LectureTools provides the instructor with tools to ask a wide range of question types including multiple choice, reorder list, free response, numerical and image-based questions, excellent for testing students understanding of graphs, images and maps.

All data for LectureTools is stored in the cloud and is available to the course instructor via a web portal that summarizes student participation on class-by-class basis. For this study the data collected during the semester was separated into three periods representing student participation between the beginning of the semester and the first exam, between the first exam and second exam, and between the second exam and third.

2) Collecting Extrinsic Data

It is reasonable to expect that there are influences on student performance that are unrelated to the conduct of the course. These could be the incoming knowledge base and confidence level of the student, their level of emotional or physical wellness and/or their level of interest in the content of the course. As others have demonstrated that student outcomes are often well correlated with the incoming GPA of students additional data was obtained from the University of Michigan student.

C. Analyses

All the data were extracted and then linked to students' hourly exam grades. Processing was accomplished using Microsoft Excel for categorical frequency analyses and Weka [10] for statistical clustering, categorization and linear regression.

III. RESULTS

A. Prior Success

As others (McKay et al., 2012) have reported, exam grades are often related to the GPA of students prior to joining a course. The data from this class do show a relationship between incoming GPA and exam grades (Figure 2) though this also illustrates a fair amount of variability in the grades regardless of GPA.

The incoming GPA of the students explains between 23 to 31% of the variance in exam grades. While this information may be of interest to an instructor as a potential harbinger of difficulty a student's GPA, by itself, does not provide guidance about what strategies to recommend to students with lower GPA's. Moreover it can be argued that instructors might not be comfortable knowing a student's record of prior success as it could influence their attitude toward the student.

Fig. 2. Scatter plot of exam grades versus incoming grade point average (GPA) for each student.

B. Attendance in Class

When students attend class they are exposed to presentation and/or discussion, which provides an opportunity to listen to and interact with someone knowledgeable in the topic. If they don't come to class, perhaps more importantly, they are declaring that other things are more important than this course on this day.

In the class studied, and probably because of the incentivization described above for participation plus the availability of the streaming lecture feed, student "attendance" is quite high. About 150 of the 160 students in the course used LectureTools and of those about 130 attended every day of class either in person or remotely.

Table 1 shows the average grades received on each exam as function of the number of days with no participation in the period prior to each exam. These results show little relationship between missed classes and grades, but the numbers of students missing class four or more times was relatively low for each exam (11, 13, 16, respectively). This would suggest that on the whole attendance was a poor indicator of student outcomes for this course.

TABLE I. THE AVERAGE GRADES ON EACH OF THREE HOURLY EXAMS AS A FUNCTION OF THE NUMBER OF TIMES STUDENTS DID NOT PARTICIPATE.

Days of Non-Participation	Exam 1	Exam 2	Exam 3
0	80.1	76.6	83.7
1-3	80.0	75.9	82.3
4-6	83.3	69.8	78.0
>6	86.0	76.7	82.1

Fig. 3. Average exam scores versus the number of slides containing notes in the period prior to the exams.

C. Taking Notes

A student taking notes is obviously participating in class though note taking by itself may or may not lead to learning. The corollary is that not taking notes presumably limits the learning possible.

In this study the number of slides for which each student took notes was calculated. Again, the class was segmented into the three periods preceding each exam and the number of slides each student typed notes on were calculated and compared with the resulting exam scores. Figure 3 shows that the average grades associated with various bins of notated slides generally increase with the more slides containing notes.

D. Participation in Class Activities

Another measure of participation is how many of the instructor-posed questions do students attempt to answer. The hypothesis is that if students "attend" class but are not answering questions they are likely disengaged.

Figure 4 compares the fraction of total questions posed by the instructors that were answered by students prior to each exam to the average grade on that exam. There is a positive relationship between number of questions answered and resulting grades with an explained variance (r^2) of 0.20, 0.23 and 0.33 for Exam 1, Exam 2 and Exam 3, respectively. This may seem in conflict with the results found for attendance in Table 1 but suggests that simply "attending" class is less predictive than participating. This is an important distinction as many instructors use attendance as a measure of participation and even grading.

It is unclear whether the students did not answer questions because of disengagement or because they didn't understand the material. Nonetheless this result suggests that instructors should be cognizant of which students are not answering

Fig. 4. The average of the three hourly exams versus the fraction of questions answered prior to each exam.

questions during class as one indicator of poorer understanding.

IV. DISCUSSION

The capacity to accurately predict student outcomes based on measurable quantities remains a significant goal for higher education. This work presents a data collection system that records student participation in multiple ways and compares those measures to student outcomes. Additionally it adds extrinsic data that represents other factors important to a student's success in class.

The fact that about 90% of students voluntarily brought technology to class is probably in part because the students saw value in having their notes available instantly on all their devices but is also partly due to the design of the class grading. The students received 15% of their grade for "participation", which was measured daily as the fraction of questions presented during class that the students answered. As the activities were central to the learning experience of the course it is important to put explicit value on their participation.

Anecdotally, it is worth addressing the concern that students with technology will be distracted. The attitude in this class was that students need to learn time management sooner or later so why not in college. That said, LectureTools offered sufficient opportunities for students to participate via questions posed, note-taking and asking questions that the course "felt" far more interactive than in previous years when interaction was verbal.

Another important outcome of the use of LectureTools is the ability for students to ask questions digitally led to dramatic increase in questions submitted. In previous years with verbal questions it was not uncommon to get questions from only a few students (and usually male students). With digital questions the number of questions rose to over 400 during the semester with female students asking more questions per capita than male students. This by itself is a strong argument for use of such technology in a large class.

V. CONCLUSIONS

This study was limited to one class and one semester and hence is not intended to represent multiple courses at multiple institutions. Nonetheless it provides a unique suite of measurements that include more parameters than have been previously reported in one set.

The results indicate that:

- Student outcomes were positively related to extrinsic influences including their incoming grade point average, their interest in the content and their physical and emotional state.

- Student outcomes were not related to measures of class attendance alone.
- Student outcomes were not related to the number of times students participated remotely.
- Student outcomes were positively related to the level of participation in in-class questions.
- Student outcomes were positively related to how many questions students got right in class.
- Student outcomes were positively related to the number of slides for which students created notes.

Next steps will be to 1) replicate all or parts of these analyses in other classes using LectureTools or similar technologies that can measure multiple aspects of student participation and 2) design an "engagement measure" for use in the studied course that identifies students with participation patterns (and possibly past performance measures) that are similar to those with low outcomes from this research. The engagement measure would be used to identify students early in the semester who could be invited to help design interventions to improve their performance.

Engineering Students' Motivational Beliefs

Development of a Scale Utilizing an Expectancy, Value, and Cost Framework

Mariafé T. Panizo, Casey M. Williamson, Olga Pierrakos, Robin D. Anderson,
Verena Bethke, Cheryl A. Welch
James Madison University, Virginia, USA

Abstract— In the current study, researchers developed a 12-item instrument (Engineering Student Motivational Beliefs Scale; ESMBS) to assess engineering students' perceived expectancies, values, and costs of being an engineering major and pursuing an engineering career. The purpose of the paper is to present the ESMBS development process, including *preliminary* psychometric information. Researchers used Benson's model of construct validation, encompassing three phases, to guide the development and preliminary validation of ESMBS. The substantive phase included a thorough review of the literature to theoretically and empirically define the expectancy, value, and cost constructs within the context of undergraduate engineering. The structural phase consisted of psychometric investigations of the scale to examine internal consistencies. Finally, during the external phase, the relationship between the ESMBS constructs and student engagement was examined. The results from this preliminary instrument development study were mixed, showing the need for further examination of the measure.

Keywords—*motivation, expectancy, value, cost, student engagement, expectancy-value theory, construct validation.*

I. INTRODUCTION

Research suggests that a person's motivational beliefs impact her or his choice to engage in a domain or task [1]. Students' motivational beliefs have been of particular interest to educational research in many different areas, including STEM fields. Motivational beliefs have been used, for example, to predict student achievement and intention to leave a given field [2][3]. Expectancy-Value Theory (EVT) provides a framework for understanding motivation. According to EVT, individuals' expectancies and perceptions of the value of a certain domain influence their level of involvement in that particular domain [4][5]. Translated into the context of engineering education, students' level of confidence in their learning capacities, and perspectives about the value of engineering most likely will influence the students' future academic and professional choices.

Recent development in the motivation literature enriches the interpretation of student motivation by focusing on a component largely ignored in previous studies: the perception

of the costs or drawbacks of a domain or task. Among the different attempts to operationalize and measure the cost component, the Expectancy-Value-Cost (EVC) model emerges as a sound framework for accounting for this component [4]. According to the EVC model, students' perception of the costs involved in a specific task is a salient construct for explaining students' behavior and should be differentiated from the other components of the expectancy-value model [6]. A number of recent instruments in the STEM education literature have attempted to capture the cost component while providing valuable insight into the discussion of STEM students' achievement and academic behavior [3][7][8]. However, these instruments follow the traditional EVT framework, ignoring the latest conceptual and psychometric contributions on the matter. We believe that there is a need for developing an engineering motivation instrument based on the EVC model in order to better account for students' experience in engineering. Thus, in the current study, a 12-item instrument (The Engineering Student Motivational Beliefs Scale; ESMBS), based on the EVC model, was developed to assess engineering students' expectancies, and perceived values and costs of the engineering major and career (in what follows: expectancy, values, and costs, respectively).

II. FRAMEWORK OF THE CURRENT STUDY

The ESMBS scale was developed using Benson's model of construct validation [9]. This model incorporates three different construct validation phases: the substantive, the structural, and the external phase. In the initial *substantive phase*, a thorough review of the literature was conducted to theoretically and empirically define the expectancy, value, and cost constructs within the context of undergraduate engineering. After defining the constructs, items were created and reviewed by content experts. These items were also presented to engineering students during two think-alouds conducted to evaluate sources of response error. The items were then edited based on the feedback from both the content experts and students. The *structural phase* consisted of psychometric investigations of the scale—including inter-correlations among the ESMBS items, and between each item and its corresponding subscale—to examine the internal consistency of the measure. Finally, during the *external phase*, the relationship between the ESMBS constructs and student engagement was examined to determine whether the constructs were related as predicted.

The authors would like to acknowledge the support of the National Science Foundation (Award #EEC-0824337 and Award #EEC-0846468). The views expressed in this paper are those of the authors and do not necessarily represent those of the National Science Foundation.

III. THE SUBSTANTIVE PHASE

The purpose of this initial phase was to gain deeper understanding of the theoretical and empirical definitions of the expectancy, value, and cost constructs and to develop a measure based on the findings. First, a literature review of seminal motivational beliefs theories and existing measures developed in STEM education was conducted. Based on the investigation, operational definitions of the constructs of expectancy, value, and cost within the context of engineering education were developed. We then generated items to measure engineering students' perceived expectancies, values, and costs. Feedback from a team of content experts and research methodologists, as well as information gained during two think-aloud procedures with engineering students were used to modify the instrument.

A. Literature Review

1) Theoretical Framework

The Expectancy-Value-Cost (EVC) model is based on the Expectancy-Value Theory of motivation developed by Atkinson and extended into education by Jacquelyn Eccles [4]. Within EVT, motivation has been described as being governed by a person's expectancy of acquiring a specific goal and the value that the individual feels that the goal has [10]. EVT has been used to research many different academic domains, including the work pioneered by Eccles on gender differences in mathematic achievement [11]. This and other studies suggest that the EVT framework is useful for understanding students' academic behavior, from the standpoint of their motivations.

The two main components of EVT are expectancies and values. The first portion of this theory refers to having an expectancy of being successful in a task. The second portion of EVT is defined as having a value for engaging in a specific task [4]. The value component of EVT is broken down into four subcomponents that include interest, attainment, utility, and cost [12]. Having *interest value* is defined as having significance for the experience from engaging in a task, or having interest in engaging in that task. *Attainment value* is the importance of doing well on a task as defined by one's personal values. *Utility value* is the perceived usefulness of engaging in a task. Finally, *cost*, is defined as the perceived amount of effort or drawbacks that will be incurred from engaging in an activity. Eccles and colleagues [5] further partitioned the cost construct into perceived effort, loss of valued alternatives, and psychological cost. *Perceived effort* was defined as how much effort is needed to be successful at a task. *Loss of valued alternatives* was defined as not being able to engage in other valued activities due to engaging in one activity. *Psychological cost* was defined as the anxiety associated with potential failure related to the task.

A recent effort in the motivation literature has been focused on investigating the so called *forgotten* component of the expectancy-value equation: cost [6]. Work in that area illustrates the need for a consensus on the operational definitions and measurement of cost [6]. In Eccles and colleagues' initial work, for example, cost was considered a

mediator of value [5], whereas in their later work it was considered as a *type* of value [12]. More importantly, as mentioned by Flake and colleagues, although Eccles and colleagues provide a strong theoretical rationale for cost they have not developed a comprehensive measurement tool [6]. In that context, the EVC model emerges as an attempt to provide a clear framework for understanding the experience of cost in motivation. After a thorough literature review of the role of cost in the expectancy value models, Barron and Hulleman [4] found that there is no conceptual or empirical support for identifying cost as a subcomponent of value. Throughout the literature, cost has been found to depict motivational dynamics that supplement the components of expectancy and value. On these grounds, the EVC model proposes that cost should be separated and examined as an independent component, which interacts with both expectancy and value to determine when someone is motivated [4]. During their own qualitative and quantitative research program, the EVC team also found new dimensions of cost: the effort required by the task itself (i.e., effort-related cost) and the effort required by other tasks (i.e., effort-unrelated cost) [13]. Finally, through a mixed-methods study, researchers found that sometimes effort-related cost was associated with *both* motivating and demotivating tasks, but in each case it was valued differently. In other words, the effort put into *motivating* tasks was perceived positively whereas the effort put into *demotivating* tasks was perceived negatively [13]. As Barron and Hulleman [4] explain, this became a key finding for measuring cost, as depending on how the effort-cost item is worded it could be perceived as something valuable (e.g., "this class is challenging") or as a burden (e.g., "this class is *too* challenging") [4]. Thus, in order to truly capture the negative connotation of cost, the EVC researchers recommended to phrase the item in a way that represents that the effort needed has surpassed a critical threshold and is perceived as overwhelming" [4].

2) EVT and EVC Related Literature in STEM Fields

Given that our interest rests in developing an instrument based on the EVC model that directly targets the engineering student population, we mainly focused our research of motivational beliefs measures within undergraduate engineering and STEM fields. These instruments are presented briefly in this section. The Engineering Motivation Survey was created using the Expectancy Value framework and several motivation instruments from engineering education [8]. The survey consists of 35 questions: 5 interest value items, 7 attainment value items, 7 utility value items, 7 self-efficacy or expectation for success items, and 9 cost items. To test the validity and reliability of the survey, a study was conducted with more than 200 freshmen engineering students at a large public university. The results showed acceptable to good internal reliability, with all Cronbach's alphas for the items being higher than .70. Factor analysis suggests that this instrument measures five constructs from the expectancy value theory, including utility value, attainment value, interest value, cost, and self-efficacy or expectancy for success. The factor analysis revealed that the cost items loaded on two different factors, suggesting that these items may be measuring different types of cost. However, the researchers

did not differentiate conceptually between types of costs and interpreted all the cost items as measuring the same construct. Some of the interest and attainment value items were shown to load on the same factors, meaning that these items may be measuring the same construct. The researchers decided to keep these two sets of items separate arguing that interest and attainment have similar definitions.

Perez and colleagues [3], following EVT, created an instrument to assess STEM students' competence beliefs, values, and costs. For this scale, the original construct of expectancies was changed to competence beliefs, in order to incorporate both expectations for success and ability beliefs. The instrument consists of 5 competence beliefs items, and 7 value items evaluating attainment, intrinsic, and utility values, all adapted from Eccles and Wigfield [12]. In addition, 20 cost items for college STEM majors, measuring effort cost, opportunity cost, and psychological cost, were adapted from Battle and Wigfield [14]. The results of this study showed that competence beliefs, values, and perceptions of cost were related to achievement in chemistry and intent to leave STEM [3].

Jones and colleagues [2] also created an instrument based on EVT, which assesses expectancies and values in engineering students. Jones and colleagues' instrument contains 2 expectancies for success in engineering items, 2 engineering intrinsic interest value items, 3 engineering attainment value items, and 2 engineering extrinsic interest value items. All items in this measure were taken directly from Eccles and Wigfield [12], and modified to assess perceptions of expectancies and values for engineering instead of mathematics. After administering this instrument, it was found that not only do students' expectancies and values for the engineering major decrease within the first year, but that value for the major is positively associated with future career plans in engineering [2].

Panchal and colleagues [15] applied the EVT framework to an undergraduate Engineering Design course in order to create a universal model for teaching design classes. At the end of the semester, students were given a thirty-question survey created by Panchal and colleagues [15] designed to measure both expectancy beliefs and values pertaining to the design project assigned in the class. The survey consisted of 9 expectancy belief questions and 9 value questions, based on the attainment, intrinsic, utility and cost constructs. The researchers found that motivation for completing the project was positively correlated with both expectancy beliefs for the use of mathematics skills and values for the project [15]. Expectancies and values were also positively correlated with learning outcomes and performance on the project. Results related to the cost items are not clearly stated but findings suggest that cost might have been *positively* correlated with proficiency in mathematics and motivation.

Flake and colleagues [6] created a non-discipline specific cost scale to study the dimensions of the cost component of the EVC model. Their investigation supported the previous dimensions of cost described by Eccles and colleagues [5] and identified a new dimension, outside effort [6]. Outside effort cost is defined as the time or effort allotted to tasks other than

the one of interest. The scale developed by Flake and colleagues consists of 5 task effort cost items, 4 outside effort cost items, 4 loss of valued alternative items, and 6 emotional cost items. None of the items on this measure pertained to a particular domain, and all of them were designed for use in a variety of classroom settings. Correlational analyses showed a negative relationship between cost and both expectancies and values, as well as grades and long-term interest [6].

After a thorough investigation of STEM measures of student motivational beliefs we have found that there is no instrument that focuses solely on engineering students and takes into account the latest contributions on the cost construct. Moreover, in some cases the theoretical implications of the unexpected findings have not been discussed. This suggests the need for developing an instrument to study the motivations of engineering students using the most up to date research on the literature.

3) Operational Definitions of the Constructs

Based on our research on the theoretical and empirical definitions of the expectancy, value, and cost constructs, we offer preliminary working definitions of these constructs within the context of engineering (Table I).

B. Development of the ESMBS Scale

TABLE I.

Operational Definitions of the ESMBS constructs	
<i>ESMBS Construct</i>	<i>Working Definitions</i>
Expectancy	The confidence that engineering students have in their current and future abilities to do well in the engineering major.
Value	Positive beliefs about engineering as a field of study and as a profession.
Value - Attainment	The importance students assign to being engineering students or becoming engineers.
Value - Interest	Level of interest students have for the engineering major.
Value - Utility	Usefulness that students grant to engineering as a major and as a profession.
Cost	Sacrifices in time and other resources students have to make in order to do well in engineering, including the drawbacks related to student involvement in the major.
Cost - Loss of valued alternatives	Sacrifices that students need to make in order to do well in the engineering major.
\Cost - Effort related to engineering	Effort students require to allot to the engineering major related activities in order to do well in the major.
Cost - Effort not related to engineering	Effort or time expended in activities not related to engineering.
Cost - Psychological cost	The mental stressors associated with the major.

In the current section, we describe the development of the ESMBS scale based on the findings of the literature review. Specifically, we explain the item generation process, the content experts' analysis of the items, and the use of two think-alouds to evaluate and clarify the items and measure.

Based on the working definitions developed in the initial stage of this investigation, 10 items were developed referencing existing items observed in other EVT-related measures. In the developing process, the research team also took into account recommendations provided by a group of EVC content experts on how to measure the expectancy, value, and cost constructs. For example, following one of these recommendations [16], instead of wording the items as statements, we worded the items as questions (e.g., "How confident are you with your current abilities to do well in the engineering major?") and developed a different scale for each item (e.g., from 1 "Not confident at all" to 7 "Very confident"), so that the scale directly responds to the specific question. Thus, three expectancy items, three value items (attainment, utility, and interest), and four cost items (loss of valued alternatives, effort related to engineering, effort not related to engineering, and psychological cost) were created in this process.

Engineering content experts and research methodologists evaluated the list of 10 items, which were then modified following the experts' feedback. For example, based on previous research showing the difference between an engineering student identity and an engineer identity [17][18][19], the engineering content expert suggested creating two attainment value items, each addressing a different kind of identity: a student and a professional identity. The engineering content expert also suggested creating an additional utility value item focused on the social aspect of engineering. According to the expert's experience in the field, women tend to be more focused on the social impact of engineering whereas men tend to focus more on the financial aspect [19].

After creating and modifying the items, team researchers conducted two think aloud sessions with engineering students (one female and one male) for evaluating sources of response error in the survey. Specifically, following Willis' [21] guide for cognitive interviewing, the sessions were focused on whether the items were interpreted as expected. After conducting the think aloud, some items were modified for

language clarity, avoiding language ambiguity or imprecision. The final ESMBS scale (see Table II illustrating sample items and their sources) is comprised of 3 expectancy items, 5 value items, and 4 cost items. Each question is answered using a 7-point Likert scale. For each subscale, responses are averaged, with the lowest score for each subscale being a 1 and the highest score being a 7. Following Flake and colleagues' [6] work on cost, question number 11 (i.e., effort not related to engineering) is reverse coded.

IV. STRUCTURAL PHASE

The purpose of the structural phase is to evaluate the psychometric properties of the instrument. We conducted a small sample size study to obtain preliminary data on the internal consistency of the ESMBS items. Future directions for further analysis of the internal structure of the instrument are discussed at the end of the section.

A. Psychometric Properties of the ESMBS Scale

Cronbach's alpha, item-to-item correlations, and item-subscale correlations were calculated in order to conduct a preliminary investigation into the structure of the measure. Spearman's non-parametric correlations were used, as recommended in the case of small sample size studies [22]. Given the small sample size of 19 students, no exploratory or confirmatory factor analyses were conducted.

1) Participants and Procedures

Twenty-one engineering students from a mid-Atlantic comprehensive university participated in this study. The survey was administered towards the end of the fall freshman semester. Incomplete surveys, surveys completed in less than 5 minutes or reflecting clear response bias (e.g., selecting only the highest point in the Likert scales throughout the entire survey) were not used. A final number of nineteen participants (3 females and 16 males) were included. Participants received an email that contained informed consent information and a link to the online survey.

2) Results and Discussion

Before examining the relationships among items and between items and subscales, data were examined for normality. Finney and DiStefano [23] suggest that skewness greater than |2| and kurtosis greater than |7| be considered indicative of univariate non-normality. An examination of ESMBS items (Table III) reveals that all skewness and kurtosis values for all the items fall within the acceptable range. However, a review of item-level scatter and Q-Q plots raised concern regarding the normality and linearity of the items, as did the restricted range of responses associated with many of the items observed in Table III. This, along with the small sample size, suggested the need for non-parametric analyses.

Cronbach's alpha was calculated for each subscale as a measure of internal consistency. For ESMBS, internal consistencies for the three subscales were 0.89, 0.87, and 0.71 (expectancy, value, and cost, respectively). According to Kline [24], values greater than .70 are considered acceptable.

TABLE II.

ESMBS Sample Items and their Sources		
Item Type	ESMBS Item	Sources
Expectancy	How confident are you with your current abilities to do well in the engineering major?	"How much confidence did you have in your ability to excel in your engineering major over next semester?" [2]
Value (utility)	How useful do you find engineering in bettering the world around you?	Content expert recommendation
Cost (effort related to engineering)	How much effort do you think is typically required to do well in the engineering major?	"This class requires too much of my effort" [13]

TABLE III.

Item-Level Descriptive Statistics					
Items	Range (actual)	M	SD	Skewness	Kurtosis
Exp 1	4 - 7	5.05	1.13	0.92	-0.42
Exp 2	3 - 7	5.11	1.29	0.48	-0.94
Exp 3	4 - 7	5.11	1.10	0.61	-0.87
Value 1	4 - 7	6.21	1.18	-1.13	-0.37
Value 2	3 - 7	5.74	1.37	-0.92	-0.28
Value 3	4 - 7	5.95	0.91	-0.87	0.54
Value 4	4 - 7	6.32	1.06	-1.35	0.54
Value 5	4 - 7	6.42	0.90	-1.52	1.59
Cost 1	3 - 7	5.53	1.43	-0.44	-1.13
Cost 2	4 - 7	6.42	0.90	-1.52	1.60
Cost 3*	4 - 7	5.37	1.01	0.58	-0.66
Cost 4	4 - 7	5.42	1.02	0.06	-0.98

* Cost item 3 is the only item negatively worded.

TABLE IV.

Spearman's correlations between expectancy, value, and cost items and their subscale total			
Items	Spearman's r_s (effect size r_s^2)		
	Expectancy Total	Value Total	Cost Total
Expectancy1	.871* (0.759)	—	—
Expectancy2	.898* (0.806)	—	—
Expectancy3	.873* (0.762)	—	—
Value1	—	.668* (0.446)	—
Value2	—	.896* (0.803)	—
Value3	—	.881* (0.776)	—

Cost3	—	—	-.138 (0.019)
Cost4	—	—	.810* (0.656)

* Statistically significant results at .01. Cohen's recommendation for categorizing p effect sizes for the social sciences: 0.1 is small, 0.3 is medium, and 0.5 is large [25]. Medium to large effect sizes have been bolded.

While the expectancy and value subscales appear to show satisfactory internal consistency, the cost subscale only minimally meets Kline's acceptable range. Table IV shows the relationship between each item and its corresponding subscale. As expected, each of the items, with the exception of cost item 3, moderately to highly correlates with its respective subscale.

A review of the inter-item correlation matrix (Table V) gives us additional insight into how the items function in relationship to one another. Items should correlate highly with other items measuring the same construct and correlate only moderately with items measuring different constructs. In the

case of the ESMBS, we would expect the expectancy, value, and cost items to relate more closely with items within their respective subscales than with items from other subscales.

In examining the inter-item correlations (Table V), we do see that the expectancy items moderately correlate with one another. This suggests that all three expectancy items may pertain to the same factor. We have a similar scenario when observing the correlations among the five value items. However, with the cost items, cost item 3 (i.e., effort not related to engineering) does not appear to relate to the other items on the cost subscale in a way that would lead us to believe it is measuring the same construct as the other cost items. Thus, in examining only how items relate to other items on the *same* subscale, the subscales (again, with the exception of cost item 3) appear to have satisfactory internal consistency. Nevertheless, when examining how items relate to items from *other* subscales, we see some issues. For example, although value and expectancy items present practically significant correlations, only *some* on these correlations are statistically significant. Also, some of these correlations are stronger than the correlations these items have within their own construct. Value item 2, for example, is more strongly correlated with the expectancy items than with the majority of the value items. This is problematic because as one would expect expectancy and value items to be positively correlated [4][12], value items should not correlate *more strongly* with expectancy items than with other items measuring the value construct. There are a couple of reasons why this may be happening. One is that the developers may have written these particular items in a way that makes their interpretation by subjects problematic. Another reason could be that the items may actually be measuring the same construct. Either way, this would indicate the need for further study (e.g. larger sample size to verify findings) and item revision.

Of particular interest, surprisingly, cost items 1 (loss of valued alternatives) and 2 (effort related to engineering) are positively correlated with all the expectancy and value items. This finding does not align with motivational beliefs theory, as costs are defined to be in tension with expectancies and values, and to hinder motivation [4]. However, research conducted by the EVC research team could help to interpret these findings. Qualitative research found that related-effort is not always perceived negatively [13], which resonates with findings in other studies [26][27]. Thus, in order to truly capture the *negative* aspect of cost the items should measure not simply effort but *overwhelming* effort [4]. In that sense, one possible explanation for the positive relationship observed between the ESMBS cost 1 and 2 items and the expectancy and value items could be the wording of the cost items. It could be that cost items 1 and 2 do not really represent *overwhelming* cost, at least not to the engineering students. This last point is important as the way students perceive cost could be related with the specific student culture. The engineering culture, for example, is known for its grit—or “perseverance and passion for long-term goals” [28]—and appreciation for sacrifice and effort [29]. Under such a culture,

TABLE V.

12. Cost 4	-.021	-.166	-.029	.568*	-.045	.216	.170	.220	.348	.500*	.034	1.000

Note: * $p < .05$, ** $p < .01$

certain aspects of cost could certainly be valued positively. To our knowledge there is no research on variations on perceptions of cost across academic fields. It would be interesting to see if certain academic fields (e.g., engineering) tend to perceive cost more positively than others, and what the implications are for measuring cost in those specific settings.

Another interesting finding is that cost item 3 is negatively correlated not only with all the expectancy items and some of the value items, but, surprisingly, also with the other cost items. One possible reason for this result could be the wording of the item. This is the longest item on the scale and combined with the negative wording this item could have caused participants some confusion. It is also important to consider that this item was created based on a new construct (i.e., “outside effort”) developed by Flake and colleagues [6], and might require further evaluation.

B. Conclusions of the Structural Phase

The evaluation of the psychometric properties of the ESMBS scale has provided valuable information regarding how the initial ESMBS items are functioning. The expectancy items present a good internal consistency, and are strongly correlated among each other and with the expectancy subscale. The same holds for the value items. However, the strong relationship among some of the value items and some of the expectancy items suggest that these items may be assessing similar constructs. The cost items present a more complex picture and require further evaluation, particularly item 3. The positive relationship observed among some of the cost items and the expectancy and value items certainly requires additional study. Future steps for evaluating the internal structure of the ESMBS scale include collecting data from a new and larger sample and conducting a confirmatory factor analysis.

V. EXTERNAL PHASE

In a construct validation process, the purpose of the external phase is to provide evidence of the relationship between the focal constructs and other constructs with which they are theoretically related [9]. The EVC motivational model suggests that students’ expectancies and perceptions of the values and costs of studying engineering are related to their engagement in engineering [4]. In a study conducted with undergraduate engineering students at a large university, Jones and colleagues [2] found that as students’ expectancies for success in engineering courses and perceptions of the intrinsic, attainment, and utility values decreased, engagement in the major also decreased. Thus, not surprisingly, when students had lower confidence in their abilities in engineering and did not value as much engineering, they tended to be less engaged in the major than when they expressed a stronger confidence in engineering and perceived its value more positively.

Unfortunately, to our knowledge, little research has focused on investigating the relationship between student engagement and students’ motivational beliefs in the context of engineering. Some research findings outside the field suggest that such a relationship does exist, though. In the school context, for example, the relationship between students’ motivational beliefs and engagement in the classroom is widely recognized [30][31][32]. Moreover, within the field of reading motivation, seminal motivation theorists have claimed that motivation is “what activates behavior” and therefore is essential to engagement [33]. These and other findings support the hypothesis that engineering students’ level of confidence in the matter and perceptions of the values and costs of engineering are related to their level of student engagement.

A. Correlations between ESMBS and Student Engagement

A small sample size exploratory study was conducted for evaluating whether the ESMBS constructs are related to student engagement as expected.

1) Participants and Procedures

The data for this study were collected under the same circumstances of the previous one, and therefore the participants and procedures are the same.

2) The Student Engagement Survey

Engineering students' level of engagement was measured utilizing the Student Engagement (SE) Survey [34]. This survey was developed utilizing the National Survey of Student Engagement [35]. Fourteen questions from the NSSE were selected for assessing student engagement, specifically collaborative learning, cognitive development, and personal skills development. Psychometric information reported by researchers provides good support for the reliability and validity of the SE. The alpha reliability for the SE was 0.84, and, when compared to the NSSE's Engagement Score, the SE provides similar values [34]. In the current study, the instructions for the three subscales (collaborative learning, cognitive development, and personal skills development) were modified for targeting the entire engineering major and not only one class.

3) Data Analysis

We examined the relationship between student engagement and expectancy, values, and costs. Given the small sample size and the non-normal distribution of the data, Spearman's non-parametric correlations were used to assess the relationship between student engagement and the ESMBS constructs [22].

4) Results and Discussion

a) Relationship between Expectancy and Student Engagement

The correlation between students' expectancy scores and student engagement was not statistically or practically significant (Table VI). This finding is particularly surprising

as higher scores in the SE represent high level of cooperative learning, cognitive level, and personal skills and development. We would expect that students with high confidence in engineering also have high levels of participation inside and outside the classroom, are engaged in high cognitive processes (e.g., they prefer to analyze instead of simply memorize), and belief that engineering provides them the tools to develop professionally and personally. More research is required to see if this finding truly represents the engineering student population.

b) Relationship between Value and Student Engagement

Statistically significant correlations were only found between student engagement and the utility value, which had a small positive correlation ($r_s=.455$, $p=.050$, $r_s^2=.207$). Thus, the more engaged students report to be, the more they report to value the utility of engineering as a source of financial stability and/or for bettering the world around us. This is expected from anyone who reports an interest in a domain: to value the utility of the domain. Contrary to what we anticipated, on the other hand, attainment, interest, and the total value constructs were not statistically significantly correlated with student engagement. However, there are some trends in the data that do align with the literature. For example, as expected, all the value constructs have a positive relation with student engagement. Again, these findings are not strong enough to make conclusions about the validity of the scale but represent trends that are worthy of attention and further evaluation.

c) Relationship between Cost and Student Engagement

Cost items 3 (effort not related to engineering) and 4 (psychological cost) were not statistically or practically related to student engagement. Interestingly, student engagement did have a small *positive*, though non-significant, correlation with the other two cost constructs: loss of valued alternatives (item 1) and effort related to engineering (item 2). This trend does not align with the main literature on cost. From the motivational beliefs literature, valuing a domain as costly will most likely go hand in hand with disengagement from that domain [4]. The misalignment between the theory and the direction that the obtained results are trending could be an indicator of the inability of our cost items 1 and 2 to accurately measure the cost constructs *within the engineering context*. As mentioned earlier, within engineering, sacrifice and effort are not perceived as negative as theory would expect. Some students might consider, for example, that it is worthwhile to make some sacrifices for becoming successful engineering students and professionals. They could be recognizing the large amount of effort and the loss of other valued alternatives that engineering comprises, but, at the same time, are willing to invest that to stay in the major or career. This would suggest the need to adjust our cost items (specifically 1 and 2) to truly represent *negative* cost, a level of sacrifice and effort that undermines students' motivation in engineering.

TABLE VI.

Correlations of student engagement with expectancy, values, and costs		
	Correlation (Spearman's r_s)	Effect size (r_s^2)
Expectancy	.197	0.039
Value: Attainment	.376	0.141
Value: Interest	.220	0.048
Value: Utility	.455*	0.207
Value: Total	.391	0.153
Cost: Loss valued	.242	0.059
Cost: Effort related	.287	0.082
Cost: Effort not related	-.206	0.042
Cost: Psychological cost	-.078	0.006
Cost: Total	.071	0.005
*Statistically significant results at .05. Cohen's benchmarks: 0.1 is small, 0.3 is medium, and 0.5 is large.		

B. Conclusions from the External Phase

With some exceptions, the relationships observed between student engagement and the expectancy, value, and cost constructs were not as predicted. Cost items 1 and 2 reported an unexpected positive—but not statistically significant—correlation with student engagement. This could be an indicator of a need to evaluate the wording of the items to better represent cost within engineering. Expectancy, attainment and interest value, effort not related to engineering, psychological cost, and the cost total, were also not statistically correlated with student engagement. This certainly requires attention as it could indicate that there is, in reality, no relationship between these variables, or that those ESMBS items are not accurately capturing the EVC constructs. However, the absence of significant patterns could also be due to a restriction of range issue. The student engagement scores do not represent a full range of engagement, as they only go from fully engaged to moderately engaged. The same is observed in the case of the expectancy, value, and cost scores. Finally, another possible contributing factor for the non-significant correlations could be the student engagement measure utilized in this study. The Student Engagement Survey operationalized student engagement as a combination of cooperative learning, cognitive level, and personal skills. This could be considered a somewhat narrow understanding of student engagement, as this construct has been defined by seminal thinkers in the area as both the amount of time and effort a student puts forth in activities that are related to desired outcomes of college and how the university propagates these activities in students [36][37].

VI. GENERAL DISCUSSION AND FUTURE DIRECTIONS

In the current study, we followed a construct validation process for developing the Engineering Student Motivational Beliefs Scale. In the initial phase, an extensive literature review of the theoretical and empirical definitions of the expectancy, value, and cost constructs was the basis for developing working definitions of these constructs within the context of engineering.

Based on these definitions and after an extensive evaluation of all the items, a 12-item instrument was created for measuring engineering students' expectancy and perspectives about the values and costs of engineering. Cronbach's alpha, item-to-item correlations, and item-to-subscale correlations were used to conduct a preliminary examination of item functioning and scale structure. Finally, the relationship between each of the ESMBS constructs (expectancy, value, and cost) and student engagement was evaluated using the Spearman's correlation analysis.

These findings provide some preliminary support for the internal consistency of some expectancy and value items, while raising questions about other items. For example, some expectancy and value items seem to be measuring the *same* construct or do not show a strong association with their corresponding constructs. Cost items 1 and 2 were positively correlated with the expectancy and value constructs; whereas cost items 3 and 4 were negatively correlated with the

expectancy construct and—mainly in the case of item 3—with the value construct. From the standpoint of the literature on motivational beliefs and cost, these are puzzling results and the initial step should be to evaluate the quality of the items and see whether they are truly measuring cost. It is important to note that cost items 1 and 2 also presented a small—although not statistically significant—correlation with student engagement. The specific participants' culture could help to explain these findings. In the think aloud sessions, for example, students indicated that while there are sacrifices and costs associated with engineering, some are positive and beneficial, teaching them valuable skills. Thus, within engineering, certain dimensions of cost (i.e., “loss of valued alternatives” and “effort related to engineering”) could be perceived as a necessary investment for being successful in the field. This resonates with what has been observed in other studies [26][27][13]. One way to address this issue could be adjusting the highest scale point on the cost item to represent an *overwhelming* level of cost (e.g., “too much effort” instead of “large amount of effort”).

The current study is a preliminary evaluation of the ESMBS scale. Initial results indicate a need for further scale development. Data are currently been collected from a new and larger sample of engineering students. So far, initial findings concerning freshmen students (N=28) show similar trends to the current study. Additional analyses, such as a confirmatory factor analysis, will allow us to examine the ESMBS structure in more detail.

A. Limitations

There were several limitations to the current study. The small sample size constrains our analyses. Findings should be interpreted cautiously. This study provides only general guidelines for future steps in the development and evaluation of the ESMBS scale. Special attention should be given to the possibility that students who participated in our study are not representative of the general engineering population. It is likely that students who chose to participate are in general more engaged than those who did not participate in the study, which is represented by the restriction of range described earlier. Also, as mentioned before, the Student Engagement Survey utilized in the study understands engagement as cooperative learning, cognitive level, and personal skills and development, which could be considered a somewhat narrow definition of student engagement. In that sense, it would be interesting to see if the relationships between expectancy, value, costs, and student engagement observed in this study are confirmed when utilizing a different measure of student engagement.

ACKNOWLEDGMENT

The authors would like to thank the engineering students who participated in the think aloud procedures and survey.

Experiments with Personal Ownership of Quality at the University of Texas at El Paso

omondragon@utep.edu

Abstract – The lack of commitment to create quality work is a long-standing problem in education, and it is a direct negative driver of student performance, disturbing students' ability to: apply imparted concepts, build team quality work, and foster industry's economy. The quality of delivered work is poor mainly because students do not spend needed time and effort to review their own work; e.g., research papers, group projects, and assignments.

At the University of Texas at El Paso (UTEP), experimental developments targeted students' commitment to create quality work, creating infrastructure to conduct personal reviews for different types of work products, and teaching students to conduct effective personal reviews of their own work. A partial implementation of check lists, review processes, and teaching material has been used in courses at UTEP. The work to be developed includes measuring time distributions of effort (time to build the product vs. time to correct the product), recording the defects injected in products, creating checklists based on the recorded defects, creating a process to review products, and defining a defect log. The goal is to create a habit within students to create quality work by using personal reviews to improve the quality of submitted work.

I. INTRODUCTION

There is an increasing trend of higher systems' complexity in the last century across all Science Technology, Engineering, and Mathematics (STEM) disciplines. Systems are no longer built by single individuals or by groups from a single discipline. All types of scientific, engineering, technology and management disciplines must work synergistically to build complex solutions and products. These complexity challenges affect all STEM areas, but, for simplicity, we will discuss engineering. To cope with system complexity, engineers have used verification and validation techniques such as pilots, mock ups, rapid prototyping, simulations, model checkers, theorem proving, peer reviews, audits, and testing.

Another method used by industry to handle the complexity of systems is specialization. There is a trend toward the specialization of engineers in

specific functional areas or phases of the production lifecycle; e.g., project management, business analysis, programming, architecture, and testing. Although specialization has its advantages, it creates a narrower view for individual engineers. Furthermore, the loss of the "big picture" may create mental or bureaucratic silos that reduce commitment toward the desired final outcome.

Specialized engineers concentrating on a single lifecycle phase may not feel personal ownership of the quality of the whole system, and they may subrogate the responsibility of the system quality to a supporting group (testing, quality assurance, auditors, and peers). The end result is inadequate and dangerous cultures, where the responsibility for and ownership of the system quality is not the responsibility of all contributors, but has instead been delegated to a given support group or to peers. As a result, there are many products, services and systems delivered with poor quality in industry. According to the Standish Group [1], of projects developed in companies: only 9% were successful, 31.1% were cancelled before they ever get completed, and 52.7% cost 189% of their original estimates. In the academic settings, a similar phenomenon occurs when students working in teams and group projects do not review their work and expect that their classmates should conduct reviews to remove their defects.

Reviews have been used in industry for a couple of decades. A brief description for some types of reviews, as well as standards for lifecycles, quality models, and frameworks that make use of review techniques follow.

A Peer Review is a process or a meeting during which an artifact, or a set of artifacts, are presented to project personnel, managers, customers, or peers for comment or approval [2]. A peer is a professional with the same set of skills. A review is the examination of an internal artifact and/or product or deliverables by a colleague with the purpose of finding errors within the scrutinized artifact. The effectiveness of the review process is dependent on the formality of the implementation

and the culture to invest in prevention and review activities rather than in re-work activities.

Peer reviews are defect removal activities. Peer reviews can be applied to any document or object at any phase during the lifecycle. Peer reviews can be performed a) synchronously: the author of the document and his/her peers examine the document together, or b) asynchronously: the document is sent to his/her peers who review the document individually and report back their findings.

An inspection is a type of formal review invented by Michael Fagan at the IBM T.J. Watson Research Lab in 1976 [3]. Inspections were needed because the cost of rework in software projects at IBM ranged from 30% to 80%. After refining the process during several years, the inspection process proved to be very effective because it achieved both reduced number of defects found by final users and increased development productivity.

Reviews have been included in standards, quality models, and process frameworks; for instance, the ISO 15288:2008 standard for Systems and Software Engineering cover the System Life Cycle Processes [4]. The Capability Maturity Model Integration (CMMI) created by the Software Engineering Institute (SEI) includes peer reviews to contribute to the quality of systems, products, and services [5]. CMMI includes a process area called Verification (VER) that addresses peer reviews to confirm that products (services) being built (deliver) are correct and comply with the specification. Also, there is a process framework called Personal Software Process (PSP), developed by Watts Humphrey at SEI [6]. Although ISO 15288 and CMM include reviews; only PSP promotes personal reviews as the key element to achieve personal quality work.

Figure 1. Skills developed by PSP.

The Personal Software Process addresses the lack of personal commitment to build quality work. PSP raises a commitment to personal quality by making the author of the artifact conscious about his/her own defect injection rate and removal cost for each defect type. PSP develops the skill to remove the author's defects through the use of personal reviews, which make use of a personalized

checklist with common defects and a revision process. PSP has made both a cultural change and a significant increment in the quality of products or systems built in the organizations where it has been applied. Figure 1 shows skills developed by PSP.

Some implementations of PSP in academia and industry had been reported. According to Guoping Rong et al., PSP was implemented with pair programming at the summer school in the Software Institute of Nanjing University, leading to higher students' involvement, more process discipline, and a workload reduction in evaluating assignments [7]. Moreover, Lutz Prechelt, and Barbara Unger, mentioned that the use of PSP improved software quality by focusing on defect content [8].

We propose to make a cultural change in STEM students by seeding the principle of personal ownership of quality work. The ultimate goal is to achieve a cultural change where teachers nurture each engineer to do quality work until he/she is proud of her work. This research focuses on developing students' skills to implement the personal review technique.

Personal reviews can increase the effectiveness of peer reviews by requiring, as a precondition, the execution of a personal review of the product. Peer reviews have been used for several decades in industry. Quality models such as CMMI require the execution of peer reviews. Also, team Software Process (TSP), created by the SEI, requires the execution of peer reviews. TSP call for all team members to have taken the PSP training. Moreover, TSP requires the execution of a personal review before a peer review.

