity and ethics interact within engineering design contexts through the use of social network analysis.

Keywords— *social network analysis; diversity; design; ethics; technical expertise*

I. INTRODUCTION

Our study explores how team members communicate and establish patterns of interaction that relate to decision-making and ethics in design. We draw from social network theories and a communicative approach to examine how members of multidisciplinary project teams in EPICS¹ talk about, make sense of, and interact throughout the design process, especially as related to ethics. Group communication scholars have examined decision-making processes in teams extensively, finding how team characteristics such as diversity and status differences affect team decision-making and performance.

Individual team members can significantly affect the team's performance, the way members relate to one another, the type of information that is shared and discussed, and a number of other factors that contribute significantly to a team's functioning and decision-making.²⁻⁶ These effects are even more pronounced for smaller teams of people⁷, such as project teams. Researchers have found that diversity among team members has several implications. First, more diversity in terms of age and educational experience have been linked positively to team performance, flexibility, innovation and

productivity.⁸⁻¹⁰ However, research has also indicated that these more diverse work groups often encounter difficulty initially in terms of group performance and functioning.⁹

Cultural diversity also impacts a team's interactions and decision-making processes, providing both benefits and challenges. Some obvious challenges include potential language barriers, but nonverbal cultural differences can also make team interactions more difficult. Cultural diversity can offer more opinions and perspectives on problems,¹⁰⁻¹¹ and could influence the team to take into consideration a wider view of the end user of the product or its functionalities. Culture can also impact the development of team norms, the quality of discussion and inclusivity of team members, and the clarity of the decision-making process. EPICS teams, like the professional world of engineering, are often highly diverse in terms of age, educational background, level of experience with either the specific project or the program in general, and national culture. Examining how this diversity impacts ethical reasoning, both within the team and as a product of the team's efforts, can inform engineering educators about the impact of diversity on their student design teams, and offer insight on strategies to enhance the positive aspects of diverse teams and counteract negative aspects that can occur if left unchecked.

II. COMMUNICATION NETWORKS

To understand the social and communicative processes that underlie ethical decision-making in diverse teams, it is important to consider how communication networks emerge within a network of individuals. Communication networks suggest the relationships among actors and highlights the social processes that undergird these networks¹². This project examines the extent to which actors with the same gender, ethnicity, disciplinary membership, and ethical understandings interact and under what circumstances these actors sought one another out. We accounted for emerging communication networks using the theory of homophily which argues that similar actors within a network will seek one another.¹²⁻¹⁴

Following Ibarra's¹⁵ classification, we also distinguished instrumental networks as task-oriented relationships (e.g., work-related, project-focused) and expressive networks (e.g., as social or social support relationships). In the current study

This work was made possible by grants from the National Science Foundation (EEC-1429114). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

the instrumental network we explored was a task network (i.e., I work with this person regularly) and technical competence network (i.e., I can rely on this person to have the technical competence needed to get the task done). The expressive networks were friendship (i.e., I consider this person a friend) and ethical consideration (i.e., I would go to this person if I had a serious ethical concern about the project). We positioned the ethical network as an expressive relationship due to the high degree of trust related to this form of interaction.¹⁶ The classification of networks serves as a broader contextual backdrop in which our observed communication networks reside. Instrumental and expressive networks suggest different social processes that influence the relationships between actors. For example, expressive networks tend to facilitate ties among similar individuals above and beyond instrumental networks. In addition, according to Ibarra, expressive relationships are less sensitive to formal structures. Typically, people have more control over those whom they consider friends and with whom they exchange trust-laden information. Thus, it is critical to examine how these expressive networks emerge and specifically what role actor attributes play in forming certain network structures. Ibarra¹⁶ argued, “expressive network relationships...are characterized by higher levels of closeness and trust than those that are exclusively instrumental” (p. 59). Table 1 illustrates our study’s three central communication networks.

TABLE I. COMMUNICATION NETWORKS WITHIN ENGINEERING DESIGN TEAMS

Communication Networks	Definition
Work-interaction network	I work with this person regularly.
Friendship network	I consider this person a friend.
Ethical consideration network	I would go to this person if I had a serious ethical concern about the project.
Technical competence network	I can rely on this person to have the technical competence needed to get the task done.