Can individuals review their own work? Three positions are discussed: 1) personal reviews are not possible, 2) personal reviews are not needed, and 3) personal reviews are powerful techniques to remove defects. There is a myth that an individual cannot find his/her own defects because an individual is too blind and too biased to identify his/her own defects. A personal review executed in an unstructured and informal way may support this claim. An unstructured personal review may have the following characteristics: a) no set of criteria to look for, b) no process for conducting the review, c) no log to register the defects found, d) lack of analysis of results found, e) conducted too fast, and f) distractions while reviewing. The output of these unstructured ways of conducting personal reviews produces an indisputable outcome: inefficiency in finding defects and a waste of resources.

Under position 2, personal reviews are not needed, as some people believe that they do not introduce defects. In other words, they believe that

they are so good and too perfect that there is no need to look for defects. The ‘inexplicable’ truth stands up when the system fails when it is put in production. The system has so many defects and these people yet ask themselves: Who injected the defects? The answer is simple, no one but themselves. The fact is that, all human beings inject defects while developing products and systems.

For position 3, personal reviews can remove defects. A formal and structured personal review that makes use of his/her defect injection history can guide an individual to find and remove his/her own defects. With practice and discipline, Watts [6] has reported an efficiency to remove defects with structured personal reviews from 50% to 70%. TPS has achieved a 0.06 defects density (# defects / 1000 Lines of Code, LOC). This value is almost two orders of magnitude better than 1 defect/KLOC achieve by CMMI level 5. The use of personal reviews improves the quality of systems as reported in PSP [6] and TSP implementations.

Why do personal reviews work? Human beings are very predictable and they inject the same type of mistakes over and over. A key factor is finding the type of mistakes introduced while developing a given type of work. Examples of types of work include documents, reports, plans, designs, and artifacts. A Pareto analysis in defect frequency and defect cost is suggested to identify a potential type of defect to be included in the checklist as a criterion. The criterion provides a hint to the reviewer to look for that specific defect when examining a type of work. The key aspect of the criterion is to become a strong and useful guide. To be effective, a criterion should come from your own history of defect data.

II. Components for successful personal review

Personal review may include a checklist, review process, a defect log, and data analysis. A brief description of each follows:

1. *A checklist* includes a list of criteria, which are common defects that are injected when developing a document or product. A “defect” is any occurrence of an error that is injected into a document/ product and requires any rework to fix the document/ product. Checklists provide structure to the review and guide the reviewer to look for these types of defects within a document. Related criteria (aspects to review) are classified into categories. Each criterion targets a historical type of defect injected by the individual. Table I shows a checklist to verify Internal Block Diagrams and category “Intended use” includes historical defects related to adding components that are not needed. The structure of the checklist is suited for criteria

that apply to all the sections of a document, for multiple documents of the same type, and for several instances of a given section.

TABLE I. Example template for the IBD checklist.

IMS Systems Engineering					
Checklist template for general criteria of the "IBD Design" review					
Purpose	Review and identify all the general defects injected in the Internal Block Diagram (IBD)				
Entry criteria	Completed "IBD" document for VERIFICATION				
		Component 1	Component 2	Component 3	
Category	Criteria Description				Comments
Flow Ports	Contains all inputs and outputs from the BDD		x		
	Ports show that they are inputs/outputs				
	Number of ports, its placement, and names are consistent with BDD	x		x	
	Port placement is consistent with BDD		x		Port allocated to wrong component
Interfaces	Port names are consistent with the BDD	x			
	All ports have a corresponding connection	x			Port with no connection
	Interfaces show what is flowing			x	
	Interfaces show the direction of flow				
Semantics	Output/input port attributes are consistent	x	x		
	Output ports are linked to input ports				
	Symbols are used correctly	x			
	Components contribute to a service			x	
Intended Use	Services can be provided with the components		x		
	Total defects per component	5	4	3	
	Total defects identified		12		

2. *A review process* provides the means to achieve consistency in the review activity. The process indicates a) the inputs to start the activity (e.g., a finished document/ product, and a checklist tailored to it), b) the steps to conduct the review activity, and c) the exit criteria. The checklist classifies common injected defects into categories. To perform a review, first, the whole document is reviewed against the criteria included in that specific category; second, the defects found are recorded in the defect log. These two steps are repeated for each category. At the end of the review, the number of defects and review time are logged in the checklist.

3. *A defect log* provides guidance and structure to record the defects found during the review. The same defect log is used to record the defects found in all the documents reviewed within a project, or product development effort. The defect log facilitates quality data analysis of the whole project, system or lifecycle. When a defect is found, it is entered in the defect log and detailed information shall be provided; e.g., the document or component name, the injection phase, the removal phase, the defect type, fix time, and the defect description, as shown in Table II. The purpose of the description is to identify common defects that may be used in the future as new criterion in the checklist. Criterion will allow the reviewer to find defects in the future.

4. *Data analysis* facilitates the generation of quality metrics such as defect densities per phase, most frequent type of defect, defect types with highest costs to fix, and the yield or efficiency of the reviews (number of defects removed divided by the total number of defects in the document). The defect log provides the required data to conduct the data analysis. The analysis of this data supports a) updating the criteria included in the checklist, b)

making consciousness on the Cost of No Quality (cost to fix the defects), c) finding most common defect types, and d) identifying process improvement proposals. According to Watts [6], gaining consciousness of a specific defect type that is repeatedly removed and logged during the reviews can reduce defect injection up to 50%.

TABLE II. Template for defect log

MS Systems Engineering			Project Practicum		
Defect Log					
Removal phase: Problem Definition Review, Analysis Review, Functional Analysis Review, Design review, SEMP review					
Defect type: Incomplete, Incorrect, not clear, ambiguous, inconsistent, interface, logic, etc					
Review Time:					
Document or Component	Defect type	Injection phase	Removal phase	Fix cost (min)	Defect description
			Total time	0	

III. Building personal ownership of quality at the University of Texas at El Paso

Nine steps have been conducted at UTEP to develop a personal commitment and ownership of creating quality work. The first step is to create student's awareness about the impact that the lack of commitment to create personal quality work has in both the school and their professional life. For instance, a commitment to quality impacts their ability to a) understand concepts covered in the courses, b) integrate their work into team or group assignments, and c) work efficiently as professionals. Also, the components of the Cost of No Quality (prevention, assessment, internal failure and external failure) are introduced. Students compare the low cost to fix defects in earlier stages of product/system development versus the high cost to fix defects at later stages during testing. Moreover, the efficiency of review techniques versus testing is discussed. Lastly, students are trained to conduct personal reviews that use tailored checklists, review processes, defect logs, and data analysis activities. In the second step, it is important to identify a set of intermediate and final documents/products to build a project or system. In our case, this set of documents is very different for each of the classes considered in this research. In the third step, the training to develop the assigned document is given, as well as the assignment to create it. Notice that students are not using a checklist yet and no structured review is conducted. The step fourth is done during class time. The delivered documents are skimmed by the class and common defects found in the documents are listed. The class analyzes the defects and paraphrased the defects as criteria. Criteria (type of defects to look for) that are related to a given aspect, characteristic, activity, or process are allocated into categories (e.g., defects related to the design of *Flow Ports* will be place in the "Flow Port" category) as shown in Table I. In step fifth, a checklist is created with all the criteria allocated in their corresponding

category. It is important to note that the identified criteria correspond to real defects injected in the delivered documents. In step sixth, students are required to perform a personal review using the checklist, review process and defect logs. Students shall submit the following: previous and new versions of the document, a marked checklist, and their defect log. For step seventh, steps 3 to 6 are repeated until all intermediate and final documents of the project or system are finished. Eighth, once the product or system is completed, several quality metrics can be derived; e.g., number of defects injected by document or phase; number of defects removed by review type, frequency of defect type, and fix cost by defect type. Notice that a defect can be injected in one document and found later on in another document created downstream. For step nine, at the end of the semester, students are asked to analyze their defect data and metrics. Students create a self-reflection report about their own quality and skills and promise to create quality work.

IV. Future work

The work will continue in refining some of the templates and training material generated so far. More work is needed to start another goal of the research: develop STEM students' skills to analyze defect data. As a result, students can achieve consciousness of the high cost to remove their defects at the end of the lifecycle and to recognize how this cost is reduced by removing defects earlier in the lifecycle through personal reviews. In addition, material has to be generated to facilitate data analysis; e.g., automating the generation of metrics from the defect logs. Ultimately, a designed experiment will be needed to prove the efficiency of the method with different samples.

V. Conclusion

The purpose of this research is to achieve a cultural change in STEM students by seeding the principle of personal ownership of quality work. The goal is that teachers nurture engineers to create quality work such that he/she is proud of his/her own work. In our professional and academic experience, many industry process improvement projects fail because organizations are reluctant to make the cultural changes necessary for quality; e.g., reward and encourage early removal or prevention of defects, establish relevant management and process controls, and provide the required training. The proposed cultural change in the STEM students will facility new process improvement projects in companies where quality models such as CMMI and TSP may be implemented. Quality in real projects does not happen by accident; it must be planned and implemented by trained and committed technical and management personnel.

Abstract— In this Work In Progress paper, we describe an NSF-funded research project designed to generate transferable tools that can be used to teach and evaluate undergraduate engineering students' metacognitive skills. Metacognition, defined as the knowledge and regulation of one's own cognitive (or thinking) processes, is critically important to student learning and particularly instrumental in problem-solving. Nonetheless, much of the research has occurred in controlled research settings and little is known about how to help students develop metacognitive skills in classroom settings. Through this project, we are working to close this gap by creating and testing a set of interventions designed to help students develop metacognitive skills and to help faculty teach and evaluate this important skill.

Keywords—metacognition, reflection, problem-solving

I. INTRODUCTION

Metacognition, defined as the knowledge and regulation of one's own cognitive (or thinking) processes [1], is critically important to student learning and is particularly instrumental in problem-solving [2, 3]. Nonetheless, much of the research has occurred in controlled research settings and little is known about how to help students develop metacognitive skills in classroom settings. Further, there are significant bodies of research on the role of metacognition in writing and solving math problems, but little work has been done on the role of metacognition within engineering disciplines. Metacognition is particularly important in the training and development of engineers as problem solvers [2].

Researchers have argued that one way good and poor problem solvers are differentiated is by their ability to reflect on and regulate their problem solving activities [4]. Specifically, metacognitive processes aid engineers in identifying and defining problems, mentally representing problems, planning solution procedures, and evaluating solution progress and the final solution [5]. Researchers have also enumerated other metacognitive strategies employed in problem-solving including establishing task demands,

formulating and executing action plans, finding similarities between problems (task knowledge), recognizing inconsistencies and confusion, identifying constraints, switching from one representation to another, activating prior knowledge, and assessing problem difficulty [6]. All of these metacognitive strategies support one's ability to navigate and persist through solving ill-structured problems.

To address this critical need for metacognitive skills in engineering students, we will generate transferable tools that can be used to teach and evaluate undergraduate engineering students' metacognitive skills. To accomplish this, we designed a three-phase project in which we first use research methods to test an intervention designed to facilitate development of students metacognitive skills and associated indicators, i.e., assessment tools instructors can use evaluate student's progress with regard to developing metacognitive skills. In Phases 1 and 2 the elements of the metacognitive intervention will be developed, implemented, and evaluated across multiple contexts. In Phase 3 the focus will be on developing lessons learned from implementing within different contexts, training faculty at the host institutions, and developing online training materials for a broader audience of engineering educators.

II. FRAMEWORK

There have been many developments and interpretations of the formal elements of metacognition in the time since Flavell's classic paper on metacognition [1]. However, there is broad agreement in the two main components of metacognition: knowledge of cognition (metacognitive knowledge) and regulation of cognition (metacognitive regulation). Some researchers consider self-regulation as a separate element, but closely related or intertwined with metacognition [7]. The metacognition framework we use in this study is depicted in Figure 1. Where, self-regulated learning is a broader construct, which wholly includes this structure of metacognition and expands to include other forms

of self-regulation, regulation of environment, behavior, motivation, and affect [8].

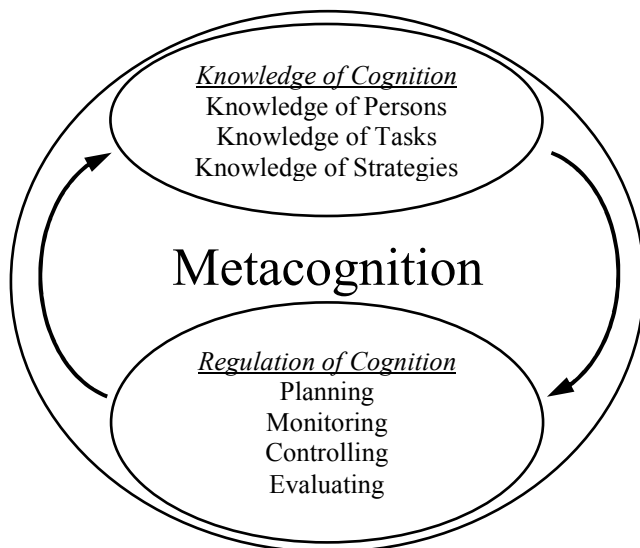

Figure 1: Conceptual Framework of Metacognition

The variables within **knowledge of cognition** have persisted from Flavell's early work [1, 9]. As shown in Figure 1, the variables include knowledge of persons, which includes self and others, knowledge of the task, and knowledge of strategies. The variables within **regulation of cognition** have been more fluid, but there seems to be reasonable agreement in including planning, monitoring, control, and evaluation, or similar elements [2, 9, 10].

The elements of metacognitive knowledge and regulation are not hierarchical, rather they interact and reinforce each other to a high degree [3, 9]. Specifically, regulation draws on and is informed by knowledge of cognition and knowledge of cognition is built, in part, through the practice of regulating one's cognition. Similarly, the elements under knowledge of cognition and regulation of cognition are interrelated with each other. These interdependencies are emphasized in the following descriptions of the sub-elements of metacognition listed. We bold and italicize the key terms in this section to facilitate connections back to the framework diagram.

Knowledge of persons can be further subdivided into self, others, and universal properties of cognition [1]. Within the dimension of self, Pintrich identifies knowledge of one's strengths and weaknesses, the extent and limits of one's knowledge, one's tendencies toward one particular strategy or another, and one's beliefs about their own motivation [3]. Our knowledge of our abilities can impact our view of the difficulty of a given task, facilitate or impede our performance, and direct our selection of strategies to approach a task. Knowledge of others mirrors knowledge of self, but is directed towards others. It facilitates self-assessment in comparison to others and impacts our individual performance and our interactions with others on a task. Knowledge of universal properties of cognition refers to elements such as knowing there are different degrees and kinds of understanding, like the difference between recall and recognition, or the transience of our memory recall [1]. Such knowledge interacts with our

knowledge of strategies and within **regulation of cognition** our abilities to *plan* and *control*. Mis-assessment or inaccuracy in one's knowledge of self can be particularly problematic, especially when it comes to using that knowledge [3].

Knowledge of task includes a variety of task dimensions, for example task demands, goals, difficulty, complexity, context, and comparisons with other tasks [1-3, 9, 10]. These dimensions are strongly related to when and why to apply specific strategies to a task. This implies a strong interaction with *knowledge of strategies* and strategy selection in *planning*, *controlling* and *knowledge of persons*.

Knowledge of strategies includes general cognitive strategies for learning, thinking, and problem solving [3] and task specific strategies [10]. General strategies are applicable across different tasks and tasks from different disciplines. An example of a task specific strategy is knowledge of the principle of Conservation of Energy in engineering analysis, and has significant connection to *knowledge of task*.

While **knowledge of cognition** is essential, it is not enough to have such knowledge. Instead, we must access and use this metacognitive knowledge to reason and make metacognitive decisions to benefit from having such knowledge. This is the essence of the **regulation of cognition**, or metacognitive regulation, which draws on metacognitive knowledge and transforms it into actions through *planning*, *monitoring*, *control*, and *evaluation*.

Planning involves using *knowledge of persons*, *knowledge of tasks*, and *knowledge of strategies* in combination to select an approach to a task [10]. The knowledge is brought together in activities such as predicting task outcomes and scheduling and sequencing sub-tasks [11]. Ambrose et al. discussed breakdowns in students' assessments of assignments and their strengths and weaknesses, which resulted in poor or inappropriate plans [12]. Generally, the more robust a student's knowledge is, the more accurate their self-assessment is, and, conversely, the more sparse and disconnected a student's knowledge is, the more they are prone to over-estimate their abilities.

Monitoring is the ongoing review of one's performance while working on a task. *Monitoring* involves tracking progress on the task, effort expended, checking for errors, self-correcting, and checking and correcting peers [10]. These efforts may be exhibited by students asking themselves, "Is this strategy working, or would another one be more productive?" [12]. The studies cited also revealed that the learning gains from *monitoring* result whether students naturally develop self-monitoring or students are explicitly taught self-monitoring strategies.

Control is the adjustment of one's approach to a task or the strategies employed, in response to *monitoring* [10]. This can be exhibited by an adaptation or change in strategy to improve task effectiveness, repeating a strategy to validate its effectiveness, transfer of a strategy to a new situation, or adopting a modeled cognitive behavior to a task. However, awareness of a deficiency in one's approach to a task does not guarantee that a change will be made.

Evaluation refers to reviewing task performance and effectiveness of the process(es) used to complete the task after concluding the task. Specifically, students assess performance by examining the products of their learning and assess their processes by reflecting on how they navigated the task, *i.e.*, how they *controlled* their behavior during the task [11]. Through the reflective practices of *evaluation*, metacognitive knowledge (*i.e.*, **knowledge of cognition**) is built and refined [11], which implicates a feedback loop where new and better knowledge is used for **regulation of cognition**, for example, resulting in better *planning* in the future.

III. METHODS

The purpose of our project is to generate transferable tools that can be used to teach and evaluate undergraduate engineering students' metacognitive skills. To accomplish this, we designed a three-phased project in which we first use research methods to test and refine an intervention designed to facilitate development of students' metacognitive skills and associated indicators, *i.e.*, assessment tools instructors can use to evaluate students' progress with regard to developing metacognitive skills. The intervention consists of training videos on metacognitive knowledge and awareness, contextualized classroom modules, and metacognitive assignment modifications to provide opportunities to practice metacognitive regulation. The first phase focuses on the development and pilot implementation of metacognitive interventions, and assessing student's metacognitive development for a sophomore engineering course at a small undergraduate-focused engineering school. In this phase, we answer the research questions: *To what degree does a teaching intervention contribute to improved student metacognition? What are some easily accessible indicators of metacognition?* In the second phase, we use the research outcomes from Phase 1 to revise the set of interventions for use in the original context and translate them for a second engineering context, a freshman course at a large comprehensive land-grant university. The goal of the revisions is to improve the interventions and to focus on the transferability of both the intervention and the indicators. The research aspect of Phase 2 refines the Phase 1 research questions and adds the focus on understanding what elements of an intervention and context are most relevant when considering transferability. In this phase we answer the research question, *Considering context and course content, what factors are relevant to transferability of the intervention and indicators?* Finally, Phase 3 will focus on faculty/instructor training and dissemination of intervention materials and answers the question, *What recommendations would help teachers to adapt and use the intervention and indicators in their own classroom contexts?* We will develop recommendations for instructors on how to further translate our intervention for use in their own classroom contexts. Further, we will develop and conduct faculty/instructor training at the host sites. These training sessions will also be used to develop online training videos to be deployed in an online repository hosting training, intervention materials, user submitted materials, and an asynchronous discussion forum for users. The third phase is particularly important as research

shows that transferring teaching innovations can be challenging and can be a barrier to adoption [13-15].

A. Phase 1

The purpose of this phase is to develop, implement (as a pilot), and evaluate teaching interventions (described at the beginning of this section) designed to improve student metacognition. Overall this phase will use an experimental design. The context for this phase is a sophomore level course focused on conservation and accounting principles: conservation of mass, momentum, and energy and accounting of entropy. The course is offered in the first quarter of the academic year and is essentially the foundation to the integrated sophomore curriculum as it outlines core principles within a common framework. The course is required for Mechanical and Biomedical Engineering students and typically has an enrollment of approximately 200 students per quarter. The course has multiple sections of approximately 25 students each enabling the use of intervention and control groups.

Data Collection and Analysis: We will use multiple research methods to calibrate indicators. We anticipate that indicators will predominantly come from classroom assignments and activities and assignment modifications created as part of the intervention itself. We anticipate seeing growth in students' metacognitive abilities as they become more aware of their metacognitive knowledge and through cycles of intentional practice of metacognitive regulation and corresponding correction and expansion (improvement) of their metacognitive knowledge [16]. It is this change over time that we are looking for as an indicator that our intervention is working. The use of an experimental design provides an understanding of what metacognitive changes typically happen during the same time period as a part of academic development in the absence of any explicit metacognitive interventions. This will help us to understand the appropriateness of our interventions with regard to challenging and pushing possible developmental norms and gauge the effectiveness of our interventions.

Student interviews: We will conduct interviews at the start of the term and again at the end of the term with ten students each in the experimental and control conditions. We will treat each pair of interviews (and survey responses) as a case such that we can compare and contrast changes with time and across cases [17, 18]. We will use early quarter interviews to gauge students' initial understanding of metacognition as well as to describe the practices in which students currently engage. By asking similar questions at the end of the semester, we can gauge changes across time. By also asking about the specific intervention activities we designed, we can gauge student's perceptions of which activities worked best and why.

Student surveys: We will also use quantitative measures of metacognition. We will adapt questions from existing instruments [19-21] for appropriateness in college engineering courses. For example, we would draw on questions that are consistent with our intervention and focus on how students evaluate their own learning such as "I ask myself questions to make sure I understand the material I have been studying in this class". We will use pre- and post-test measures (matched by participant) so that we may assess changes in individual

student use of metacognitive strategies. We will use descriptive statistics and comparative t-tests. The surveys will also help provide a backdrop against which we can situate interview findings for greater transferability and generalizability.

Indicators: Interviews and surveys are research-tested ways of identifying metacognitive engagement. However, they can be cumbersome and time-consuming to implement, making them difficult to use for in-class assessments. They can also be in formal language that does not match typical student/instructor vernacular. Our development of indicators will focus on equipping instructors with tools (e.g., rubrics) to assess metacognitive engagement in the classroom and on homework extensions during the learning process. Potential indicator assessments include the use of reflective writing assignments, short think aloud opportunities, and direct observations of students at work. Previous work in identifying metacognitive engagement will be used to inform the development of these in class indicators [22-24]. We will then use interviews and surveys to corroborate the effectiveness of the indicators that are designed into the course.

B. Phase 2

The purpose of this phase is to refine the pilot metacognitive teaching interventions and to test the transferability of the interventions and assessment tools for the instructors to evaluate students' development of metacognitive skills. To do so, we will repeat the implementation at the primary site with improvements based on outcomes from Phase 1. We will also develop contextually relevant materials and test them at a second site. The second site is an introductory course in a first-year engineering program at a large land-grant university in the mid-Atlantic region of the United States. At the course level, the context change specifically consists of changes in student level, student major, and course content providing an opportunity to study whether the metacognitive teaching videos function well in both contexts relative to topics and delivery. The order and the timing of the sequence of paired videos, in-class modules, and assignment extensions may need to be altered for different contexts, although the introductory overview video will be kept first. At the university level, one school is a teaching focused technical school and the other is a research intensive school. The new context will engage multiple instructors, including faculty and graduate teaching assistants, compared to one or two instructors in the pilot, which may necessitate refinements for consistency and ease of transfer, while maintaining effectiveness.

Data collection and instruments: The interview and survey methods described in Phase 1 will also be used in Phase 2. We anticipate only minimum adaptations in these research tools, particularly for context, but will make other changes as necessary. We also anticipate that the indicators will be similar to those used in Phase 1 adapted for the contextual differences. For example, some of the assignment modifications will have to be adapted to the new context. It is also likely that the scope and instructions for assignment modifications be altered to reflect different student levels and course content. There is still debate as to whether metacognitive engagement is domain general (common skills

across all domains) or domain specific (specific skills necessary for different domains) [25]. Thus, the adaptations to indicators and survey methods will relate to difference in context as well as the differences in domain content. As the developmental process of metacognition is understudied in higher education and specifically, engineering, we do not yet know if there will be differences between first- and second-year engineering students. Therefore, piloting of survey methods and indicators will also focus on ensuring that these methods are suitable for different developmental stages.

C. Phase 3

The purpose of this phase is to create resources that can be disseminated to other faculty to support transformational change in undergraduate classrooms, specifically with regard to helping students develop metacognitive abilities, and to provide faculty/instructor training on what metacognition is and how to use these metacognitive teaching interventions. Because our approach in designing interventions is grounded in theories on learning, we expect it to be widely applicable with relevant adaptations for context. Our basic approach to student learning involves a pairing of developing knowledge with practice and intentional feedback [16, 26]. The resources will comprise two sets. The first set will come directly from our research including descriptions of the metacognition interventions and indicators and guidelines for adapting them to different contexts. Because we have intentionally examined two different research sites with specific contextual differences (university and course-specific differences), we will have identified factors in tool adaptation that matter. These resources will facilitate transformation because knowledge of pedagogy alone is not enough; knowing how to make pedagogy work in different settings also matters as has been demonstrated by recent research on transfer of innovations in teaching [e.g., 13, 14, 15]. The second set of tools will be a set of suggestions for developing effective researcher-teacher partnerships. These will emerge from formative and summative reflections generated by all research team participants.

IV. RESULTS

We are currently in the first phase of this project collecting interview and survey data relative to student's metacognitive beliefs and practices. Simultaneously, we are developing the intervention materials including the training videos on metacognitive knowledge and awareness, contextualized classroom modules, and metacognitive assignment modifications to provide opportunities to practice metacognitive regulation.

ACKNOWLEDGMENT

Abstract— A common approach to the problem of predicting students' exam scores has been to base this prediction on the previous educational history of students. In this paper, we present a model that bases this prediction on students' performance on several tasks assigned throughout the duration of the course. In order to build our prediction model, we use data from a semi-automated peer-assessment system implemented in two undergraduate-level computer science courses, where students ask questions about topics discussed in class, answer questions from their peers, and rate answers provided by their peers. We then construct features that are used to build several multiple linear regression models. We use the Root Mean Squared Error (RMSE) of the prediction models to evaluate their performance. Our final model, which has recorded an RMSE of 2.93 for one course and 3.44 for another on predicting grades on a scale of 18 to 30, is built using 14 features that capture various activities of students. Our work has possible implications in the MOOC arena and in similar online course administration systems.

Keywords—automatic assessment; score prediction; peer-assessment;

I. INTRODUCTION

Automated prediction is a technique that has become prevalent in several fields and sectors including education, medicine, biology, politics, and finance. This prevalence is strongly attributed to recent advances in machine learning techniques.

Although the approaches adopted by prediction systems may vary, they all follow the same notion – make an *educated* guess about the value of a parameter by observing what variables affect that parameter and how they have affected it in the past. Ideally, the explanation that this guess is not random but educated is provided by the factoring of historical data about the variables and how they relate to the parameter into the prediction process.

The amount of data needed to make a *good* prediction depends on how complex the parameter being predicted is. That is, it depends on how many variables affect the value of the parameter. In reality, parameters to be predicted are fairly complex and large amounts of data are usually required to build decent prediction systems.

The availability of data does not necessarily guarantee that the prediction will perform well. Modelling the parameter to be predicted by identifying the variables and weighing their impact is a challenging task essential to the realisation of a successful prediction system.

In higher education, such systems have been used to predict the intermediate and final scores of students at different levels. Timely prediction of scores facilitates early intervention to identify students that may require special supervision and can be used to provide students with progress feedback.

Automated score prediction could also have a significant implication in the Massive Open Online Courses (MOOC) arena. Predicting the performance of students could help provide early insight into the attrition rates of courses administered in MOOC format. Such early indication would allow MOOC providers to explore corrective measures accordingly in order to increase the retention rates of their courses, as the majority of today's MOOCs suffer from immense attrition rates [10][18].

Student assessment techniques such as standardised tests and exams are able to obtain information about specific traits of students at a certain point in time. Gathering information about students that could explain their progress requires continuous recording of their activities using more sophisticated techniques. If designed well, such techniques could capture data that explain how students behave, communicate, and participate in learning activities and have the potential to predict how they would perform on end-of-course exams.

One practice that engages students in activities intended to improve their learning by evaluating other students' work is peer-assessment. Topping [24] defines peer-assessment as "...an arrangement in which individuals consider the amount, level, value, worth, quality, or success of the products or outcomes of learning of peers of similar status."

The reliability and validity of peer-assessment as either a formative or summative assessment tool has been studied in detail. Although there is agreement over the perceived values it brings to students and teachers, uncertainties remain regarding its use as an effective practice. A meta-analytic review by Falchikov and Goldfinch [25] and a critical analysis of peer-assessment studies by Topping [26] reveal these uncertainties.

Regardless of these uncertainties, peer-assessment provides a rich platform to gather significant information about students as they engage in assessing the works of their peers. In this study, we use an online peer-assessment framework to gather such information about students, which we then use to build our prediction model. Students participate in online peer-assessment task by submitting questions on pre-specified topics, by answering questions from their peers, and by rating their peers' answers.

In this paper, we present a linear regression model that utilises data generated by the activities of students in two courses to predict their final exam scores. This paper is organised as follows: In section II, we discuss several peer-assessment systems that are currently used in education in order to provide a comparative view of our peer-assessment framework and review previous work in score prediction. We then briefly discuss our peer-assessment framework and describe our prediction model in section III. In section IV, we provide details of the experiments and the results we obtained. We conclude our discussion in section V with a review of our work and our plans for the future.

II. PREVIOUS WORK

A. Peer-Assessment

Although they may differ in the techniques they use or their overall design, all peer-assessment methods involve the practice of having students evaluate the works of their peers. Peer-assessment methods have been in use in education and other institutions for decades. See [13] for a detailed review of peer-assessment tools. Here, we discuss four peer-assessment platforms that we believe are relevant to our work.

PRAISE (Peer Review Assignments Increase Student Experience) is a generic peer assessment tool that has been used in the fields of computer science, accounting and nursing [3]. It has been used in introductory programming courses by students coming from different disciplines. Before distributing assignments, the instructor will specify criteria. Once assignments are distributed, students review details of each assignment and submit their solutions. The system waits for the number of submissions to reach a specified number and assigns review tasks to students. Students then review the solutions of their peers according to the criteria. Once all reviews for a solution are complete, the system checks if all reviewers agree according to the criteria and suggests a mark based on the criteria. If there is a disagreement among reviewers, the system submits the solution to the instructor for moderation. The instructor then needs to decide a mark and confirm the release of the result before a student can see their overall mark for the assignment.

PeerWise is a peer assessment tool, which students use to create multiple-choice questions and answer those created by their peers [4]. When answering a question, students are also required to rate the quality of the question. They also have the option comment on the question. The author of a question may reply to a comment that has been submitted by the student who rated the question.

PeerScholar is another peer-assessment tool that was initially designed for an undergraduate psychology class. It

aims to improve writing and critical thinking skills of students [17]. First, students submit essays. Next, they are required to anonymously assess the works of their peers, after which they have to assign scores between 1 and 10, and write a comment for each of their assessments. Students are also allowed to rate the reviews they have received.

Workshop is a peer-assessment module for the Moodle E-Learning platform that lets students view, grade and assess their work or that of their peers [16]. The instructor coordinates and controls the assessment phases and is able to monitor the involvement of each student in each task. The instructor also has the ability to specify the criteria for computing grades and is also able to give different weights to different questions. The tool also allows assigning separate grades to submission of answers and assessment of submitted answers.

B. Score Prediction

The prediction of certain traits of individuals and groups from data generated by social networks and other platforms has been explored in several sectors. However, the vast majority of studies that relate to prediction of performance of students have had a particular focus on either computer science or computer literacy courses.

One early study conducted by Alspaugh [1] uses test results from three standardised tests – Thurstone Temperament Schedule [21], IBM Programmer Aptitude Test [14], and the Watson-Glaser Critical Thinking Appraisal [22] – and concludes that students who possess second level college calculus skills, have low levels of impulsiveness and sociability, and high reflectiveness have a good aptitude for computer programming.

Several studies have also investigated factors that can be used to predict the final scores of students. Fowler & Gorfeld [7] build a logistic classifier based on students' current GPA, math skills, SAT scores, and students' ages, which classifies students as having high or low aptitude for programming. The model is built using data from 151 students, 122 (81%) of which it classifies correctly.

Evans & Simkin [5] use six outcome variables as measures of computer proficiency – homework scores, scores in a BASIC programming exam with 19 matching questions, scores in a BASIC programming exam with 15 fill-in-the-blank questions, and first and second midterm scores. 49 predictor variables grouped into four categories – demographic, academic, prior computer training and experience, and behavioural – were used in building the models. A stepwise multiple regression model was built for each of the six predicted variables. The performance of these models was reported in terms of the coefficient of determination (R^2), with the model predicting homework scores having the highest value of 0.23.

Wilson and Shrock [23] conducted a study involving 105 students to predict success in an introductory college computer science course by examining twelve factors. Among these, three factors – comfort level, math skills, and attribution to luck for success – were found to be more important in

predicting mid-term scores. The performance of the linear model was reported to have an R^2 value of 0.4443.

As discussed above, most previous work in predicting the performance of students focused on very similar factors for making such predictions. Of these factors, the most common were math skills, high school scores, and standardised test scores.

Recent work has sought to exploit other more latent factors to predict success in computer science courses. Keen & Etzkorn [11] have built a model for predicting the average test scores of students of a computer science course by observing the buzzword density (the ratio of computer science related words to the total number of words) in the teacher's lecture notes. The intuition that higher buzzword density would imply more complex lecture notes and would, as a result, lead to lower average scores was supported by a strong negative correlation of -0.521 between buzzword density and average scores.

A recent study by Fire et al. [6] investigates the impact of interactions among students on their success in computer science courses as well as the correlation between students' scores. The study uses data from 163 students and applies graph theory and social network analysis techniques to predict students' final test scores and final grades. The features used for predicting students' final test scores include personal information features such as assignment scores and students' departments as well as topological features such as students' number of friends in the social network, which is built from homework assignment data and website logs, and friends' scores. Using these data, a single linear regression model is built to explore relationships among students. Another multiple linear regression model with stepwise inclusion is built to predict whether a student would score below 60, the passing mark for the course. The multiple regression model produces an R^2 value of 0.174 and Mean Absolute Error of 10.377.

Performance prediction has also been applied in MOOCs. One study uses students' performance on assignments from the first week together with their activity in the discussion forums and their peer-assessment task completion rate to build two logistic regression models that predict whether students will earn certificates of completion and whether they will achieve distinction, with accuracy levels of 79.6% and 92.6%, respectively [9].

Another study uses student behaviour data in a course administered in a MOOC format to predict whether a student will provide the correct answer for an in-video question at the first attempt [2]. Summary quantities such as the fraction of the video played and the number of pauses are extracted from clickstream data for each video-student pair and used to predict the likelihood of a student correctly answering questions in that video at the first attempt.

Automated prediction in MOOCs has however focused on early prediction of attrition rates from student behaviour. See [12], [19], and [20] for such studies.

III. BUILDING THE PREDICTION MODEL

A. The Peer-Assessment System, Participation, and the Data

The prediction model was built on data that were generated from the activities of students enrolled in two undergraduate level computer programming courses, Informatica Generale I (IG1) and Programmazione II (PR2), at the University of Trento in Italy. The central mechanism of the data collection required students to participate in a set of peer-based online homework activities throughout the course.

The online homework activities were carried out using a web-based peer-assessment platform that we built specifically for this purpose. The homework activities included three main tasks – *Ask A Question*, *Answer A Question*, and *Rate Answers*. Every week during the course, students would ask questions about topics that had been discussed in class, answer other students' questions, and vote for answers submitted by other students. They would also rate the levels of interestingness, relevance, and difficulty of questions.

The week starts with the teacher assigning the 'Ask A Question' task to all students, in which students submit questions regarding topics specified by the teacher that had already been discussed in class the previous week. After the deadline for completing the task has passed, the teacher filters the questions and selects a subset that will be used in the next task. The peer-assessment process is designed to obtain at least four answers to each question. Hence, the system recommends the number of questions to be selected by the teacher, taking into account the number of students participating.

The teacher then assigns the 'Answer A Question' task to all students. The system handles random assignments of the selected questions. It also guarantees that students will not be asked to answer their own questions and that each student is assigned only one question. When submitting their answers, students rate the difficulty, relevance, and interestingness of the questions on a scale of 1 (lowest) to 5 (highest).

The last task of the cycle is the 'Rate Answers' task, which asks students to rate the correctness of answers provided by students for the questions that had been selected on a scale of 0 (incorrect) to 5 (excellent). During assignment of the tasks, the system guarantees that the student that had asked the question is asked to rate the answers for their question. The system also guarantees that each question-answer set is assigned to at least four students and that the assignment of the tasks remains random for those who had not asked the questions that were selected by the teacher.

The web-based peer-assessment system was accessible through the Internet and students could complete their tasks at a location of their choice. Anonymity was preserved as students did not know whose question they had answered and whose answer they had rated or vice versa. All student activity including time of completion of tasks was logged by the system. Details of the design and implementation of an earlier version of the peer-assessment system are discussed in [15].

Because participation in the online peer-assessment activities was optional, some students did not participate at all while others opted out at several points during the course.

The university's exam policy permits students to withdraw from an exam without having their work assessed. Usually, students who expect to score lower than the minimum passing mark, 18 out of 30, either withdraw from or do not sit the exam, which, depending on the course, was either oral or written.

Although it is still possible to fail an exam, all students whose data were used to build the prediction model had passed their exams. The implication of this is that the model could not predict grades below 18 and was not able to predict dropping out. It is possible that future editions of the courses will record failing students, whose data can then be used to train the model to make such predictions.

Students also have the option to sit an exam in any of the five sessions available in an academic year. Therefore, although some students participated in the online peer-assessment activities, their final grades were not available as they had not sat their exams at the time of this experiment.

Consequently, although a total of over 400 students participated in the online homework activities for the two courses together, data from only 206 students were used in our experiment.

B. Preliminary Investigation

One of the online peer-assessment tasks requires students to evaluate a set of answers provided by other students for a question by assigning votes to the answers. At the end of the course, the number of votes a student has earned for all their answers will, among other measures of activity, constitute the overall degree of performance of the student in the online homework activities.

An intuitive approach to predicting the final scores of students using such data would be to explore the relationship between the number of votes a student has earned for their answers throughout the course and their final exam score.

This final exam score is represented as a whole number ranging from 18 to 30. We were not certain about finding a strong relationship, however, as these votes are assigned by students themselves and may, as a result, be inconsistent and inaccurate due to several factors such as inexperience of students in evaluating answers. A preliminary investigation of the existence of such a relationship and its strength would then be necessary to address this uncertainty.

We carried out this investigation by clustering students according to the number of votes they earned, which ranged from 0 to 21, and by computing the average final score for each cluster. We observed a rather weak relationship. We found that a linear fit hardly captured any relationship and that, although a better fit, a fourth degree polynomial was not an ideal model either. Attempting to model this relationship with polynomials of higher degrees would have eventually led to over-fitting.

This led us to conclude that student votes alone would not be strong predictors of final exam scores. We therefore decided to proceed with exploring more parameters that would explain the performance of students such as the amount of tasks they completed and the perceived level of difficulty of the questions they provided answers for.

C. Features of the Prediction Model

Our initial investigation explored 7 parameters in order to build a linear regression model. 16 additional parameters, most of which were computed from the initial 7 parameters, were later used to create more models. In favour of brevity, only a list of the parameters of the final model is presented below.

Tasks Assigned (TA) – The number of tasks that were assigned to the student

Tasks Completed (TC) – The number of tasks that the student completed

Questions Asked (QAS) – The number of 'Ask a Question' tasks the student completed

Questions Answered (QAN) – The number of 'Answer a Question' tasks the student completed

Votes Cast (VC) – The number of 'Rate Answers' tasks the student completed

Questions picked for answering (QP) – The number of the student's questions that were selected by the teacher to be used in 'Answer A Question' tasks

Votes Earned (VE) – The number of votes the student earned for their answers

Votes Earned Total Difficulty (VED) – The sum of the products of the votes earned for an answer and the difficulty level of the question, as rated by students themselves, for all answers submitted by the student

Votes Earned Total Relevance (VER) – The sum of the products of the votes earned for an answer and the relevance level of the question, as rated by students themselves, for all answers submitted by the student

Votes Earned Total Interestingness (VEI) – The sum of the products of the votes earned for an answer and the interestingness level of the question, as rated by students themselves, for all answers submitted by the student

Selected Q total difficulty (SQD) – The sum of the difficulty levels of the student's questions, as rated by students themselves, which were selected to be used in subsequent tasks

Selected Q total relevance (SQR) – The sum of the relevance levels of the student's questions, as rated by students themselves, which were selected to be used in subsequent tasks

Selected Q total interestingness (SQI) – The sum of the interestingness levels of the student's questions, as rated by students themselves, which were selected to be used in subsequent tasks

Number of Attempts (NA) – The number of attempts the student made to pass the course

D. The Prediction Model

The data were normalised using min-max normalisation, which converts the values of each parameter into a value between 0 and 1. We used the Weka data-mining toolkit [8] to build three sets of linear regression models – one for each course and an additional set using the combined dataset from both courses. First, we built models using the initial 7 features. We then built more complex models by adding a set of the computed features step by step. As a result, 3 sets of 7 linear regression models each were built.

Each model was tested using 10-fold cross-validation. The Root Mean Squared Error (RMSE) of the models was used for performance evaluation.

The model with the least RMSE was built using the 14 features discussed in III.C. The final score prediction model m is given by:

$$m(i) = C^T S_i + 27.8967 \quad (1)$$

, where S is a 14-by- n matrix built from the 14 parameter values for n students, S_i is the i^{th} column in S representing student i , C^T is the transpose of the column vector C given by,

$$C = \begin{bmatrix} -3.98 \\ -0.32 \\ 0.63 \\ 0.68 \\ -2.16 \\ 0.10 \\ 0.71 \\ 22.92 \\ -16.29 \\ -5.02 \\ 4.54 \\ -3.71 \\ 0 \\ -4.42 \end{bmatrix}, \text{ and } S_i = \begin{bmatrix} TAI \\ TCi \\ QASi \\ QANi \\ VCI \\ QPi \\ VEi \\ VEDI \\ VERi \\ VEIi \\ SQDi \\ SQRi \\ SQIi \\ NAI \end{bmatrix}, \text{ for } i = 1, \dots, n.$$

As can be observed from the column vector C , the model rewards students for earning votes for answering difficult questions as well as for asking challenging questions.

We believe that the two features that capture this information, VED and SQD, are good discriminators among students of different performance levels. This characteristic of the model is also coherent with the manner in which a teacher would award points to students.

I. EXPERIMENTS AND RESULTS

A. Testing with Unseen Data

The final model was built on data from the IG1 course only. This provided us with the opportunity to test how the model

would perform on data coming from another course. We thus tested the model with 101 instances from the PR2 course. The RMSE was found to be **3.44**. This result is encouraging, taking into account the fact that the test data come from a different course. Although the levels of the two courses were different and were attended by different groups of students, the prediction errors of the system were comparable when predicting performance of students attending the PR2 course using data from the IG1 course.

B. Is the Prediction any Better than Random Guessing?

In order to determine if our prediction model outperformed random assignment techniques, we developed several mechanisms of random guessing. First, we assigned a grade to each of the 206 students by randomly selecting a number from the valid range of grades, 18 to 30. We performed this random assignment 10000 times and evaluated the average RMSE of these assignments. We performed this grade assignment for students of both courses IG1 and PR2. The average RMSE for this technique was computed as **5.04**.

We then performed a systematic random assignment of grades by sampling from a prior distribution of grades from previous editions of the courses. As shown in Fig. 1, the distributions of grades for the two courses are not similar. We therefore decided to sample grades from separate prior distributions, one for each course.

After exploring several probability distributions, we found that the best possible fits for both courses were kernel distributions. Fig. 2 shows these distributions plotted against the probability density function plots of the two courses.

For each course we sampled from its respective distribution and assigned grades to students. We performed this assignment 10000 times, averaged the RMSEs of all assignments, and obtained an average RMSE of **4.94** for IG1 and **5.01** for PR2.

Finally, we sampled from the prior distribution of grades by assigning an index to each grade and by randomly selecting a number from these indices, which formed a uniform distribution. This would allow us to include instances which would not be captured by the kernel fits shown in Fig. 2.

We performed this sampling for the two courses separately. As before, we performed the random assignment 10000 times and averaged the RMSEs, obtaining an average RMSE of **4.89** for IG1 and **4.96** for PR2. Tables I and II provide a comparison of the random assignment techniques and our model. As our model is tested with the respective data for each course, there is a variation, albeit slight, in its performance on data from the two courses.

The histograms in Fig. 3 show the prediction errors. In an ideal prediction model, errors would be significantly low. Hence, the histogram of such a model would have a slender shape, with its peak near the centre of the horizontal axis.

Although our model outperforms all random assignment techniques, its strength is evidenced in how it outperforms assignment techniques even when random assignment is aided by information from previous editions of the courses to reduce the frequency of assigning grades that were not common. The

strength of our model is also reflected by the fact that none of the 10000 assignments for each technique scored an RMSE lower than that of the model.

TABLE I. EVALUATION OF PREDICTION METHODS FOR IG1

Prediction Method	RMSE
Sampling from a uniform distribution	5.04
Sampling from a kernel distribution	4.94
Sampling from previous scores directly	4.89
Linear regression model	2.93

TABLE II. EVALUATION OF PREDICTION METHODS FOR PR2

Prediction Method	RMSE
Sampling from a uniform distribution	5.04
Sampling from a kernel distribution	5.01
Sampling from previous scores directly	4.96
Linear regression model	3.44

II. FROM PREDICTING SCORES TO PREDICTING GRADES

It would be interesting for teachers to group students into several categories based on their performance. While scoring on a scale of 18 to 30 may be too broad a range to provide such information, grades, numerical or otherwise, provide this functionality. Such grading systems may also be fine-tuned to decide the granularity of these groups.

Here, we transform the scores of students on an 18 to 30 scale to numerical grades on a scale much similar to the A to F grading system. Numerical grades range from 0 to 4, with a grade of 4 corresponding to an A, 3 to a B, and so on. Scores are converted to numerical grades by assigning a single grade to a range of scores. Hence, scores 28 to 30 will be assigned a grade of 4, 25 to 27 a grade of 3, 22 to 24 a grade of 2, 18 to 21 a grade of 1 and those below 18 a grade of 0.

In order to perform this experiment, we used the same features explained in section III.C, to build a new model that predicts the numerical grade of a student using the newly transformed data. As before, we used 10-fold cross-validation to evaluate the performance of our model. The model that was built using data from the IG1 course performed better than that built on the PR2 course, albeit slightly. We therefore report the performance of the winning model only.

Although it might seem that this way of predicting grades is a 5-class classification problem, the fact that the input variables assume continuous values makes the classification task impossible. Indeed, classifiers such as Naïve Bayes Classifier, Decision Trees, and Logistic Regression have prohibitively poor performance.

Figure 1. Distributions of grades for IG1 (left) and PR2 (right)

Figure 3. Histograms of the prediction errors for IG1 (left) and PR2 (right)

Figure 2. Histograms of the final scores of students of IG1 (left) and PR2 (right) plotted against kernel distributions

Figure 4. Histograms of the grade prediction errors for IG1 (left) and PR2 (right)

Linear regression, on the other hand, can handle such data as the grades are still numerical. However, the prediction values are continuous and do not necessarily map into one of the five grades. We therefore use a function that rounds prediction values to the nearest integer to make the prediction valid. As a result, the RMSE of the rounded predictions, which is slightly higher than the RMSE computed on the actual predictions, is reported.

The winning model scored a 10-fold cross-validation RMSE of **1.12**, a significant decrease from the previous value of **2.93** when predicting numerical scores. When tested on unseen data from the PR2 course, the model scored a much lower RMSE of **1.44** than the previous score of **3.44**. The prediction errors of this model for both courses are depicted in the histograms in Fig. 4.

In the following tables, we report comparisons between our model and baselines constructed in the exact manner as before.

Here, we sample from normal distributions instead of kernel distributions as they fit better the grade distributions for both courses.

TABLE III. EVALUATION OF GRADE PREDICTION METHODS FOR IG1

Prediction Method	RMSE
Sampling from a uniform distribution	1.83
Sampling from a normal distribution	1.68
Sampling from previous grades directly	1.53
Linear regression model	1.12

TABLE IV. EVALUATION OF GRADE PREDICTION METHODS FOR PR2

Prediction Method	RMSE
Sampling from a uniform distribution	1.86
Sampling from a normal distribution	1.65
Sampling from previous grades directly	1.53
Linear regression model	1.44

Table V shows the performance of the grade predictor in terms of accuracies. For IG1, 83% of its predictions fall within the range 0 to 1 grade point difference whereas for PR2, it performs less, with 63% of its predictions falling in the same range.

TABLE V. PREDICTION ACCURACIES OF THE MODEL

Course	Exact Prediction	Within 1 Grade Point	Within 2 Grade Points
IG1	0.30	0.83	0.99
PR2	0.24	0.63	0.97

The grade prediction model m is given by:

$$m(i) = C^T S_i + 5.75 \quad (2)$$

, where S is a 14-by- n matrix built from the 14 parameter values for n students, S_i is the i^{th} column in S representing student i , C^T is the transpose of the column vector C given by,

$$C = \begin{bmatrix} -0.16 \\ 0 \\ 0.06 \\ -0.02 \\ -0.01 \\ 0.05 \\ -0.47 \\ 6.29 \\ -4.95 \\ 0.16 \\ 2.10 \\ 1.55 \\ -3.53 \\ -0.30 \end{bmatrix}, \text{ and } S_i = \begin{bmatrix} TAi \\ TCi \\ QASi \\ QANi \\ VCi \\ QPi \\ VEi \\ VEDi \\ VERi \\ VELi \\ SQDi \\ SQRi \\ SQLi \\ NAI \end{bmatrix}, \text{ for } i = 1, \dots, n.$$

Similar to the previous model, this model rewards students who earn votes for answering questions that are regarded as difficult and interesting, as well as for asking questions which are challenging and relevant.

III. DISCUSSION AND CONCLUSIONS

Performance prediction in educational activities has been studied before. Most previous studies, however, were limited to analysing previous performance information of students to make such predictions. Most of this information came from high school level performance data and college entrance examination scores.

Today, students themselves generate significant amounts of data throughout their studies. The major goal of our work was to take advantage of such information in order to predict student performance. In this paper, we presented a linear regression model for predicting final exam scores of students by observing data that are generated from their online course activities. We implemented our web-based peer-assessment system in two courses and used the data from the system to build our model. The preliminary results of our prediction model are encouraging.

We believe the techniques and settings we used to generate data about students and make predictions about their performance are novel. Although work in predicting student success has recently gained more focus, most of the attention has been directed towards predicting attrition rates in courses administered online, specifically MOOCs. Studies in close supervision of students and early detection of at-risk individuals are therefore in order and we believe that predicting student performance in higher education settings and in mandatory courses at the undergraduate level is an important part of such studies.

US-style grading techniques help group students into several performance groups and predicting grades instead of scores on longer ranges aids in this aspect. We therefore built a similar regression model for predicting the grades of students. The prediction errors are much lesser for this model and it can predict, within a grade point range, the grades of the large majority of students, as seen in table V.

In the experiments we conducted, prediction of scores was made after courses had ended and before students had sat final exams. However, prediction is only effective when it is done in a timely manner and is no good if it provides important information about students at a time when little can be changed to help them improve. In an upcoming study, we intend to apply the prediction model discussed in this work to student performance data as it is generated in order to make predictions on a weekly basis to facilitate early detection and supervision of students that may require special attention.

As more and more higher education institutions make their courses available for learners through platforms such as Massive Open Online Courses (MOOCs), the immense amount of data generated make it possible to provide continuous and automated assessment of student progress.

The peer-assessment framework that we use is complementary to traditional classroom lessons. Nonetheless, the prediction system is not tied to the pedagogy. This makes it easy to extend this approach of student supervision and assessment to non-traditional learning environments such as flipped classrooms.

We are hopeful that, although the framework we utilised in this study is not very similar to MOOCs, the way we built a prediction model on top of the data can be adopted by MOOCs and similar platforms. There are already studies that use such data to predict attrition rates of courses administered in a MOOC format but we have demonstrated in this study that it is possible to go further and learn students' trends as they participate in courses to provide timely supervision from such rich data.

A Quantitative Case Study in Engineering of the Efficacy of Quality Cheat-sheets

Yang Song, David Thunte
Department of Computer Science
NC State University
Raleigh, U.S.
{ysong8, djthuent}@ncsu.edu

Abstract—Although authorized cheat-sheets have been widely accepted as a common examination format, their effectiveness is still being questioned. Some researchers believe authorized cheat-sheets are more like a "crutch" and have no effect on students' performance. In this study, we created a cheat-sheet rating scheme to evaluate the quality of authorized cheat-sheets collected with each exam (N=155) and investigated the effect of cheat-sheet quality on students' grades. This study reveals that 1) the average cheat-sheet's quality varies significantly between those students who scored in the top half of the class versus those whose score was in the lower half of the class; 2) students' grades are highly related to their cheat-sheet quality and 3) if students manage to improve the quality of their cheat-sheets from one examination to the next, their grades tend to improve for that subsequent examination.

Keywords—authorized cheat-sheet; examination; cheat-sheet quality

I. INTRODUCTION

The three main categories of examinations based on resources students have access to during exams are closed-book exams, open-book exams (sometimes even open-everything, including the Internet) and exams with authorized cheat-sheets. An authorized cheat-sheet (also known as "authorized crib sheet") refers to notes that test takers are allowed to make beforehand and use during exams.

A. Criticism on open-book exams

In 1951, Tussing suggested that open-book exams are a better exam format than closed-book because it 1) reduces anxiety 2) emphasizes reasoning instead of memorization and 3) reduces cheating [1].

However, in later research, open-book exams receive more criticism than praise. First, the open-book policy can be a hindrance for students' preparation before exams. Having access to teaching material can make the students take the exams less seriously than they do for closed-book exams [1]. Second, this policy does not help students, particularly weaker students learn better. Previous research found that the students who performed poorly in the closed-book exams tend to refer to the teaching material more in the open-book exams, and this does not help them perform better [2]. This is especially true for exams requiring the full period to complete.

B. Exams with authorized cheat-sheets

A fundamental reason that open-book exams do not work well is that it allows students to refer to "free" extra material that they have never assimilated. Authorized cheat-sheet policies help students focus on the higher level learning. Authorized cheat-sheets should always include restrictions such as the size of the cheat-sheets and they must be hand-written by that student. These restrictions are intended to force students to separate the essential and less important material and to, at least, become familiar with the material as they write it. In this process, students need to read through the appropriate learning material, process information actively, select and organized the cheat-sheet content [3], [4].

Exams with cheat-sheets do receive some criticism similar to that for open-book exams. For example, students may study less comprehensively [5]. Dickson and Bauer also believe that when students create authorized cheat-sheets, they do not learn the content, instead, they depend on cheat-sheets during exams [5].

In Dickson and Miller's 2005 work, they surveyed undergraduate students who used authorized cheat-sheets for multiple-choice exams. They found fewer students used cheat-sheets as the semester progressed and students only thought the cheat-sheets were useful as memory aids for low level questions. In addition, they stated cheat-sheets made fewer than half of the students less anxious about exams, and the cheat-sheet did not improve students' performance on the exams [6]. However, in 2007, Erbe claimed that cheat-sheets do have the function to both increase learning and reduce test anxiety [7]. Pedagogically it does appear reasonable that cheat-sheets would be less useful for multiple-choice exams since these exams are less likely to involve more complex ideas and reasoning for which the cheat-sheet could provide the basis.

Another recent work (2012) not in favor of authorized cheat-sheets is Mathew's [8]. Mathew reported that the students tend to overestimate the helpfulness of cheat-sheets and do not perform any better in exams using cheat-sheets than open-book. This conclusion echoes Dickson and Bauer's idea that the cheat-sheets are more of a "crutch". One can easily argue, however, that the process of creating cheat-sheets requires the student to review the material and at least become aware of key components of it. Hence, the students will learn more using cheat-sheets than they do in the open-book category. This aspect of cheat-sheets is independent of the exam scores received. We will not pursue this avenue of

research but only mention it as an added benefit of cheat-sheets exams over open-book exams.

Although researchers reached different conclusions based on their own experiments, we found that they used different courses, exams designs and dissimilar student populations. Therefore, it is hard to draw a conclusion on the efficacy of cheat-sheets from the existing publications. Also few works considered the quality of cheat-sheets (see Table I).

In our study, we consider the quality of students' cheat-sheets and try to answer the following questions:

- What feature(s) make cheat-sheets good?
- What group(s) of students make better cheat-sheets?
- Do students who create good cheat-sheets perform better than students who do not?
- Do students who improve their cheat-sheet quality also improve their examination performance?
- Are the top students' performances more related to cheat-sheet quality than that of the lower students?

II. BACKGROUND AND METHODOLOGY

We collected data including cheat-sheets and exam grades from two sections of a 400 (senior) level computer science networking course at North Carolina State University.

A. Class setting

A total of 59 students were evaluated in this study. Those sections were taught in consecutive semesters by the same instructor and TA. The instructor and the TA had previously worked together for three semesters for one section of the exact same undergraduate networking course and three graduate networking classes. The undergraduate and the graduate classes are taught at significantly different levels. The graduate courses are not considered in this study. The settings of the two sections for this study were essentially the same. Each class had two midterm exams and a final exam. Each midterm exam had approximately 20 questions evenly split between computation, explanation, and more subtle why problems. The midterm exams were allocated 90 minutes

and the final exam 180 minutes. The final was comprehensive with slightly over 50% new material and a total of 30 questions. The distribution of content for the final was similar to the midterms but with a little more emphasis on the subtle why problems. The computation questions reflected homework questions, but were significantly different. The exams were designed to use the full exam periods. For each exam, students were allowed (but not required) to create their own signed hand-written single-sided $8\frac{1}{2} \times 11$ cheat-sheet. Student were allowed one cheat-sheet for each exam, and one for the comprehensive final. They could and did bring their midterm cheat-sheets plus a new one for the final. No cheat-sheet instruction or training was given to students. Therefore, students are free to choose the cheat-sheets content.

All midterm cheat-sheets were submitted with the exam and were returned with the exam papers. We marked all the cheat-sheets with special pens so that students could not make a new one if they lost their cheat-sheet(s) or did not have one in a former exam. No backfill of earlier cheat-sheets was allowed. This was also enforced by our cheat-sheet markings. Students submitted all cheat-sheets with the final exam, but we did not return final exams or cheat-sheets for the final. The exams were of comparable difficulty but, for consistency, we normalized exam grades by scaling to the median of midterm exam 1 in session 1 for this research. For example, the median grade for midterm exam 1 in session 1 was 87 and the median grade for midterm exam 2 in session 1 was 85. To make the grades comparable, we modified the grades for midterm exam 2 in session 1 by multiplying the grades with $87/85$.

B. Cheat-sheet rating scheme

In the previous research, only two authors tried to rate or code the students' cheat-sheets. Mathew rated the students' cheat-sheets on organization and richness based on a 10 point scale [8]. However, neither justification nor a detailed rating scheme was given. In de Raadt's work, seven features in two categories were tagged, but the coding was done in a binary approach and appears to be over simplified [9]. We found, for example, that the density of the cheat-sheets grouped around the mean of "moderately dense" but there were numerous outliers at the extremes from nearly empty to essentially no space left at all. There was no reasonable way to represent this with binary encoding as required in de Raadt's work.

Before we devised our rating scheme, we reviewed 20 students' cheat-sheets (namely, all the students in midterm 1 of section 2) and identified a set of features which varied significantly between students:

- density
- organization
- number of sample answers
- number of formulas
- number of graph representations.

Based on these observations, we tagged these five features first. Density was tagged in the Likert Scale, namely, from "very sparse" to "very dense". However, we

TABLE I. COURSE LEVELS AND DATA COLLECTION ON RELATED TOPIC IN RECENT 10 YEARS

Authors	Course Level	Data Collection
Mathew [8]	Undergraduate psychology/ statistics	Student survey, exam grades
de Raadt [9]	Undergraduate programming	Cheat-sheet quality, exam grades
Butler & Crouch [10]	Undergraduate statistics	Student survey
Dickson & Bauer [5]	Undergraduate psychology	Exam grades
Erbe [7]	Statistics, research methods, methods of teaching mathematics, and computer use in education	None
Stangl, Banks, House and Reiter [11]	Undergraduate statistic	Exam grades
Dickson & Bauer [6]	Undergraduate psychology	Student survey
Skidmore & Aagaard [12]	Undergraduate teacher education	Exam grades

did not use the Likert Scale to tag organization because it is more subjective. Instead, we rated it "well organized", "moderately organized" or "poorly organized". For the remaining three features, we counted the number of sample answers, formulas, and graphs.

When we rated the cheat-sheets density, we assign 1 to "very dense" and "very sparse", 2 for "somewhat dense" and "somewhat sparse", and 3 for "moderate density". The reason is that we offered larger cheat-sheets (compared with Dickson and Miller's 5×8 inches in [6]) and students do not generally need to write down complete information if they have good understanding of the material. Students with a solid grasp of the topics tend to write outlines of topics and methods rather than a complete discourse. Another reason that we do not believe dense cheat-sheets indicate a good understanding of the course material is that at one time the teaching staff allowed printed cheat-sheets. Extremely dense cheat-sheets were observed multiple times and, in general, the instructor observed that students with very dense cheat-sheets unfortunately, performed poorly on the exam. The result of this experience has been to require all cheat-sheets to be hand-written in the student's own hand and signed. In discussions with students with these dense cheat-sheets, they indicated that they felt they were not able to get prepared properly for the exam and the cheat-sheets were considered as somewhat desperate final attempt to get the material into a form where it could be used on the exam. However, without enough understanding, the dense cheat-sheets were not terribly helpful and during exams, the students spent considerable time searching for information (one of them even brought a magnifying glass to the exam) and were not able to complete the exams. We also argue that a very sparse cheat-sheet indicates either the student did not have enough time to prepare for the exam, or did not have an adequate idea of what to write down. The instructors regularly tell the students they need to prioritize the material that is included on the cheat-sheets and this should be done well ahead of the exam and, for most part, as the material is presented. We have observed over many years a few, very few, cases where a student did not prepare a cheat-sheet or only used cheat-sheets with limited content but they still did very well on the exam.

We assign 1, 2, and 3 to "poorly-organized," "moderately organized" and "well organized" cheat-sheets respectively. The reason for this rating is a well-organized cheat-sheet indicates that the student has a clear idea on how to effectively organize the content to make the cheat-sheet useful for exams. Conversely, a poorly organized cheat-sheet indicates that student does not have a clear plan on what or how much material to write on the cheat-sheet. A well organized cheat-sheet can significantly improve access to the material on it during the exam and the opposite is true for a poorly organized cheat-sheet.

A cheat-sheet receives a "number of sample answers" score of -1 if it contains more than twice the median number of sample answers, otherwise it receive a -0. In the cheat-sheet review phase we found the students who wrote down many sample answers performed poorly. In this class the students had seven homework assignments with a total of 67

questions and most of these had multiple parts. We provided answer keys for the homework totaling 38 pages. No student could possibly obtain adequate coverage of the material by copying homework answers or previous test solutions. Hence, they would have limited coverage of the material and could not do well using this as a basis for their exam. Also no questions were ever repeated from homework or previous exams. Thus we can easily support our observation that extensive copying of answers is not beneficial. Please note that this approach also affects density as well and provides additional rationale that a dense cheat-sheet is not usually a good cheat-sheet. The copying of answers scoring and results is similar to de Raadt's finding [9].

Similarly, cheat-sheets which contained more than twice of the median number of formulas and graph representations received -1 on those two features. One of the reasons that the instructor first used cheat-sheets was to reduce the stress on students to remember key formulas and initially started with 3x5 inch cards. This was appreciated and successful and the students requested more space. However, we argue that students with a good understanding of the material should not and do not need to refer to the *basic* formulas. If a student uses homework answer keys as critical cheat-sheet material, they get many and too many formulas. Indeed, at least half of these formulas for the homework are considered simplistic (only 2 or 3 notations, limited log, power or square root, etc.) and intuitive (e.g. round trip time equals twice the one way trip time, $\log_{10} = 1$, etc.). We understand that students need the important formulas, but too many formulas indicates a lack of preparation, lack of confidence and can be an extra burden on finding information. If the student looks up every basic formula used throughout the exam (whether they needed to or not) they will frequently not have time to complete the exam.

We also give -1 to the cheat-sheets when the number of complete graph representations was more than twice the median for similar reasons that were used for the number of formulas. Among 67 homework questions, approximately 20 included graph representations. When one includes the graphs from the courses slides and the text we have well over two hundred graphs. This means that if a student uses the homework answers as key learning material, they may have 20+ graph representations, which take long time to draw, leave limited space for other content and each representation provides narrow knowledge coverage. If the graph representation is very modest in size and is used as a memory mnemonic, then in most cases, we do not consider it complete and is not counted.

Students without a cheat-sheet are assigned a -2. This was a very unusual case and the most common reason for it was that the student forgot to bring the cheat-sheet to the exam.

For each exam, we divided the students into two groups: more competitive students (MCS) if their grades are at least at or above the median score and less competitive students (LCS) if their grades are below the median score. We used and rated cheat-sheet scores from 59 students and 155 cheat-sheets.

III. COMPARISON OF THE MCS AND LCS GROUPS CHEAT-SHEET QUALITY

We want to determine if the quality of the cheat-sheets differs for the MCS and LCS groups.

A. Hypotheses

We used the Student's t-test for independent samples. Our hypotheses are:

H0: there is no significant difference on the cheat-sheet scores between MCS and LCS groups.

H1: there is significant difference on the cheat-sheet scores between MCS and LCS groups.

B. Result analysis

From the data analysis we find all the p-values are smaller than 1%, indicating that we are at least 99% confident that the population of the cheat-sheet scores of MCS group is different than the population of the cheat-sheet scores of LCS group (see Table II). Those p-values, together with the average cheat scores, indicate that the students who performed better on exams were better at creating high quality cheat-sheets.

IV. COMPARISON OF CHEAT-SHEET QUALITY AND EXAM PERFORMANCE

Our second analysis looked at the correlation between the quality of cheat-sheets and students' grades. Ideally, if a student spends enough time preparing for an exam and has good understanding of the material, the cheat-sheet should be of good quality and the student should get a good grade as well.

A. Hypotheses

We used the correlation coefficient test and linear regression analysis to test the relation between students' grades and their cheat-sheet quality. Our hypotheses are:

H0: there is no relationship between the scores of the students' cheat-sheets and the students' exam grades.

H1: there is a positive relationship between the scores of the students' cheat-sheets and the students' exam grades.

B. Result analysis

We performed correlation coefficient analysis between students' grades and their cheat-sheet scores for each exam. The results are shown in Table III.

There is a significant correlation between students' grades and the students' cheat-sheet scores because the p-values are less than 0.01. We also observe that the correlation becomes stronger for the final exam than for the midterms which means the students got more experienced creating good cheat-sheets through the semester and they got rewarded for doing that. This indicates that the cheat-sheet creation process may help students review the material and organize it, and the cheat-sheets later served as a helpful aid in the exams.

We also did linear regression analysis between students' exam grades and cheat-sheet scores (see Table IV). We found the highest correlation between the students' grades on the final exam and their cheat-sheet scores. The Rsquare is

the highest and the slope is more than five in final, which means that if a student's cheat-sheet score was one point more than average, the grade in the final exam was likely to be five points more than the average. The linear regression analysis for the final exam is shown in Fig. 1^a.

V. COMPARISON OF CHEAT-SHEET QUALITY IMPROVEMENT AND EXAM PERFORMANCE IMPROVEMENT

Our third analysis looked into the students' progress across the three exams and the relationship to the change on cheat-sheet quality.

A. Hypotheses

We used the correlation coefficient test and linear regression analysis to test the relationship between students' grade improvement and their cheat-sheet quality improvement where we understand improvement can be positive or negative. We compared 1) improvement between midterm 1 and midterm 2; 2) improvement between midterm 2 and the final exam; 3) improvement between average of midterms and final exam for each student with the cheat-sheet score change. Our hypotheses are:

TABLE II. COMPARISON ON CHEAT-SHEET SCORES FOR DIFFERENT STUDENT GROUPS

Group	Avg. Cheat-Sheet Score: Midterm 1	Avg. Cheat-Sheet Score: Midterm 2	Avg. Cheat-Sheet Score: Final
MCS group	3.1325	3.5438	4.0909
LCS group	1.000	2.1785	1.9231
p-value	0.0006	0.0059	<0.0001
Overall p-value	0.0003		

TABLE III. CORRELATION COEFFICIENT ANALYSIS BETWEEN STUDENTS' GRADES AND CHEAT-SHEET SCORES

Exam	Correlation Coefficient	P-value
Midterm 1	0.4661	0.0002
Midterm 2	0.3353	0.0094
Final	0.6404	<0.0001
Overall	0.4819	<0.0001

TABLE IV. LINEAR REGRESSION TEST ON STUDENTS' GRADES AND CHEAT-SHEET SCORES

Exam	Rsquare	Slope
Midterm 1	0.2172	2.2735
Midterm 2	0.1124	2.1586
Final	0.4102	5.2510
Overall	0.2323	3.0124

a. It is possible that the grades are greater than 100 because of the normalization.

Figure 1. Linear regression result between student's grades and cheat-sheet scores on final exam

H0: there is no relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

H1: there is relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

We also looked into the MCS and LCS groups to see if their grade improvements are similarly related to cheat-sheet score improvements.

H0a: for the MCS group, there is no relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

H1a: for the MCS group, there is relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

H0b: for the LCS group, there is no relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

H1b: for the LCS group, there is relationship between the improvement of scores on students' cheat-sheets and the improvement of students' exam grades.

B. Result analysis

We performed correlation coefficient analysis between the students' grade improvement and their cheat-sheet score improvement between each test. The results, shown in Table V, all have the p-values less than 1%.

This indicates that the students' grade improvement is related to their cheat-sheet quality improvement. This again confirms that the cheat-sheet creation process is not just forcing students to write down course content without understanding but they either understood the content when creating the cheat-sheet or they figured out what is important to have on the cheat-sheets and know how they can use the content to help them during the exams. The results for the linear regression test is in Table VI and Fig. 2.

We separated our students into the MCS and LCS groups and did the same correlation coefficient analysis again. We found that with all the exams together, there is significant correlation between grade improvements and cheat-sheet quality improvement for both MCS group and LCS group. However, the correlation is stronger for LCS group. This indicates that for students who did not perform well in an early exam, we are more confident that if they prepared a better cheat-sheet, their grades will be better in later exam. This becomes a very strong argument for the use of cheat-

sheets since it helps the weaker students improve more and gives them a specific technique for doing so.

Table VIII shows the result of the linear regression between students' grade improvement and cheat-sheet quality improvement. The slope for LCS group is larger than that for MCS group. This suggests that if two students both improved 1 point on their cheat-sheet score, the LCS student would have a higher probability of a larger grade improvement on that exam as shown in the scatter plots in Fig. 3.

TABLE V. CORRELATION COEFFICIENT ANALYSIS BETWEEN STUDENTS' GRADE IMPROVEMENT AND CHEAT-SHEET SCORE IMPROVEMENT

VI. CONCLUSIONS

In this study we use data analysis to show for an undergraduate engineering course which allows students to use single page hand-written cheat-sheets:

- on average, the students who performed better in exams created better cheat-sheets;
- there is a positive correlation between the quality of cheat-sheets and students' grades;
- there is a positive correlation, sequentially across exams, between the improvement on cheat-sheet quality and the improvement on students' grades, and
- this correlation is stronger for the students who did not perform as well in previous exams.

These findings show that cheat-sheets do have a positive impact on students' performance in exams. This echoes de Raadt's work [9] and provides numerical evidence for Erbe [7]. Cheat-sheets help the weaker students improve more over the course of the semester than the stronger students. This is obviously a very desirable outcome.

These findings are based on a cheat-sheet rating scheme which we created after reviewing part of the students' cheat-sheets. Based on our observations, a good cheat-sheet should be of medium density, well organized and with a limited number of sample answers, formulas and graph representations. However, it is hard for students with poor understanding to create this kind of quality cheat-sheets. Instead, when the students manage to learn the course material well, the cheat-sheet quality can be improved naturally, and the improvement is likely to happen to their grades too. This has been proven to be especially true for students who did not perform well previously.

A. Suggestions

Based on this research, we suggest that if instructors allow students to use authorized cheat-sheets, students should be advised to:

- take cheat-sheet creation seriously, especially for the ones who do not perform well previously
- create hand-written cheat-sheets
- avoid trying to write down information exhaustively
- try very hard to organize the content, and
- avoid relying on sample answers too much.

The instructor should take a small amount of time to teach the students how to organize review material and how to prioritize material for the exams. Then the instructor can explain how these translate into quality cheat-sheets and lead to improved grades. It would appear to be tempting to provide a sample cheat-sheet for the first exam each semester. However, this would make it nearly impossible to gain the beneficial experience of creating the cheat-sheet and, in a real sense, defeats the purpose of the cheat-sheet. These are senior students and we really should not have to teach them at this point how to prepare for examinations. Perhaps it would be beneficial to provide the students with an outline of how to create cheat-sheets (no course content involved). We think it would improve exam scores. It would be interesting to do a comparative analysis of providing the cheat-sheet outline versus the current situation of limited suggestions for material.

B. Future Work

A limitation of this study is that we did not collect data for the time and strategy that students used on cheat-sheet creation. It would be interesting to know the students' cheat-sheet creation strategy: if they do tentative cheat-sheet creations from the first day of class or create cheat-sheets as they do the reviewing, or do they review first and then determine the content for the cheat-sheets. This study suggests that cheat-sheets have a positive impact on undergraduate students' performance. We hope to do similar research on graduate courses as well as lower level undergraduate computer science courses and hope others will apply these techniques in other disciplines.

Innovation Within the Constraints of Sustainability

Analysis of Product Development Projects

Abstract—Innovation thrives within constraints. This seemingly counterintuitive notion is now increasingly adopted and practiced in companies known for innovation. The main question to address in this research is whether constraints imposed by such concepts as sustainability are liberation for or impediment to students' becoming more innovative and creative in their product development projects. This paper presents an on-going investigation into the theme by analyzing and reflecting on new product development projects in a course called "Sustainable Manufacturing" at Syracuse University. The new course has been developed and offered once a year since 2010. Students' projects are analyzed from initial opportunity ideas, to intermediate development stages, and ultimately to the final projects including physical prototypes, in order to measure the level of students' understanding of sustainability concepts and its impact on students' capacity for innovation and creativity as exhibited in their projects. The preliminary results suggest that imposed constraints are indeed a booster for, but at least not an impediment to creativity and innovation.

Keywords—Innovation; Creativity; Sustainability; Constraints; Product Development

I. INTRODUCTION

Innovation thrives within constraints. This seemingly counterintuitive notion is now increasingly adopted and practiced in companies known for innovation and creativity [1, 2, 3]. Notably, Stokes asserts this thesis by drawing numerous examples and data from various fields including music, art, literature, fashion, architecture and advertising [4]. Yet, no systematic investigation on the theme seems to have been reported in the field of engineering education. This paper presents an on-going investigation into the theme by analyzing and reflecting on new product development projects in a course called "Sustainable Manufacturing" at Syracuse University [5]. In the course, a main constraint is to address "sustainability" issues in every step of the way of developing new products.

A widely accepted definition of sustainability as coined by the United National World Commission on Environment and Development Sustainability is an ability to "meet the needs of the present without compromising the ability of future generations to meet their own needs" [6]. In addressing sustainability issues, the role of engineers who come up with tangible and practical solutions is becoming increasingly

important. Therefore, it is essential to educate the next generation of engineers with meaningful presence of sustainability in their curricula.

A new course on sustainable manufacturing has been developed and offered once a year since 2010 at Syracuse University [5]. In the course, students learn (i) the vision of sustainable manufacturing and product development, and its relation to larger societal issues, (ii) processes, techniques and tools for developing sustainable products, (iii) sustainable manufacturing processes and systems, (iv) how to measure sustainable manufacturing practices, and (v) effective strategies to deploying sustainable manufacturing.

One of the main components of the course is a semester-long project of developing sustainable products. Students start with conceiving new product ideas and progressively develop their products throughout a semester, culminating in their physical prototypes and detail manufacturing plans. The project also provides students with a context where they can apply methods, techniques and tools that they learn from the course. While students are encouraged to think as broad and wildly as possible, a major constraint imposed on their projects is sustainability. Students need to prove that they are addressing sustainability issues every step of their projects.

The objective of this research is to confirm or dispute the theme, "innovation thrives within constraints," by analyzing and reflecting on the last five years' students projects. The level of students understanding of sustainability concepts and its impact on students' capacity for innovation and creativity is measured, as exhibited in their projects by analyzing the projects from initial opportunity ideas, to intermediate development stages, and ultimately to the final projects including prototypes. The paper presents preliminary results as well as ideas for further investigations.

II. CREATIVITY AND ENGINEERING EDUCATION

Engineering is essentially a creative profession. The word "engineer" has its origin in the Latin words meaning "clever invention" [7]. Throughout human history, whenever engineers develop new solutions to address any technical, commercial and societal problems, their creativity are at work.

However, "few courses require or even encourage creativity" in typical engineering curriculum [8]. As a result,

students often think that creative behavior is not a desirable attribute for competent engineers, and instead focus on developing analysis aspects of engineering. Research suggests that this gap in engineering curricula needs to be addressed through necessary engineering education reforms. In recent years as the society recognize the importance of creative thinking in engineering education curriculum [9], various schools began to develop new courses, devise pedagogical methods, or conduct research on creativity and engineering education [10]. Among many areas of engineering subjects, some consider that new product development is one of the natural subjects to incorporate creativity components into [11].

III. APPROACH

A new course, "Sustainable Manufacturing" had been developed and was offered for the first time in 2010 at Syracuse University [5]. The course is an elective course available to undergraduate seniors and graduate students from any engineering field. So far, over 200 students have taken the course and nearly 70 projects have been carried out. All the projects begin with students' actively thinking about opportunity ideas for new sustainable products. From all the generated product ideas, better ideas are selected mainly by students' votes. After three or four rounds of tournament style selection process [12], final product ideas along with student teams are determined.

While students' work progresses on a weekly basis, there are three milestones in the project schedule: (i) generation of initial opportunity ideas, (ii) generation of product concepts to realizing the chosen opportunity ideas, and (iii) final projects. In the first milestone, students are generating raw ideas for new sustainable products and express them in sentence. After a couple of more lectures and assignments, students develop product concepts that illustrate how they are going to accomplish the proposed opportunity ideas. Typically students present the product concepts using drawing, sketches along with narrative descriptions. The final project is the culmination of the semester's work and comprehensive including all the details of design and manufacturing processes along with physical prototypes.

Since numerous learning opportunities for sustainability issues are provided to students throughout the semester [5], our assumption is that students' understanding of sustainability is gradually deepening as they go through these three milestone stages. Therefore, we consider that constraints imposed by sustainability become tighter and tighter as students' understanding of sustainability concepts is deepening.

In this research, students submissions in these three milestone stages are evaluated then exhibited creativity and innovation are assessed by three methods: (i) instructor's observation and assessment, (ii) quantitative analysis of past five year's student projects, and (iii) testimonies from students.

The second method uses a rubric based on the assessment rubric presented in [13]. The rubric is composed of four sections: (i) generating ideas, (ii) digging deeper into ideas, (iii) openness and courage to explore ideas, and (iv) listening to one's inner voice. Four scales of development are used in the rubric assessment. One of the used rubrics is shown in Table 1.

	Creativity Level			
	<i>Not Evident (1 point)</i>	<i>Emerging (2 points)</i>	<i>Expressing (3 points)</i>	<i>Excelling (4 points)</i>
High levels of curiosity	low level of curiosity	have high levels of curiosity but single sided	have high levels of curiosity in multiple faces	excellent to maintain high levels of curiosity in developing, marketing, technology and research
Capacity for fantasy and imagination	hard to find any fantasy or imagination	working hard to find any fantasy or imagination	have good capacity for fantasy and imagination	have excellent capacity for fantasy and imagination
Tolerance for ambiguity	unable to tolerant uncertainty or inexactness in idea/design/concept	try to tolerant uncertainty or inexactness in idea/design/concept	able to tolerant for uncertainty or inexactness in idea/design/concept	properly tolerant uncertainty or inexactness in idea/design/concept
Openness to experience ideas and not frightened by the unknown	unable to experience ideas and not frightened by the unknown	try to experience ideas and not frightened by the unknown	able to experience ideas and not frightened by the unknown	excellent to experience ideas and not frightened by the unknown

Table 1. A Part of Rubric for "Openness and Courage to Explore Ideas" in Creativity Measurement

IV. RESULTS

Preliminary results from the three methods to evaluate the levels of students' creativity and innovation are presented in this section.

A. Instructor's Assessment

The course instructor has also taught other courses that involve new product development project. They are an undergraduate-level course in manufacturing processes (9 times), a graduate-level course in manufacturing systems (2 times) and a graduate-level course in product lifecycle management (2 times), all at Syracuse University. In addition, he has taught short courses in new product development in several other countries. One main difference in these courses' projects is that no sustainability constraint had been imposed. When the sustainable manufacturing course was offered for the first time, the instructor wasn't sure of the effect of this new constraint on student projects. Also, it wasn't clear how students would respond as their understanding and knowledge on sustainability are deepening as the course progresses.

Reflecting on student projects in all these courses as well as the sustainable manufacturing course, the instructor could not tell any differences in quality in creativity and innovation. In

fact, such an observation became the main motivation for starting this research.

One notable example is from a team that has developed a portable signaling device connected to GPS via a cell phone app. Their initial idea was stated as "Create a cyclist navigation system with simple LED lights on handlebar which synchronize with the GPS and maps on users' cellphone so cyclist can reach destination without stop to seeing the phone." Such an idea statement is any less creative than other ideas presented in other courses, despite of the sustainability constraint.

That initial idea had been developed further after the students learned more about sustainability by adding the impact of bike riding on sustainability, but articulating the need for safe navigating. The student team further illustrated that improved safety and convenience in bike navigating can appeal to a wider audience so extending its impact on sustainability.

In a later stage of generating product concepts, students were further challenged to consider more sustainability issues, but such additional constraints didn't seem to withhold students' creativity and innovation. Their final project was the exhibition of most creative and innovative activities in the semester.

B. Assessment by using the Rubrics

A quantitative analysis has been devised to measure students' achievements related to the research theme. The past five year's student projects have been evaluated using the developed rubrics (Table 1). Only a portion of the results are shown in Figures 1 - 4.

Fig. 1. Overall creativity evaluation, 2010-2014

Fig. 1 shows average composite indicator over three distinct project stages. The definite improvement is observed over the stages, although the composite indicator is mostly influenced by the factor, "digging deeper into ideas" as illustrated in Fig. 2 for 2014. However that steep pattern is common in other measures over all five years.

The factor, "listening to one's inner voice" doesn't seem to show any definite trend (Fig. 3). On the other hand, the factor, "idea generation" shows that some components are not

unilaterally improving, rather deteriorating in the concept generation stage as illustrated in Fig. 4. This might attribute to temporary set back due to students perceived additional requirements that they had to meet.

The magnitude of such contrary trends is less than the general trend of improvement over the five years, resulting in the increasing pattern of composite indicators (Fig. 1).

Fig. 2. Evaluation on "digger deeper into ideas" in 2014 projects

Fig. 3. Evaluation on "listening to one's inner voice" in 2014 projects

Fig. 4. Evaluation on "idea generation" in 2010 projects

C. Students' Testimonies

Numerous students provide their own assessment on creativity and innovation. For example, some example comments include:

"Initially I was concerned if I can generate enough number of ideas since we have to address sustainability in our product ideas. But I was surprised that I was able to come up with many ideas."

"Moreover, I feel more creative in class. The class creates an innovative environment would enhance awareness of creativeness too. Questions and answers interaction gets me nervous at first but activate my curiosity to explore ideas as well."

"After class, we have applied for competitions about innovation. In the Innovation and creativity competition, we used our class product and won the most creative award. And in SPARK Innovation Competition, we applied those sustainability constraints in an engineering consulting plan and won 2nd prize."

As noted in the last comment, some students grew more interested in and energized by their projects, ultimately pursuing further entrepreneurial opportunities. This again at least indirectly validates that students' creativity can be stimulated under constraints.

V. DISCUSSION AND FUTURE WORKS

The theme that innovation thrives under constraints has been increasingly adopted in corporations known for their innovation. Also it has been researched in some fields. However, to our knowledge, there is no formal investigation into this theme reported in the engineering education literature. This paper presents preliminary results by analyzing student projects of a course where sustainability has been its major constraint. Therefore, there are plenty of opportunities to extend this research.

One of the contributions of this research is to provide a way to quantify the degrees of creativity and innovation found in student project. Although the rubric (Table 1) is modified to address the research question, there is still room for improvement for future use. Especially, when multiple assessors are involved, some of the items need to be modified in order to provide more consistency over between assessors.

In the current results partially presented in Figures 1 - 4, the evaluation scores may have confounded causes beside pure creativity and innovation measures. For example, the structural approach of developing new products [11] could have been a critical factor for such evaluation results. The structural approach itself can be considered as imposing constraint. Therefore, separating such constraints' effect from that of sustainability needs to be considered in future investigations.

Another work that can be done is to create a control group and compare the results from the group and experimental groups. The current study is essentially a reflective

investigation into past data, which had been generated without anticipating such a study. With a clearer research objective established, it might desirable to create a control group and carry out comparison studies in a systematic way.

Also a same group of students may be assessed, but once before the course starts when students do not have much idea on constraints under which they will work, and another time after they are introduced to constraints under which they need to work.

Developing countries face serious challenges to work under additional constraints [14]. This course can be co-taught with partners in such developing countries. US-based students can have a chance to understand extreme conditions that other parts of the world have to face and potentially to become more creative and innovative under such additional constraints. Students in partner institutions can also benefit from different way of thinking as well as working truly as a part of one world.

Abstract—Designing and assessing learning outcomes could be a challenging activity for any Software Engineering (SE) educator. To support the process of designing and assessing SE courses, educators have been applied the cognitive domain of Bloom's taxonomy. However, to the best of our knowledge, the evidence on the usage of Bloom's taxonomy in SE higher education has not yet been systematically aggregated or reviewed. Therefore, in this paper we report the state of the art on the usage of Bloom's taxonomy in SE education, identified by conducted a systematic mapping study. As a result of the performed systematic mapping study, 26 studies were deemed as relevant. The main findings from these studies are: i) Bloom's taxonomy has mostly been applied at undergraduate level for both design and assessment of software engineering courses; ii) software construction is the leading SE subarea in which Bloom's taxonomy has been applied. The results clearly point out the usefulness of Bloom's taxonomy in the SE education context. We intend to use the results from this systematic mapping study to develop a set of guidelines to support the usage of Bloom's taxonomy cognitive levels to design and assess SE courses.

I. INTRODUCTION

Learning outcomes represent the knowledge and skills that students are expected to have by the end of a course. Designing and assessing learning outcomes of a course could be a challenging activity for any instructor. Higher education courses are usually part of some degree program; the learning outcomes should synchronize and align the courses with the corresponding degree program.

The Bloom's taxonomy [1] is a classification of learning outcomes that has as one of its main goals motivating educators towards designing more holistic courses. Such taxonomy has been used in many domains and it is considered as foundational and essential by the education community. Bloom's taxonomy has been used to both design [2] and assess [3] learning outcomes.

One of the knowledge fields in which Blooms taxonomy has been applied is Software Engineering (SE), i.e. the study and usage of engineering methods and techniques to design, develop and maintain software systems. SE has its particularities that make the teaching and learning process of this discipline even more challenging. For this reason, many researchers have reported the usage of Bloom's taxonomy aiming at systematizing the design and assessment of different SE related courses. Niazi [4] reported his experience on applying

Bloom's taxonomy cognitive levels to teach a Global Software Engineering course. Khairuddin and Hashim [5] presented an approach to apply Bloom's taxonomy cognitive levels to asses SE students. O'Leary *et al.* [6] designed a software engineering curriculum for the emerging software industry in China, which was structured using Bloom's taxonomy cognitive levels.

To the best of our knowledge, the evidence on the usage of Bloom's taxonomy in SE higher education has not yet been systematically aggregated or reviewed. Therefore, the main goal of this paper is to identify and report the state of the art on the usage of the Bloom's taxonomy in SE higher education. To do so, a systematic mapping study [7], [8] was performed aiming at:

- Characterize the state of the art research on the usage of the Bloom's taxonomy in the SE education.
- Identify and analyze the reflections of the SE instructors who have used the Bloom's taxonomy in their courses.

Considering the relevance of such research topic, a systematic mapping study is deemed important as its results could inform SE educators.

The remainder of this paper is organized as follows: Section II briefly presents Bloom's taxonomy. Section III details the employed research methodology, followed by the presentation and discussion of the results of this work in Section IV. The validity threats are discussed in Section V. Finally, Section VI presents the conclusions and view on future work.