III. ETHICS

Cheney, Christensen, Zorn, and Ganesh¹⁷ identify several contemporary issues involving the communication of ethics within organizations. First, the nature of *corporate legitimacy* has dramatically changed. Whereas decades ago the sole responsibility of a corporation was to be profitable, now organizations are called upon to be responsible to their members, communities, and other stakeholders. This contemporary issue frames the overall ethical landscape in which organizations in general and work teams in specific reside. Engineering teams are held to a standard above and beyond creating a product that is fiscally viable. Second, the rapid increase in *new technologies* is creating newer and more complex ethical dilemmas. Engineering teams in particular must consider the social impact of new innovations. As a result, it is critical to examine ethical reasoning among this particular work group. Third, *multicultural and international dynamics* challenge taken-

for-granted routines. Multiculturalism is forcing organizations to assess “normal” ways of doing business.

Diverse ethnic, cultural, and national understandings of ethics challenge the status quo of what organizations believe it means to be ethical. Thus, it is also critical to examine the extent to which diversity functions in perceiving others as ethical (or not). Finally and similar to multiculturalism, the question of *whose standards* addresses whose and what standards are being used as ethical foundations for complex decisions and outcomes. We use the Engineering Ethical Reasoning Instrument (EERI)¹⁸ as a measure of individual ethical reasoning within the engineering context. Furthermore, we explore the impact of diverse disciplines on the network. Michael Davis¹⁹ has argued that engineering ethics addresses “special morally permissible standards of conduct that, ideally, every member of a profession wants every other member to follow, even if that would mean having to do the same” (p. 93). It is important to account for the ways a group of diverse members together come to understand and interact regarding ethical considerations.

IV. SOCIAL NETWORK ANALYSIS

We are utilizing social network analysis (SNA) to explore communication networks, as well as the impact of diversity. According to Monge and Contractor,¹² SNA “at its core...consists of applying a set of relations to an identified set of entities” (p. 30). In terms of the current study, the engineering students enrolled in EPICS were the entities and the relations applied consisted of the four primary communication networks. Moreover, SNA examines relationships between these engineering students alongside their individual attributes (e.g., gender, ethnicity, disciplinary membership, and EERI score). In other words, SNA allowed us to examine to what extent individuals with similar attributes formed ties within certain communication networks.

There are also network structure influences that must be taken into consideration. *Density* refers to the connectedness of individuals within a particular network.¹² This network level measure indicates the ratio of the total number of actual links to the total possible links. Therefore, highly dense networks are highly connected representing many linkages among actors. This is important to consider because density provides context for the ways actors potentially perceive of the relationships they have with one another. That is, network density suggests whether the structure of communication networks facilitates or hinders certain relationships. For instance, highly dense networks typically facilitate stronger ties among expressive ties such as friendship.¹⁶ Therefore, due to this study’s emphasis of expressive networks it is important to consider how density facilitated communication among different communication networks. Ibarra¹⁶ sheds light on the connection between network density and relationships among contacts: “Network density, which refers to the extensiveness of contact...focuses on how a...individual is affected by relationships...” (p. 63).

V. HOMOPHILY

The theory of homophily suggests individuals select one another based on similarities.^{12,15,16} These similarities may be based on various dimensions, including but not limited to: age, gender, social class, education, race, occupation, attitudes, and beliefs. Homophily theory in social networks provides an explanation for how communication networks form.

McPherson and colleagues¹³ provided an in-depth literature review on homophily within social networks. They categorize these various dimensions into *status* homophily and *value* homophily. Status homophily typically includes demographic factors, such as age, sex, and occupation. For the current study, as stated previously, we included: gender, ethnicity, and disciplinary membership. Value homophily focuses more on internal states, such as attitudes, values, and beliefs. According to McPherson et al.,¹³ these internal states may indicate orientation toward future behavior. As indicated earlier, we are using the Engineering Ethical Reasoning Instrument (EERI) as a dimension of value homophily. We situated the EERI as such because it represents an internal set of beliefs or principles that orient individuals toward future behavior (e.g., ethical decision-making practices).