II. BLOOM'S TAXONOMY

Bloom's taxonomy has 11 levels, which are categorized in the following three different domains [1]:

- **Cognitive** - Skills in this domain are related to the way people recall knowledge, comprehend and critically think about a particular topic. The six levels of this domain are *knowledge*, *comprehension*, *application*, *analysis*, *evaluation* and *synthesis*.
- **Affective** - Skills in this domain are related to the way people emotionally react about another living being pain or joy. The five levels of this domain are *receiving*, *responding*, *valuing*, *organizing* and *characterizing*
- **Psycho-motor** - Skills in this domain are related to the way people manipulate tools or instruments (such as

hand or hammer). Benjamin Bloom never designed levels for this category. Some researchers have proposed levels for such domain, but there is no consensus about the usefulness of their proposed levels.

The cognitive domain has received more attention from Benjamin Bloom and consequently it has been applied the most by educators; no study in SE has employed the affective and psycho-motor domains (see Section IV). For this reason, herein we describe only the levels of the cognitive domain, as follows:

- 1) **Knowledge** - The student is able to recall facts, basic concepts and terms on a given topic.
- 2) **Comprehension** - The student has to be able to organize, compare, translate, interpret, give descriptions and state the overall idea related to a given topic.
- 3) **Application** - The student is able to apply the retrieved knowledge in different ways to solve a given problem.
- 4) **Analysis** - The student is able to identify motives and causes regarding a given topic, so that generalizations could be supported.
- 5) **Synthesis** - The student is able to identify patterns from different elements or combine different parts to compose a whole.
- 6) **Evaluation** - The student is able to deem information, validate ideas and evaluate quality of information using a defined set of criteria.

There is a hierarchical relationship between the above-discussed levels (Figure 1); the higher the level (evaluation), the bigger is the complexity inherent to the level. Thus, the learning process must start from the knowledge level and incrementally progress to the evaluation level.

Figure 1. Bloom's taxonomy cognitive domain levels.

Some endeavors were made over the last years to improve the levels of the cognitive domain of Bloom's taxonomy, e.g. Anderson *et al.* [9]. Notwithstanding, just the original cognitive levels were described in this paper, because they remain as the most used ones.

Note that there are other taxonomies that can be used to describe and classify learning outcomes, e.g. SOLO [10] and Finks [11] taxonomies. However, herein in this paper we considered only Bloom's, because it is the most widely adopted learning outcomes' taxonomy.

III. RESEARCH METHODOLOGY

This section details the performed systematic mapping study, which includes the research questions and the procedures employed in the performed work.

A systematic mapping study is a method that allows for categorizing and summarizing the existing information about a given research topic in an unbiased manner [8]. We employed the guidelines by Kitchenham and Charters [7] and partly implemented the mapping process provided by Petersen *et al.* [8] to conduct the systematic mapping study reported herein.

We choose the systematic mapping study method because it is a better option to deal with broadly defined research areas [7], [8], which is the case of the topic associated to the research reported in this paper. The employed systematic mapping process is detailed as follows.

A. Research questions

The following research questions were framed to guide this systematic mapping study:

- **Question 1 (RQ1)** - How Bloom's taxonomy is used in the SE education context?
 - **Question 1a (RQ1a)** - What are the SE subareas for which Bloom's taxonomy has been used in the education context?
 - **Question 1b (RQ1b)** - What are the SE program levels at which Bloom's taxonomy has been used?
 - **Question 1c (RQ1c)** - What are the objectives for which Bloom's taxonomy has been used in SE education?
- **Question 2 (RQ2)** - What levels of Bloom's taxonomy have been used in the SE education context?
- **Question 3 (RQ3)** - What are the reflections of the SE educators on the use of Bloom's taxonomy in their courses?

B. Search strategy

After defining the research questions, we set up a strategy to design a search string and, consequently, identifying the primary studies. To avoid researcher bias, we used the following procedure:

- 1) Analyze the research questions and identifying the main words;
- 2) Collect and analyze relevant papers and checking the keywords;
- 3) Identify alternative spellings and synonyms for major terms;
- 4) Use the Boolean OR to connect the identified alternative spellings and synonyms;
- 5) Link the main terms using the Boolean AND;
- 6) Pilot the search string.

To cover as many studies as possible, we included all the knowledge areas defined in the *Guide to the Software Engineering Body of Knowledge* (SWEBOK Guide) [12], as well as emergent SE subareas that are not explicitly embraced by the SWEBOK guide, such as Global Software Engineering

and Software Product Line Engineering. Finally, we explicitly included the term *programming*, since it is directly connected with one of the knowledge areas of the SWEBOOK guide (software construction) and is related to a popular course in both Software Engineering and Computer Science programs. As a result, we obtained the following search string:

("software engineering" OR "software requirement" OR "requirements engineering" OR "software architecture" OR "software design" OR "software construction" OR "software testing" OR "software maintenance" OR "software quality" OR "software project management" OR "software configuration management" OR "software engineering tool" OR "software engineering method" OR "software process" OR "software development process" OR "global software development" OR "global software engineering" OR "distributed software development" OR "agile software development" OR "agile method" OR "agile process" OR "model driven development" OR "software product line" OR "aspect oriented programming" OR "software errors" OR "software bugs" OR "software risks" OR "software defects" OR "software measurement" OR "software metrics" OR "software cost estimation" OR "software development" OR "programming") AND ("bloom's taxonomy" OR "bloom taxonomy" OR "cognitive taxonomy")

C. Search process

The employed search process had two steps: identify primary sources and search primary studies using the designed search string (Subsection III-B). Table I presents the reviewed primary sources and the number of primary studies returned by each of the primary sources.

Scopus¹, Compendex/Inspec² and Web of Science³ were the reviewed primary sources. Those primary sources cover most of the important SE databases, such as IEEE, Springer, ACM and Elsevier. In addition, we surveyed ERIC⁴, which is a data base dedicated to education-related studies. The primary studies were collected by means of a title/abstract-based search. The search process was limited to peer-reviewed conference papers and journal articles.

Table I
SUMMARY OF SEARCH RESULTS

Database name/Search Engine	Search Results
Compendex and Inspec	82
Scopus	55
Web of Science	51
ERIC	1
Total	189
Total Without duplicates	144

¹www.scopus.com

²www.engineeringvillage.com

³apps.webofknowledge.com

⁴eric.ed.gov

D. Study selection

The study selection was carried out by applying the following inclusion and exclusion criteria:

- Inclusion criteria:

- 1) Studies that are about application of Bloom's taxonomy in SE education AND;
- 2) Studies described in English AND;
- 3) Are reported in peer reviewed workshop OR conference OR journal.

- Exclusion criteria:

- 1) Studies that do NOT apply Bloom's taxonomy in SE education OR;
- 2) Studies that are NOT written in English OR;
- 3) Studies that are NOT reported in peer reviewed workshop OR conference OR journal.

We conducted the selection process using a two-stage screening procedure. The level-1 screening (first stage) consisted on reading the studies' titles and abstracts. To avoid researcher bias, the total number of 144 studies was fully screened by both authors. The results were compared and consensus was reached, so that a total of 44 studies were judged as potentially relevant.

The level-2 screening (second stage) consisted on applying the inclusion and exclusion criteria to the full-text of the studies deemed as relevant in the first stage of the study selection process. Both authors screened the full set of studies. The results were compared and consensus was reached, so that a total of 26 studies were judged as relevant. A list that contains the 26 included primary studies is available on-line⁵.

E. Data extraction

Both authors extracted data from the 26 studies selected. A data extraction sheet was designed to guide the data extraction process. Such sheet was piloted on a sample study to assess its completeness and to ensure that both authors shared a common understanding of the data extraction process. The results for the data extraction were compared and consensus was reached, so that all the data extracted for the 26 studies was analyzed.

F. Data Analysis

To draw conclusions from the collected data, both qualitative and quantitative data analysis were performed. Tables were designed in order to ease the understanding of the extracted data.

IV. RESULTS

This section details the results of the mapping study. We firstly describe the general results and then the results for each research question are presented.

A. General results

General results about country, year and venue wise distribution of the studies on application of Bloom's taxonomy in SE education are described in this subsection.

⁵<https://drive.google.com/file/d/0B2kvKpmJJREDUkd0bmgzR2NwSGc/view?usp=sharing>

1) *Country wise distribution*: The countries in which Bloom's taxonomy was reported to have been applied in SE education are displayed in Table II. Results show that the USA (13 studies) is the leading country where Bloom's taxonomy has been applied in SE higher education. Australia (3 studies), Taiwan (2 studies), Spain (2 studies), New Zealand (2 studies) and Malaysia (2 studies) are other countries wherein more than one study have been reported. It is interesting to note that almost all continents (North America, Oceania, Europe, Asia and Africa) are represented in Table II, indicating the application of Bloom's taxonomy in SE education all over the world.

Table II
COUNTRY WISE DISTRIBUTION OF PRIMARY STUDIES

Country	Study ID	Frequency
USA	2, 3, 4, 5, 6, 9, 11, 14, 20, 24, 25	11
Not stated	17, 18, 21, 22	4
Australia	9, 16, 23	3
Taiwan	8, 19	2
Spain	12, 15	2
New Zealand	10, 20	2
Malaysia	7, 13	2
UK	14	1
Norway	2	1
South Africa	26	1
Saudi Arabia	1	1
Netherlands	2	1

2) *Publication type wise distribution*: The types of publications of the included primary studies are displayed in Table III. Results show that the majority of the studies (80% - 21 studies) from the included primary studies were published as conference papers, while 20% (5 studies) were published as journal papers. Journal papers demand more rigor in the study design and execution. We believe that there is a need to conduct and report more rigorous studies on the use of Bloom's taxonomy in SE education to increase the quality of evidence of the subject matter.

Table III
VENUE TYPE WISE DISTRIBUTION OF PRIMARY STUDIES

Publication type	Study ID	Frequency
Conference	1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 12, 15, 16, 17, 18, 19, 21, 22, 23, 24, 25	21
Journal	8, 13, 14, 20, 26	5

3) *Year wise distribution*: The year wise distribution of the included primary studies is presented in Table IV. The following interesting patterns were observed in the results:

- All the identified primary studies were published after year 2000. In the past, SE had been treated mostly as a subarea of Computer Science. It is only recently that SE has been treated as a separate discipline.
- Multiple studies are published on use of Bloom's taxonomy in SE education from year 2008 onwards, thus

indicating an increase in the interest in the topic. As the search was performed in October 2014, papers published after such date were not included in the search.

Table IV
YEAR WISE DISTRIBUTION OF PRIMARY STUDIES

Year	Study ID	Frequency
2000	22	1
2001	21	1
2002	11, 20	2
2003	23	1
2004	6, 24	2
2005	19	1
2006	5, 10	2
2007	26	1
2008	4, 8, 9, 17, 18	5
2009	15, 16	2
2011	3, 13, 14	3
2012	7, 25	2
2013	1, 2	2
2014	12	1

4) *Study type wise distribution*: This section categorizes the included primary studies based on the research approach used in each study. We used an existing classification of research papers proposed by Wieringa et al. [13] and recommended by Petersen *et al.* [8] for systematic mappings studies. The categories of Wieringa *et al.*'s classification scheme are as follows:

- **Validation Research**: It involves the work that is novel and has not yet been implemented in practice. Typical example is the work done in the lab settings.
- **Evaluation Research**: Work proposed is implemented and evaluated in practice.
- **Solution Proposal**: This type of research involves proposing a solution for a problem. The proposed solution can be novel or build on top of some existing work. The applicability of the solution is usually explained with the help of small example or just by good line of argumentation.
- **Philosophical Papers**: This type of research present a new way of looking at existing things. Examples include new taxonomies or conceptual frameworks.
- **Opinion Papers**: These papers present personal opinion of authors on some intervention without taking into account related work or research methodologies.
- **Experience Papers**: These papers present personal experience of the authors related to how something has been used in practice.

Table V presents the categorization of the included primary studies according to the aforementioned classification scheme. Results show that 62% (16 studies) of the primary studies are of solution proposal type. The solution in this case is the design or revision of different SE courses for a given context. Six studies (23%) studies are categorized as experience papers, wherein the authors shared their experiences on designing or assessing SE courses using Bloom's taxonomy. No paper from

the included primary studies was found to be of philosophical or evaluation type.

Table V
STUDY TYPE WISE DISTRIBUTION OF PRIMARY STUDIES

Study type	Study ID	Frequency
Solution proposal	2, 4, 6, 7, 8, 12, 13, 15, 17, 18, 19, 20, 21, 22, 23, 25	16
Experience	1, 3, 10, 11, 24, 26	6
Validation	14, 16	2
Opinion	5, 9	2

B. RQ1: Bloom's taxonomy usage

This section presents the results for the first research question.

1) *RQ1a: Software engineering subareas*: The aim of this question was to find out SE subareas in which Bloom's taxonomy has been applied for course design or assessment. The Table VI presents the results and shows that software construction is the leading area in which Bloom's taxonomy has been used to design or assess courses (54% - 14 studies). Bloom's taxonomy has also been used for course design or assessment of SE general courses (3 studies) and program comprehension courses (2 studies). Bloom's taxonomy has been used in one study only for each of other areas listed in Table VI, which indicates the need to conduct and report more studies in those areas. The SE subareas for which no study has been published yet reporting the usage of Bloom's taxonomy are: software design, software maintenance and software configuration management.

Table VI
SE SUBAREA WISE DISTRIBUTION OF PRIMARY STUDIES

SE area	Study ID	Frequency
Software construction	7, 8, 9, 10, 11, 14, 15, 18, 21, 22, 23, 24, 25, 26	14
Software engineering (general)	17, 19, 20	3
Application/Program Comprehension	3, 4	2
Software testing	16	1
Software project management	12	1
Software engineering tools	5	1
Software requirements	13	1
HCI	6	1
Global software engineering	1	1
Cloud computing	2	1
Software quality	14	1

2) *RQ1b: Program level*: The aim of this question was to report the SE program levels at which Bloom's taxonomy has been applied. The results are presented in the Table VII and show that 85% (22 studies) of the primary studies reported the usage of Bloom's taxonomy at the undergraduate level. Only three studies were carried out at master's level. Two studies have not stated the program level for which the course

was designed or assessed using Bloom's taxonomy. One study reported the case of a SE training course wherein the Bloom's taxonomy was applied.

Table VII
PROGRAM LEVEL WISE DISTRIBUTION OF PRIMARY STUDIES

Program Level	Study ID	Frequency
Bachelor	5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26	22
Masters	1, 2, 14	3
Not stated	3, 4	2
Training	2	1

3) *RQ1c: Study Purpose*: The aim of this question was to identify the purpose for which the Bloom's taxonomy has been applied in SE education. Bloom's taxonomy can be used for two purposes: course design and course assessment. The results are presented in Table VIII and show that in 38% (10 studies) of the primary studies Bloom's taxonomy was applied focusing on course assessment, while in 27% of the studies such taxonomy was applied focusing on course design. Nine studies (35%) studies employed Bloom's taxonomy focusing on both course design and assessment. These results suggest that both course design and assessment have received equal importance when it comes to the usage of Bloom's taxonomy.

Table VIII
PURPOSE WISE DISTRIBUTION OF PRIMARY STUDIES

Focus	Study ID	Frequency
Assessment	7, 9, 10, 12, 13, 14, 16, 17, 18, 23	10
Both	2, 3, 15, 19, 21, 22, 24, 25, 26	9
Design	1, 4, 5, 6, 8, 11, 20	7

C. RQ2: Bloom's taxonomy levels and version

The aim of this questions was two fold: i) To see which cognitive levels of the Bloom's taxonomy have been used during design or assessment of SE courses; ii) To identify which version (original or revised) of the Bloom's taxonomy has been applied in SE education.

The used levels of Bloom's taxonomy are displayed in Table IX. The results show that except for one study (Id 14), all other studies (25) have described the levels they have used. Most studies (85% - 22 studies) have used all six cognitive levels of Bloom's taxonomy during course design or assessment. The results also show that comprehension and application were the most frequently used levels of the Bloom's taxonomy in the SE education context. Such finding complies with the nature of SE, which is an applied discipline and its graduates are required to understand and subsequently apply its concepts, techniques and tools.

The used versions of Bloom's taxonomy are displayed in Table X. The results show that 85% (22 studies) of the

Table IX
BLOOM'S TAXONOMY LEVEL WISE DISTRIBUTION OF PRIMARY STUDIES

Bloom's levels	Study ID	Frequency
Comprehension	1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26	25
Application	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26	25
Knowledge	1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 19, 20, 21, 22, 23, 24, 25, 26	23
Analysis	1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26	23
Synthesis	1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26	23
Evaluation	1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 16, 17, 19, 20, 21, 22, 23, 24, 25, 26	22
Not stated	14	1

included primary studies have used the original version of Bloom's taxonomy, while only 15% (4 studies) reported the usage of the revised version of Bloom's taxonomy. Results clearly show that the original version of Bloom's taxonomy is the one that is well received and most frequently applied by SE educators.

Table X
REVISED VS ORIGINAL BLOOM'S TAXONOMY

Taxonomy version	Study ID	Frequency
Original	1, 2, 4, 5, 6, 7, 8, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 26	22
Revised	3, 9, 10, 25	4

D. RQ3: Reflections

The aim of this question was to extract and report the reflections of the SE teachers on the usage of Bloom's taxonomy in their courses. Only four studies provided such reflections. The reflections are described herein for each of these four studies.

1) *Teaching Global Software Engineering: Planning and Preparation Using a Blooms Taxonomy*: This study [4] is an experience paper in which the author reports how he employed Bloom's taxonomy to design a master's level course on Global Software Engineering in a university in Saudi Arabia. The author's reflections related to the usage of Bloom's taxonomy cognitive levels are as follows:

- **Knowledge level**: "The use of knowledge level seemed more appropriate for those students who appreciated the discussion of the basic concepts and principles of global software engineering [...] However, this level did not seem appropriate for higher caliber students."

The author find the knowledge level of the Bloom's taxonomy useful for the effective discussion and delivery of the course basic concepts; however, for the advance learning, this level is not enough in the opinion of

the author. This is understandable as for the advanced concepts and deep learning, higher levels of Bloom's taxonomy are more appropriate.

- **Comprehension Level**: "This level helped students to move from recalling state to understanding state."

The author find this level an improvement to the previous level, as he observed students moving up to the understanding state from just the memorization state.

- **Application Level**: "I have observed that some of the international students (from Asia) have difficulties in applying the concepts and theories learned in the lectures in the labs."

When students were asked to apply the concepts in the labs settings, The author noticed that some of them faced difficulties in this process. The application of the concepts is not an easy endeavor, but is crucial for applied fields like SE. When teachers use the application level of Bloom's taxonomy for designing the learning activities, it is important to provide the required support and assistance to students to facilitate the transition from the comprehension level to the application level.

- **Analysis Level**: "I have observed, in the labs, that some students were facing difficulties in breaking down the bigger problem into smaller components in order to better understand it. To address this problem I have provided students with simple problems first and then I moved them to harder problems"

The author noticed here as well that students faced problems at the analysis level when they were to divide the larger problems into smaller parts. The author tackled this problem by starting from simple problems to support the transition to the analysis level.

- **Synthesis Level**: "Students have mix responses for the synthesis level of Blooms Cognitive domain. I also think that such preliminary exercises should be done at a high school level so that when students come to Universities they should be able to understand and can complete more complex synthesis problems."

The author suggests that proper education and training at high school level could help students achieve synthesis level.

- **Evaluation Level**: "Students had some minor problems in the evaluation level of Blooms Cognitive domain."

These reflections suggest that going beyond comprehension level of the Bloom's taxonomy could impose some challenges for students and the instructors. It is therefore suggested to carefully plan the advance levels of the taxonomy.

2) *Bloom's taxonomy for CS assessment*: This study [14] is an opinion paper in which the authors used the revised version of Bloom's taxonomy to design assessments for programming courses. The authors' reflections are as follows:

- "Once staff involved in the teaching of a course were consulted, we found considerable agreement in the categorization of questions according to the Bloom taxonomy. We consider this to be a positive outcome which suggests

that the revised Blooms taxonomy can be effectively used to discuss examination questions in the programming domain.”

The authors find the revised Bloom’s taxonomy useful for the design of assessments for programming courses.

- “We felt that a shared understanding of the interpretation of the revised Blooms taxonomy to the programming domain would prove valuable to teaching staff developing examination questions, particularly in courses that involve multiple staff members.”

It is important that all teaching staff in these type of courses have a consistent interpretation of the taxonomy to achieve the desired benefits.

3) Experimentation in the computer programming lab:

This study [15] is an experience paper in which the author shared his personal experience on applying Bloom’s taxonomy to design and assess a lab based programming course at bachelors level at a university college in the USA. The author’s reflections are as follows:

- **Knowledge level:** “[...]The drill and practice component of the lab experiments supports memorization.”

The author noticed that the practice of asking students to manually enter the code from the printed lab handout served as a valuable cognitive processing tool.

- **Comprehension Level:** “The laboratory experiments are used to reinforce important concepts [...] Students are required to explain their results, describe their actions, and generalize[...].”

The author observed that the practice of asking students to describe and explain their results and actions helps in achieving the comprehension level.

- **Application Level:** “Students must draw upon learned information to satisfy experiment completion requirements. Some problems have a clear best solution while some may be solved from a variety of directions. Students collect information from readings and lectures and prepare solutions. The experiments enforce the use of learned facts”
- The author found the use of experimentation very useful to support the application level of Bloom’s taxonomy as they offer the opportunity for the students to apply the learned concepts.

- **Analysis Level:** “Students must learn to take a body of information and differentiate between important facts [...] They are required to separate the information into manageable chunks based upon limits, relevance, importance, and efficiencies.”

The author supported the students to achieve the analysis level of the Bloom’s taxonomy using exercises wherein students had to divide the information and problem into manageable parts.

- **Synthesis Level:** “Laboratory experiments reinforce and teach synthesis through the design of algorithms and solutions to challenging issues. Students are asked to revise code and rearrange data to meet the parameters of a problem. They are encouraged to try different attacks

at the solution.”

The author noted that synthesis level is achieved by employing a number of means in laboratory experiments e.g. revision in the existing code and data structures, solution testing and algorithm design exercises.

- **Evaluation Level:** “Students are asked to interpret and critique sample code. They are often required to defend their solution methods and answers in the results and experimenter notes sections of their experiment handouts.”
- In order to support the learning at this level, the students were required to review sample codes and provide their critical assessments. Students were also asked to provide clear justification for the use of particular methods in their solutions.

4) *Teaching Java backwards:* This study [16] is also an experience paper in which the author shared personal experience on using Bloom’s taxonomy for the design of a undergraduate level JAVA programming course at a South African University. The author shared following general reflection on the use of Bloom’s taxonomy during course design:

“The use of Bloom’s Taxonomy as a basis for course design is supported by the findings reported here. Students were able to move on to more advanced material in the next course, despite having a compressed introduction, compared with previous similar classes.”

The author found the use of the Bloom’s taxonomy useful in effectively teaching the basic concepts, since it was observed that students were successfully able to transition to the advanced material in the follow up course.

V. VALIDITY

The major validity threat to this work is related to the coverage of the relevant literature, i.e. whether or not the search was able to identify all relevant primary studies. To mitigate this threat, we performed a very comprehensive search strategy.

The designed search string encompassed terms related to all software engineering knowledge areas defined by the SWEBOK guide. Additionally, the terms related to emergent Software Engineering areas, such as Global Software Engineering and Aspect Oriented Programming, were also considered. Finally, we also included the term *programming*, which is directly connected to many courses in both Software Engineering and Computer Science programs.

Another threat is related to the data extraction process and inappropriate classification, i.e. the possibility of a study being classified differently by different researchers. To mitigate such threat, the selection and data extraction procedures were performed by both authors to validate each others’ decisions.

VI. CONCLUSIONS

This paper presented a systematic mapping study carried out to aggregate the evidence on the usage of Bloom’s taxonomy in the Software Engineering education. The initial search returned 144 results and the application of a 2-stage screening procedure resulted in the inclusion of 26 primary studies.

The included studies are reported from many countries across five continents, wherein the USA is the leading country in this regard. Twenty six studies (80%) were published as conference papers and there is an increased interest in the topic from year 2008 onwards. Most primary studies were categorized as solution proposals (16 - 62%) or experience reports (6 - 23%).

Software construction is the leading SE subarea in which SE educators have applied the Bloom's taxonomy for the course design and assessment. We believe that there is a strong need to conduct and report more studies in other SE subareas.

It was identified that 85% (22) of the included primary studies applied the Bloom's taxonomy at undergraduate level, while only 12% deal with master's level SE programs or courses. Bloom's taxonomy has been applied almost the same number of times for both course design and assessment, indicating the relevance of taxonomy for both design and assessment of SE courses.

The original version of the Bloom's taxonomy has been applied most of the times (85% - 22 studies), while the revised version is used in only 15% (4) of the primary studies. Majority of the studies (85% - 22 studies) applied all six levels of Bloom's taxonomy in the design or assessment of SE courses. Most frequently used levels of Bloom's taxonomy are "comprehension" and "application", which complies with the applied nature of the SE discipline.

The reflections provided in four studies on the application of Bloom's taxonomy for the design and assessment of software engineering courses clearly points out the usefulness of the taxonomy. We believe that more reflections would have further helped in understanding the usefulness of the Bloom's taxonomy in SE education.

We believe that philosophical and evaluation studies [13] should be conducted to strengthen the evidence on the usefulness of Bloom's taxonomy in the context of SE education.

We intend to use the results from this systematic mapping study to develop a set of guidelines aiming at supporting the usage of Bloom's taxonomy cognitive levels to design and assess SE courses.

AUTHORS' CONTRIBUTION

Ricardo Britto and Muhammad Usman both contributed equally in the design and execution of the study reported herein; all the work was equally divided between both of them. They also wrote and reviewed this paper jointly.

ACKNOWLEDGMENTS

We would like to thank CNPq (National Council for Scientific and Technological Development - Brazil), UFPI (Federal University of Piauí - Brazil) and INES (National Institute of Science and Technology for Software Engineering - Brazil) for partially supporting this work. We also would like to thank Professor Åse Nygren for her feedback on a previous version of this paper.

A Project-based multi-disciplinary elective on digital data processing techniques

Firas Hassan, Joao Lucas Magalini, Victor de Campos Pentea, Rodrigo Azevedo Santos
Electrical and Computer Engineering and Computer Science Department
Ohio Northern University
Ada, OH, USA
f-hassan@onu.edu

Abstract— Today's era of internet-of-things, cloud computing and big data centers calls for more fresh graduates with expertise in digital data processing techniques such as compression, encryption and error correcting codes. This paper describes a project-based elective that covers these three main digital data processing techniques and can be offered to three different undergraduate majors: electrical and computer engineering and computer science. The course has been offered successfully for three years. Registration statistics show equal interest from the three different majors. Assessment data show that students have successfully completed the different course outcomes. Students' feedback shows that students appreciate the knowledge they attain from this elective and suggest that the workload for this course in relation to other courses of equal credit is as expected. **Keywords**—source coding; cryptography; channel coding; multi-disciplinary; project based

I. INTRODUCTION

Digital data processing techniques such as source coding, encryption and channel coding that are available in digital communication systems offer combined one of the largest advantages of digital communications over analog communications. Without these techniques applications such as video streaming, online commerce, and wireless communication with high fidelity would have never existed.

Typically digital communication is covered from the perspective of signals and systems and focuses on modulation and demodulation techniques at the binary and M-ary level and their performance in the presence of noise. Even a higher level elective in digital communication will usually cover wireless communication techniques such as spread spectrum, CDMA and OFDM.

Because digital data processing techniques process data instead of signals, students do not require the signals and systems background to understand them. Instead they only need a background in digital systems and statistics which is usually a common knowledge among multiple disciplines such as computer science, computer engineering, and electrical engineering. This opportunity has been utilized at XXX University in a form of a project-based multi-disciplinary elective that focuses on digital data processing techniques. The elective has been offered successfully for multiple years.

The class is divided into three modules. The first module covers a number of text, audio, image and video compression techniques. During this module, students are required to compress a scanned image of text using run-length coding.

The second module covers a number of private and public key encryption techniques such as stream encryption, RSA encryption and elliptic curve encryption. During this module students are required to build an RSA encryption technique and simulate it. The third module covers a number of channel coding techniques such as linear block codes, convolutional codes and Reed-Solomon codes. During this module students are required to build an RS encoder/decoder and simulate it. At the end of the semester, students are asked to solve a practical industrial problem that requires the combination of the three data processing techniques.

This paper describes the structure of the class and its associated projects. It also shows a sample of students' work and assessment data based on students' work and feedback and enrollment statistics.

II. COURSE ORGANIZATION

The course is designed to be offered as a senior level elective for Electrical and computer engineering and computer science undergraduate majors. It requires a background in hardware and statistics. Hence, the list of prerequisites consists of a course on digital logic and another on statistics, which are usually core courses in the three majors in most institutes. It is offered as a 3 credit, 15 week semester based course.

The first three blocks of any digital system are source coding or compression, encryption and channel coding or error-correcting codes. The class is divided into three modules that cover those three blocks in order. Every module requires students to take an exam that tests their knowledge in the material and finish a project that examines their ability to apply this knowledge. In addition, there is a final project that groups the knowledge they have learned from the three different modules. The first module covers compression techniques in 4 weeks and its associated project requires two weeks of work. Similarly, the second module covers encryption techniques in 4 weeks and its associated project requires 2 weeks. The third module covers channel coding techniques in 8 weeks and its associated project requires 4 weeks. The final project requires two weeks of work. The grading policy is as follows:

Module 1	
Exam	10%
Project	10%
Module 2	

Exam	10%
Project	10%
Module 3	
Exam	20%
Project	20%
Final project	10%

The main text book used is Digital communication fundamentals and applications by Bernard Sklar[1]. But, a number of other references are also used for extra material[2, 3, 4, 5 and 6]. A detailed description of the three different modules and their associated projects, as well as, the final project is described in the following sections.

First Module

The first module starts by introducing the different sources of data such as text, audio, image and video. The large size of data of the different sources is emphasized implying the importance of compression techniques in today's era of Big Data. In addition, there will be a general discussion on the type of redundancy in different sources and how to utilize this redundancy to achieve compression. Following this introduction, is a review of statistical concepts such as random variables, probability density functions, joint probability density functions and dependent random variables. The concepts of information theory such as entropy of discrete sources, memory/memoryless sources and first order Markov sources are discussed next.

Variable length codes are essential for compression, but unlike fixed length codes they are much harder to be decoded without favorable properties such as uniquely decodable and prefix free. Huffman Codes are prefix free uniquely decodable variable length codes that assign shorter number of bits for symbols of high probability. A famous subset of this family of codes are the run length codes that create symbols from different runs of ones and zeros. After these codes are introduced students will be ready to take their first project.

While students are working on their first project, specifics about the compression techniques of different sources are introduced starting by the Lampel-Ziv algorithm for text files and followed by audio, image and video compression. A review of sampling and quantization precedes the discussion of Differential Pulse Code Modulation (DPCM) which is considered the basis of every audio compression technique. DPCM utilize the redundancy between Nyquist samples to predict future samples from current and past samples and quantize the error in the prediction instead of the samples. This concept is also utilized in video compression using frames instead of samples.

Huffman codes achieve high compression rates for discrete sources that have large difference between the probabilities of occurrence of their different symbols. On the other hand, most natural images have almost flat histograms indicating equiprobable symbols which make them a very bad candidate for compression without a sort of transformation that can change the statistics of their symbols. Examples on such transformations are Discrete Cosine Transform and Wavelets that are used in JPEG and JPEG2000 compression techniques, respectively. In addition, it is also necessary to zero the

transformation coefficients of low magnitude to create sparse matrices that can be effectively compressed using run length codes. Hence, image compression techniques of high compression rates are not lossless. But, the data lost is not visually important.

The first module ends by discussing video compression which combines concepts of DPCM and source transformation. Frames are divided into I, B and P frames. I-frames are compressed using image compression techniques. B frames are represented by motion vectors that predict the position of each object in the frame. P frames are used to correct the error in prediction. This concept is used in many famous video compression techniques such as MPEG.

Second module

The second module starts by a hooking lecture discussing the importance of encryption in today's era of internet-of-things which is raising a lot of questions about security and privacy. Next, encryption techniques are divided into public and private key and students are asked to choose the encryption family appropriate to a specific application. For example, while private key is appropriate for applications that need subscription such as satellite broadcasting and cell phones, it is completely not appropriate for applications such as e-commerce and digital authentication that requires public key.

The purpose of any encryption technique is to make it computationally impossible for the cryptanalyst/hacker to deduce the encryption key from the cipher text and use it to decrypt the message. Shannon suggested two concepts to frustrate the cryptanalyst. Confusion involves substitutions that render the relation between key and cipher text as complex as possible. Diffusion involves transformations that smooth out the statistical differences. Any successful encryption technique, whether public or private, should have these two properties.

Private Key encryption techniques utilize Pseudo Random Generation Algorithms (PRGA) to confuse the relation between the private key or password and the cipher text. PRGA can be done either in software or hardware. They also use permutation blocks to smooth the statics of the cipher text and avoid plain text attacks. It should be noted here, that compression should always precede encryption because it helps in reducing the redundancy of the message smoothing its statistics even before encryption.

Public Key encryption techniques are based on the concept of trapdoor one-way functions. A one-way function is an easily computed function whose inverse is computationally infeasible.

A trapdoor one-way function is a one-way function whose inverse is easily computed if certain features, used to design the function, are known. Famous examples of one-way functions include Knapsack problem, prime factorization of the product of two extremely large prime numbers and elliptic curve discrete logarithm problem.

After covering these concepts, the famous Rivest-Shamir-Adelman (RSA) encryption scheme is introduced. RSA is divided into the following six steps:

1. choose three prime numbers: $d > p > q$
2. $n = pq$
3. $\phi(n) = (p - 1)(q - 1)$
4. $e \bmod \phi(n) = 1$
5. $C = M^e \bmod n$
6. $M = C^d \bmod n$

Euclid algorithm and fast exponentiation are utilized to compute steps 4 and 5/6, respectively. Both algorithms are discussed in details in the class. The second class project is based on RSA.

While students are working on their second project, elliptic curves are introduced and discretized to a finite number of points on the curve using prime fields. Next, elliptic curve arithmetics such as addition and doubling are discussed. Encryption techniques that are based on elliptic curves require much smaller keys relative to RSA. A 160-bit key in Elliptic Curve Cryptography (ECC) is considered to be as secured as 1024-bit key in RSA. These techniques are based on the fact that given a point P on the curve and a constant k , it is easy to get to the point $Q = kP$ using the addition and doubling operations. However, given two points on the elliptic curve P and Q , it is computationally impossible to find the relation between them. A cryptanalyst should start from a generating point on the curve and find the relation between all the points on the curve and this generating point to create a cyclic subgroup over this generating point before being able to solve the elliptic curve discrete logarithm problem. This module ends by discussing two basic ECC techniques: ELGamal and Menezes-Vanstone.

Third module

In today's era of data centers and cloud computing, it is becoming extremely important to protect data from any hardware faults using parity check-sums and redundant backup capabilities. On the other hands, applications on our cell phones such as video streaming has made our channels both bandwidth and power limited. In addition, both compression and encryption exaggerate the problem because compression reduce redundancy in the message increasing the effect of error and encryption smooth statistics between symbols causing an error propagation problem. Hence, channel coding should always follow those two blocks to provide us with the best tools to deal with these challenges. As a hooking experience, students at the beginning of this module are asked about the required probability of error for today's applications. For example, nowadays it is for granted that a customer can download a complete book on his phone in an extremely short time and without a single character in error.

Channel coding techniques are generally divided into three categories: linear block codes, convolutional codes and iterative codes. Under the category of linear block codes, there exist the cyclic codes that can be used for bits or symbols. A famous class of cyclic codes that work with symbols and are capable of protecting data from bursts of error are Reed-Solomon (RS) codes. Before introducing this class of codes,

students should understand important concepts such as representation of binary data in polynomials, generating code words by using polynomial multiplication between the generating polynomial and the message polynomial, calculating the syndrome of a received word using polynomial division, and decoding the error pattern from the calculated syndromes. Students should also learn how to implement a basic binary cyclic encoder/decoder in hardware.

These concepts can then be easily extended to symbols of multiple bits by using finite Galois Field (GF) arithmetic including addition and multiplication. After discussing GFs the instructor explains the hardware and functionality of an RS encoder. He also explains how to calculate the syndrome of the received vector at the input of the decoder. Decoding the error patterns from their respective syndromes is much harder in RS than in binary cyclic codes because the decoder should locate both the location and value of the error, while in the binary case only the location is important. RS decoding algorithms such as auto-regressive modeling techniques are used to decode the error pattern from the calculated syndromes. After introducing these concepts, students will be ready to take their third project.

While students are working on their third project, the instructor will describe how to enhance the capabilities of RS codes against burst errors by interleaving the message data before encoding. At the receiver side, the data will be deinterleaved transforming the burst of error into randomly distributed error. This will change the channel characteristic from a memory channel, where there is a lot of dependence between the probability of error of neighboring symbols, as close as possible to a memoryless channel. Interleaving is very famous in memory platforms such as DVDs where data is not written and read at the same time. However, the buffering memory and time required to interleave/deinterleave the message data will quickly become very costly in real-time applications.

Although, interleaving help tackle bursts of error, it does perform poorly against randomly distributed errors. In fact, it can take randomly distributed error and transform it accidentally to a burst of error. Hence, it is important to concatenate channel codes, such that one will work on the message before interleaving and the second will work on the message after interleaving. Concatenated codes are covered briefly in this module.

Next, the instructor will backup to binary linear block codes that use generating and parity check matrices instead of polynomial multiplication and division. He will also touch on the positive effect of channel symbols on the probability of error curves of different communication techniques. In general, channel codes are used to achieve one of three different things. First, reduce the energy per bit required to achieve a particular probability of error. The amount of reduction is the Coding Gain (CG) and is usually calculated in decibels. Second, increase the bit rate for the same probability of error. Because the energy per bit is inversely proportional to the bit rate, a higher bit rate is an indication of a lower energy per bit. Third, reduce the probability of error for the same energy per bit.

Convolutional codes are built to work with Close-Circuit (CC) applications such as phones and CCTV, where messages cannot be divided into different blocks or packets because they are streamed continuously. Convolutional codes are used in such applications to insert the parity bits and check them while the data is being streamed. The instructor explains the operation of convolutional encoders and their representation using Trellis diagram. He then covers the Viterbi decoding algorithm and touch on its implementation in hardware. Finally, he covers the properties of the convolutional codes and their corresponding CG for hard and soft decision receivers.

By this time, students have submitted their third project and are ready to take their fourth and final project that uses the three modules that are covered in this class. For the last two weeks in the class and while students are working on their final project, the instructor will cover iterative codes, the most recent channel coding category. The instructor will focus on how to utilize soft decisions and feedback in decoding to increase the CG. The log-likelihood algebra and the maximum a posteriori decoding algorithm are covered as part of this focus.

III. PROJECTS DESCRIPTION

Students are asked at the beginning of the year to form multi-disciplinary groups of two or three members to work on the different projects. The instructor will explain to the students, that they need expertise in different areas to finish the projects successfully and ask them to be thoughtful about picking their group members. At the end of the first week of classes, students form their groups and submit a document to the professor showing the expertise of the different members in the group and explaining how the group will be successful in finishing the future assigned tasks. The instructor will then assign group members based on students' recommendation. After the groups have been assigned, students are only allowed to change their groups between projects, if they prove to the instructor that their group lacks the necessary expertise to finish the allocated tasks, and that there is another group in the class that can benefit from a swap of expertise. There should be a mutual agreement between the two groups that want to swap their members.

All projects require a weekly progress report. The first three projects that are associated with different modules require presentation/demoing of the simulation results. The final project is in a form of a technical report that proposes a solution for a practical problem in the field. However, students should also pitch their solution to the virtual customer represented by the instructor. The grading policy of the first three projects is as follows: 20% are associate to timeliness and are based on whether the students are following the schedule correctly. 10% are associated to trouble shooting and are based on whether the students required the help of the instructor to finish their task. 40% are associated with the completeness of simulation results. 20% are associated to the presentation skills of the different members of the group. Finally, 10% are associated to the coding language used and whether students have used a high level or low level description of the system, which is as close as possible to

hardware. The grading policy of the final project is as follows: 20% are associated to timeliness, 50% are associated to the technical content of the report and 30% are associated to the pitching of the solution. The following sections describe the projects in details.

Project 1

Students are given two weeks to:

- Construct a 128×128 image in paint made up of text and save it in monochrome bit map format.
- Read the image and find its runs of Black and White.
- Find the probability of each run and construct the Huffman coding table.
- Use the Huffman coding table to compress the image.
- Add the Huffman coding table to the header of the compressed image.
- Save the file and compare its size to the original file format and calculate the saving.
- Decompress the image by reading its symbols and using its header to decode its symbols and display it.

Project 2

Students are given two weeks to realize an RSA encryption/decryption system. The block diagram of the encryption technique is shown in Figure 1. At Bob's side: given three 16-bit prime numbers d , q , and p the system will find the public key (e, n) and transmit it to Alice. Alice will use fast exponentiation algorithm to get the cyphered text C from the message M and the public key. Then Bob will use the fast exponentiation algorithm to find M from C and his private key (d, n) . Both M and C should always be less than n . Students can use any type of message data to simulate their system such as text, audio or video. Extra points are given for students who can increase the precision of the prime numbers and implement the special cases of the fast exponentiation algorithm.

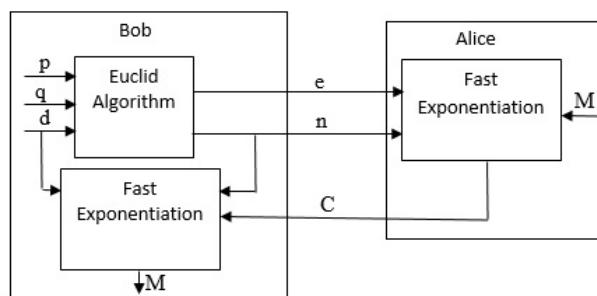

Fig. 1. Block diagram of project 2

Project 3

Students are given four weeks to build the following:

- RS encoder
- RS syndrome calculation block
- Syndrome to error pattern decoder
- A complete RS system that shows the error correction process

The RS code used is the (7,5) which is created out of 3bit symbols and can correct one symbol in each block. Deliverables and divided into four different weeks.

Week 1

- Derive the generating polynomial of the (7,5) code.
- Sketch the encoder for the (7,5) code and run an example by hand.
- Sketch the syndrome calculation block of the (7,5) code and verify the following:
 - The code word has two syndromes $S_0=S_1=0$.
 - Pick an error pattern and find its syndromes and verify that the code word corrupted by this error pattern has the same syndromes.
- Find the syndromes of all the error patterns that can be corrected. Notice that we are only interested in the five message symbols and each symbol can be corrupted in seven different error patterns. Hence, you have to calculate the syndromes for a total of 35 error patterns.

Week 2

- Describe the encoder in your chosen language.
- Run several simulations to verify that your hardware description is working correctly.

Week 3

- Describe the syndrome calculation block in your chosen language
- Run several simulations to verify that your syndrome calculation is working correctly.
- Describe the syndrome to error pattern decoder and check its functionality.

Week 4

- Describe the whole system using the previous hardware blocks.
- Find a method to induce an error pattern into the transmitted channel block and verify that the RS decoder can correct this error for single symbol error patterns.
- Verify that RS decoder cannot correct all error patterns.

Project 4

For the final project, students are given the following problem statement:

"A manufacturing company is currently installing two-wire cables in their products. The cables are used as a communication link to update the different parts of the products. The updates should be done in the fastest time possible because their customers cannot operate their products while they are in update mode. Also, the updates should be reliable and secure. Although the two-wire cables are considered old technology, they can withstand mechanical stress, typical in the product operation, better than any other

newer cables such as coaxial or fiber optics. Therefore the company is interested in achieving the fastest reliable and secure bit rate on the two-wire cables. There is also a constraint on the voltage level through the cables. The company understands that the solution to their problem will involve a combination of all the different techniques that we have studied in this class."

Students are then given two weeks to construct a proposal for the company and effectively communicate it. The proposal should include:

- The different techniques that need to be implemented to solve the problem.
- The hardware platform required to implement these techniques
- The cost of implementing these techniques in hardware.
- The time of delivery of the prototype
- Testing plan

All projects are designed to test students in their ability to effectively collaborate in a team setting and apply critical and creative thinking to ambiguous problems. In addition the final project also test the students on their ability to construct and effectively communicate a customer appropriate value proposition. All there outcomes are highlighted as key components for a successful entrepreneurial engineer/scientist.

IV. SAMPLE OF STUDENTS WORK

Through the years of offering this elective, different groups of students have excelled in accomplishing achievements beyond the required tasks of the four different projects. Highlights include:

- Design of user interfaces that can demo the different steps of the first three projects.
- Creating a new library in Matlab that can implement addition and multiplication and find the quotient and remainder of the division of binary data with user-set bit precision. The library was utilized in project 2, where students were able to show simulated data with large bit precision.
- Describing Booth multiplication and suggesting Booth-like modulo operator to be used in project 2. The results of this group of students' work were presented in the Midwestern Symposium of circuits and systems.
- Experimenting with different sources of data in project 2 and 3 such as text, audio and images.

The most impressive highlight was achieved by a group of students who are co-authoring this paper for their efforts in implementing the third project at the lowest level of hardware description, and showing both low level and high level simulation results.

The RS encoder, syndrome calculator and error decoder were described in structural VHDL at the gate level. As an example, Figure 2 shows a step-by-step demonstration of the operation of the RS encoder. In addition, Figure 3 shows a snapshot of the simulation of the whole system in Modelsim.

In addition, students were able to write a testbench that can do the following:

1. read a text file and transform it to a binary message
2. run the binary message through the RS encoder
3. insert errors at controlled locations in the encoded message
4. Validate that RS(7,5) can successfully correct all error patterns that are limited to a single symbol per code word.
5. Validate that RS(7,5) could potentially make things worse if the error exceeds its limit.

Figure 4 a shows the text message used to test the system. The corresponding binary message is shown in Figure 4b. Figure 4c highlights the error locations in red. Figure 4d shows how the system can correct the inserted errors (highlighted in green). Figure 4e shows a dramatic case where the error highlighted in red exceeds the capabilities of RS(7,5). Figure 4f shows that although RS(7,5) can still correct some bits (highlighted in green), it fails to correct other bits (highlighted in red) and may even introduce new errors (highlighted in blue).

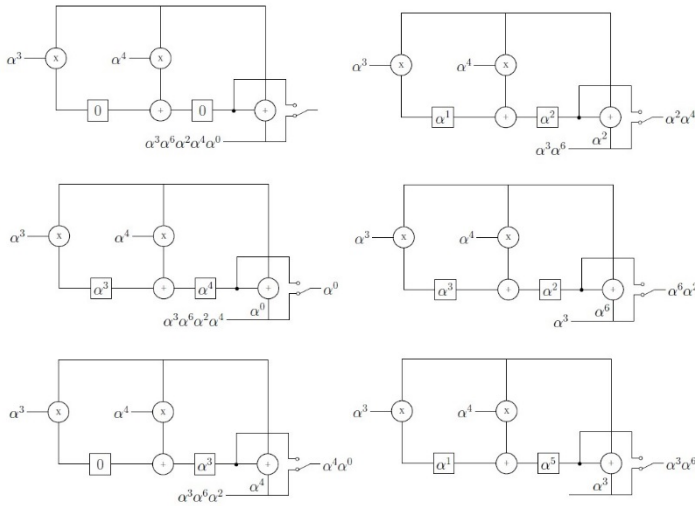

Fig. 2. A step by step demonstration of the operation of the RS(7,5) encoder.

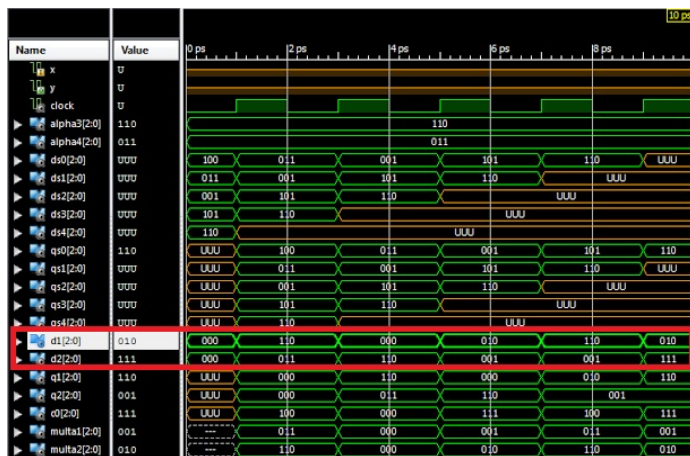

Fig. 3. A snapshot of the Modelsim simulation of project 3.

What we observe is not nature itself, but nature exposed to our method of questioning. Werner Heisenberg

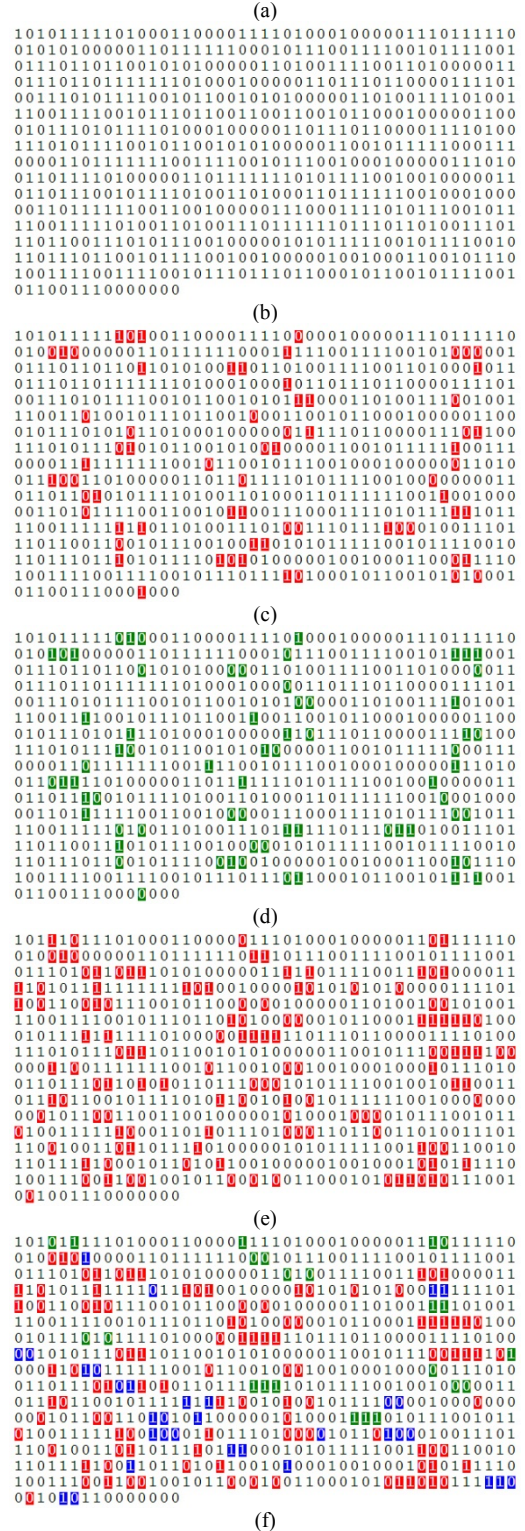

Fig. 4. High level simulation of project 3.

V. ASSESSMENT

The proposed project-based multi-disciplinary elective on digital data processing techniques has been offered for three consecutive years. Table I summarizes the number of students

from the three different majors that has registered and successfully completed this course. As shown in the table, students from the three different majors have shown equal interest in this elective.

Table I. Summary of the number of students from different majors who have registered in the class in the last three years.

CS	CPE	EE	Total
20157	2	4	13
20144	4	8	16
20130	4	6	10
Total11	10	18	39

The course have four main outcomes:

CO1: Implement and simulate digital communication systems with error correcting capabilities

CO2: Realize some encryption and decryption techniques

CO3: Implement different source coding techniques.

CO4: Construct and effectively communicate a customer appropriate value proposition

CO5: Effectively collaborate in a team setting and apply critical and creative thinking to ambiguous problems

These outcomes were assessed by the course instructor using four levels: Proficient (P), Meets expectation (M), Developing (D), and Below expectation (B). Table 2 summarizes the result of this assessment and provides the mean for every course outcome, where P, M, D and B are scaled by 4, 3, 2 and 1, respectively. As shown in Table II, all course outcomes were meet with means higher than 3.3.

Table II. Summary of course outcome assessment

	P	M	D	B	Mean
CO1 23	8	6	2		3.33
CO2 23	10	3	3		3.35
CO3 26	6	3	4		3.38
CO4 25	9	5	0		3.51
CO5 30	6	3	0		3.69

Finally, students have evaluated the course through the three different years using institution anonymous course/instructor evaluation surveys. The main statements in the survey that are related to the course evaluation are:

F1: The course was designed to foster learning of the course material

F2: The course provided me with an important skill set needed for further studies in this field

F3: The course enhanced my problem solving abilities

F4: The workload for this course in relation to other courses of equal credit was as expected.

Students comment on each statement by Strongly Agree (SA), Agree (A), Neutral (N), Disagree(D), and Strongly Disagree (SD). Table III summarizes the result of these surveys and provide the means, where SA, A, N, D and SD are scaled by 5, 4, 3, 2, and 1, respectively. Based on the table the mean of students' feedback is higher than 4.

Table III. Summary of students feedback

	SA	A	N	D	SD	Mean
F1	9	7	0	0	0	4.5
F2	6	5	3	1	0	4.1
F3	6	9	2	0	0	4.2
F4	8	7	1	1	0	4.3

VI. CONCLUSION

In conclusion, this paper provides a summary of a senior level project based elective that can be offered to three different undergraduate majors: computer science, computer engineering and electrical engineering. The paper describes the course organization and its associate projects. It shows a sample of students' work and show the assessment data for three different years of offering this course.

Developing a Course Module for Teaching Cryptography Programming on Android

Jinsheng Xu, Xiaohong Yuan
Department of Computer Science
North Carolina A&T State University
Greensboro, NC, USA
jxu@ncat.edu, xhyuan@ncat.edu

Abstract— Mobile platforms have become extremely popular among users and hence become an important platform for developers. Mobile devices often store tremendous amount of personal, financial and commercial data. Several studies have shown that large number of the mobile applications that use cryptography APIs have made mistakes. This could potentially attract both targeted and mass-scale attacks, which will cause great loss to the mobile users. Therefore, it is vitally important to provide education in secure mobile programming to students in computer science and other related disciplines. It is very hard to find pedagogical resources on this topic that many educators urgently need. This paper introduces a course module that teaches students how to develop secure Android applications by correctly using Android's cryptography APIs. This course module is targeted to two areas where programmers commonly make many mistakes: password based encryption and SSL certificate validation. The core of the module includes a real world sample Android program for students to secure by implementing cryptographic components correctly. The course module will use open-ended problem solving to let students freely explore the multiple options in securing the application. The course module includes a lecture slide on Android's Crypto library, its common misuses, and suggested good practices. Assessment materials will also be included in the course module. This course module could be used in mobile programming class or network security class. It could also be taught as a module in advanced programming class or used as a self-teaching tool for general public.

Keywords— computer science; programming; Android programming; cryptography; security; course module; cryptography programming; SSL

I. INTRODUCTION

Mobile platforms have become extremely popular among users and hence become an important platform for developers. Computer science students are increasingly more interested in learning mobile development. Therefore, mobile application development has become an important topic in computing curricula. New privacy and security issues arise with the prevalence of mobile computing. Mobile devices often store tremendous amount of personal, financial and commercial data. As such, mobile devices attract both targeted and mass-scale attacks. Therefore, it is vitally important to provide education in mobile computing and security to students in computer science and other related disciplines.

Several studies have shown that most of the mobile applications that use cryptography APIs have made mistakes. In one of the study, the authors developed a tool that automatically check apps on Google Play market place and they found that 88% of the 11,748 apps have made at least one mistakes [1]. Some of the apps were vulnerable to chosen plaintext attacks. The common mistakes in this category include using Electronic Code Book (ECB) mode for encryption and using non-random Initial Vectors (IV) for Cipher Block Chaining (CBC) mode. The other mistakes include using constant key for symmetric key encryption, and using constant salt for password-based encryption. In another recent study, the authors studied the misuse of SSL in Android apps on Google Play. They found that 448 out of 614 apps did not verify digital certificate, which make these apps vulnerable to Man-in-the-Middle (MITM) attacks [2]. Another study analyzed 13,500 popular free apps on Google Play market place and found out that about 1,074 (8%) of them were potentially vulnerable MITM attacks [3]. Validating SSL certificates is not an easy task. A study titled "The most dangerous code in the world: validating Secure Socket Layer (SSL) certificates in non-browser software" found that SSL validation was broken even in security-critical applications [4]. Although studies have shown different statistics, it is safe to say that there are significant number of applications that have not used cryptographic APIs correctly, which can potentially harm the mobile users by losing private information to the hackers.

It is important to educate computer science students who are going to develop mobile apps in the future to know how to develop secure cipher applications. It is very hard to find pedagogical resources on this topic that many educators urgently need in their classrooms. In this paper, we introduce a course module that addresses this problem. This module contains four main components: learning objectives, lecture, hands-on assignment, and assessment. This course module could be used in mobile programming class or network security class. This project is part of a larger project of developing twelve course modules on mobile computing and mobile security and integrating them into computer science courses at the Department of Computer Science, North Carolina A&T State University. Such an approach allows universities that do not have resources to create standalone new courses on mobile computing and mobile security to introduce these concepts to

their students. This course module fits the Platform-Based Development Knowledge Area in the ACM/IEEE Ironman Draft (version 0.8) of the Computer Science Curricula [9].

The rest of the paper is organized as follows. Section 2 describes the background research on android programming with encryption, and with SSL. Section 3 introduces the course module including the learning objectives, lecture, hands-on assignment, and assessment. Section 4 concludes the paper and discusses future work.

II. BACKGROUND RESEARCH

A. Android Programming with Encryption

Android apps need to encrypt data for many reasons. Android has multiple storage options including databases, internal storage, and external storage [5]. Data that are stored in external storage with SD cards are “world-readable”, which means any app running on the same device can access them. If apps want to store data on external storage and still want to keep them private, apps need to apply encryption to the data before storing them. Data that are stored in internal storage are private to the apps that created them. However, sensitive data (e.g. third-party passwords) should always be encrypted even if they are stored in internal storage. Rooting android devices, bugs in apps, or the bugs in Android could all potentially cause the data stored in the internal storage to be lost without encryption.

Android provides system level full disk encryption (FDE), which automatically encrypts data before storing to the storage. This protects the data in case mobile devices are lost or stolen by making it very hard for hackers to recover the stored data. However, FDE usually does not apply to the external storage and not all devices have FDE feature turned on. Recently, some Android Lollipop devices do not have FDE turned on due to performance issues even though Lollipop was designed to have this feature turned on by default [6]. For Android app developers, it is always a good practice to encrypt sensitive data regardless of the status of FDE.

Android’s cryptography SDK includes Java Cryptography Extension (JCE) providers that implements common symmetric ciphers, hash functions, message authentication code (MAC) algorithms, secure random number generators, and key management. Android app developers can easily access these APIs to encrypt the data. There are two types of common mistakes when Android app developers are using the crypto libraries:

(1) Not choosing the more secure modes of operation or using the constant initial vectors (IV) for safer modes of operations. Instead of using ECB mode, programmer should use CBC mode with random IV’s to make the cipher text much harder to break.

(2) Implementing key management incorrectly. The encryption keys should not be stored together with the cipher text or hard coded into the source code. The reason is the same as why passwords should be encrypted, which are explained in a previous paragraph. The solution is to ask for the keys when encrypting or decrypting. Because random keys are almost

impossible to remember, passwords are used to generate the encryption keys. One idea is to use the passwords as the keys. Since passwords are very likely to be shorter than the keys, the passwords are padded with constant values to length of the keys. This method is not strong because people tend to use passwords that are quite easy to break with password crack tools with rainbow tables. A more secure method is to generate secure random number with the passwords as the seeds. However, the gain in security is very small. JCE provides strong password based key derivations function 2 (PKBDF2) that uses salt to make rainbow tables useless and repeat password based key generation process many times to make password cracking much slower. The suggested number of iteration is at least 1,000, which can make it even very hard to break the weaker passwords.

B. Android Programming with SSL

The secure socket layer (SSL) is one of the most common protocols for encrypting the communications between clients and servers. It is widely used to secure web applications using the HTTPS. It is also used to secure other application layer protocols including SMTP, IMAP, and POP3. SSL is based on Public Key Infrastructure (PKI) where servers send digital certificates signed by Certificate Authorities (CAs) to the clients. The format of digital certificates is specified in X.509 standard. The purpose of a digital certificate is to confirm that the included public key belongs to the included name of the server. CAs provide this confirmation by signing the digital certificates with their private keys. Currently, Android contains over one hundred trusted CAs. If a digital certificate is signed by a CA that is not in this list, the verification fails.

One of the main security threats to SSL is the MITM attacks. This type attack replaces the digital certificates with digital certificates of the attackers. Since the traffic is encrypted with the keys generated based on attackers’ public keys, attackers can decrypt the traffic and retrieve login passwords or credit card numbers. MITM attacks are easy to succeed if attackers have access to Local Area Networks (LANs), wired or wireless. One of such cases is public Wi-Fi networks or hotspots, which are increasingly popular methods of connecting to the Internet. Therefore, it is critical for Android apps to verify the digital certificates in at least two aspects. First, apps must verify if digital certificates are signed by a trusted CA. Second, the apps need to verify that if the subjects of the certificates match the hostnames of the servers. The hostname verification is important because attackers could also get digital certificates signed by a trusted CA.

In Android programming, there are two ways SSL can be used: (1) Using *HttpsURLConnection* class. Android apps developed with this class establish HTTPS connection with the web servers with digital certificates. Android APIs will automatically verify the digital certificates including the hostname verification. (2) Using the *SSLSocket* class. This library can be used to encrypt the communications of non-web applications (e.g. SMTP, POP3). Currently, Android APIs will not do host verification for *SSLSocket*. Therefore, programmers need to develop the code for this step.

There are a large number of Android apps that use SSL to communicate with servers that have only self-signed digital certificates. One of the reasons for this could be the high cost of purchasing a digital certificate from a trusted CA. The other reason could be the difference between the ways web services are accessed from desktop computer and mobile devices. In desktop environment browsers are the main software for users to access web servers. In mobile environment, service providers tend to develop their own apps that access their servers remotely. For example, desktop users use browsers to shop at Amazon.com while the mobile users tend to use Amazon's mobile apps to do the same thing. Many mobile apps communicate with the servers that are dedicated to serve their own apps only. Android APIs allow apps to develop their custom *TrustManager* and *HostnameVerifier* to bypass trusted CA requirements and even modify the hostname verification process. Therefore, there is no significant incentive for mobile developers to purchase the digital certificates from the CAs. Customizing the default Android's certificate verification process leaves huge room for making mistakes. For example, a modified *TrustManager* that accepts all certificates can make MITM attackers easily succeed by substituting the certificates with their own. Although there are security risks in using self-signed certificates for mobile apps, it can be secure against MITM attacks if the program was written correctly.

One common way of securing mobile apps with self-signed certificate is called "certificate pinning" [7]. In this method, the certificate can be hard coded into the mobile apps and loaded into *KeyStore* by the mobile apps. This method is secure but the limitation is that when servers change the certificates, the mobile apps have to be updated to accept new certificates. Another common method is to hard code the CA into the mobile app and the app load the CA to the *TrustManager*. Any digital certificates signed by the loaded CA will be accepted by the app. Google provides an automated network traffic security testing tool called "Nogotofail" [8] that can find if an Android has SSL vulnerabilities.

III. DEVELOPING THE COURSE MODULE

We are developing a course module on learning Android cryptography programming. This module contains four main components: learning objectives, lecture, assignment, and assessment.

A. Learning Objectives

Upon completion of the course module, students should be able to:

- 1) Use Android cryptography SDK to correctly implement password based encryption.
- 2) Correctly validate digital certificate and secure communication between a mobile app and web service using SSL.
- 3) Identify the weaknesses in programs that use Android Cryptography APIs.
- 4) Apply knowledge of cryptography to real-world problem solving.

B. Lecture Component

The lecture component introduces common mistakes programmers make when developing apps that use Android cryptography APIs and SSL. Recommendations of good practices of using cryptography APIs and SSL are introduced. This lecture is intended for students with some background in cryptography who are interested in learning the application of cryptography in real world, particularly in developing secure mobile applications. This lecture is intended to cover one hour by instructors. Students will be given study materials for developing Android cryptography programs and using SSL. This lecture will lead students to the assignment components.

C. Assignment Component

This component includes a programming assignment, in which students are asked to secure an existing Android app by using cryptography APIs. This Android app is an online contact list app that allows users access their contacts from anywhere and from any Android device. This app is based on Derek Banas's Youtube tutorial on Android programming [10]. The contact list sample program allows users to create, delete, and modify contacts and save them to Android's local SQLite database. We will modify the app to make it retrieve and store the contacts on a web server with a XML based web service APIs. The web service APIs will have both clear text and SSL with self-signed digital certificate. The code given to the students will be using the clear text version. Figure 1 shows a screenshot of the app running on an emulator.

Fig. 1. A screenshot the sample app.

Students will be asked to modify this contact list app to make it a super private. The requirements are: 1) the details of the contacts are not even knowable to the server; 2) all communication between the app and web service must be encrypted. To achieve this students should need to apply both SSL and password based encryption. The login password and the password for generating the encryption keys should definitely be different. The contact information must be encrypted before using the SSL web service to store it on the server. Other than these requirements, students can apply various methods to achieve the goal. This assignment is intended for students who already had some training in Android programming.

D. Assessment Component

One good way to assess students is to let them evaluate their peer's work. After students have finished the assignment component, they will present their solutions to all students in the classroom. Students will evaluate other students' solution with criteria including strength of security, simplicity, and performance. This will not only let students know how their peers solved problem differently, but also help them think deeply by analyzing different solutions, which is another great way of reinforcing their learning. Instructors can also judge students' understanding based on the quality of students' evaluations. In this assessment module we are to develop the peer evaluation forms and the instructor evaluation forms. We all create several quiz questions to test students knowledge in this area.

IV. CONCLUSION

In this paper, we introduced a course module that are designed to teach students to develop more secure cryptography programs on Android. This course module is targeted to two areas where programmers commonly make many mistakes: password based encryption and SSL certificate authentication. The course module includes an assignment that requires students to use Android's cryptography correctly to make a "super private" contact list app. This course module could be used in mobile programming class or network security class. It could also be taught as a module in advanced programming class or used as a self-teaching tool for general public. Future work includes using the course module in classes, evaluating its effectiveness, and disseminating the course module to other educators in computer science or information technology fields. This course module will be posted on <http://williams.comp.ncat.edu/mobile/>.

An Insider Threat Activity in a Software Security Course

Daniel E. Krutz, Andrew Meneely, and Samuel A. Malachowsky
Rochester Institute of Technology
{dxkvse, axmvse, samvse}@rit.edu

Abstract—Software development teams face a critical threat to the security of their systems: insiders. A malicious insider is a person who violates an authorized level of access in a software system. Unfortunately, when creating software, developers do not typically account for insider threat. Students learning software development are unaware of the impacts of malicious actors and are far too often untrained in prevention methods against them. A few of the defensive mechanisms to protect against insider threats include eliminating system access once an employee leaves an organization, enforcing principle of least privilege, code reviews, and constant monitoring for suspicious activity.

At the Department of Software Engineering at the Rochester Institute of Technology, we require a course titled Engineering of Secure Software and have created an activity designed to prepare students for the problem of insider threats. At the beginning of this activity, student teams are given the task of designing a moderately sized secure software system. The goal of this insider is to manipulate the team into creating a flawed system design that would allow attackers to perform malicious activities once the system has been created. When the insider is revealed at the conclusion of the project, students discuss countermeasures regarding the malicious actions the insiders were able to plan or complete, along with methods of prevention that may have been employed by the team to detect the malicious developer.

In this paper, we describe the activity along with the results of a survey. We discuss the benefits and challenges of the activity with the goal of giving other instructors the tools they need to conduct this activity at their institution. While many institutions do not offer courses in computer security, this self-contained activity may be used in any computing course to enforce the importance of protecting against insider threats.

Keywords—Software Security, Software Engineering, Computing Education

I. INTRODUCTION

Organizations devote vast amounts of time and resources protecting themselves against outside threats. These protection mechanisms include but are not limited to firewalls, data encryption, and defensive coding practices. A much more difficult threat to protect against is one which comes from within the company. An *insider threat* is a current or former employee, business partner, or contractor who has access to an organization's data, network, source code, or other sensitive information who may intentionally misuse this information and negatively affect the availability, integrity, or confidentiality of the organization's information system. Examples of insider attacks include data harvesting, abuse of privileges sabotage, and masquerading attacks. Additionally, a user could act as an insider threat and have no actual malicious intent. Inadvertent use of computing resources or data could make a system

susceptible to attack, or could unintentionally release sensitive data [6]. Insider threats are much more difficult to identify since potential threats are often users of a system which they themselves developed (potential leaving back doors and having deep intimate knowledge of the system) while, as developers, not being considered to be potential threats to the system [12]. Companies often choose mitigate the risk of insider threats through the use of policies and regulations [7].

Far too often, software engineers are not prepared to deal with fact that their co-workers, people who they should trust as allies, are in fact potentially malicious users capable of performing a wide range of destructive actions. In educational environments, students typically either work alone, or with teams — with instructors preaching the importance of teamwork and trust. While these concepts are important real-world examples dictate that the opportunity for a security threat must be considered.

At the Rochester Institute of Technology, we created an upper division Engineering of Secure Software applications course to help students understand how to incorporate proper security protection practices when designing, creating, and maintaining software. Some course topics include defensive coding practices, deployment & distribution strategies, vulnerability assessments, and threat modeling. In this course, we created an activity to help acclimate students with how to understand, protect, and recognize insider threats. Students teams are formed and students are given the task of designing a small application and planning for proper security. One student from each team is quietly pulled aside and told that they are the insider threat or *mole* for their team. Their goal is to have their team design an application containing a vulnerability which the mole would be able to later use. After the activity, the moles are revealed and a discussion takes place regarding how the moles were able to create the vulnerability, if the team recognized this vulnerability, and what could have been done to prevent this insider threat.

The rest of the paper is organized as follows: Section II describes the course including learning objectives. Section III discusses how the activity was conducted. Section IV provides student feedback about the project including quotes and post activity survey analytics. Section V presents some related works and Section VI discusses possible future work and improvements to the activity. Section VII provides concluding remarks about our work.

II. ABOUT THE COURSE

Primarily comprised of upper division Software Engineering students, the Engineering of Secure Software course¹ was created in 2012 and is focused on instructing students in the proper practices of design and creating secure software. The only prerequisite is the Introduction to Software Engineering course in which students are introduced to core concepts in software engineering such as development methodologies, team work in software development, basic testing principles, and software design.

The course has a primary learning outcome of preparing students to mitigate security threats in software systems and processes. The focus is on proper methods of designing, developing, testing, and maintaining secure software. While the course is language-agnostic and focuses on principles and practices, specific tools and technologies are used to reinforce the learning objectives of the course. For instance, Microsoft's SDL Threat Modeling Tool² is used to instruct students on the proper methods of designing the architecture of a secure system. Specific Java-based examples are used to demonstrate SQL injection attacks, log overflow attacks, hashing and salt, and path traversal exploits. Short Vulnerability-of-the-Day activities serve to introduce students to real world examples of exploits and demonstrate the importance of software security [11]. Students work in small teams on several course projects including the creation of a web fuzz testing tool and a case study which examines a real-world software project for vulnerabilities.

While we do not expect all students taking the course to become security experts, our goal is to instill fundamental principles of secure software development in the students while demonstrating its importance in the real world. Students are graded on several criteria such as three exams, several short projects, and brief in-class activities. Class size is typically 25-35 students and is a required course in the Software Engineering major.

In the course, we also discuss several ways of protecting against insider threats. While there is no easy or simple silver bullet protection mechanism against insider threats, there are some best practices which may be used to help alleviate this risk. Some of these protection practices include properly screening potential employees, implementing end point data leak protection, monitoring databases & sensitive records, and the proper use of rights management systems [15].

III. INSIDER THREAT ACTIVITY

In this section we describe the sample project, the activity conducted by the students, provide example vulnerabilities which the insider threats were able to create, and finally describe goals of the post activity discussion.

A. Sample Project

To begin, students are told that they are being asked to design a secure software system. In our course instances, we asked them to design a student grading system, much like ones which are typically used at many institutions. We selected this

example since we felt it was complex enough for students to have to actively consider numerous possible vulnerabilities and would allow for our insider threats to act maliciously, but simple enough for teams to design it in a class meeting or two. Additionally, we felt that students would be reasonably familiar with a system of this type.

Some basic requirements for this system were: Students should be able to view their grades, but not alter them or view the grades of their classmates. Instructors should be able to view the grades for all students, but only modify grades for students in the specific courses they were teaching. School administrators should be able to view and alter the grades of all students, at any time. All users are required to access the system using their username and password, and if any they have forgotten their password, the system should send a reminder to the person via email and allow them update the password from that link. The application also needed to be accessible from anywhere in the world using a basic web connection. A non-functional requirement was that the application database should be backed up on a nightly basis to an off-site location. For debugging purposes, it was required that all errors and user actions should be logged for system administrators.

B. Activity

Once students were given the basic requirements for their system, student teams of 4-6 students are formed, as this is often the size of groups in industry and has been found to be conducive to student learning in previous research [8], [14]. Before the start of the activity, a subset students were emailed asking them to be insider threats. They were asked to not share this information with anyone and to act just like any other member of the team. Their goal was to have their team design a system that would leave the door open for them to act maliciously in some manner. Examples included being able to view other student's grades view at a higher level of access, or change data which they should not be able to modify.

Example sections of our courses were offered in a 50 minute long format with this activity spanning two class periods. Teams were allowed the entire first class period to work on designing their system while the instructor answered any requirements specific questions the teams had. Teams were then asked to work on the activity outside of class. At the beginning of the second class meeting, teams were asked to review their security design and make any last minute updates. Teams were then informally polled to see how many felt their system was secure. This serves to gauge the confidence each team has in their design. Based on the confidence of the teams and the instructor's knowledge of each team's design, the team with the highest confidence and best design was asked to briefly present their design to the class and talk about why they felt it was secure. The class then asked questions about the design and try to discover any vulnerabilities.

After this brief discussion, the insider threat student for the presenting team is asked to make themselves public and describe the vulnerability they had left in the system design. The insider threats for other teams are then asked to expose themselves and describe the vulnerability they introduced into their team's design as well.

¹<http://www.se.rit.edu/~swen-331/>

²www.microsoft.com/security/sdl/adopt/threatmodeling.aspx

While the insider threats added vulnerabilities in a variety of ways, there were some commonalities in the methods chosen to ensure the application was exploitable. Most often, it was as simple as recommending poor security strategies to leave vulnerabilities in the system. In some instances, insiders would add a vulnerability into the team's design between class meetings which would not be caught during the review on the second class meeting. This mimics the real world situation of an insider adding malicious code into a project during off hours or without the knowledge of the rest of the team. Interestingly, insiders would often ensure that vulnerabilities existed in a system by simply doing nothing. They would notice their teammates leaving a vulnerability in the design due to a simple but honest mistake, doing nothing to fix this known issue.

C. Examples of Introduced Vulnerabilities

In order to provide some context regarding some of the introduced vulnerabilities, we will explain some of them in further detail and provide some examples of how they were used within the activity.

Not Limiting Failed Login Attempts

Limiting the number of failed login attempts is an important protection mechanism against brute force attacks. Without this limitation, attackers may systematically try password combinations until they achieve the correct password. This type of attack has been successfully made against a wide range of organizations, including Apple [13]. In one team, the insider made the argument that users should not be limited by their login attempts since this could be annoying to users and could hurt their user experience with the application. The team agreed and no limiting was done.

Publicly Saving Logs

A requirement of the system was to log all system errors and actions taken by users. Attackers could use these error logs to potentially gain information which could help them compromise the system. Some of this could include call stacks, information about how to create a log overflow, or any other sensitive information which was output to the log messages. Additionally, since the log files contained many alterations made to the system, this could expose potentially sensitive changes to malicious users such as the grades of students. In one team, the insider argued that these logs should be publicly available since it would provide easier access to developers when troubleshooting issues. On another team, they placed the generated log files outside of the trust zone of the system, which would expose these files to outside users. Their teams did not raise any objections to doing this.

Openly Transmitting Data Backups

A requirement was to backup the system database on a nightly basis to an off-site location. In a properly designed system, the database information would be encrypted before it leaves the trust zone, or sent via a secure or encrypted transmission so malicious users could not intercept the data being sent. Several insiders made sure that this database backup file was sent via insecure channels, meaning that it could have been

intercepted by a malicious or unintended party.

Use of Improper Cipher Techniques

Cipher techniques (which are covered in the second half of the course) are a way of encrypting information so they may not be deciphered by anyone but the intended parties. While advanced cipher techniques such as AES and RSA continue to provide high levels of security, older techniques such as DES no longer provide an adequate level of protection and can be broken with relative ease. In several groups, the insider was able to convince their team to use DES or another outdated cipher technique. This would have left the encrypted information susceptible to attackers.

Storing Passwords in Source Code

Developers should not store passwords in the source code of an application, even if it has been compiled. This creates several potential problems including the ability of a malicious user to reverse engineer the code to discover the user name and password. Since passwords should be routinely changed, altering them in compiled code is typically more difficult and much more infrequently done. In several instances, insider threats convinced their teams to store the database login information in compiled code since they argued that the information would be secure since it was compiled (an inaccurate statement) and that the passwords did not need to be updated (also inaccurate). This left the applications not only vulnerable to reverse engineering, but in the event a developer left the company, they would know that the database login and password information was unlikely to be changed making it susceptible to their attack. Interestingly, one insider was able to convince their team to make the login information be merely "root" and no password since this would be simpler for development. Giving an application root access which violates several security standards, including the *principle of least privilege* and having no password at all is bad for a variety of reasons.

Providing Too Many Privileges for User or Component

A basic principle of software security is the *principle of least privilege*, or the granting of the minimum number of privileges that an application needs to properly function [16]. Granting more privileges than the application needs creates security problems since individuals or software components could intentionally or unintentionally use these extra privileges for malicious reasons. In a few instances, insider threats observed instances of too many privileges and chose not to disclose the error, allowing it to propagate into future designs.

D. Post Activity Discussion and Goals

After the insiders were identified and the ensuing discussion about what malicious activities could have been performed on the software, a post-activity discussion takes place. The goal of this discussion is to foster student thinking about insiders, ways that insiders could maliciously act, and prevention methods against them. This discussion should be easy going to foster and encourage student led discussions and to encourage free thinking among the students. Due to

the nature of the activity, there are a wide range of potentially beneficial discussion topics. Some of these are outlined below.

Who Can Be Insider Threats?

Before the activity, many students thought of threats as being people external to the organization, and did not consider inside actors to be threats. Students who may have considered the possibility may not have realized that these threats which could be planned for. One potential outcome is a discussion of who can be insider threats. Regardless of the role on the team, each individual or group of individuals is a potential insider threat who needs to be protected against. In our activities, students discussed the various roles of teammates who were insiders and how similar roles in real-world projects could be hazardous.

What Malicious Actions did the Insiders Take?

Insiders conducted a wide variety of malicious actions in our activity using many different methods — many with relative ease. Students are encouraged to discuss the actions that insiders took on their systems and what some of the negative ramifications could have been. They are also encouraged to significantly explore and analyze the negative ramifications of the threats. As an example, in the situation where student records were publicly exposed, consequences which may not be immediately considered are the legal ramifications involved and potential lawsuits by students with publicly exposed grades. A related activity that could be done to augment this discussion would be to ask students to explore and report upon real-world examples of malicious actions taken by insiders.

What Damage Did the Insiders Cause?

In our activity instances, insider threats would have typically been able to inflict a significant amount of damage on the software project. Understanding the possible negative ramifications is a good way for students to realize the importance of protecting against insider threats and to plan for similar occurrences in their real-world development teams.

Did the Students Realize the Insiders Were Doing Anything Wrong?

In our discussions, students often reported that they had at least a feeling that the insiders were acting in a malicious manner, but failed to stop them. Some reasons included not wanting to create controversy, the feeling that security was not a prominent area of concern, or that their teammate *must have known what they were doing*. Points of discussion could include warning signs of vulnerabilities being placed in a system either for intentional or unintentional reasons, methods of alerting teammates about potential issues in a constructive manner and individual project ownership and empowerment.

How Could Thinking Like an Insider Help to Protect Against Them?

Thinking like an insider is a good way to prevent against them. If developers are always considering different ways that their system can be compromised, they will be more likely to develop their application using proper defensive

measures and to detect malicious actions by real inside threats.

What Could Have Been Done to Prevent Insider Threats?

One of the most important discussion topics should be what could have been done to prevent these insider threats (and similar ones) from occurring in future projects. Students are encouraged to discuss ways of preventing these threats from occurring in real-world projects. Some discussed methods include code reviews, internal accountability, maintaining an open culture, increasing auditability, and analysis by outside security auditors.

IV. STUDENT FEEDBACK

Students have expressed a significant amount of satisfaction in this activity and it has contributed to their overall satisfaction with the course. At the conclusion of the project, students are asked to submit an anonymous survey asking them to provide feedback regarding the project. Some of the questions were based upon the Likert scale, while other asked students to provide written feedback. Several of these questions and student responses are shown in Table I. The survey has been posed to students in the last three course offerings, all of which have used this activity component. A total of 68 students from these sections have chosen to respond.

These results indicate that the vast majority of students not only enjoyed the activity, but would also recommend it to a classmate as well. Additionally, most students felt that it reassembled a project which they were likely to encounter in the real world and were similar to tasks they were asked to complete while on cooperative internships.

The following are samples of written feedback that have been received:

“The surprise not only teaches the lesson but leaves an impression. This is probably due to the deception aspect of the activity.”

“It was really interesting to see how few people were looking for an insider threat and many threats went completely unnoticed. It showed that we weren’t prepared to consider our classmates as threats.”

“I liked how it showed me how easily insider threat can destroy a project..”

“Being continually consciously aware of all possible security threats, for not all risks lie within the implementation.”

“It might seem silly, but the first-hand experience of having someone betray the team, even on an insignificant level, leaves an impression that the same could actually happen in the real world.”

This feedback indicates that students not only enjoyed the activity, but felt that it was an effective learning mechanism as well.

TABLE I: Student Responses

	Strongly Agree	Agree	Undecided	Disagree	Strongly Disagree
You enjoyed the activity	19	37	10	2	0
You learned a lot as a result of the activity	14	39	11	2	0
The activity better prepared you for insider threats	21	39	5	1	2
You feel you are more prepared to deal with an insider threat	16	38	9	5	0
You would be likely to recommend the activity to a friend	16	29	15	7	0

V. RELATED WORK

Numerous works have examined insider threats from a general security perspective. Leyden [10] and Brancik [5] both discussed the importance of protecting against insider threats and the possible negative ramifications. Nostro et al. [12] developed a process for insider threat detection and mitigation using a variety of existing tools and new techniques with the goal being to define the objectives of the attacker and subsequently determining appropriate countermeasures. Other works have discussed various interesting ways of detecting insider threats; Almeahmadi et al [2] investigated the use of using physiological features to detect attackers and found that an abnormal deviation in a user's electrocardiogram amplitude could properly predict an attack before it occurred.

This activity fully engages students in the learning process, which is important as research has shown that students learn better when they are actively engaged in the process [1]. Various other learning techniques that use "active", "collaborate", and "cooperative" learning techniques have been recommended over the years [3], [4], [17], [18].

To our knowledge, this activity was the first of its kind to introduce an insider threat into a software security classroom activity. However, Krutz and Vallino [9] used a similar activity to teach freshman seminar students about problematic teammates. In this activity, moles were added to teams and performed roles such as non-contributors, side trackers and absentee team members. A post-activity discussion focused on these problematic team members and how they can be properly addressed. Creating an activity that was not only informative but also enjoyable for the students is an important objective.

VI. FUTURE WORK

This project has been utilized in several sections of our Engineering of Secure Software course and has been very successful, but there are a few enhancements to the activity and further data which may be collected. In future iterations, we would like to further record and analyze the exploits created by the insiders. This would not only be helpful for better planning future offerings of this activity, but would likely be interesting to researchers as well. Once an insider's exploit is exposed during the class discussion, a secondary activity could be for the team to resolve that exploit like they would in a real-world environment. This could include steps taken to mitigate the exploit and measures which could be taken to ensure that a similar exploit did not occur in the future.

Should instructors have more time to complete this activity, a formal code inspection by the team before revealing the insiders could be a beneficial activity, teaching the students about the code inspections themselves and helping to solidify their importance in detecting insider threats. If the team did

not identify the threats, this would help to demonstrate the many challenges in detecting an insider threat.

When conducting this activity, we chose to give the insiders a significant amount of freedom in deciding what kind of threats to add to the system since a large amount of variability existed between each team's design and the dynamics of the team. However, some insiders have expressed the desire for more direction on the types of threats they should be looking to create. Future instructors should take this into consideration, but also remember to provide balance: too much direction which would inhibit the creativity and ability of the insiders to create threats.

VII. CONCLUSION

Organizations suffer from insider threats on a constant basis — posing risks that could impact them not only monetarily, but also through the loss of invaluable and often private data. Some of this harm is irreversible for organizations from both a data and customer trust perspective. Unfortunately, students are typically unprepared to deal with this notion and do not understand that it can occur, and how it may occur.

We have described a novel and innovative activity to instruct software security students about the dangers of insider threats and some of the damaging ramifications such an actor could have on a system. Students have expressed their satisfaction with the activity from both an enjoyment and learning perspective. We encourage instructors at other institutions to use this activity in their security courses as well.

A structured approach to training open-ended problem solving

Sofia Cassel Björn Victor
Department of Information Technology
Uppsala University
Sweden

Abstract—Students in engineering are well trained in solving specified problems, but some have trouble when given problems where there is more than one solution. In their professional life they are much more often confronted with open-ended problems, where there may be more than one solution, and where there may be many ways to reach each one. The goals may be vague, the problem may be underspecified, and the fresh graduate frustrated by the new situation.

We present a structured approach to training students in open-ended problem solving. We have introduced a half-day workshop to help students learn to work with open-ended, ill-structured problems, using a different approach than they would for the well-structured problems they are used to.

Our results indicate that students have become more creative. Compared to previous years, the students explore more paths towards the goal, and use more elaborate methods. Their approach is similar to that typically used by the best students in previous instances of the course. Students mention creativity and group dynamics as positive aspects of the workshop and the following lab.

We conclude that with proper guidance and training, even weaker students can become more creative when solving open-ended problems.

I. INTRODUCTION

An engineering graduate is typically well trained in solving specified problems. They practice, e.g. in labs where they apply the theory they have learned in a guided and well-specified setting, essentially following a recipe designed by the teacher. By training, they learn to quickly solve many kinds of such problems, and to quickly learn how to solve such problems.

In their professional life, engineering graduates are much more often confronted with ill-structured and open-ended problems, where there may be more than one solution, and where there may be many ways to reach each one. The goals may be vague, the problem may be underspecified, and the fresh graduate frustrated by the new situation. Tackling an ill-structured problem with the methods of well-structured ones will not always work very well. Hauer and Daniels [1] consider open-ended problems to be more complex or realistic than well-structured problems, noting that in many cases, their bounds or end goals are unspecified, unclear or insufficient in various ways.

To deal with open-ended problems, a basic skill required is creativity. By training their creativity, we want to develop students' problem solving competencies.

This paper describes a workshop we designed to give the students a structured approach to the creative process, and training to tackle problems of this kind.

The results indicate that the approach has positive effects: students explore more paths toward the goal, use more refined methods, and their work is more similar to that of the best students previous years.

We also describe our plans to further develop the approach.

A. Course context

The course *Secure Computer Systems 1* is given in the fourth year of the Computer and Information Engineering programme at Uppsala University. The course is also open for international Masters students in their first year, and for exchange students in the final year of their Bachelor studies or at the Masters level. It is taught and assessed in English, which for most of the students is not their first language. The course gives 5 credits, which means that students are expected to do all course work (attending lectures, doing labs, writing reports, studying for the exam etc) in approximately 120 hours distributed over a period of 8 weeks. There are usually 40-60 students taking the course.

The course uses continuous assessment with three sets of assignments including both theoretical questions and practical tasks. Students collaborate in predefined groups, and each group is encouraged to independently discuss and develop their solutions. Assignments are assessed through both written reports and oral presentations and discussions. Solid argumentation and logical reasoning, supported by references where applicable, are required. Students train their reflective skills in several ways, e.g. by peer review of hand-ins and by structured discussion roles in assessment seminars. (A more detailed description of the course design can be found in [2].)

The third and last assignment has a practical part where the students perform penetration testing: given a set of IP addresses of computer systems, they should select the right tools and methods to try to break in¹ to the systems and find a secret file. No login accounts or other specific information about the systems is given, but the students need to discover what they need to know.

Creativity is an integral part of the third assignment. It has been argued [3] that a good penetration tester must be

¹This is done in a highly controlled environment.

both technically competent as well as creative, since the goal of penetration testing is to find solutions, paths, or security holes that no one has previously discovered. This means that students are required not only to apply the material learned throughout the course, but also to do so creatively: What clues can be found about the systems and their software, and how can these be used to find a way in? How can methods learned earlier in the course be combined in clever and constructive ways? How far can an attack go, if it is not fully successful?