There are a few noteworthy points regarding this study's dimensions of status homophily (e.g., gender, ethnicity, and disciplinary membership). First, based on the restricted nature of the modern workplace, women are forced to form relationships with men in both instrumental and expressive networks. Studies have shown that these cross-sex ties are typically associated within instrumental networks, where expressive networks tend to present more gender homophily.^{13,15} Ibarra¹⁵ found that women formed more instrumental ties with men and particular women within expressive networks.¹² Second, race and ethnicity, historically, have been shown to be the strongest predictors for homophily in social networks.¹³ Interestingly, as with gender, findings indicate that racial and ethnic minority members typically form more cross-race ties within instrumental networks and demonstrate more racial/ethnic homophily within expressive networks. Lincoln and Miller,²⁰ as cited in Monge and Contractor,¹² "found that similarities in sex and race of organizational employees were significant predictors of their ties in a friendship network" (p. 226). Lastly, organizational or disciplinary membership homophily has also shown to account for networks structures. In the present study, we operationalized disciplinary membership as the academic major of the students given the highly multi-disciplinary nature of the program (greater than 70 majors participated in an academic year). We did not analyze disciplinary membership in terms of level of education because most students are undergraduates. Studies have shown that organizational membership homophily occur more frequently in instrumental relationships than in expressive networks.¹³

Before we address statistical approaches for social network research, we present the potential "downside" for highly homophilous groups.¹⁶ Similar groups tend to

reproduce information and provide redundant resources, and can participate in "group think".^{21, 22} For instance, highly homophilous groups may share similar viewpoints, ideas, or decision-making premises. This is a critical point for groups such as engineering teams that require original ideas to produce creative innovations. The downside of homophily has implications for ethical decision-making. Ibarra¹⁶ argued "restricting network interactions to similar others...reduces access to information from disparate parts of the social system"²³⁻²⁵ and strengthens peer group enforcement of norms concerning appropriate behavior"²⁶ (p. 61). Reinforcement of norms therefore becomes important to consider. The prevalence of certain norms over alternative approaches opens a group (e.g., engineering design teams) to the risk of ethical threats. As a hypothetical example, let us say there is a high degree of disciplinary homophily within the ethics network. This could suggest that certain disciplinary norms or design approaches are privileged without consideration to other alternatives. This could lead to certain values being embedded within the design process that ultimately could lead to greater ethical dilemmas. For these reasons, it is critical to investigate diversity within communication networks and the role diversity plays for ethical consideration, that is, how diversity functions within communication networks not whether or not there is diversity per se in teams. In terms of engineering education, it is important to understand the structures that emerge within engineering design teams. Engineering team dynamics may afford unique contexts different than in other disciplines (e.g., management, marketing, accounting).

VI. EXPONENTIAL RANDOM GRAPH MODELS FOR SOCIAL NETWORK (p^*)

Exponential random graph models for social networks (ERGM) or p^* models apply statistical premises to observed social networks²⁷. Where traditional social networks properties such as density, centrality, and betweenness provide good descriptions of network compositions, ERGM models extend social network analysis by exploring regularities within network ties. By accounting for randomness, ERGM models are able to examine whether these regularities occur above and beyond mere random chance. Following theoretical mechanisms, statistical models allow hypotheses to suggest what social processes are behind the emergence of certain structural properties.²⁷ Robins and colleagues²⁷ provide a prime example of how statistical models are able to do so:

For instance, clustering in networks might emerge from endogenous (self-organizing) structural effects (e.g., structural balance), or through node-level effects (e.g., homophily). To decide between the two alternatives requires a model that incorporates both effects and then assesses the relative contribution of each.²⁷ (p. 175)

Thus, ERGM models accounts for various networks structures at multiple levels to suggest how these structures emerge. An ERGM approach allows us to predict the propensity of ties within our observed networks by examining the statistical relationships of the simulated graphs. These graphs are produced by PNet and compared to

the observed network. Analysis using PNet utilizes Markov Chain Monte Carlo (MCMC) maximum likelihood estimation.^{27, 29, 30} The estimation process produces various simulated graphs that are compared to the observed network. To determine convergence, the *t* ratio output must be less than 0.1 in absolute value.²⁹ Parameter estimates more than twice their standard error are statistically significant.^{29, 27}