B. Related work

Engineering students are typically trained in solving precisely formulated problems using detailed guidelines, e.g., in mathematics. The authors of [4] have studied to what extent students' previous education affects how they approach new, ill-structured problems. Their findings suggest that students do this differently depending on their background (primarily mathematics or design), and that students trained in mathematics tend to expect there to be only one solution that can be fairly easily found.

Open-ended problems, i.e., where there are multiple possible solutions, give students the opportunity to practice generating creative ideas [5]. Since the 1960s, many training programs have been introduced to develop students' creativity. Scott et al [6] analyze 70 studies of such programs. Their findings indicate that successful creativity training combines the development of cognitive skills with domain-specific heuristics. The students thus do not become experts in creative thinking, but they learn a *set of methods* that they can apply to solving real-world problems in more creative ways.

One of the analyzed programs is described in Cropley and Cropley [7]. They study the effect of explicit creativity training on engineering students by comparing two groups of students: both groups attended lectures on creativity, but the first group also received individual counseling based on their results on a creativity test [8]. Both groups were then given an ill-structured engineering problem and asked to solve it. The authors assess the outcomes of the training by comparing creativity test results before and after, and by evaluating the quality of the solutions to the given problem. Their results show that students who were counseled became more innovative, whereas the control group simply became less inhibited. Interestingly, the counseled students' scores on the second creativity test were less varied than those of the control group. Thus, the training appeared to reduce individual differences in creativity.

An important aspect of creativity is *divergent thinking*, which involves generating multiple ideas, generating multiple answers from the available information, producing new ideas, changing existing ones, etc. The opposite is *convergent thinking*, which focuses on using available information to find the single best solution to a problem. The differences are summarized and discussed, e.g., by Cropley [9]. Divergent and convergent thinking are combined in approaches such as *creative problem solving*.

A framework proposed by Treffinger et al [10] for assessing creativity is based on four creativity characteristics, two of which correspond to divergent thinking (generating ideas) and convergent thinking (digging deeper into ideas). Daly et al [5] use Treffinger's framework to evaluate creativity training in seven engineering courses at a US university. The course instructors had the goal of fostering creativity, but explicit creativity teaching was often not present. Students were exposed to ill-structured and/or open-ended projects as a means of training their creativity. The authors note that both instruction and assessment were focused on convergent rather than divergent thinking, meaning that students were neither taught (nor rewarded for) using their skills to find many different solutions to a given problem.

The interplay between divergent and convergent thinking is also central to Liu et al [11], who propose a model for teaching creativity to engineering students, based on the creative learning model by Treffinger et al [12].

II. METHOD

Our method closely follows the model proposed by Liu et al [11]. Their model has three hierarchical levels:

- 1) *Learning and using basic thinking tools*,
- 2) *Learning and practicing a systematic process of problem solving*, and
- 3) *Working with real problems*.

At the first level, thinking tools such as brainstorming are used. The goal is to encourage divergent thinking and help students prepare and generate ideas. At the second level, students learn and practice strategies for solving problems efficiently. Case studies, simulations, and role-playing are mentioned as examples. At the third level, students are expected to solve real-world problems.

We have introduced a half-day workshop to help students learn to work with open-ended, ill-structured problems, with a different approach than the well-structured problems they are used to. The workshop consists of three phases, each of which we detail below. Each phase relates to one of the levels in the model by Liu et al [11].

The students' task is to find as many ways as possible to break in to a computer system. The overall goal of the workshop, however, is not so much about successful hacking, but rather about guiding the students through different ways of thinking creatively about penetration testing: first, in very free and abstract terms (while brainstorming), then, in theoretical, but realistic, terms (while planning their attacks), and finally in practical terms (while attacking the system).

At the start of the workshop, students are introduced to the concept of penetration testing. We discuss what the purpose of penetration testing is: are you trying to exploit a specific vulnerability in someone else's system, or are you are trying to find as many ways to attack the system as possible? What are the challenges in each case? We also provide a brief overview of different tools that are available to them. This gives the students a platform to start from in the three following phases.

Fig. 1. Example of an attack tree after brainstorming.

Phase 1: Brainstorming

Following [13], the students are asked to come up with *many* different ideas, to withhold any criticism of other group members' ideas, and (after collecting initial ideas) to combine and improve the ideas presented. We encourage them to think about the different aspects of penetration testing, and start with questions such as

- How can we break in to a system?
- What info do we need?
- Whom can we ask?
- What sources of info can we use?
- What tools can we use?
- What vulnerabilities can we try to exploit?

The goal of the brainstorming session is for the group members to start thinking creatively about ways to attack an unknown computer system. Ideally, after the session each group has a number of different ideas that they can apply in the next phase.

Phase 2: Planning

In this phase, students start with the ideas they collected by brainstorming, and try to find sequences of actions by which they can attack the unknown system. They are encouraged to use all means at their disposal: information on the Internet, course books, experiences from other group members, the list of tools from the workshop introduction, etc. The teachers provide some guidance to help keep each group on the right track.

Each group arranges their sequences of possible actions in a tree-like structure similar to the attack trees of [14], representing possible ways to attack an unknown system. An example of such a tree after an initial brainstorming session can be seen in Figure 1. The root node represents the starting point, and each other node in the tree represents a possible step on the way to attacking the system. During the planning phase, the groups discuss and research possible ways to extend and refine the initial attack tree. When this phase is finished, each group hands in their attack tree.

We believe that the attack tree has several properties that can be useful both for penetration testing, for group work in general, and for assessment. First, organizing attack attempts in a tree can help the students understand their methodology and improve attacks in a structured way, rather than simply trying different methods or tools haphazardly. Second, the attack tree can be used by the group to help facilitate communication and division of labor, e.g., by assigning different branches to different group members. Third, the attack tree both allows and

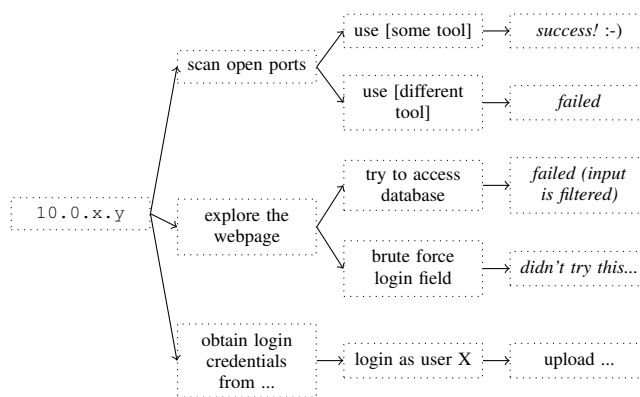

Fig. 2. Example of an attack tree after the practical phase.

encourages the representation of partial attacks, which means they are available for assessment (rather than discarded for being unsuccessful).

Phase 3: Attacks in practice

Using the attack trees as guidelines, students now begin actually attacking the unknown computer systems. During this phase, they also extend and refine the attack trees by noting when attacks fail or succeed, and by adding more actions as necessary. They are encouraged to split up and attack several computers at the same time within the group. An example of an attack tree after this phase can be seen in Figure 2. Here, some leaf nodes represent successful or failed attacks, while others represent partial attacks that are not yet finished.

After this phase, the smaller groups are dissolved, and students gather to discuss the results of the workshop. They share their experiences from brainstorming, planning, and attacking. The following week, the students work in their original group with the full lab.

III. EVALUATION AND RESULTS

The four-hour workshop was not mandatory, but 34 out of 38 students (89%) participated. Approximately half the students attended one day, and half the other day.

We evaluate the workshop in two respects: its implementation and its effects on students. Can we shift the focus from practical (but haphazard) hacking to incorporate more of creatively finding ideas and planning the work?

a) *Implementation*: In order to evaluate the workshop implementation, we used an anonymous questionnaire at the end of the workshop, where we simply asked what was good about the workshop, and what could be improved. We also observed the students during the workshop, how they interacted with each other, and what types of questions they asked. The students recognized the advantage of working in a new group during the workshop: instead of assuming their usual roles in their standard group, they contribute more equally. Different perspectives were seen, and students reflected in their questionnaire responses that they helped in tackling the problems.

Our (informal) observations indicate that most of the students were active in researching possible attack paths. They discussed with each other and drew attack trees together. Questions were mostly asked by the group as a whole, and not by individuals.

b) Effects: Our evaluation of the workshop effects was based on observing the students plans and results in different stages.

We collected the attack trees (a) after Phase 2 of the workshop, (b) at the end of the workshop, and (c) with the hand-in for the finished lab. The initial development during the workshop (a–b) demonstrate the effects of reflecting on the practical work in Phase 3 of the workshop: the trees gain detail, both in depth and breadth, and in descriptions in nodes in the tree (cf. Fig. 1 vs Fig. 2).

We also did a qualitative comparison with the student group of the most recent course instance, focusing on the quality of attempted solutions and approaches rather than only on whether or not the attacks were successful. The solutions in the previous course instance had a greater variation between the stronger vs weaker groups: the weaker groups had narrower approaches, tried fewer alternative solutions, and typically presented less refined solutions. This year, after the workshop, the broader approaches (wider trees) and more refined solutions (e.g. deeper trees) of the current students indicated that they were using strategies similar to those of the stronger students in the previous cohort.

The attack trees in step (c) show that students have broader approaches, but also that more attacks were tried in practice (not always successfully). The previous cohort asked for examples or templates, and had problems when such were not provided. Some students in the current group also asked for walk-throughs or demonstrations, but only at the end of the workshop, not during the following actual lab work.

IV. CONCLUSION AND FURTHER DEVELOPMENTS

We have presented a structured approach to training students in open-ended problem solving, by means of a workshop at the start of a lab period. We combine free brainstorming, graphical planning, and practical experiments.

Although our developments are not completed, our results indicate that the approach has positive effects in at least two main directions: students explore more paths toward the goal, and there is less variance in the student group.

After the workshop, we noted that more students than in previous years tried many different ideas (demonstrated by the broader attack trees) and presented more refined solutions (using deeper attack trees). In general, their behavior resembled that of the more successful students in previous years. This is an indication that the students have become more creative, and a preliminary result similar to what Cropley and Cropley found in their study [7].

Encouraged by these results, we plan to improve the workshop further.

One improvement would be to elaborate the brainstorming phase and give more structure to this “chaotic” creative process. Using the principles of Rossiter and Lilien [13], not much time would be needed for brainstorming, but structure and instructions are more important. In the model of Liu et al [11] which we followed in our workshop, a range of alternatives to brainstorming are presented; some of them, e.g. *idea checklists* or *attribute listings*, could perhaps be applied in our context to encourage students to think of the attacks in new ways. Elaborating further, the brainstorming and planning phases could both be integrated in a case study-like framework to emphasize the connection to real-world problems.

We will continue to use the attack trees as documentation of the students’ ideas, and will thus be able to follow up on how well the creativity training works. One option is to also let the students take a creativity test (e.g. [8]) before and after the workshop and course, to assess their strengths and weaknesses. This could also help emphasizing the creativity aspect, making the students more consciously aware of it. Giving individual feedback on how to behave more creatively, as suggested by, e.g., Cropley and Cropley [7] should also help improve the training.

1. Abstract

Mobile computing has become extremely popular in our daily lives [1] and hence it is an important platform for software developers. Mobile platforms enable students to learn in a modern context when they are used as teaching tools in Computer Science (CS) or Information Technology (IT) education. Meanwhile, mobile security is an important topic in security curricula partly due to the popularity of consumer mobile devices and a shift in computing landscape towards mobile devices' apps development. Due to the rapid demand and popularity of mobile devices [2-3], the security of mobile computing is vital to the growing army of users and for the future of our social, economic and political systems. Hence, it is important and needed to develop hands-on learning materials on mobile security that produce a well-educated and trained workforce, who understands the many concerns of security, privacy, integrity and reliability, and is able to develop strong protection mechanisms and apply fundamental principles and best practices in solving real world problems [4-6]. Many colleges and universities are developing and offering courses on mobile programming and development. However, pedagogical materials based on real world applications running on a portable isolated network are still in infant stage.

2. Significance and Contribution

The Information Assurance and Security (IAS) is the leading national concern, in which mobile security is growing important because of the popularity of mobile devices. It is well known that the best way to learn is by doing it [7-8]. Although IAS had been added as a new core knowledge area in the ACM/IEEE Computer Science Curricula 2013 [9], most universities found difficulties to teaching this subject due to a number of factors including running short of lab resources, lack of faculty expertise, and hard to implement online labs. We propose to develop a series of hands-on learning modules based on a low cost portable lab. The hands-on learning labware design based on the portable lab makes it possible and affordable to offer online lab intensive curriculum on IAS. The significance and contribution of this project is three-fold. First, the learning labware design is based on an affordable portable lab (PLab), which allows online courses to include intensive lab assignments. Second, the isolated network configuration of the PLab provides an independent platform for secure software testing. This isolated network is achieved by USB reverse tethering [10], which connects a laptop and an Android device without other routing devices. Third, the state-of-the-art technology to solving real world problems better prepare students for the demanding workforce. This significance of this topic is

also reflected in the job trends, in which mobile application developers are the best computer job through 2020 [4].

3. Related Work

Despite a number of educational research projects have been proposed to improve curriculum and laboratory materials in mobile security education [11-20, 34-37], to our best knowledge, curriculum or laboratory material development of networking and security based on the PLab-like architecture has not been explored before. Yang et al. has developed a mobile security that covers secure coding, cryptography, security architecture, network security, web security, and security policy and management for faculty capacity building [34]. Wagner et al. developed a content delivery system based on a laptop for security education [35]. Bhattacharya et al. proposed to develop a mobile security curriculum that teaches student mobile threats and protections [36]. Yang et al. developed a module based computer security course and laboratory based on campus networks [37]. Shetty et al. proposed to build a Smartphone Virtual Computing Laboratory (SVCL) for teaching smartphone application (app) security, smartphone operating system (OS) security, smartphone cloud security, and smartphone network security [38].

4. Learning Module Description¹

The proposed labware is designed according to the IEEE/ACM CS 2013 [9]. Each module is independent and self-contained to be easily integrated into existing courses. The labware consists of 5 self-contained learning modules, as depicted in Table 1, and each of which is designed for inclusion in a set of suggested courses. Each learning module may be tailored to accommodate an instructor's need based on content and time of a course. Currently, the network security module is near complete. The rest will be completed within 2 years.

The labware covers fundamental concepts in security and important mobile threats/attacks along with countermeasures. Each module includes pre-lab activities (concept introduction and lab preparation), hands-on lab activities (pairs of hands-on labs on domain concepts and security issues in each subject), and post-lab

activities (review questions, assignments, and case study). An open repository has been configured to host the labware for wide access and collaboration at <https://sites.google.com/site/iasoncs/>.

Table 1 The Proposed Learning Modules in the Project and its Mapping to IEEE/ACM CS 2013

Module	Topics	Mapped IAS Topics Recommended by IEEE/ACM CS 2013
Network Security	<ul style="list-style-type: none"> Internet protocol (IP) IP Spoofing and countermeasures TCP 3-way handshaking protocol, TCP SYN flood attack, Man-in-the-middle attacks and countermeasures Sniffing and traffic redirection (routing) attack with their countermeasures Network intrusion detection and prevention Cryptography (secure/unsecure channels, attackers and their capabilities, encryption, decryption, keys, signatures, cipher types, public key infrastructure, etc.) 	<ul style="list-style-type: none"> Fundamental Concepts in Security Defensive Programming Threats and Attacks Network Security Cryptography Secure Software Engineering
Database Security	<ul style="list-style-type: none"> Security challenges for databases Access Control(authentication and authorization) Data protection with encryption SQL Injection Attack examples Preventing attacks 	<ul style="list-style-type: none"> Fundamental Concepts in Security Principle of Secure Design Threats and Attacks Network Security Cryptography Web Security Security Policy and Governance Secure Software Engineering

Though the labs are developed based on PLab, the nature of the network programming and vulnerabilities remain the same as they are applied to other platforms. Therefore, the labware would also help students understand IAS in such platforms.

Network Security Module: This module brings the IAS aspect into the network domain. Our curricular designs focus on the vulnerability of a protocol or a network component. For example, when introducing TCP 3-Way hand shaking protocol, we will also illustrate if an attacker is trying to initiate lots of TCP connections at once, which typically will crash a server, and is known as TCP SYN flood attack. Topics in this module include foundational concepts in network security such as CIA (confidentiality, Integrity, Availability), concepts of risk, threats, vulnerabilities, attack vectors, traffic engineering, and network intrusion detection and prevention.

Database Security Module: This module overviews security challenges for databases such as confidentiality, integrity, and availability. Topics include access control (authentication and authorization), data protection with encryption, SQL injection, attack examples, and preventing attacks. A hands-on tutorial is included for an SQL injection instance, along with techniques in its protection.

Defensive Programming Module: This module provides learning materials that allow students to avoid common security defects, to analyze the relationship between defensive programming and confidentiality, integrity and availability, and to write a secure program. Topics include defensive programming, Secure input validation and output handling, buffer overflow attack and prevention, vulnerabilities in mobile programming, access control and confidential information, mobile malware, restriction on access to components, and isolation of file system and database, injection and inclusion, accessibility and extensibility, mutability, and serialization and deserialization.

Web Security Module: Web application development is one of the popular jobs for CS/IT graduates. The Web security model will educate students in understanding root causes of web-based attacks, countermeasures for those attacks, and secure web application development. Topics include overview of Web App security, web-based threats such as user interface impersonation, client side attacks, server side attacks, security policy and governance such as secure browser, cross-site scripting, custom application scripting, HTTPS, authentication, cookie manipulation, and frames busting.

Systems Fundamentals: This module aim to provide IAS learning materials from the systems perspective, including hardware, application programming interface, and operating systems. According to the guidelines on hardware rooted security in mobile devices, mobile devices are required to implement the following fundamental security primitives: roots of trust, an application programming interface (API) to the platform, and a policy enforcement engine. We believe it is important to verify these primitives' integrity with hands-on experiments. Another focus in this module is low level programming (assembly programming in X86, ARM, or MIPS), and software reverse engineering, which are mandatory requirements for designation as a center of academic excellence in cyber operations by National Security Agency. Spyware will be exercised in this module along with its countermeasures. We will demonstrate and analyze a sample malicious application using OllyDbg and IDApro.

5. Acknowledgment

This material is based in part upon work supported by the National Science Foundation under Grant Numbers 1438858, 1244697, and 1241651. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

6. Conclusion and Future Work

The advancement in mobile devices makes them a perfect instructional tool. This project aims to develop a new, portable, affordable, isolated networking platform (PLab) with easily-adoptable modular labware by making use of the existing mobile devices to enhance networking and security education. This real world relevant labware content can be easily integrated into multiple existing CS/IT courses. The goal of this project is to use mobile device based computer network labs to help students better understand networking and security fundamentals via hands-on practice and immersive experiences. Modern mobile smart devices are playing more and more important roles in all aspects of our society nowadays. It is essential for computer science undergraduate students to be exposed to the concepts of wireless mobile networking and security. We have successfully implemented critical components in the PLab such as reverse tethering, and network programming interfaces with preliminary learning modules developed and tested. In the future, we will be working on the rest of the learning modules including labs and real world projects.

Abstract—Systematic reviews are a new, fundamentally different approach to synthesizing engineering education research. The primary goal of the session is to increase the awareness and knowledge of engineering educators about systematic review methods. Systematic review methods, widely used in fields such as medicine, psychology and education, have only recently been applied in engineering education to analyze the state of the art. The paper presents steps to illustrate processes involved in a systematic review, sources of standards for systematic reviews, and strategies for information retrieval.

Keywords—literature; synthesis; review

I. INTRODUCTION

One of the characteristics indicating progress in a field in science and engineering education is the development of distinctive theories and other syntheses of the field that provides foundations for further development [1]. In engineering education, the most common form of synthesis has been the narrative review. Multiple notable examples of narrative reviews and the methodologies used to perform them exist in engineering education literature [2-6]. In this session, we present an alternative type of methodology, termed “systematic review,” which has been and is being frequently used in fields of such as medicine, psychology, education, and medical education. Systematic reviews are a new, fundamentally different approach to engineering education. Despite its broad use in another fields and potential utility to enhance engineering education research, many researchers are not familiar with methodologies associated with systematic reviews. Therefore, this special session will provide participants with an introduction that will (within the

constraints of a special session) enable participants to decide how appropriate systematic reviews are for their work and to formulate approaches to developing a systematic review. The session will also describe roles of meta-analysis within systematic review, and how systematic review is different from other approaches to literature review or meta-analysis.

II. GOALS AND OBJECTIVES

The primary goal of the session is to increase the awareness and knowledge of engineering educators about systematic review methods. Specifically, participants will be able to:

- Describe the benefits of systematic review and the differences between systematic reviews and other types of literature reviews
- Locate recent systematic reviews on engineering and computing education topics
- Describe the basic sequence of steps in conducting a systematic review
- Develop a preliminary plan for conducting systematic review on a topic relevant to their own research
- Identify librarians and other prospective collaborators for conducting a systematic review
- Locate resources for additional guidance on conducting a systematic review
- Describe how to talk with librarian about documentation needs for review

III. DESCRIPTION

Systematic review refers to a growing set of research methodologies that critically appraise and synthesize research to inform policy and practice. Systematic review methods, widely used in fields such as medicine, psychology, education and medical education, have only recently been applied in engineering education to analyze the state of the art [7]. In our prior work, we have identified high quality systematic reviews on engineering and computing education topics that may be of interest to FIE conference attendees [7]. These serve as examples of how systematic review methods can be applied in engineering and computing education. In this session, we will use examples from [7] to familiarize participants with systematic review methods. Specifically, participants will work in small groups to complete an exercise that utilizes a form structured according to the systematic review process to learn details of a published systematic review. Through this exercise, participants will become familiar with various key aspects of conducting a systematic review, such as search terms, selection criteria, and number of studies identified. Then, participants will develop their own ideas for additional topics appropriate for systematic review and work together to develop preliminary plans for conducting a review.

IV. SESSION AGENDA

Table I shows the agenda for the special session.

TABLE I. TABLE I. AGENDA OF PARTICIPANT ACTIVITIES

Time (minutes)	Activity
5	Participant and presenter introductions
10	Introductory presentation
30	Small Group Activity: Participants will evaluate existing systematic reviews using the Campbell Collaboration Education Coordinating Group Systematic Review Checklist [8]
15	Small Group Activity: Participants generate potential ideas for systematic review topics
15	Small Group Activity: Participants develop questions, search terms, and inclusion/exclusion criteria for a specific systematic review topic
10	Generate next steps including: potential collaborators, potential funding sources, and publication venues
5	Report back and wrap up

V. STEPS IN A SYSTEMATIC REVIEW

The following steps in a systematic review are intended to illustrate the process; they are not intended to be definitive in the sense that alternative processes would not be appropriate. The steps are taken from an introduction to systematic reviews for engineering education [9].

- (1) **Deciding to do a Systematic Review:** Quantity, quality, and accessibility of primary studies will determine whether a systematic review is feasible. Preliminary searches, sometimes referred to as scoping searches, can be done to estimate the quantity of primary studies as well as locate related reviews to determine the novelty of the proposed review question and as well as potentially situate its contributions in the context of prior work.

- (2) **Identifying Scope and Research Questions:** Like other research methodologies, formulating research questions is a crucial step that influences many of the subsequent decisions. The guidance for formulating research questions for a systematic review is similar to the guidance for any research study.
- (3) **Defining Inclusion Criteria:** Unlike research methodologies that generate empirical data, empirical data for a systematic review are studies that have been done. The purpose of this step is to decide the characteristics of primary studies to be synthesized.
- (4) **Finding and Cataloging Sources:** Searching literature databases (see following section) provides a main approach to locating primary studies that are candidates for the set of studies that will be synthesized.
- (5) **Selecting Primary Studies:** Once potential primary studies have been identified, researchers apply the inclusion (and exclusion) criteria to construct the set of primary studies that will be synthesized.
- (6) **Critique and Appraisal:** “After the primary sources have been selected, identified, and sorted, the next step is to systematically assess the quality of each primary study” [9].
- (7) **Synthesis:** Although presented here as only one step in the systematic review process, this step will occupy a considerable amount of time in the systematic review process. Scope of this introductory article does not allow space to explore methods and options for this step.
- (8) **Limitations, Validity, and Reliability Concerns:** Systematic review, like any research methodology, has limitations. These limitations, as well as threats to validity and reliability of the systematic review should be acknowledged.

VI. STANDARDS AND GUIDES

There are three important organizations which provide standards to consider when conducting education-related systematic reviews:

- Institution of Education Sciences developed a website, What Works Clearinghouse, that collects and promotes systematic reviews [10].
- Campbell Collaboration is an international non-profit organization that seeks to provide a forum and guidance for education, criminal justice, and social work.
- Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement provides a checklist of items to report when publishing a review as well as flowchart. Although this developed in medicine, its terms are generic enough to match any discipline [11].

VII. INFORMATION RETRIEVAL STRATEGIES

When searching for studies, there are several strategies that can be utilized, with the most important being bibliographic databases. Table II shows a sample of the bibliographic databases that could be used for engineering education research. The Campbell Collaboration provides a policy brief providing a longer, more detailed list [12].

TABLE II. LITERATURE DATABASES

Database	URL
Interdisciplinary	
Academic Search Complete	https://www.ebscohost.com/academic/academic-search-complete
JSTOR	http://www.jstor.org/
Subject specific	
Compendex	http://adat.crl.edu/databases/about/compendex
ERIC	http://eric.ed.gov/
Education Full Text (EBSCO)	https://www.ebscohost.com/academic/education-full-text
PsycINFO	http://www.apa.org/pubs/databases/psycinfo/
Citation tracking	
Scopus	http://www.scopus.com/
Web of Science	http://wokinfo.com/

Each database has a set of fields, e.g., title, abstract, body, and author that can be searched by keyword. Complex search strings can be composed by using logical connectives (e.g., AND, OR), wildcards, and database-specific functions to limit returned articles to the ones most likely to help address your research. Here is an example of a search string that was used in ERIC to search for systematic reviews related to engineering education :

Search String: ((SU.EXACT.EXPLODE("Engineering Technology") OR SU.EXACT.EXPLODE("Engineering") OR SU.EXACT.EXPLODE("Engineering Education")) OR all(engineer*)) AND (SU.EXACT.EXPLODE("Meta Analysis") OR ti(review) OR abs(("systematic review" OR "meta analysis")))

To use some of these databases, participants may need to gain access through their institution's library. Collaboration with librarians skilled in systematic review methodologies considerably facilitates the process, giving the ease and power with which your research team can find relevant databases and construct appropriate search strings.

Additional search methods include citation searching, requesting studies, hand searching, and unpublished studies. Citation searching involves searching through references of included and relevant articles and those articles that cited the selected articles after publication. Requesting articles is conducted by posting the description of the review and inclusion criteria to appropriate sites or listservs. Hand searching is the manual browsing of selected journals and conferences abstracts that are not well indexed by

bibliographic databases. Unpublished studies, sometimes referred to as grey literature, can be searched through institutional repositories, government documents, dissertation and theses databases, the Internet search engines (Google Scholar) and specific grey literature databases.

VIII. ACKNOWLEDGMENT

This work is funded by the U.S. National Science Foundation grants no. 1446319, 1446323, and 1446369. The opinions are those of the authors and do not necessarily represent the views of the National Science Foundation.

Abstract— The field of engineering education has initiated a focus on ensuring engineering education research is disseminated and implemented within the classroom. Numerous researchers have investigated the reasons for the adoption of evidence-based practices, or, more often, the lack thereof. The Professional and Organizational Development (POD) network community is an underutilized potential ally for ensuring the implementation of engineering education research due to their focus on organizational change and improving teaching practice. Using the Diffusion of Innovation framework and best practices for adoption, this session will guide faculty in envisioning a wide variety of channels for moving engineering education research into the classroom. Participants in this special session will brainstorm ways to encourage collaboration between these two communities culminating in a "message in a bottle" to the POD community to help them understand the activities and needs of engineering education researchers. This message will be delivered to faculty development professionals, centers for teaching and learning, organizational change specialists, and others in the POD community at their annual conference in November 2015.

Keywords—*Faculty development; dissemination; professional and organizational development*

I. GOALS OF THE SESSION

Through this session, we hope to enhance the connection between engineering education research and the day-to-day teaching practices of university instructors. Specifically, we will pose the Professional and Organizational Development (POD) network community (which includes Educational Development Offices, Centers for Teaching & Learning, etc. as well as a national organization linking such centers) as a venue whose existing initiatives provide opportunities to disseminate engineering education research to a wide variety of faculty members. Participants will leave with concrete methods and contacts for engaging the POD community in their own research-to-practice efforts.

II. DESCRIPTION OF TOPICS/SUBJECTS/CONTENT OF SESSION

Over the past several year, creating a seamless research-to-practice cycle has been a central focus within the engineering education community [1, 2]. In this time period, numerous researchers have investigated the reasons for the adoption of evidence-based practices, or, more often, the lack thereof [3-

9]. Using the Diffusion of Innovation framework [10] and best practices for adoption, this session will guide faculty in envisioning a wide variety of channels for moving engineering education research into the classroom.

Specifically, the facilitators will guide the participants in a brainstorming discussion around the following scenario: you are writing the job description for 1-5 new hires that will disseminate your engineering education research group's results into engineering education practice. What would you want that position to look like? What specific requirements would you include? What would the new hire(s) need to be able to do for which communities? What shouldn't be in the job description?

Having articulated the "ideal" setup for a "dissemination position" as a group, we will then investigate what the Professional and Organizational Development ("POD") community offers while highlighting any overlapping features. Participants will explore their knowledge of local and national POD resources (campus Centers for Teaching and Learning, etc.) and work to create a plan to engage with them. During these discussions, participants will also collaboratively create an "FIE message-in-a-bottle," a time-capsule-like snapshot of the current work, needs, and concerns of the engineering education research community. This message-in-a-bottle will be opened several weeks later during a linked session at the 2015 POD Network conference, and used to start a dialogue with professional and organizational development professionals there.

III. SESSION AGENDA

(0-15 min) **Icebreaker/Community Building:** An important element of adoption is knowing your audience and their needs. To begin this process, the session will open with an icebreaker activity to help identify the different levels of experience that are present at the session. We are hoping to engage a variety of participants with varied levels of experience with POD or similar communities. Following the group icebreaker, participants will be divided into small groups so they can get to know each other better; creating social connections can also aid in the adoption of new ideas and practices.

(15-20 min) **Introductions:** Facilitators will briefly introduce themselves and the goals and schedule of the session.

(20-35 min) **Inspired Brainstorming:** Small groups will be given the “write a job description” scenario previously described. Guided by facilitator-provided discussion questions, each group will create a list of desired “features” for the hypothetical new hire(s). Each feature should be supported by a specific need of at least one person at the table. Every need and its corresponding feature/solution will be written on a separate notecard. Two examples are shown in Table 1.

Table 1: Examples for the Inspired Brainstorming

Feature(s)	Underlying Need
<ul style="list-style-type: none">• The new hire(s) would continuously offer lunch seminars on my campus that are based on my research on teaching.• They would be available for 1:1 chats with curious faculty.• They would let me know about new insights/observations that pop up in those conversations.	<ul style="list-style-type: none">• Colleagues know I do research on engineering teaching, and they keep asking me the same questions on how to apply it, even after reading my papers. I feel like I’m having the same conversations over and over again, but my colleagues genuinely need to talk with somebody about this.
<ul style="list-style-type: none">• The new hire(s) would curate an annual summary for practitioners that explains how to apply the education research generated by my institution, not just my group.	<ul style="list-style-type: none">• I want something to hand out at technical conferences when people ask me about teaching.• I don’t know what other education research groups on my campus are doing. Maybe I could apply their work to my teaching, too.

(35-50 min) **Feature request synthesis:** Without speaking, participants will carry their table’s “features” and “needs” notecards to the front of the room, and synthesize them into one large table of features/needs by merging/clustering their ideas with the ideas from other tables. Tape will be provided. (If there are too many participants to do this as one large group, we will split into 2-3 large groups.)

(50-60 min) **Presentations and discussion:** Each large participant group will present/explain their synthesis to the room in 90 seconds or less. These will be used to start a whole-room discussion.

(60-65 min) **Presentation of POD resources:** Facilitators will briefly explain the POD network and some of the resources they offer, as well as examples of POD groups (Centers for

Instructional Excellence, etc.) working specifically with engineering education. Diffusion of Innovation (Rogers, 1995) will be used to highlight the benefits of using these new resources for dissemination. Dearing’s list of “Top 10 dissemination mistakes” (2009) will also help to highlight the benefits of bringing in POD resources to aid in dissemination.

(65-80 min) **Development FIE “Message-in-a-bottle”:** Participants will discuss the group feature map and think of potential overlaps between their group’s 5 most important features and potential or existing POD resources. The groups will also be asked to make a list of the top 5 most important things about engineering education that they would like to be shared with POD practitioners.

(80-90 min) **Unlocking the Black Box of Dissemination Debrief & Wrap Up:** Groups will share their lists, followed by a short wrap up by the facilitators.

IV. BRIEF DESCRIPTION OF PROPOSED PEER-REVIEWED FULL PAPERS FROM SESSION PRESENTERS

Mel Chua is a PhD candidate in Engineering Education at Purdue University. She was a POD Donald H. Wulff Diversity Fellowship in 2014. She has studied conceptual change in engineering faculty workshop participants [11, 12] and the teaching practice shifts of computing professors working with open source communities [13, 14]. Her ongoing dissertation portrays engineering and technology faculty as learners within their own narratives of large-scale, design-centered curriculum revisions.

Alexandra Coso Strong graduated from Georgia Tech in May 2014 with a Ph.D. in Aerospace Engineering. Her dissertation focused on the development and implementation of tangible tools that faculty could use to support students’ understanding of design in a senior design capstone course. She is currently an assistant professor of systems design and engineering at Olin College. In 2014-2015, she was a postdoctoral scholar in Georgia Tech’s Center for Excellence in Teaching and Learning where she works closely on programming to support graduate students as they prepare for academic careers [15]. She has been an active member of ASEE since 2008 [16] and attended her first POD Network Conference in 2014.

Stephanie Cutler graduated from Virginia Tech in May 2013 with her PhD in Engineering Education. Her dissertation research focused on faculty adoption of research-based instructional strategies [7, 8, 17]. She currently works for the Rothwell Center for Teaching and Learning Excellence at Embry-Riddle Aeronautical University’s Worldwide campus. She presented at the POD Network conference in 2014 regarding her Center’s work on helping faculty to adopt inquiry-based learning [18].

Transitioning Students Navigating Engineering Identities

DeLean Tolbert, Morgan Hynes, Darryl Dickerson, Monica Cardella

School of Engineering Education

Purdue University

West Lafayette, USA

dtolber@purdue.edu

Abstract— How do transitioning underrepresented minority (URM) students evaluate their engineering ability? To investigate this question seven students in a summer pre-college program provided insight on their confidence in their abilities and were asked to recollect the experiences which helped them make sense of these developing identities. As part of a larger study to investigate the impact of a Midwestern University's Minority Engineering Program's (MEP) impact on the success of its participants, the objective of this component of the study is to qualitatively explore the experiences of Academic Boot Camp (ABC) participants throughout their first year in college. Participants of ABC are students who have been accepted to the University's college of engineering and intend to enroll at the University in the fall semester. ABC is a rigorous five week program which simulates the students' first semester course work to support the students' transition from high school to college. The purpose of this paper is to explore the diverse ways that URM students, who are transitioning into a college engineering program, perceive their confidence in their abilities using Figueiredo's (2008) quadrant of engineering epistemologies. In this study, the engineering epistemologies are also considered engineering identities. Based upon data gathered from the interviews and from the research team's interactions with the students, we can infer that their participation in the Academic Boot Camp supports the students' goals. For these students, goals typically include developing time management strategies, mastering course material, learning and exposing oneself to engineering skills and habits, successfully transitioning from high school to college and remaining true to one's identity. The findings from this study may not only provide qualitative support for the impact of the Minority Engineering Program and its Academic Boot Camp but may also provide insight into ways engineering educators can support the development of both the students' individual and engineering identities.

Keywords—Engineering Identity; Transition Programs; Underrepresented Minority

INTRODUCTION

How do transitioning underrepresented minority (URM) students evaluate their confidence in their engineering ability? To investigate this question students in a summer bridge program provided insight into their perceived abilities, their engineering identities and were asked to recollect the experiences which help them make sense of these developing identities.

As students are transitioning from the high school environment to the college engineering environment, almost

all students face challenges[3]. However, in addition to those commonly experienced challenges URM students face additional obstacles which may cause them to differ in the way they view themselves and their abilities Such as racial identity issues, isolation and academic under preparedness [4-7]. This paper will focus on these students at the moment in time when they are initially transitioning from high school to the college of engineering at their Midwestern University, via a summer college prep program.

The research question guiding this study is: How do incoming first year engineering students perceive their confidence in their engineering abilities? The purpose of this paper is to explore the diverse ways that URM students, who are transitioning into a college engineering program, perceive their abilities using Figueiredo's [1] quadrant of engineering epistemologies (what engineers know and how they know it). In this study, the engineering epistemologies are also considered engineering identities. A recent study has shown that summer programs like the Academic Boot Camp ABC can have a positive impact on participants' perceptions of their engineering identities[2]. The findings from this study may not only provide qualitative support for the impact of the Minority Engineering Program and the Academic Boot Camp but may also provide insight into ways engineering educators can support the development of both the students' individual and engineering identities.

BACKGROUND

As part of a larger study to investigate the impact of a Midwestern University's Minority Engineering Program's (MEP) impact on the success of its participants, the objective of this component of the study is to qualitatively explore the diverse ways that incoming college engineering students perceive their engineering abilities. The participants of this study were members of an incoming cohort students who have been accepted to the university's college of engineering and intend to enroll in the fall semester. The participants attended the Academic Boot Camp (ABC) ahead of the start of the semester. The ABC is sponsored by the MEP and is a five-week simulation of the first semester, where students take non-credit bearing courses in STEM and learn engineering using a project based learning approach. They are introduced to the campus and its resources and are engaged in professional development through networking with alumni and future peers[8].

PERSPECTIVES

How does one make sense of the transitioning student's developing engineering identity? This following discussion will address perspectives of development and cognition which relate to self-efficacy, motivation, identity and engineering epistemology.

Chemers, Hu and Garcia [9] conducted a longitudinal study on students over the course of their first year in college. The data show that students with high self-efficacy have high academic expectations and the high academic expectations positively impacted the students' academic performance. These findings support Chemers et al. [9] claim that individuals who set specific and difficult goals usually perform well. By setting goals individuals are creating standards of performance and therefore exhibiting the motivational effects of having a positive self-efficacy.

With respect to engineering skills and knowledge, students' goal setting behaviors may align with their perception of their identity. In many arenas engineering and science have competing identities, rather than simply comparing engineering and science behaviors, attitudes and skills, Figueiredo [1] offers a different characterization of engineering. He presents the essence of engineering as operating in four dimensions as illustrated in Fig. 1. Figueiredo, as cited in Adams et al. [10] suggests that as engineering educators who engage future engineers, we must allow them to experience the "unique identity of engineering" and the various combination of its four dimensions. Students can learn to work within and across these dimensions even as they are developing their own engineering identity.

Due to the strong academic records of the participants, the Academic Boot Camp under study uses a model that focuses on transition as opposed to academic remediation. Dickerson et al. [11], conducted a study which supports that programs such as ABC positively impact its participants in areas such as first semester retention and academic performance, as well as on social, emotional, and affective dimensions. Stolle-McAllister [12] contends that transition focused bridge programs are particularly helpful in assisting the students navigate their identity by raising their social capital. Through summer pre-college transition programs students develop community and networks on and beyond campus which they can access as they develop as individuals and as engineers. This supports successful academic transition from high school to college.

It is also important to note the role of intersectionality in this study. Participants in this study may be affected by both their race and gender in complex and interconnected ways. In addition to the common hurdles that transitioning students face, students who are members of 2 or more underrepresented groups often face increased challenges due to their race/ethnicity or gender. Factors such as: "gendered stereotypes, pedagogical techniques, limited exposure to technology and role models, which may lead to lower academic preparation for STEM disciplines, work in tandem and serve as obstacles for minority women[13]. Furthermore, compared to their representation in the United States

population, African American and Latina women are underrepresented in STEM. This may lead to isolation and academic difficulties during the college transition and matriculation, unless these students are supported appropriately.

METHODS

Throughout the participants' five week ABC experience, the research team engaged with the students in diverse ways in order to establish rapport[14]. At camp registration, the research team provided information about the study along with performing onsite interviews. Once each week, the interviewer co-lead a workshop focused on developing self-discipline. This allowed for engagement with the students and allowed the students to feel comfortable volunteering for interviews throughout the camp. Student-researcher interaction was also helpful because this is the first phase of an on-going study with the same population of students.

The relationship formed between the students and the research team, helped to make their interviews more accessible. Students appeared more comfortable sharing this information as they had increased encounters with the interviewer. The interviews were designed to take 10-15 minutes. The actual time spent interviewing varied with the amount of information the students shared.

Participants were informed that they would be participating in a self-guided video recorded interview but that the researcher may have additional follow-up questions. The interview protocol invited students to respond to questions related to campus resources, their confidence in their abilities and what they hoped to learn from their experience during the ABC.

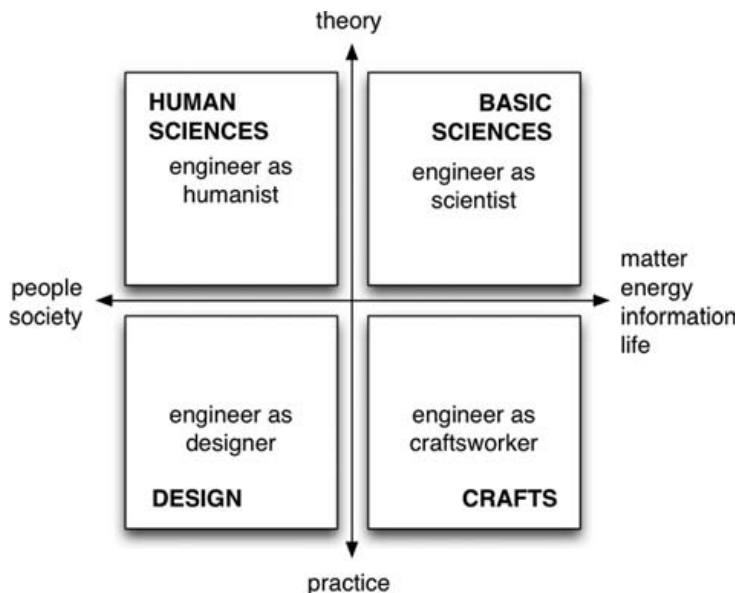

Figure 1. Four dimensions of engineering

RESULTS

Seven students volunteered to be interviewed. Each student responded to seven questions related to their expectations for the program, resources available to them on the Midwestern University's campus and their confidence in their abilities along the four dimensions of engineering epistemology. The results discussed in this paper will specifically address the initial findings from the students' responses to the following questions:

Q1. On a scale from 0 – 10, (where 0 is not confident at all and 10 is extremely confident), how confident are you in your ability to do [basic and natural science, human science, open ended tasks or craft work]?

a. What experiences led you to rate yourself that way?

Q2. Order the four categories below from 1 to 4, with 1 being the category you enjoy most or most, excel at and 4 being the category you least enjoy or least excel at.

a. Craftwork

b. Human Sciences

c. Design

d. Basic/Natural Sciences

The students' ratings for each of the identities (categories), which they most and least excel/enjoy, are tabulated in Table 1. Statistical analysis was not performed in order to determine statistical significance; however, the differences may surface from the students' responses to the follow-up question: "What experiences led you to rate yourself that way?"

The research team provided descriptions of each engineering identity in the interview protocol, which the

students read. The engineer as scientist identity was described as basic and natural sciences were represented as logic, analysis, math, physics, chemistry and biology. Human sciences abilities, which represent the engineer as humanist, were described as including social sciences, business, communication and political science. The engineer as designer identity from Figueiredo's quadrant was characterized by open-ended tasks with more than one solution, synthesis, creativity, innovation. Engineer as a craftwork was characterized by the students' confidence in their ability to craftwork, including physically making or building things, drafting and art.