Within PNet several control parameters are used to account for the emergence of ties within a study's multiple matrices. These parameters are categorized as endogenous or exogenous effects. As Lee and Lee²⁹ indicate, "endogenous effects refer to the internal structures to form in the focal network" (p. 67). These parameters control for structural effects *within* a particular network. For instance, these effects account for local social processes that are representative of the network itself (i.e., self-organizing). On the other hand, exogenous effects refer to the attributes members bring *into* the network. In terms of the current study, gender, disciplinary membership, and ethnicity represented exogenous or node-level effects. These parameters were operationalized as categorical variables. Additionally, we used the EERI as a continuous variable to measure individual ethical reasoning. The EERI also represented an exogenous effect.

VII. METHOD

Participants for the current study included 40 EPICS students representing two teams. Team 1 included 15 students and Team 2 included 25 students. The total sample included 15 female students and 25 male students. Of the total participants, 11 (28%) were ethnic minorities, with one unreported ethnic classifications. In terms of disciplinary membership, there were 6 (15%) enrolled in First Year Engineering, and 31 (78%) in Upper levels of Engineering coursework, with 2 (5%) Non-engineering, and one unreported.

Data were collected via a social networks analysis survey. Wasserman and Faust¹⁴ present complete networks as a form of social network data. A complete network assumes all actors can have ties to all other actors. Respondents of each team, therefore, were given a complete roster of the team that included students, teaching assistants, and advisors. Each student was instructed to select other students with whom they reported that they interacted. The four relations we examined were: work-interaction, friendship, technical competence, and ethical consideration. These relations were designated as directional relations. That is, the tie or relation was recorded when one student indicated a tie to another student and/or vice versa. Thus, this analysis produced 6 distinct matrices. Team 1 produced 3 15 x 15 matrices and Team 2 produced 3 25 x 25 matrices.

VIII. PRELIMINARY FINDINGS

Preliminary findings highlight the role of technical competence within engineering design teams. One of the study's guiding propositions stated that networks would demonstrate a structural tendency for reciprocity. Beginning with Team 1, the *ethical consideration* network was not

found to be statistically significant. The three additional networks did show significant results: *work-interaction* (Estimate = 3.36, SE = 0.55), *technical competence* (Estimate = 1.11, SE = 0.42), and *friendship* (Estimate = 1.29, SE = 0.48). The results indicate these networks maintain a self-organizing effect that suggests reciprocated ties. Outside of *work-interaction*, *friendship* produced the strongest estimate.

For Team 2, the *ethical consideration* network was also not found to be statistically significant. All other networks produced significant estimates: *work-interaction* (Estimate = 4.25, SE = 0.41), *technical competence* (Estimate = 1.63, SE = 0.25), and *friendship* (Estimate = 1.71, SE = 0.38). Similar to Team 1, *work-interaction* shows the strongest probability for reciprocated ties. Simply put, Team 2 results suggest that individuals are more likely to reciprocate with those they perceive they work with on a regular basis.

Importantly, however, reciprocated ties among *technical competence* could suggest that a local structure exists where individuals perceive one another as technically competent. These findings could indicate that many of the interactions within an engineering team are rooted in an individual's perception of the other as technically competent. This self-organizing structure within engineering design contexts may suggest that technical competence or the perception of being technically competent may override traditional diversity attributes (e.g., ethnicity, race, gender) that otherwise play significant roles in homophily within *other* organizational settings (e.g., corporations, NPOs, governmental groups). In terms of ethics, this finding might also suggest that technical competence is more easily perceived or acknowledged than ethics. Individuals are more likely to reciprocate another as technically competent above and beyond reciprocating ethical concerns. Not only might technical competence be more easily ascertained or perceived than ethical considerations but our findings about the importance of technical expertise in relationships might be a consequence of the many times in which team members are evaluated in different courses based on their technical expertise. Thus, assessment of technical competence or perceived technical competence alone might make this variable more salient than other considerations, such as ethics.