On average, the participants had higher confidence in their ability to do craftwork and use basic sciences. This is consistent with their academic backgrounds. Students who choose careers in engineering and science often state that they were good in the basic sciences (i.e. logic, analysis, mathematics, physics and chemistry) or told that were good at craftwork (i.e. physically making or building, art and drafting). The two categories represent common narratives used to suggest that students have engineering potential. Often in high school classrooms and in extracurricular activities, engineering is not perceived as something that relates to the human sciences (i.e. social science, business, communication) and students are often given closed ended design tasks. This might contribute to the participant's lower overall confidence rating in these two identities. This idea is demonstrated in the following excerpt:

I am able to find a solution to a task that is given to me. I feel that the way that I have been taught in school growing up, that they always give you a worksheet to go through as a path that they give you. So I will probably end up struggling with open ended tasks where it's not a clear path- Darek

			Rating from 0-10 (where 0 is not confident at all and 10 is extremely confident)				Most Excel	Least Excel
Participant Pseudonym	Gender	Ethnicity	Basic Sciences	Human Sciences	Design	Craftwork		
Catalina	Female	Hispanic	6	7	8	5	Design	Craftwork
Jennifer	Female	Black	5	5	5	7	Design	Basic Sciences
Michele	Female	Black	7.5	8.0	5	5	Basic Sciences	Design
Andres	Male	Hispanic	8	7.5	6	9	Basic Sciences	Craft Work
Damon	Male	Black	8.5	7	9	10	Craftwork	Human Sciences
Darek	Male	Black	8	7	7	7.5	Craftwork	Design
Jacob	Male	Black	5	6	7	6	Design	Human Sciences
Overall Average			6.9	6.8	6.7	7.1		
Female Average			6.2	6.7	6.0	5.7		
Male Average			7.4	6.9	7.3	8.1		

Table 1. Students' self-reported rating on Figueiredo's four dimensions of engineering
2015 IEEE Frontiers in Education Conference

Across all four identities, female participants rated themselves lower than their male colleagues. For some of the students, external factors and lack of previous experience and exposure led them to have lower perceived confidence. Catalina's response supports this idea:

Because I went to a small all-girls school in Houston and I think it was mainly focused towards the liberal arts especially like in English and social studies. And it is slowly trying to gear its way into the STEM fields but it still isn't all that way [yet]. ..I would say the school I went to was mainly geared toward the liberal arts and I have really been prepared that way.

Catalina's (and the other female participants') lower confidence is supported by literature which suggests that women exhibit lower self-confidence than men in achievement settings. However, this does not mean that they actually have lower achievement [15].

Students also shared experiences that led them to have lower confidence in these identities. They expect that the ABC and additional engineering experiences will help them overcome these deficiencies. Andres and Michele shared their past challenges with open ended tasks and are able to identify their strengths as well:

I am a really creative person and I do like finding solutions to things that have more than one answer but I do tend to bog down...every idea I had I would just shoot it down – Andres

I don't have any creative ability, really at all. I'm more of a give me [how to] structure it the way it's supposed to be and I'll do it. But if I have to structure it myself, and come up with the ... design and aspects [then] I struggle with that a little bit. So I have to go and ask for help...I can't just come up with it on my own. – Michele

Throughout the interview students provided experiences that supported their confidence with respect to specific engineering identities. For example Darek reflects on his logical nature as he discusses his confidence in his basic and natural science ability:

In terms of logic and analysis, I always found myself as a logical person and always find efficient ways to get things done...Math is kind of the result of logic and analysis.

The students in this study were members of the 2014 college of engineering cohort of first-year engineers. How might these students' most and least excel or enjoyed categories compare to other members of their cohort? All students (N=106) in one section of an introductory engineering course (ENGR 131) were asked: "Which category do you enjoy most/least or most/least excel at?" The results are as follows. Most excel: Basic Sciences (48%), Craftwork (26%), Design (22%) and Human Sciences (4%). Least excel: Human Sciences (70%), Craftwork (19%), Basic Sciences (6%) and Design (6%).

Although, the number of participants in this study is a limitation to doing direct statistical comparisons between the groups, the ABC students do appear to represent the 2014 cohort. At first glance there appears to be a difference between the 2014 cohort and the ABC students' experiences with design and craftwork categories. This difference would best be investigated with a larger ABC population and could be a potential direction for future work

SIGNIFICANCE

This study is phase one of a recently launched effort to measure the impact of the Academic Boot Camp on its participants. The objective of this work is to investigate student experience in the program and help to provide qualitative evidence for the impact that this summer bridge program has on the students' transition and identity development. Although more data will be collected, from the available data it appears that students choose to participate in ABC because it will help them accomplish academic, personal and professional goals. This may be an indicator that the students have academic expectations which could lead to high academic performance. Students clearly articulate that they believe MEP and their experience in the Academic Boot Camp will provide them with knowledge or skills which they can apply as they transition to college.

Based upon data gathered from the interviews and from the researcher's interactions with the students, we can infer that their participation in the Academic Boot Camp is aligned with the students' cognized goals. For these students, goals typically include developing time management strategies, mastering course material, learning and exposing oneself to engineering skills and habits, successfully transitioning from high school to college and remaining true to one's identity.

To the transitioning student, retaining their identity even while navigating the college and engineering identity is a concern for the students. Although these students may express deficiencies, their academic backgrounds indicate that these students have strong potential for success in the college of engineering. These participants believe that with practice, the areas of lack can be strengthened. The diverse ways that students perceive their engineering identities may impact the ways that they engage in classroom tasks and activities. As students contend with competing identities and recognize their strengths and weaknesses across the engineering epistemologies, it is important that curricula and programs are designed to support their development across all four dimensions of engineering identities.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of the Minority Engineering Program in providing access to its participants for this investigation.

Is changing pedagogy a good bait in attracting students to engineering?

Josef Rojter

College of Engineering and Science

Victoria University

Melbourne, Australia

Josef.Rojter@vu.edu.au

Abstract— In line with the new policy on pedagogical innovation adopted by Victoria University (VU) Policy in 2005, engineering schools at VU decided to introduce Problem-Based Learning (PBL) into their undergraduate engineering programs. It was hoped that such an action would attract more students to engineering courses at VU with higher equivalent national tertiary entry ranking (ENTER) cut off scores, be more attractive to girls and therefore address the predominating gender imbalance in engineering professions. The introduction of PBL was followed by intense publicity in secondary schools and vocational colleges. The management of both engineering schools at VU decided base their PBL model on one adopted on and used for a number of years at Aalborg University in Denmark. The initial implementation begun in some subjects in 2006 and by 2007 half the subjects in engineering curricula were designated for PBL delivery. Yet, despite the substantial investment in human resources and capital dedicated to the construction of PBL learning studios, there was little to show for the investment. There was a relatively little increase in popularity in attracting greater number of students to engineering at VU, which in terms of attractiveness remaining lowest in the packing order among engineering education providers in Melbourne. The proportion of girls selecting VU engineering as their course of study remained low. Surveys taken since 2008 among second year engineering students were part of a study to determine students' perceptions and motivations for choosing engineering as their course of study, and choosing VU engineering. The study hoped also to explore the effect PBL had on popularity of studying engineering at VU. This is the subject of this paper. The survey results revealed a mixed-bag. There was some good news. Over the seven years, the awareness of PBL at VU amongst final year secondary students has risen. More students indicated that knowledge of PBL would be more likely to attract them to VU engineering than act as a disincentive. It must also be noted that almost half of students were neutrally disposed towards PBL. Despite the liking PBL pedagogy, large proportion of students felt preferred the subject delivery was to be done in more traditional pedagogies. It suggested that students liked constructivist approaches within a more accessible framework. The relative high proportion of students indicating their desire to transfer to another university or course is a concern and needs to be addressed by the curriculum planners.

Keywords— *Engineering pedagogy, engineering attractiveness, problem-based learning*

I. INTRODUCTION

In contrast to other 1 courses for professions such as medicine, dentistry and law, students entering engineering education have diverse range of Australian tertiary admission ranking (ATAR) scores. Victoria University (VU), sited in the lower socio-economic western Melbourne regions, attracts students with lower cut off ATAR scores for most its courses, including engineering, than the other universities in Melbourne. The lower ATAR scores translates into having a relatively high proportion of students entering engineering at VU being ill-equipped for university studies. The lack of inadequate knowledge base in fundamental sciences and mathematics and poor communication skills has a profound effect on course standards and student attrition rates.

The decision by the university in 2005 to introduce a new pedagogical paradigm was driven by the desire to reduce the relatively high attrition rates and improve the attractiveness of VU as a study destination. It was also hoped that these changes would also address external perceptions of poor academic standards, and allow the university to reposition itself in the student market. It was hoped that such educational shift would assist in raising the profile of VU engineering and lead to:

- Educational differentiation from other universities translating into greater interest among senior secondary students to consider engineering as a course of study at VU;
- Generating greater interest in engineering among senior secondary students. This may lead to a greater participation in engineering education at all universities and address concerns of current and future shortages of professional engineers in Australia [1],[2];
- Enhancement of professional graduate attributes such as the ability to work in teams and autonomously, communication skills and social awareness, ability to contextualize engineering work in terms of economic, sustainable, social, ethical and political frameworks

and instil good habits of life-long learning-curiosity;
and

- The reduction of attrition rates and the improvement of progression rates in engineering at VU. Approximately 10-12% of undergraduate engineering students at VU complete their course in the minimum time. Poor completion and retention rates of domestic engineering students have been of particular concern [2][3].

In 2006 problem-based learning (PBL) pedagogy was introduced in 50% of curricula at both engineering schools at VU. This was immediately followed by an extensive publicity and marketing campaign in the press and at secondary schools throughout Melbourne. Whereas prior to 2006 the marketing of engineering at VU was largely based on course offerings, the new and more intensive marketing included pedagogical differentiation as a selling point. The objective of this project is to ascertain the effectiveness of the marketing campaign and evaluate whether any positive outcomes could be attributed to either pedagogical differentiation or just increased marketing of engineering courses at VU.

II. METHODOLOGY

The enquiry used a simple questionnaire shown below to evaluate:

1. Reasons why student pick engineering as their choice of course of study among their two top initial preferences prior to the change of preference period. Latter student preference selections are likely be influenced by students' academic outcomes.
2. Students' preferences of choosing VU engineering among the first cycle of selection of preferences.
3. Students' awareness of PBL delivery prior to their selection of primary preferences and its influence on choosing VU engineering.
4. Students' attitudes to PBL delivery and how such attitudes affected their likelihood on continuing with their course.

The investigation was restricted to domestic students in the School of Architectural, Civil and Mechanical Engineering and relied on, with one exception, to 30 to 90 responses. School of Electrical and Electronic Engineering was ignored in the survey because of its low domestic student enrolment. The survey based on the questionnaire shown in Table A was restricted to first semester second year students because they were already well exposed to PBL teaching and were still in position to make a decision concerning their future academic path. Surveys were conducted in weeks 8-9 of the semester during common classes such as solid mechanics or materials technology.

TABLE A. Student questionnaire

(Tick the appropriate answer)	
Did you place engineering as a preferred course prior enrolling at VU? (Was engineering amongst your top two preferences?):	
<input type="checkbox"/> Yes	<input type="checkbox"/> No
Was VU amongst your first two preferences (before change of preferences) on your selection of university 6 months before enrolling at VU?	
<input type="checkbox"/> Yes	<input type="checkbox"/> No
Were you aware of PBL pedagogical course delivery in engineering course delivery prior to enrolling at VU?	
<input type="checkbox"/> Yes	<input type="checkbox"/> No
Would the knowledge of PBL as a teaching method make a choice of engineering at VU?	
<input type="checkbox"/> A more attractive option 6 months before you selected your preferences	
<input type="checkbox"/> A less attractive option 6 months before you selected your preferences	
<input type="checkbox"/> No difference in selecting preferences	
Do you prefer PBL subjects to delivered:	
<input type="checkbox"/> In the current form of discovery and working in teams	
<input type="checkbox"/> The PBL subjects delivery be supplemented with lectures and tutorials	
Given another chance would you enrol into a different engineering discipline course?	
<input type="checkbox"/> Yes	<input type="checkbox"/> No
Are you considering transferring into another (other than engineering) course?	
<input type="checkbox"/> Yes	<input type="checkbox"/> No
Are you considering transferring to another university?	
<input type="checkbox"/> Yes	<input type="checkbox"/> No

III. RESULTS

The results outlined in this paper cover the period 2008-2013 inclusive. The first second-year cohort was not included in the survey because it was not till 2008 PBL pedagogy was shaped to resemble current the form. Earlier data has been published elsewhere [4]. The first two questions were designed to ascertain whether choosing engineering as a course of study was given a high priority by students in their first preference selection cycle. The data is presented in table1. The results of the survey showed that a relatively high proportion of second year VU engineering students placed high preference for engineering as their choice of course (Table1-figure1). These figures varied between 82 to100 percent. The proportion of students choosing engineering at VU was lower in comparison to students choosing engineering as a course of study Nevertheless, with the notable exception for 2011, a respectable 50-60 percent of second year students placed VU engineering in their final year at school amongst their top two preferences.

Table I. Proportion (%) of students who initially selected engineering in top 2 preferences

YEAR	2008	2009	2010	2011	2012	2013
Overall	88.1	100.0	95.4	94.1	90	82.4
For VU	48.8	57.1	60.5	25.0	55.2	56.3

Figure I. Graphical representation of table I.

The third question tried to evaluate the effectiveness of the publicity campaign informing secondary students of the new pedagogical pathway in the delivery of engineering education at VU (tableII-figure II). Unfortunately the publicity penetration was fairly disappointing. Only a third of second year students in 2013 had any awareness of PBL suggesting that the 2010 publicity campaign effectiveness declined.

TableII. Proportion (%) of students being aware of PBL at VU engineering prior choosing their initial preferences

YEAR	2008	2009	2010	2011	2012	2013
%	16.3	14.3	26.2	11.8	33.3	20.0

FigureII. Student awareness of PBL at VU engineering prior choosing their initial preferences

By the end of the first semester, second year students have been exposed to at least 3 semesters of PBL pedagogy allowing them to form concrete views on PBL delivery. TableIII and figureIII indicate that substantial (but decreasing) proportion would have been influenced in preference selection in their final year at school had they have known more about the practical aspects of PBL pedagogy.

Table III. The impact of student awareness of PBL on likely preference selection of VU

YEAR	2008	2009	2010	2011	2012	2013
Overall	69.8	66.7	52.6	46.7	57.1	35.3
Students with a positive attitude to PBL	69.8	33.3	48.8	13.3	50.0	17.6
Students with a negative attitude to	0.0	33.3	3.8	33.3	7.1	17.6

PBL						
Δ (Positive-negative)	69.8	0.0	45.0	-20.0	42.9	0.0
$R = \Delta / \text{Students with neutral attitude to PBL}$	2.31	0.0	0.86	-0.38	0.85	0.0

Figure III. The impact of student awareness of PBL on likely preference selection of VU

Students would be more likely to preference VU engineering on the basis of their positive PBL educational experience. Students would be less likely to preference VU engineering on the basis of their negative experience with PBL. Table III (figure IIIa) suggests that the net positive empathy Δ for PBL varies between 70 to -20%. It needs to be noted that 30 to 65% of students have neutral attitude towards PBL.

FigureIIIa. Difference between students having positive and negative perspectives on PBL

Table III introduces a ratio R , which quantifies the impact of PBL on engineering attractiveness at VU. Positive values of the Ratio R indicate positive impact of PBL. With the exception for 2008 the impact of PBL on placing VU engineering high on selection preference would be minimal or negative.

FigureIIIb. Graphical representation of table 3

Students were asked to suggest whether an augmentation in PBL pedagogy can be achieved by using traditional instructive teaching of lectures, tutorials, seminars. Table IV provide student attitudes to PBL.

Table IV. Proportion (%) of students who prefer the inclusion of traditional teaching delivery in PBL subjects

YEAR	2008	2009	2010	2011	2012	2013
Overall	67.4	71.4	62.8	47.1	59.3	76.5
Students who are positively disposed to PBL		71.4	56.5	0.0	46.7	68.0
Students who are negatively disposed to PBL		55.6	53.3	47.1	36.7	40.0
Students who are neutrally disposed to PBL		66.7	69.4	0.0	71.4	80.6

Figure IV. Student preference for PBL subjects to include instructional teaching delivery

An area of concern is the relative high attrition rates of engineering undergraduate students at VU. One of the objectives was to evaluate the impact of PBL pedagogy on students' retention. The results are shown in table V.

Table V. Proportion (%) of students considering transfer to another university

YEAR	2009	2010	2012	2013
Overall	49.4	33.6	33.7	38.2
Students who have a positive view of PBL	42.9	32.6	18.2	52.6
Students who have a negative view of PBL	77.8	46.7	23.4	33.3
Students who have a neutral view of PBL	48.9	31.6	32.5	46.4

Figure V. Overall proportion (%) of students considering transfer to another university

IV. DISCUSSION

The good news (figures I&II) is that over 80% of second year students chose engineering as their preferred course of study. Furthermore, more than 50% of students picked VU engineering amongst their top two destinations of study. Given the status of VU in the ranking amongst Melbourne universities, VU engineering certainly punches above its weight. However, it needs to be pointed out that student choice is not often based on reality of well thought out reflection. Choosing engineering does not necessarily translate into passion for studying engineering. Owore et al, in an American study, showed that engineering students often had wrongful impressions of engineers' work restricted to fixing and building [6].

The enrolment growth in engineering at VU, based on 2004 data, for domestic students commencing studies was healthy (figure 6). This rate of domestic student enrolment was above the national domestic commencing engineering student growth rate till 2012 [7]. It needs to be noted that some universities have weaned themselves on the dependence on domestic enrolment. The same statistical data also shows that both RMIT and SUT, with similar historical profile to VU, had a relatively high proportion (between 40-55%) of commencing engineering students are full-fee paying overseas students. In comparison, the proportion of commencing overseas student enrolment in Mechanical, Architectural and Building engineering at VU varied between 8 and 20%. SUT, for instance, reduced its dependence on domestic student market by placing a strict academic entry criterion for domestic students. This was reflected in comparatively low growth rate in commencing domestic student enrolment. The downturn in the commencing growth rate at VU from 2010 could be attributed to the uncapping of university places at Australian universities.

Figure VI. Comparison of growth rates in domestic commencing engineering students with the national with RMIT and SUT, both institutions with comparable history and traditions to VU.

The marketing accompanied by the publicity in extolling the virtues and differentiation of PBL pedagogy in education showed to be clearly ineffectual (figure II.) Marketing and publicity penetration was relatively modest and the with majority of students who chose engineering at VU were unaware of PBL teaching and learning approach prior to their enrolment. It was hoped that word of mouth

could improve both students' quality and quantity enrolment in engineering at VU. Students communicate their educational experience to friends, their siblings and other relatives. Figure III shows that initially 70 % of second year students expressed that had they been more aware in their final year at school about PBL delivery, they would be more likely to choose engineering at VU. However, the consolidation of PBL teaching at VU over the years did not lead to better outcomes. Figure III suggests that the impact of PBL on students had not lived up to expectations. This could be due to the fact that PBL constructivist pedagogy may itself be problematic. The process by which students acquire knowledge and intellectual skills by working in small teams on allocated projects must be placed in students' socio-economic contexts. PBL education requires students' high participation in team meetings to meet their project objectives. It is not an ideal educational situation for students who are balancing paid work with academic demands. PBL is also a natural learning process for self-starters and good learners but is problematic for students who are not well prepared for university education. New ways of learning can be alienating for students who at their early years of a university course expect their learning experience to mirror one of secondary school [8]. It is the expectation of teaching rather than learning. Figure IV demonstrates that students irrespective of their attitudes to PBL would prefer their PBL subjects to be augmented by traditional instructional methods. Surveys showed that majority of students felt that lectures were beneficial to their learning [9]. Disengagement from the education process translates in student leaving for other academic pastures. An unusually high proportion of students, at the end of their first semester of second year course, are considering transfer their studies to other universities (figure V).

Another approach in determining a success of a four-year engineering course is by comparing published data of the proportion of commencing domestic students who complete their course in four years (figure VII). This aggregate data includes attrition rates (indicating whether a course is unpopular), latter year entries from other institutions (course is popular), as well as remaining students who are at various stages in their course. Such figures can therefore exceed 100% [5]. It is a "rough" measure but provides a relative snapshot of progression rates and course popularity of courses at other universities.

Figure VII. Ratio (%) of domestic graduates to commencing domestic students 4 years earlier

The educational output at VU engineering clearly demonstrates undesirable attrition rates. It does not necessarily reflect management of PBL delivery. Rather whether PBL education is appropriate or introduced too early. Attrition rates have also been shown to be a consequence of the socio-economic profile of the student body, attractiveness of other institutions and student to staff ratio, which is significant. The student to staff ratio at VU engineering is more than 20 % higher than at SUT and 10 % greater than at RMIT. This is a problem because PBL pedagogy requires greater pastoral involvement than the traditional instructional delivery.

V. CONCLUSION

Attracting more and better academically qualified students to engineering courses by introducing new pedagogies could be effective if better information concerning the new pedagogy and how it would enhance students' educational experience and outcomes was provided to secondary colleges. The publicity and marketing programs of VU engineering has had a modest impact at best. Successful publicity of a product works best if the product itself is attractive. Students in general were not inspired by the programs run at VU with majority preferring supplementary traditional instructive teaching methods such as problem solving learning (PSL). Obviously either the current PBL curricula need to be re-designed or introduced in the third and fourth year of the engineering course. That itself would present a dilemma in trying to differentiate engineering at VU from engineering at other universities. Though large amount of capital and financial resources were invested in teaching and learning spaces, it was not accompanied by investment in human resources, which are needed to support PBL programs because of their pastoral demands. The university needs to shift its balance from research to teaching to ensure the viability of Engineering at VU.

Abstract— Through support from the National Center for Women & Information Technology (NCWIT), the University of Texas at El Paso (UTEP) and the El Paso Community College (EPCC) began a program to collaborate on adoption of Peer-Led Team Learning (PLTL) at EPCC. The NCWIT-funded effort aims to transfer this effective retention practice to the EPCC in order to establish early connections with female students, create community, and provide activities that improve students' problem-solving skills. PLTL provides an active learning experience for students and creates leadership roles for undergraduates. For the peer leaders, the experience of working with faculty and guiding their peers through a challenging course is rewarding, and they learn communication, teaching, leadership, and interpersonal skills. Peer leaders become more confident about their career path, and many continue to be involved in the department through undergraduate research positions. This is important for retention and advancement efforts, since the peer-leading experience influences the students' motivation to attend graduate school. This paper describes how the UTEP-EPCC partnership was structured, how the practice was transferred, and the challenges that were encountered. It also presents the evaluation results.

Keywords—*Peer-Led Team Learning; peer mentoring; community-college relationships; retention in CS*

I. INTRODUCTION

According to the Bureau of Labor Statistics, the number of jobs in computer science is projected to increase by 15 percent from 2012 to 2022, faster than the average for all occupations [1]. Despite the growing demand, women have historically been underrepresented in lucrative computing positions. The Taulbee Survey [2] reports that in 2012-2013 only 14.2 percent of bachelor's graduates in computer science were

female. Committed to correct the imbalance of gender diversity, the National Center for Women & Information Technology (NCWIT) serves as the lead organization for addressing the advancement of women in computing fields through a variety of programs. One such program is the NCWIT Extension Services for Undergraduate Programs (ES-UP). ES-UP, which employs a multi-pronged strategic planning model, provides customized consultation to undergraduate departments of computing to help them develop high-impact strategies for recruiting and retaining more women students.

The University of Texas at El Paso (UTEP) was one of the first of two cohorts of 15 universities that were funded by the NCWIT ES-UP program in 2013. Peak Research worked with the department to analyze departmental data, define strategic plans for recruitment and retention, and learn about research-based practices to support their efforts. In 2013, UTEP set forth a plan that included introducing the Peer-Led Team Learning (PLTL) effective practice [3] [4] to the El Paso Community College (EPCC) to increase students' computing knowledge, confidence, motivation, and course completion rates in critical, "gate-keeper" courses for CS majors. This proven practice emphasizes student achievement through active learning activities in peer-led sessions. PLTL also cultivates student pedagogical leaders, who serve as role models for undergraduates, and it supports the advancement of students along the academic computing path. By hiring female peer leaders, the effort aims to establish early connections with female students.

Section II provides a background of the universities involved to provide a context for the initiative. Section III describes the initiative, followed by the initial evaluation

results. The paper ends with a summary and a discussion of next steps.

II. BACKGROUND

Overviews of UTEP and EPCC are provided in the subsections that follow. A discussion on UTEP's adoption of PLTL is included in the UTEP subsection.

A. The University of Texas at El Paso

The University of Texas at El Paso (UTEP) is a minority-serving institution located on the U.S./Mexico border serving a largely Hispanic population in a region of Texas with one of the lowest median incomes. Computer Science (CS) is one of six departments in the UTEP College of Engineering.

In fall 2013, the ES Consultant conducted a survey of UTEP's CS and Electrical and Computer Engineering pre-engineering students. The survey found that 70% of new pre-engineering majors reported that they live off campus. One quarter (28%) of incoming students declared that none of their parents attended college. UTEP is their main source of information regarding professional opportunities and role models. In addition, 50% of incoming students reported that they must work to support their studies. Under the guidance of the ES Consultant, the CS Department created Recruitment and Retention Plans using the NCWIT Strategic Planning for Recruiting (Retaining) Women in Undergraduate Computing Workbooks and taking into consideration the aforementioned factors. The retention plan includes the adoption of PLTL at the local community college using female peer leaders and integrating the training with UTEP peer leaders.

UTEP is the lead institution for the Computing Alliance of Hispanic-Serving Institutions (CAHSI), which was founded in 2006 as a consortium of over ten institutions focused on the recruitment, retention, and advancement of Hispanics in Computing [3]. The founding institutions are UTEP, California State University-Dominguez Hills (CSU-DH), Florida International University (FIU), New Mexico State University (NMSU), Texas A&M-Corpus Christi (TAMU-CC), University of Puerto Rico Mayaguez (UPRM), and University of Houston-Downtown (UHD). CAHSI's motivation lies in the rapid growth of the Hispanic population and the urgency of building a U.S. computing workforce to maintain the nation's prominence in technology. It is critical for the economic and social health of the United States that we maintain a globally competitive STEM workforce and expand our engagement of diverse individuals who can contribute to innovation and advancement in STEM areas. Engaging large segments of our society who have traditionally not been involved, i.e., students from underrepresented groups, is critical in addressing workforce needs and innovation, especially in technical fields. CAHSI has been making a difference by sharing resources and promoting effective, evidence-based practices.

CAHSI activities and initiatives allow students to develop social networks of academically-minded computer scientists and engineers among their peers at their university and beyond. The major initiatives include: *CS-0*, a pre-CS course that uses graphics and animation to engage and prepare students who have no prior experience in computing; the

Affinity Research Group model and course that emphasizes the deliberate and intentional development of technical, team, and professional skills and knowledge required for research and cooperative work; Mentor-Grad, an initiative designed to engage under-graduates in experiences and activities that prepare them for success in graduate studies and onto the professoriate; Fellow-Net that focuses on mentoring students to support the submission of competitive fellowship applications; and PLTL. CAHSI sponsored several workshops in coordination with City College of New York to introduce UTEP and other CAHSI institutions to the PLTL strategy [5] [6].

At UTEP, PLTL is used in the first three computer science courses. The first two fundamental courses, CS1 and CS2, are four-credit courses with closed labs that meet for three-hours per week. Each lab has a teaching assistant assigned to it. Peer leaders also work with students during the lab hours. CS3 has an open lab, although a teaching assistant and a peer leader are assigned to the course.

B. The El Paso Community College

The EPCC offers several associate degrees in information technology; one of them is the associate in arts in computer science. EPCC offers four fundamental courses in CS, these include CS1, CS2, CS3, and computer organization and machine language. In these courses, several instruments are used to articulate the student learning outcomes established by the institution.

Computer Science courses meet two days per week with each session lasting two hours. EPCC offers smart classrooms where every student has a computer and the faculty can monitor the student's workstation through a master computer. Due to the long period of time the lecture meets, the instructors have designed activities using inquiry-based techniques and active learning [7] [8] to keep the students' engaged. Traditional evaluation instruments are used in CS1 to evaluate student-learning outcomes; these include weekly quizzes, programming labs, hands-on activities, exams, and a final exam. The computer programming labs use hands-on activities that are based on cooperative learning techniques.

For CS1, EPCC has adopted a progressive and constructivist approach [9] where the student learns the fundamentals of computer programming by developing assignments based on implementations of previous assignments. As a result, the student is responsible for his or her own learning by adding new programming components to previous work. Faculty at EPCC have proposed a series of sequential computer programming assignments that assess the CS1 learning outcomes. One of the purposes of these assignments is to motivate the learning process of the student by developing a real-world application in addition to smoothing the transition between courses so students can transfer successfully to UTEP or other institutions.

Students work on hands-on activities every week with classmates selected randomly for team assignments. Activities are designed to provide problem-solving techniques, pseudo code practice, and finally implementation of the code. Each member has a different duty depending on the problem, and at the end of the implementation, each team must present his or

her work in front of the class. The students provide discussion and feedback of each implementation.

C. Articulation Agreement

UTEP and EPCC entered into an Articulation Agreement in 2007 as a mechanism to align the courses listed as the field of study curriculum for Computer Science, i.e., CS1, CS2, and CS3. Identifying essential elements for assuring that the course content and delivery are comparable is an important step in facilitating the success of students transferring from EPCC into the CS program at UTEP. The agreement outlined that UTEP and EPCC CS faculty will align the outcomes and assessments of the CS courses, and UTEP agreed to accept EPCC's CS1, CS2, and CS3 as credit toward UTEP's Bachelor in CS. In addition, UTEP and EPCC agreed to meet each semester to discuss course assessment results, curriculum changes in the fundamental areas, and student-support strategies and opportunities.

UTEP and EPCC also have a reverse Articulation Agreement that allows students to transfer courses from UTEP to EPCC. The long-standing relationship between the leadership from both programs has laid the foundation for the PLTL initiative.

III. PEER-LED TEAM LEARNING

A. Overview of PLTL

Peer-Led Team-Learning (PLTL) was first developed by the City College of New York in 1990 [4] [10]. The approach is based on strategies of collaborative learning and problem solving. The model uses small group sessions, which are led by near peers, to assist students in mastering complex concepts. The sessions provide students with extra time to work on problems and get questions answered. A feature of the approach is that students build a sense of community in which they can learn from each other, and they take responsibility for their learning. Students gain confidence as they develop problem-solving skills, and they acquire team and communications skills.

A critical component of PLTL is the training provided to the peer leaders, who receive a stipend for their efforts. They attend an orientation and weekly meetings facilitated by a faculty member(s) who works with them to ensure that the problems presented to students are well aligned with the topics covered in class. The training sessions include review of problem-solving strategies and reasoning that are integral to the group sessions.

The CAHSI PLTL model, as implemented throughout CAHSI, hinges on the components found in cooperative learning [11] [12] [13] [14]: positive interdependence, face-to-face promotive interaction, individual accountability, professional and interdisciplinary skills, and group processing. A short description of these essential elements follows:

1. *Positive Interdependence*: Students are linked to others in the team in such a way that they cannot succeed unless their teammates do and that they must coordinate their efforts with the efforts of other members to complete a task.

2. *Promotive Interaction*: Members of the team promote each other's success by sharing needed resources and helping, supporting, encouraging, and praising each other's efforts.
3. *Individual Accountability*: Each member must be accountable for contributing his or her share of the work. Individual accountability exists when the performance of each individual student is assessed, the results given back to the individuals and the group, and the student is held responsible by team members for contributing his or her fair share to the group's success.
4. *Professional and interpersonal skills*: Group members must know how to communicate and function as a team. Skills must be taught, modeled, and practiced.
5. *Group processing*: Group processing refers to reflecting on a team activity to describe which team behaviors were helpful and not helpful and to make decisions about what actions to continue or change.

During the PLTL group sessions, students create a learning environment that is far different from the traditional classroom. In this non-traditional setting, cooperation and participation are encouraged over competition and individualism. PLTL is based on the Peer Cooperative Learning Program (PCLP), which is embedded within the course. It shares commonalities with two other PLCP programs, namely the "Emerging Scholar's Program" (ESP) of Treisman in the early 1980's at Berkeley [15] [16] and the Video-Based Supplemental Instruction (VSI) developed at University of Missouri at Kansas in late 1980's [17]. The philosophy driving cooperative programs like these is that institutional structures need to adapt to meet students' needs, rather than focusing on students' deficits.

Extensive studies involving students from different majors and different have shown that students using PLTL methods consistently perform better than their counterparts who used traditional methods of learning [3] [4] [6] [18]. PLTL at CAHSI institutions has significantly contributed to students' persistence in the major [19]. Prior to the implementation of PLTL in "gate-keeper" courses in the major, only 77% of students completed the course, while 87% of students completed the course after the advent of PLTL. This ten percent increase in course completion rates is statistically significant ($\chi^2(1, N=5195) = 53.07, p < .01$). Likewise, Hispanic students showed a six percent increase in course completion ($\chi^2(1, N=2716) = 17.4, p < .01$) after PLTL was implemented, also statistically significant.

B. The UTEP-EPCC PLTL Initiative

The UTEP-EPCC initiative, which has been in place for two semesters, transferred this effective retention practice by establishing early connections with female students, creating community, and providing activities that improve students' problem-solving skills. EPCC and UTEP peer leaders share strategies and lessons. The PLTL effort supports academic performance and retention in the gatekeeper courses by providing role models to boost students' confidence and knowledge. One of the significant reasons for failure is lack of

support inside and outside the classroom, and PLTL addresses this.

Students are chosen as peer leaders based on their performance in the CS1 course. The EPCC initiative identified three female peer leaders for the CS 1 course only. UTEP incorporates PLTL in its CS1, CS2, and CS3 courses. For the peer leaders, the experience of working with faculty and guiding their peers through a difficult course is rewarding. They learn communication, teaching, leadership, and interpersonal skills. Peer leaders become more confident about their career path, and most of them decide to apply for research positions or internships at a later time. This is very important to our retention efforts, since this experience influences the students' motivation to attend graduate school.

In PLTL sessions, small groups of students meet weekly for 30 minutes outside of class time to solve carefully developed sets of problems under the guidance of peer leaders. The differences in the course taught at UTEP and the EPCC course is that UTEP students register for a specific lab and, therefore, have assigned lab times. At EPCC, students have open lab hours.

UTEP hosted a six-hour orientation for the UTEP-EPCC peer leaders in which the activities were conducted in a cooperative learning environment. During the orientation, peer leaders learn and practice the elements of cooperative learning. In addition, the orientation emphasizes the basic premise of PLTL, i.e., creating sessions that facilitate problem-solving, which distinguishes PLTL from tutoring and assistance. Activities include having peer leaders develop an activity to be used during the first PLTL session of the semester based on the lecture schedules provided by the course instructors. As part of the peer leaders' integration, EPCC team leaders attended a peer leader session at UTEP each semester. This helped them understand the program and the activities by experiencing the sessions themselves, and it supported their integration with the UTEP PLTL team and faculty. The UTEP/EPCC peer leaders not only worked together in providing sessions, but also shared their personal recommendations and challenges based on their own experiences. In addition, the EPCC peer leaders made new connections with UTEP faculty and students who were involved with research.

The peer leaders are required to attend all lectures for the class to which they are assigned. They are also required to attend weekly meetings with the program coordinator for discussion about and peer review of the previous week's activity along with additional training. Each peer leader is required to document their activities. The reports include what went well and what could be improved with suggestions for improvement. The peer leaders are required to meet regularly with the instructor of the class to which they have been assigned to provide feedback about problem areas they found during the PLTL sessions and to make sure that the activity belongs to the scope of the material covered in class.

Every week, the peer leaders design a group activity based on the current material the faculty is covering in the classroom. The PLTL activities emphasize problem-solving techniques. The students in the courses are required to attend

the sessions, although it is difficult in the EPCC courses because of the open lab concept. To address this, peer leaders at EPCC schedule sessions on different days, e.g., Wednesdays, Thursdays, and Saturdays, with the purpose of reaching students who have different schedules. Peer leaders at both EPCC and UTEP work 10 hours per week.

In the PLTL sessions, the students are randomly assigned to work in teams of 3 to 5 people to complete the cooperative learning activity presented to them. The activities are typically visual, active, and memorable. Since the purpose of the sessions is to reinforce the information covered in lecture rather than introduce new material, the peer leaders are trained to question and assess the teams' approaches and solutions and not simply provide the answers. The peer leaders encourage the teams to use multiple approaches to solve a problem along with promoting equal participation of all team members.

In fall 2014, peer leaders and faculty from both UTEP and EPCC attended the "Stereotypes & Stereotype Threat Affect Computing Students" presentation from NCWIT. The group discussed various personal experiences in relation to stereotype threat. Everyone agreed that there is a need to address stereotype issues in the programs. The group noted that having informed advocates and peer leaders (male and female) is key to addressing these issues. As a result, the presentation will now become part of the required meetings.

C. Example Activity

The activity below is an example lesson that guides the peer leader.

Algorithm Lesson

Purpose: To reinforce students' understanding of algorithms.

Group Size: 3

Method for Assigning Students to Groups: Count the number of students in the class, divide by 3, count off from 1 to the quotient, and group identical numbers.

Materials: Handout (one copy per group) with the task description and questions to be answered at the end of the session

Roles: Robot, recorder, and direction giver

Individual Accountability: The size of the group will be small to make sure everyone can participate. Also, each group will be observed during the activity to make sure all members are contributing.

Activity Summary:

1. Each group will prepare a written algorithm for getting a "robot" to reach a pre-determined location.
2. The algorithm will be given to a different group to verify that it works. This time the "robot" (student) will be blindfolded. The robot will be given the written instructions. If it does not work, the group that designed the algorithm will revise their algorithm and try again.

Group Questions:

Have the groups discuss what is needed to write an effective algorithm. They will answer the following questions:

- What did you have to consider when writing an algorithm?
- What changes did you have to make to the algorithm after you tested it?
- Why is verification important?
- What did your experience teach you about writing computer algorithms?

IV. EVALUATION

A. Evaluation Results

Surveys were developed to assess student attitudes about the PLTL course and computing both before and after the PLTL experience. Nine pairs of statements were rated by students with a retrospective pre-test and post-test design. IRB delays prevented administration of a true pre-test, but use of this method allowed participants to reflect on changes that occurred over the semesters, providing both pre- and post-ratings after the intervention. This method reduces rater bias and has comparable validity to standard pre-post methods [20]. Participants often comment that they overinflate pre-test attitude ratings with traditional survey design because they do not yet know what they do not know.

Surveys were administered to 139 total undergraduate students at UTEP (n=120) and the EPCC (n=19) who participated in a PLTL course over two semesters (spring 2014 = 51 participants; fall 2014 = 88 participants). Survey results are shown in Tables 1 and 2.

TABLE 1. SIGNIFICANT IMPROVEMENTS WITH PLTL PARTICIPATION

Increased Persistence in Computing	Increased Engagement in Computing	Increased Confidence in Computing	Increased Computing Skills
Significant increase in grades ($p < .01$) from pre to post PLTL	Significant increase in feelings of belonging in the major ($p < .01$) from pre to post PLTL	Significant increase in confidence in computing ($p < .01$) from pre to post PLTL	Significant increase in programming skills ($p < .01$) from pre to post PLTL
Significant increase in confidence about earning degree in CS ($p < .05$) from pre to post PLTL	Significant increase in enjoyment of programming ($p < .01$) from pre to post PLTL	Significant increase in interest in a computing career ($p < .05$) from pre to post PLTL	Significant increase in understanding of CS course materials ($p < .01$) from pre to post PLTL

Increases in eight of nine key Mini Grant goals were significant from pre- to post-PLTL experience. These improvements included: increased feelings of belonging in the PLTL course, increased confidence in computing, increased understanding of CS course materials, increased enjoyment of programming, increased programming skills, improved grades, increased intent to earn CS degree, and increased interest in a career in computing. Survey items were rated on a 4-point scale from low to high, “Strongly Disagree” to “Strongly Agree.”

The only PLTL goal that did not achieve significant increases in ratings of agreement was plans to major in CS. Ratings of this statement were positive both before the PLTL course (mean score = 3.38), and after the PLTL experience (mean score = 3.45).

B. Qualitative Peer Leader Reflections

The PLTL coordinator met with the peer leaders each week to plan activities. EPCC peer leaders reflected on the experience of working in this role and provided the following insights and outcomes:

- PLTL participation needs to be mandatory to be most effective.
- Faculty communication was useful to peer leaders and also made them feel supported.
- The UTEP and EPCC collaboration improved communication and made everyone feel like a part of the team.
- Two of three EPCC peer leaders have transferred to UTEP and will continue to study CS.
- One of these transfer students will continue in her role as a peer leader at UTEP.
- One transfer student has joined an undergraduate research team at UTEP because of her experience with the PLTL project.
- The remaining PLTL peer leader will continue in that role at EPCC until she transfers.
- This peer led approach provided an effective transition for students who may have struggled as they transferred from community college to university programs in Computer Science.

C. EPCC Reflections

EPCC faculty have observed a positive effect with the PLTL model mainly in two aspects: increased motivation in team work and retention in CS2. The experiences have provided students with an opportunity to meet other students in the program and to become more conscious about time constraints (regarding budgeting the time to finish an activity). In particular, students have learned problem breakdown (divide-and conquer) techniques and task delegation when the main task has been assigned to a team. It is important to note that the majority of students in the spring 2015 semester who have continued to the CS2 course are those who attended the PLTL sessions in fall 2014.

The EPCC students had a positive reaction to the PLTL sessions. Several students claimed that the sessions have helped them gain a deeper understanding of the concepts they learned in the classroom. In addition, the PLTL sessions helped them improve their problem solving skills in quizzes and tests. Students have adapted successfully to PLT because of the way that it complements with the cooperative learning techniques that faculty apply in the classroom. Other students suggest that it is less intimidating to work with peer leaders because of their accessibility. The EPCC peer leaders reported that being a peer leader was challenging at the beginning because they never believed that they would be leading class

activities. Their experience has increased their confidence in the field of computer science. They also note they have better understanding of the material for CS2, since they now have the ability of synthesize information learned in the classroom.

Finally, the peer leaders have expressed their desire to transfer to a four- year institution after they complete their associates in computer science at EPCC.

TABLE 2. COMPARISON OF PLTL OUTCOMES WITH RETROSPECTIVE PRE-POST TEST DESIGN – PAIRED SAMPLES T-TEST

	<i>n</i>	<i>Mean</i>	<i>SD</i>	<i>Standard Error Mean</i>	<i>t</i>	<i>df</i>	<i>Significance (2-tailed)</i>
PAIR 1 - Before: I feel like I belong in PLTL After: I belong in PLTL	133 133	2.92 3.27	.68 .67	.06 .06	-6.02	132	.00
PAIR 2 - Before: PLTL will improve my confidence in computing After: PLTL improved...	132 132	3.17 3.48	.61 .61	.05 .05	-6.00	131	.00
PAIR 3 - Before: PLTL will increase my understanding of the material covered in CS Courses After: PLTL Increased...	132 132	3.32 3.53	.61 .61	.05 .05	-3.61	131	.00
PAIR 4 - Before: PLTL will increase my enjoyment of programming After: PLTL increased...	133 133	3.04 3.44	.77 .71	.07 .06	-6.32	132	.00
PAIR 5 - Before: PLTL will make me a better programmer After: PLTL made me a better programmer	132 132	3.26 3.52	.61 .60	.05 .05	-4.59	131	.00
PAIR 6 - Before: PLTL will improve my CS grades After: PLTL improved...	131 131	3.22 3.43	.65 .66	.06 .06	-3.66	130	.00
PAIR 7 - Before: I plan to major in CS After: I plan to major in CS	133 133	3.38 3.45	.93 .91	.08 .08	-1.22	132	.23
PAIR 8 - Before: I will earn my degree in CS After: I will earn my degree in CS	133 133	3.30 3.42	.94 .92	.08 .08	-2.38	132	.012
PAIR 9 - Before: I am interested in a career in computing After: I am interested in a career in computing	133 133	3.46 3.58	.77 .74	.07 .06	-2.30	132	.02

D. Evaluation Challenges

Our project team encountered several challenges related to working with two academic institutions. The first involved different Institutional Review Board (IRB) requirements and standards for working with students and administering surveys. The second involved the use of laboratory time for PLTL sessions. Because open lab periods were used, and attendance was not required, it was challenging to ensure that students were able to attend group sessions.

CAHSI evaluation of peer leaders has revealed that being a peer leader also boosted students' oral communication, teaching, leadership, and interpersonal skills. Most peer leaders (94%) of respondents agreed or strongly agreed that being a peer leaders had improved their oral communication skills. Almost all (97%) agreed or strong agreed that PLTL had developed their teaching and leadership skills. All

respondents agreed or strongly agreed that leading PLTL had improved their interpersonal skills, i.e., their ability to cooperate with others.

V. SUMMARY

This paper describes the NCWIT Extension Services Mini Grant project that was designed to address multiple retention challenges faced by CS students transferring from the EPCC to UTEP. Using a data-driven approach, team members identified four strategies to improve retention for these students: 1) rebuild a collegial relationship between the academic institutions with the current Articulation Agreement to ensure adequate preparation and equitable retention; 2) create opportunities for transfer students to engage in research, leadership opportunities, and relationship-building activities to increase their connections and supports at UTEP; 3) increase opportunities to spend

more time on campus to increase success, as UTEP has a large commuter population; and 4) increase confidence, sense of belonging, understanding, and persistence with innovative methods, such as PLTL, to help EPCC transfer students, who exceed the number of UTEP freshmen, find their place. As many as a quarter of students surveyed said they plan to change major at least once, so creating a sense of place and feeling of belonging might help these students excel.

Nine goals were identified for PLTL participants. These goals addressed known retention indicators, such as increased confidence in earning a CS degree, interest in the major, intent to pursue a CS career, and improved grades.

PLTL participants reported significant improvements in eight of the nine goals after just one semester. Only plans to major in CS did not increase significantly, possibly because ratings of intent were high in both pre- and post-PLTL.

The PLTL course collaboration between EPCC and UTEP was effective in implementing all four retention strategies. Collaboration improved the relationship between the institutions, increased communication about Student Learning Outcomes for equitable courses, and increased understanding of the PLTL method. Peer leaders reported increased understanding of the content areas taught, as well as increased opportunities to participate in research and leadership activities once they transferred. Participants reported significant increases or improvements in eight of the nine PLTL participation goals.

ACKNOWLEDGMENTS

The author would like to acknowledge the support of the National Center for Women & Technology for their support of the project through the ES and ES-UP programs. The work was also partially funded through NSF's grant number CNS 05040592.

The Creation and Inauguration of Engineering Leadership

UTEP and Olin College Innovation Project

Needham, MA 02492 USA

Abstract— The Franklin W. Olin College of Engineering (Olin College) and The University of Texas at El Paso (UTEP) are partnering in a project to create a new engineering program that educates career-ready engineering innovators while simultaneously increasing recruitment and retention among historically underrepresented students. Through the *Olin-UTEP Partnership for Change: Adoption and Adaptation of Innovative Practices for 21st Century Engineering* project, supported by the Department of Education and the Argosy Foundation, UTEP is pioneering a novel undergraduate engineering leadership program (E-Lead), focused on innovation, collaboration, communication, and human-centered engineering embedded in rigorous technical education. The program is being modeled on the curriculum and pedagogy of Olin College, a private, highly selective engineering college respected and nationally recognized for its premier innovative engineering education. The adaptation to UTEP is of national interest, since UTEP is a public, urban institution with a 21st-century demographic [1] and successful transformation of Olin approaches to UTEP can demonstrate scalable impact broadly pertinent to many other commuter campuses and public institutions. By conveying these approaches to UTEP, a minority institution serving a largely Hispanic population in the region of Texas with the lowest median income [2], we aim to demonstrably adapt and scale successful innovation-supportive pedagogies to meet important national needs for a diverse and empowered 21st century engineering sciences workforce.

Keywords—engineering leadership, Olin, UTEP, innovation

I. INTRODUCTION

Traditional engineering programs at public urban institutions across the United States largely focus on distinct disciplinary education [3]. In contrast, the new undergraduate program in engineering leadership at UTEP is designed to emphasize the broad, interdisciplinary education that is necessary to develop innovation leaders of the 21st century, along with the skills of communication, collaboration, and sustainable, and systems engineering thinking, needed by industry and reflective of our complex technical society needs. This is not to say that the E-Lead program does not emphasize technical skills, for it is a very carefully developed degree plan that is designed to maximize

learning of engineering problem solving, amidst pathways to gain critical educational experiences in business, education, or traditional disciplines. In this regard, the program includes minors in engineering disciplines as options available to students. The goal is to provide flexibility to meet targeted individual needs – oftentimes now called personalized learning [4] – while maintaining emphasis on engineering leadership and professional competencies acumen as being the program core. This approach is just the opposite of that adopted in traditional engineering programs, where professional skills are developed subsequent to emphasis on engineering problem solving (technical skills). To achieve this transformation in engineering education at UTEP, Olin College is working closely with UTEP's new Department of Engineering Education and Leadership, established to advance new paradigms for engineering education at UTEP.

Olin and UTEP are working in partnership to translate the Olin College philosophy and practices of innovative, interactive and student-centered engineering education into the new E-Lead program in the UTEP College of Engineering. The partnership supports this innovative engineering education approach with an aim to introducing and sustaining the program at UTEP through its institutionalization and our hope provide similar mentorship beyond UTEP to other engineering programs interested and ready to adopt new approaches to engineering education. In the current work a major outcome for this cooperative project is to attract, retain, and graduate an increase in throughput of minority students, especially Hispanic engineering students, resulting in higher graduation rates and shorter time to graduation.

The results of the Olin-UTEP partnership can have broad applicability for a growing number of public, urban institutions, educating diverse students for the benefit of our community and local west Texas region, the state of Texas and the nation.

II. GROWING STUDENT-CENTERED ENGINEERING EDUCATION

Educational emphasis on leadership, innovation and

pedagogical format and process is central to growing student-centered engineering education. Engineering leadership (E-Lead) at UTEP is advancing pedagogical paradigm shift in higher education to 24-h learning environments, encompassing several delivery formats including online courses, blended/hybrid designed courses, and the traditional face-to-face (f2f) lecture classes have increased student access and engagement into global, lifelong learning [5]. There is a synergistic interest in these learning approaches at Olin and UTEP.

E-Lead classes are being taught in a studio environment, typically utilized in advanced courses at Olin, where students participate in developing engineering competencies through project-based learning. E-Lead's multidisciplinary projects play a critical role in the E-Lead educational paradigm because they challenge students to apply their knowledge to deliver a tangible project. This learning experience requires students to work in highly collaborative groups and, unlike many other engineering degrees, E-Lead students develop a vital sense of community among themselves and their professors, allowing students to learn the power of teamwork. Community is built in and outside of the classroom to ensure the E-Lead experience is more than a classroom activity.

The E-Lead program also develops a culture where students actively contribute to their own education and where individual contributions are valued and important. E-Lead students strive for excellence because they have a sense of ownership and power over their own education.

Most people view leadership as a process or endpoint. At UTEP students and faculty perceive it as a cycle of leadership trait self-development shared and perpetuated through encouraging and building such traits in the people around them. At the core of engineering leadership studies at UTEP is the effort to kindle an understanding of leadership practice founded on the development of students' character, competence and capacity. The approach is indeed similar to that embedded in innovative companies, of all sizes and kinds, where leadership is every employee's opportunity and responsibility. At UTEP, character, competence and capacity symbolize the three pillars upon which engineering leadership education is structured. Thus it forms the foundation of growing leadership styles.

III. ENGINEERING LEADERSHIP EDUCATION AT UTEP

Engineering Leadership (E-Lead) is the first degree of its kind in the nation, involving collaborations with key entities such as Olin College, West Point, and other key educational institutions, the curriculum designed for E-Lead seeks to transform the classroom experience of engineering students. E-Lead moves beyond content and focuses on project application and the integration of the students' skills and knowledge in real-world scenarios.

E-Lead creates a culture of innovation, excellence and collaboration from its students, meant to extend beyond their years of undergraduate study. Grounded in leadership development, E-Lead maximizes each student's collaborative capacity. Mentoring character and personal growth helps students reach a level of personal and professional achievement that goes beyond traditional instruction. E-Lead develops the student into an action-driven leader with an innovative mindset.

Students see leadership growth as a cycle in which everyone in a cohort develops leadership traits in themselves and in those around them. At the core of engineering leadership studies is the effort to imbue leadership practices founded in the development of student character, competence and capacity [6]. Character, competence and capacity are thus the foundation of creating leadership styles and can serve as the three pillars upon which engineering leadership studies, content, and experiential learning are structured [7]. When the three pillars of engineering leadership are assimilated through experience and learning, the result is a cohesively competent graduate – one who is ready to face the challenges of the 21st century.

A. Leadership Character

Character is about discovering the truth, deciding what is right, and demonstrating the courage to act accordingly [8] and is impacted by personality, values and conduct [9]. Students in engineering leadership are encouraged to be individuals who boldly advance shaping their individual values, integrity and personality, which is at their core. To achieve this, the engineering leadership faculty and students cultivate an environment where individuals are encouraged and mentored to grow and develop an inherent understanding of their true selves, to become people of integrity and to nurture selflessness. Without character, leadership is incomplete. Good leaders care about the improvement of the lives of all, in a holistic sense, they become involved in their community – including professional, local community issues, regional concerns and global challenges. This one trait alone greatly reflects the intentions of the students in this program.

B. Leadership Competencies

Leadership competencies are leadership skills and behaviors that contribute to superior performance. By using a competency-based approach to leadership, organizations can better identify and develop their next generation of leaders [10]. Essential leadership competencies and global competency development strongly impact future business trends and engineering leadership education strives to advance the development of leadership competencies.

While some leadership competencies are essential to all firms, an organization should also define what leadership attributes are distinctive to the particular organization to create competitive advantage, according to the Society for Human Resource Management (SHRM), which identifies top workplace trends [11]. Among these, building leadership

capability through attracting, growing and leveraging organization talent were seen as vitally important for organizations to differentiate and thrive in the next decade. Collaborative, project-based learning experiences help students apply leadership theory, and synthesize and identify those leadership opportunities, all while applying their technical knowledge. Engineering leadership further develops competence by diversifying subjects and allowing students to focus on tracks that pique their interests. Engineering leadership gives students a synthesized, multidisciplinary education that prepares them to thrive in today's world.

C. Capacity for Leadership

Leadership is about learning that leads to constructive change [12]. Thus leadership is about capacity and those such as Lambert [13] who are redefining leadership situate it in the processes among us, rather than in the skills or disposition of a leader. As a concept separate from, yet integrated with, leader, leadership (notably a *verb*) stands as a broader notion, a more encompassing idea. This breadth is evident when we consider the connections or processes among individual leaders that are embedded in the context, the culture of an organization. These processes include problem-solving; broad-based, skillful participation (leadership capacity); task enactment, conversations, and stories. These processes engender a wave of energy and purpose that engages and pulls others into the work of leadership.

Engineering leadership students at UTEP are presented with diverse team-based challenges that incorporate multiple disciplines from day one of class. From project managing to research, students have the ability to excel at diverse roles, even teaching, widening the future possibilities available to them. Engineering Leadership develops capacity by providing students with multiple opportunities to apply and synthesize diverse competencies, thereby building experience.

IV. ENGINEERING LEADERSHIP DEGREE AND CHARACTERISTICS

The Bachelor of Science in Engineering Leadership (E-LEAD) degree program was approved for offer at UTEP by The University of Texas System in mid-2014 and ratified by the Texas Higher Education Coordinating Board in November 2014. The goal of the E-LEAD program is to offer students a world-class innovative engineering education experience that is ABET-accredited.

The innovative engineering degree program features a practice-based approach to graduate engineers who shall complete and themselves possess a broad-based, multidisciplinary engineering education incorporating a balanced set of technical skill and attainment of professional competencies. In aggregate it is these skills will position E-LEAD graduates to becoming shining stars, so to speak, not just in practicing engineering but contributing to business, industry, government and professional services, such as medicine,

law, and other emerging service sciences. Figure 1 summarizes the curriculum plan for the Bachelor of Science in Leadership Engineering program.

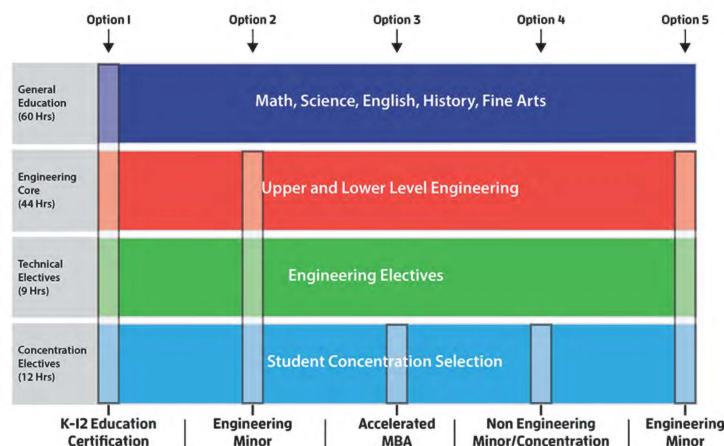

Figure 1. Engineering leadership curriculum overview.

The engineering leadership program is designed to meet engineering accreditation requirements (see www.abet.org/accreditation). It is a very innovative program, which is understood in the context of a historical perspective, namely IBM's contribution to the establishment of the now ubiquitous undergraduate programs in computer science/engineering, discussed next.

V. ESTABLISHING NEW ENGINEERING DOMAINS

Back in the 1950s, when IBM was seeking to ensure the availability of professionals capable of driving adoption and utilization of IBM mainframes, the company, both directly and through organizations like the Association of Computing Machinery (ACM), partnered with universities to create Information Science curricula and courses. These efforts, combined with similar actions by dozens of other IT vendors and organizations, spawned generations of professionals that have been instrumental in establishing IT as a critical foundation of virtually all 20th century organizations. [14]. UTEP's new engineering leadership program is comparable with computer science/engineering when it was an emerging undergraduate program across the U.S. in the 1960s.

Within the current paradigm, engineering education is reforming in piecemeal fashion. Yet the converging competitive and market forces require sweeping change in engineering education through a change in paradigm from the land grant/flagship institutions of the 19th and 20th centuries to possibly the university of the 21st century—a regional, urban institution like UTEP with demographics more closely matched to the future demographics of the U.S. where the majority will be Hispanic.

While a common objective of U.S. engineering programs is to produce future engineering leaders, few programs have curricular content specifically designed to develop the skill set of leaders. Many current engineering leaders developed

their skills through post-graduate leadership training (for example, by obtaining an MBA) or in industry settings (such as the Lockheed Martin Engineering Leadership Program [15]. In their investigation of existing undergraduate programs in engineering leadership worldwide, Graham, Crawley, and Mendelsohn [16] found leadership programs to be either extra-curricular or adjunct (i.e., ranging from a single course to a full minor) to an existing undergraduate engineering program in a traditional discipline. They define these programs as those that develop all or a portion of the following general skill set: Initiative and decision-making, systems thinking, networking and relationship building, creating a compelling vision, teambuilding and management to project completion, problem solving and critical inquiry. Of particular interest to us is the aforementioned skill set defined in these various leadership programs—a targeted competency set of the UTEP engineering leadership program.

Moreover, STEM educators and professional societies such as ABET, the American Society for Engineering Education (ASEE), and the National Science Foundation (NSF), have long understood that the development of life-long learning capabilities is vital for students' success in today's global and rapidly changing engineering environment. With this in mind, Olin College faculty have historically devoted significant effort in designing courses with an aim of instilling a set of skills in students that allow them to pursue knowledge long after they have left the academic environment; in short, they "learn to learn" and become life-long learners. This is accomplished in part through curriculum equipped with the safety net of a supervised pedagogic environment that nurtures in students the curiosity to know [17], [18].

For many institutions, including UTEP, the development of this curiosity to know, or life-long learning skill, in our students is an unmet need. Many STEM curricula create an enormous gap between the highly teacher-directed experiences comprising the vast majority of each student's education and the ambiguous challenges that they face in the workforce. For most of their education, students are told what to study, how to study it, and when to do so. Only when they leave school – or perhaps in a culminating capstone experience – do they confront the need to decide what to learn and how to acquire that knowledge. Scaffolds build on learners' prior knowledge in order for them to facilitate learners in expanding their capacity to learn; thus, learners become more knowledgeable.

VI. THE OLIN-UTEP PROJECT EXPERIENCE

The Olin-UTEP cooperative project builds on an emerging partnership between UTEP and Olin College supported by the Argosy Foundation [19.] A core part of the Argosy-supported effort is a "Collaboratory" [20], a program designed to catalyze educational innovation through cross-campus collaboration. The exchange creates partnerships with departments or programs committed to educational

change, embedding faculty from partner schools for year-long residencies at Olin College, providing participants with time, space and support for planning transformative activities at their home campuses. Partnerships are typically expected to include two consecutive years of residencies at Olin, with varying faculty participants. The multi-year program will include a comprehensive assessment of the exchange's impact on the partner schools as well as Olin.

In the Olin-UTEP program, faculty members from the UTEP College of Engineering are undertaking residencies at Olin College, immersing in Olin's approach to engineering curriculum and pedagogy and collaboratively re-designing UTEP engineering courses.

Shane Walker, a Civil Engineering professor at UTEP has reported on his experiences [21], Stella Quinones, an Electrical and Computer Engineering professor at UTEP has also spent a semester at Olin, and currently co-author Meaghan Vaughn is serving as a visiting Associate Professor at Olin, during spring semester 2015. The collaboration has been vital in underpinning this emerging partnership through its provision of significant support for the development of UTEP's BSLE program, including renovation of space to support interactive, studio-style pedagogy crucial to the education of engineering innovators; support for the UTEP program leadership to pursue innovation and professional development; and extended engagement by Olin faculty members in the development of the UTEP BSLE program.

Working with Olin College provides the opportunity for UTEP to plan, reflect, and undertake continuous quality improvements from E-LEAD program startup through regularly meeting to review progress toward achieving student outcomes in courses, methods, and approaches to teaching and implementation. Olin and UTEP faculty are sharing best practices, and UTEP is benefiting from the learning process undertaken through Olin College's own process of start-up and ongoing efforts to achieve outstanding results for students.

The specific characteristics of Olin's approach to curriculum design being embraced and customized to the UTEP BSLE Program are: (1) Curricular frameworks and instructional approaches for student-centered learning, and (2) Techniques that foster intrinsic motivation, self-direction, and autonomy through authentic project, professional practice and leadership experiences, and (3) Culturally and socially responsive curricula, in which students creatively investigate and solve social problems through innovative technological design.

The principal components of the *Olin-UTEP Partnership for Change* is: (1) Design of undergraduate engineering courses for the UTEP Bachelor of Science program to incorporate student-centered innovative

curriculum design approaches adapted from Olin College; (2) Faculty development to build capacity for implementing the curricular and pedagogical approaches of the Adoption and Adaptation of Innovative Practices into the BSLE program courses; (3) Renovation of UTEP spaces into studio classrooms to support the newly-created undergraduate BSLE courses that will be centered on design; and (4) Institutionalization of innovative curriculum and pedagogy at UTEP with a view to expand beyond UTEP to other MIs (Minority Institutions) and HSIs (Hispanic Serving Institutions).

VII. DESIGN & TRANSFORMATION OF OLIN COLLEGE APPROACH IN UTEP LEADERSHIP ENGINEERING COURSE INNOVATIONS

The following is a summary of course innovations and emphases in the engineering leadership program completed to the present time.

A. *EL 1050 Engineering Leadership I & EL 1205 Graphic Fundamentals*

The EL1050 curriculum developed and taught in Fall 2014, for example, focused on three major disciplines: leadership identity development, innovative thinking, and hands on skills. The EL1250 course content, on the other hand, focuses on developing spatial reasoning skills and communication of ideas graphically. These disciplines were taught in a studio environment through group discussions and interactive individual and group projects. This summer, students will again be redesigning this curriculum for the incoming class and the focus of the curriculum may shift based on the needs of the incoming students identified by the current students.

Taught simultaneously as co-requisites during the first semester of the BSEL degree plan, these courses are designed to foster fundamental engineering skills as well as establish the culture of the Engineering Leadership program. These courses are unique, however, in that they are not designed and led by faculty - but by second year E-Lead students.

During a faculty led workshop each summer, a group of students who took the courses the prior fall redesign the courses. By allowing students to design and teach the EL1050 course in particular, retention increased from 60% in 2013 to 92% in 2014 [22]. More importantly, this experience of being placed in the curriculum development driver seat, also served to help the second year students to redefine leadership, gain a better understanding of leadership, and increase their leadership skills (4.5, STDV 0.55; 4.67, STDV 0.52; 4.67, STDV 0.52; based on an ordinal scale with 1 being strongly disagree and 5 being strongly agree; [22]).

The purpose of these co-requisite courses is not only to give second year students a leadership opportunity and an understanding of the importance of guiding people, but also to introduce a unique culture being created in the Engineering Leadership program and provide leadership models for incoming students to learn from second year students.

B. *EL 1301 Introduction to Engineering Leadership & Design & EL 1200 Design Nature*

This course is typically taken during the Spring Semester by students enrolled in their first year of the Engineering Leadership program. The course has been designed with the assistance of colleagues from the Olin College of Engineering. Though its structure is unique to UTEP, the course draws partially from the practices and principles set forth in Olin College's course, ENGR 1200 - Design Nature.

EL 1301 provides an introduction to mechanical design and prototyping imbedded with a semester leadership experience plus readings and focused assignments to connect students to business thought and connection to current world events. On design, we take nature as a theme and develop bio-inspired ideas into functional prototypes.

Students complete individual and team projects in a studio environment where we seek to develop a shared practice and understanding of engineering design. The project focuses on mechanisms that hop and are eventually integrated into a larger board game format. Projects are evaluated by faculty, the students themselves and the "customer" (the end users of the board game; typically middle school-age children).

In addition, students choose a semester long "leadership activity" to begin the process of integration into the university or community environment. This is a co-curricular activity that students have a chance to develop on their own and evaluate how they integrate effectively with the selected community. Students also read a seminal book on business or leadership that is assigned by the professor. Weekly discussions are held on the book. Students are also required to keep up with current world events and seek to understand the effect that these events have upon the broader aspects of our culture, specifically in how leadership played a role in these developments.

Team building skills are an important part of the latter half of the course. Students take individual lessons learned and combine them to produce a more sophisticated project integrated into a larger framework of a board game for an end user. Team development and interactions are focused upon and evaluated.

C. *EL 2301 – Engineering Leadership I & EL 2302 – Engineering Leadership II*

The EL 2301 course is typically taken during the Fall Semester by students enrolled in their second year of the Engineering Leadership program. The course has been designed with the assistance of colleagues from the Olin College of Engineering. Though its structure is unique to UTEP, the course draws heavily from the practices and principles set forth in Olin College's course, MTH 1111 (Modeling and Simulation of the Physical World.)

EL 2301 provides an introduction to mathematical modeling and computer simulation. Through examples that are drawn from the physical world, students learn to model systems. The course begins with the study of discrete time systems which can be modeled using concepts from sequences and difference equations. In the second half of the course, physical phenomena that can best be modeled using continuous time systems are introduced. This segment of the course involves fundamental concepts from differential and integral calculus, including differential equations. MATLAB provides a programming platform upon which computer simulations can be developed. These simulations allow students to conduct experiments to test the validity and utility of scientific hypotheses.

In addition to the development of student competencies in qualitative and quantitative analysis, the course seeks to develop teamwork and communication skills. Students work in a laboratory environment on a number of open-ended projects throughout the semester. Faculty take care to provide appropriate scaffolding of projects early on in the course to promote student confidence and achievement.

Both individual and team-based projects are features of the class. Latitude in the choice of projects is given to students in the selection of their capstone team-based project. The semester culminates in a formal poster session open to the public in which students present the results of a team-based project.

The EL 3302 – Engineering Leadership II – course is typically taken during the Spring Semester by students enrolled in their second year of the Engineering Leadership program. As is the case with EL 2301, the course has been designed with the assistance of colleagues from the Olin College of Engineering. The course draws together concepts and topics from two courses that are offered at Olin: ENGR 110 (Introduction to Modeling and Control) and ENGR 1121 (Real World Measurement.)

EL 3302 provides an introduction to the fundamentals of electric and electronic circuits and how they can be used to develop measurement devices. Through a sequence of hands-on laboratory experiments, students are given the opportunity to build, test, and de-bug circuits. This process strengthens student competencies in bread boarding, circuit hygiene and diagnosis of problems. Special emphasis is placed on the building of circuits that perform basic operations with which the students have some familiarity. Examples include the construction of electronic differentiators, integrators, and filters.

In the course students learn to build the electronics necessary to produce measurement data which can be collected by means of computer based data acquisition systems. Along these lines, students learn to use various elements of MATLAB programming to process and analyze data.

The course seeks to build teamwork and communication skills of student. All laboratories are conducted by teams of students and require the submission of informal and formal reports. Teams of students also complete a capstone design project at the end of the course.

D. EL 3331—Systems Engineering & EL 3304 – Engineering Leadership III

In development is the Systems Engineering course to be taken during the fall semester of the third year in the BSEL degree plan. This course, to be offered for the first time in the fall of 2015, will focus on Human Centered Design techniques as students learn to design a product, service, or system relevant to their target user group. This particular course is part of a Design and Entrepreneurship sequence of courses and will therefore flow directly into the spring BSEL course Engineering Leadership III (EL 3304).

Together, these courses allow students to work the engineering design process from initial interaction with users through to final deployment of a relevant product or service in their own business or non-profit. During the courses, students learn to work in teams, interact with a user group, learn and apply project specific engineering principles, prototype, develop and business model, and communicate their work. Like other engineering leadership courses, these offerings will be taught as project based courses in a studio environment.

VIII. FINAL REFLECTIONS

Unparalleled converging factors, notably including changing demographics coupled with competitive market forces, impacted by an unanticipated era of engineering-enabled technological changes, provide new opportunities for imagining and creating appropriately reconfigured and inspired new engineering education pathways. In lockstep with James Duderstadt's vision for new paradigms, presented in "Engineering for a Changing World [23]" the new program being developed by Olin and UTEP is going to create a new cohort of engineers, who are as comfortable with leadership roles in community and public organizations, as they are within technical problem solving places, long the self-perceived domain of engineering undergraduates. These graduates are those being sought after by businesses, companies, education providers, and innovative enterprises.

We know they are sought after, because our program has its roots in the call for change not only by distinguished engineering individuals (such as Duderstadt) and influential engineering policy makers (such as the National Academy of Engineering), but also by companies such as IBM, nurturing T-type engineering education, and Halliburton, seeking leadership engineers to guide complex technical systems of engineering.

In some useful comparison, our new undergraduate degree also parallels the medical school training model that is credited with propelling advancement in medical practice during the last century, where the BS degree includes a broad-based curriculum of engineering design, project management, technology, ingenuity and innovation, along with business, communication, ethics, and social sciences. Through this contribution we will expand on the attributes of the new degree, and provide insight into the challenges (and opportunities) it provides when making a “new start” in engineering education that is so inclusive of leadership development that it is included in the degree title.

Developing such competencies is vitally important. For, as Halliburton Energy Services’ President and CEO David Lesar has asserted, engineers lacking 21st century competencies will be unable to move into senior leadership positions within organizations [24]. Such assertions have been supported by National Science Foundation data, suggesting that engineers who have master’s degrees in fields other than engineering are more likely to become senior managers [25]. Engineers seeking to advance to management positions within companies will need a much broader, more liberal arts oriented background than most engineering programs currently offer to students. The E-LEAD program at the UTEP attempts to provide this “liberal education” within a highly structured engineering program.

In a survey of 465 UTEP engineering students in 2011, 43 percent indicated an interest in leadership studies, and 71 percent showed an interest in using leadership coursework as documentation for employers and graduate schools. In 2012, a follow-up survey of 145 high school seniors, 112 engineering freshmen, and 28 engineering seniors also revealed strong student support for a Engineering Leadership degree program: 98 percent of the high school seniors surveyed indicated they would be “likely” or “very likely” to choose the proposed E-LEAD program as their field of study. Similarly, 71 percent of UTEP engineering freshmen surveyed indicated they would be “likely” or “very likely” to choose the E-LEAD program, and 36 percent of graduating engineering seniors indicated that they would be “likely” or “very likely” to choose the program.

Based on our polling of students involved in the Hispanic Engineering Institute (HELI) at UTEP, it has been estimated that about 35 students would apply to the proposed program and that approximately 21 new full-time and four new part-time students would enter the program each year, with an annual increase of five students in years 2-5.

Strong support for the E-LEAD program has been received from several corporations in Texas, such as

AT&T, IBM, and Halliburton Energy Services. These corporations have already agreed to partner with our program and to provide student internships.

It is anticipated that job opportunities for our E-LEAD graduates will be promising, including those seeking engineering jobs in Texas. Our initial review of a national engineering jobs source [26] in October 1, 2012 suggested that E-LEAD graduates would qualify for 30 of the 93 engineering jobs in the El Paso region; 75 of the 470 engineering jobs listed for the West Texas region, and 3,470 of the 15,351 jobs listed in Texas. The actual number of jobs that BSLE graduates would qualify for may actually be higher since we anticipate three primary markets for our graduates: industry, secondary education, and graduate engineering education.

Much progress has been made in our longitudinal pathway to inaugurating the degree, commencing with ideation in 2007, through to conceptualization during 2009, followed by planning, and necessary iteration processing during 2011, application for offering in 2012, and inauguration in 2014. This journey is well worth sharing, to help innovators in engineering understand the practices and procedures involved in causing change at the fundamental program level. We also share their impact on traditional engineering programs, and current experiential learning occurring through implementation. In many ways a journey, and definitely finding a destination, our student mavericks are our future ambassadors for this intriguing entrance into the new discipline of engineering leadership.

The partnership in faculty professional development activity with Olin College has promise to transform engineering education at UTEP. What we learn in this project can lead to transfer of a model of innovative engineering education practices to other minority institutions with an aim of increasing retention and persistence to graduation.

ACKNOWLEDGMENT

The Olin-UTEP Partnership for Change: Adoption and Adaptation of Innovative Practices for 21st Century Engineering project, is supported by a grant from the U.S. Department of Education through the Minority Science and Engineering Improvement Program (MSEIP), UTEP Award #P120A140066 and the Argosy Foundation.

Becoming Boundary Spanners in Engineering:

Identifying Roles, Activities, and Competencies

Purdue University
West Lafayette, IN USA

Abstract—Engineers are increasingly acting as “boundary spanners” who coordinate, collaborate, and communicate across many different kinds of boundaries. The research project described in this work-in-progress paper is shedding additional light on this trend by responding to two main research questions: 1) What specific boundary spanning roles, activities, and competencies are most important and prevalent for early career engineers, and 2) How do early career engineers experience boundary spanning challenges? One major goal of this project is to generate a typology of boundary spanning roles, activities, and competencies for multiple engineering fields. This paper more specifically describes methods and reports preliminary findings for the initial phases of our research. The first phase involves a systematic review of more than 80 journal articles and book chapters on boundary spanning and related concepts using established procedures for literature meta-analysis. In this paper we summarize the major themes and categories emerging from this process. The second phase of the project involves semi-structured interviews with engineering students and early career engineers. In this paper we focus on our interview methods, including development and use of a “primer” document to familiarize subjects with boundary spanning. We conclude by discussing the implications of our work, especially in relation to leading-edge approaches for instruction and assessment.

Keywords—*boundary spanner; boundary spanning; competencies; early career; engineering education; engineering practice; global; professional*

I. PROJECT BACKGROUND

Future engineers will be *boundary spanners*, capable of connecting teams in disparate geographic locations, translating stakeholder needs into effective design solutions, and leveraging expert knowledge from multiple disciplines. They will be empathetic in the midst of diverse perspective, adept as listeners and messengers, able to cultivate trust and mutual respect, and skillful at seamlessly integrating the social and technical aspects of their work. In short, boundary spanning engineers can effectively *communicate, collaborate, and coordinate across organizational, disciplinary, geographic, demographic, stakeholder, and other boundaries*. These next generation professionals are also ideally positioned to advance organizational and national competitiveness, address global grand challenges, and become leaders.

While the need for such capabilities can be traced back many decades, it has intensified due to trends like globalization pressures, organizational restructuring, and rapid technological change. As aptly framed by former NAE President William Wulf, “understanding other cultures, speaking other languages, and communicating with people from marketing and finance will be just as fundamental to the practice of engineering as physics and calculus” [1]. Bordogna similarly asserts that “[d]emands are increasing for a holistic breed of engineers—graduates with the skill to work across intellectual, social, and cultural boundaries” [2], while Duderstadt advocates for “fluency across boundaries” and “integration of knowledge across an increasingly broad intellectual span” (p. 45) [3].

A growing body of literature adds further weight to such assertions. Studies by Lynn and Salzman, for instance, lead them to conclude that engineers urgently need “cross-boundary skills” to enable working “across disciplinary, organizational, cultural, and time/distance boundaries” (p. 82) [4]. Research by Hanneman & Gardner has similarly identified boundary spanning skills and competencies as a key emerging requirement for college graduates, including engineers [5-6]. Demand for such capabilities also persists as professionals progress in their careers. In one study, 86% of more than 100 senior executives indicated it is “extremely important” for them to work effectively across boundaries, yet only 7% believed they were “very effective” at doing so [7].

Nonetheless, a persistent lack of alignment between current workplace realities and the capabilities of graduates means that most early career engineers are simply not ready for boundary spanning work. As Brunhaver et al. describe, many students leave school with “narrow views of professional practice” and employers find that most engineering graduates are “unprepared to practice” [8]. These gaps are exacerbated by compartmentalized learning outcomes coupled with a segmented and crowded engineering curricula, which in turn reinforces the boundaries between the technical and social/professional aspects of engineering practice rather than integrating them in a more holistic and authentic manner [9-10]. In addition to generating disillusioned students and employers, maintaining this status quo may erode the diversity, relevance, and influence of engineering degree programs and their graduates. Concerns have also been raised that such issues

may be exacerbated by ABET's recent proposal to streamline accreditation criteria for engineering degree programs [11].

This project responds to these challenges by proposing *boundary spanning* as a core *meta-attribute* for engineering graduates and early career professionals. This approach provides a powerful framework for relating and uniting a host of complimentary technical and social/professional capabilities, including multiple ABET accreditation criteria, while opening up new opportunities for innovations in instruction and assessment. However, there remains a lack of understanding regarding what counts as boundary spanning in engineering practice, including across sectors and career levels. Further, we know very little about how engineering students and early career engineers experience boundary spanning challenges, much less what instructional strategies best cultivate boundary spanning competence. These gaps are addressed through the project's three primary objectives, which are organized around a competency-based approach [12] to defining, developing, and assessing boundary spanning capabilities in engineering:

- Objective 1: Develop a typology of boundary spanning roles, activities, and competencies for multiple engineering fields.
- Objective 2: Design and evaluate an instructional framework to instill a *boundary spanning mindset* among engineering students and early career professionals.
- Objective 3: Create and pilot a situational judgment test (SJT) to assess key dimensions of boundary spanning competence in engineering practice.

This work-in-progress paper describes methods and presents preliminary findings for the initial two phases of research, which primarily support the first project objective. The sections that follow describe these phases in more detail, with particular attention to methodological considerations.

II. PHASE I: LITERATURE META-ANALYSIS

The first phase of this research project involved conducting a systematic literature review [13] to collect relevant literature discussing multiple facets of boundary spanning, including definitions, boundaries spanned, typical boundary spanning behaviors, and related competencies. The literature search and selection process followed the PRIMA process [14], as suggested by Borrego et al. [13]. The primary criteria initially used to identify literature for this study involved asking whether a given candidate paper: 1. was explicitly and substantially focused on boundary spanners, boundary spanning, and/or closely related topics (e.g., knowledge brokers/brokering), 2. discussed boundary spanning at the individual level, in whole or in part, and in contrast to focusing on the group or organizational level, and 3. was published since 2000 in order to better capture the contemporary state of the literature. To further improve the quality of results while keeping the scope of our efforts more manageable, we limited our search to book chapters and journal articles.

The first step in our process involved searching for relevant literature in the Engineering Village database, resulting in 213

unique articles. Second, we screened all of the associated abstracts and discarded 171 papers because they were not relevant for the scope of this study based on the preceding criteria. We then appraised the full text and discarded an additional 19 articles because they did not meet the requirements for inclusion.

Additionally, while appraising the papers, we used a snowball approach to identify other relevant papers cited by the papers themselves. This process added 21 more papers to our collection. Finally, we added 19 more papers to the collection that we had known about and referenced in the original grant proposal for this project, and which had not shown up in our systematic literature search. These two steps also involved relaxing our initial evaluation criteria, especially to bring in a number of influential historical sources that were frequently cited by other papers in our data set. We ultimately identified a total of 82 papers for further analysis.

The analysis of the papers was conducted using a hybrid deductive-inductive thematic analysis as suggested by Fereday and Muir-Cochrane [15]. The first round of analysis was primarily deductive. To start, we documented a number of descriptive characteristics, including whether a given paper was empirical or conceptual, the primary discipline(s) of the author(s) and/or publication outlet, and whether or not each paper explicitly discussed engineers or engineering. We also examined each paper based on four pre-defined themes: 1. specific types of boundaries discussed, 2. definitions of boundary spanner and related concepts, including more specific boundary spanning roles, 3. descriptions or definitions of boundary spanning activities and processes, and 4. specific individual attributes and competencies associated with boundary spanning. These themes were identified based on the focus of the larger project and authors' pre-existing knowledge of the phenomenon of interest and associated literature. However, the researchers were also encouraged to take notes on other concepts and themes that did not fall in these four categories but might be worthy of further exploration. At least two researchers analyzed every paper and then met to discuss and compile results in an Excel spreadsheet, which included researcher notes supplemented with quotes from the original papers. Having multiple researchers involved in this process increased the amount of information we were able to glean from each paper, while also allowing us to collaboratively refine our interpretations and understandings of each text.

The second round of analysis was inductive, allowing us to identify emergent themes within the four pre-defined topic areas noted above. The two lead authors searched for themes independently and then met several times to compare, contrast, redefine, and finalize themes. These results are currently being written up for publication as a journal paper. Yet as detailed in the following section, we also used our findings to develop a new "primer" document that we are leveraging in related data collection and instructional/training efforts. In the following section we give an overview of this document, with special attention to how our expanding knowledge of the extant literature helped ground its development.

An Introduction to *Boundary Spanners* and *Boundary Spanning*

Most generally, *boundary spanners* are people who link or connect with others across various kinds of boundaries. Three kinds of boundary spanners are shown below (with boundary spanners shown in red).

Fig. 1. Header text and illustrations from boundary spanning primer document

III. PHASE 2: INTERVIEWS WITH EARLY CAREER ENGINEERS

In parallel to our literature review efforts, the lead author conducted two pilot interviews with early career engineers. The subjects were both undergraduate engineering students in their final year of study at a large Midwestern research university. Each of these students had completed two prior internship experiences at two different companies. In line with the larger focus of this project, both students' experiences were in manufacturing or related work environments. One student's disciplinary background was in mechanical engineering, while the other was in chemical engineering. After having each participant complete a brief demographic survey, interviews were carried out with each student following a semi-structured format with a duration of 60 minutes or less. The protocol for the pilot interviews was in part based on a critical incident approach [16], coupled with the lead author's pre-existing knowledge of boundary spanning and related concepts. As noted below, the lead author also conducted a second, follow-up interview with one of these individuals. Data collection was carried out under Purdue IRB protocol number 1208012567.

Transcripts from the two pilot interviews were reviewed and discussed by members of the lead author's research group, along with one external colleague who agreed to provide feedback after reading one of the transcripts. This process led to a number of suggestions for improving our data collection procedures, including some new question prompts, as well as the idea of creating a primer document to help sensitize subjects to the primary phenomenon of interest (i.e., boundary spanning). The authors in turn realized that their literature review efforts could be very useful in guiding creation of such a document.

The resulting primer was developed based on our growing knowledge of the extant literature, and is organized around four major sections. To make the primer as usable and accessible as possible, we limited its length to just one page, and tried to avoid excessive use of jargon. The first part of the document, as shown in Figure 1, gives a broad definition of the term *boundary spanner*, followed by illustrations showing boundary spanners in three typical kinds of connecting or linking situations. These portrayals were informed by the results of our literature meta-analysis, namely in terms of

seeing boundary spanners often framed in the extant literature as: 1) "linking pins" that connect people to other people and/or to the external environment [17], and/or as 2) individuals who link otherwise disconnected individuals, i.e., they bridge "structural holes" in social networks [18].

The second section of the primer briefly describes three typical kinds of *boundary spanning activities*, namely:

- Coordinating work tasks with others
- Strategically managing relationships with others
- Enabling the movement of knowledge and information

Identification of these three types of activities emerged through inductive analysis of the papers in our literature collection. While these types of activities appear frequently in the extant literature, we also acknowledge that effective boundary spanning may involve or even require various other kinds of actions and behaviors. Additionally, these three activities compliment and extend how we had conceptualized boundary spanning in previous proposals and presentations, namely as being comprised of the "three Cs": coordination, collaboration, and communication.

The third section of the primer summarizes many different *types of boundaries* often encountered by professionals. A major first category centers on organizational boundaries, which can further be subdivided by considering: *horizontal* boundaries involving different business units, divisions, teams, etc.; *vertical* boundaries among lower and/or higher-ranking colleagues; and *job/functional* boundaries that separate people with different roles and responsibilities. The other types of boundaries presented in the primer include:

- Between an organization and external organizations or stakeholders, like customers or vendors.
- Across disciplines, professions, specialized areas of expertise, etc.
- Across geographic locations, including local, region, and global.
- Between different cultures and languages, whether in the same or different locations.
- Involving demographic characteristics like gender, race/ethnicity, and socioeconomic status.

This list was developed based on deep engagement with the prior literature, and was particularly inspired by other papers presenting similar overviews [19]. This list is also not fully inclusive, as our in-depth literature review revealed other important kinds of boundaries that receive extensive discussion in the literature but are not as easy to communicate with individuals who are new to the concept of boundary spanning, e.g., the idea of “knowledge” boundaries [20].

Fourth and finally, the primer gives two brief examples or vignettes that illustrate typical boundary spanning situations encountered by technical professionals. The first vignette, which we titled “Wafer Fab Debug”, was adapted from an empirical case study included in our literature collection [21]. The second example, presented in Figure 2, was drawn from one of our pilot interviews. This example was intended as a realistic portrayal of boundary spanning as encountered by a typical subject in our study, namely an engineering student working as an intern within a large company.

Example 2: Cafeteria Co-op

As a summer co-op employee at a food processing plant in the central U.S., engineering student Natalie reports to a facilities manager who oversees all on-site construction and maintenance. Natalie has been asked to help coordinate a remodeling project in the plant’s cafeteria while her manager is on vacation. She quickly finds herself in the middle of many boundary-spanning situations as she interacts with the human resources staff who originally requested the project, the contractors doing the actual remodeling work, and higher-level managers inquiring about budgets and timelines.

Fig. 2. Sample vignette from boundary spanning primer document

After developing the primer document, the lead author conducted a second interview with one of the original pilot interviewees. (The other student had gone on to enroll in graduate school, and therefore no longer met the criteria for participating in the study, i.e., early career engineers working in the private sector.) The primer was shared with the interviewee prior to the scheduled conversation. While the primer did not receive much explicit attention during this interaction, the interviewer found that it was a very useful document to have close at hand, especially to provide guidance and inspiration in posing follow-up questions and making sure that the phenomena of interest was explored in sufficient breadth and depth (e.g., by explicitly asking the interviewee about types of boundaries which had not already surfaced in the conversation). The interviewee also indicated that the “Cafeteria Co-op” example was a reasonable representation of the actual experience as it was described in the first interview.

IV. FUTURE PROJECT PHASES

The authors’ near-term work on this project is continuing in two major directions. First, results of the literature meta-analysis are being written up for publication as a journal paper. This will be a foundational outcome for this project, helping to establish a firm conceptual and theoretical basis for subsequent project phases. Secondly, the authors are conducting additional interviews to evaluate how well the primer document works in orienting new study subjects to boundary spanners, boundary

spanning, and related concepts. This process will spur further refinements to the interview protocol, which will ultimately be used to collect interview data from at least 15-20 subjects. The authors are also exploring the possibility of collecting reflection data from interviewees [22]. Engineering students in internships or practicing engineers within the first year or two of graduation would be asked to complete 3-5 reflections over a period of 2-4 months. The prompts would ask participants to report and reflect on boundary spanning incidents and situations using a critical incident framework and informed by the primer document.

Over a longer period, this project will begin to transition toward greater emphasis on instructional interventions and assessment, or Objectives 2 and 3 as noted above. Regarding the former, the authors see the primer document as a first step toward creating workshops and other kinds of instructional interventions designed to enhance the boundary spanning capabilities of early career engineers. The authors are also planning to generate new assessment strategies and tools related to boundary spanning in engineering. At least three possibilities are being explored. First, the literature review is allowing us to identify a variety of attributes and capabilities that may undergird effective boundary spanning, and could potentially be measured using existing tools. For example, capabilities such as empathy and perspective taking may be important antecedents for boundary spanning [23-24]. If this proves to be the case, a measure such as the Interpersonal Reactivity Index (IRI) could serve as an important predictor of an individual’s predispositions and/or actual capabilities related to boundary spanning [25]. A second, complimentary assessment method involves developing a set of items that can be used to rate one’s own or other’s boundary spanning capabilities. This approach is commonplace in engineering education, as in many ongoing efforts to evaluate ABET learning outcomes [26].

Third and finally, the authors are especially excited about creating and using scenario-based and situational assessment tools to measure meta-attributes such as boundary spanning [27]. As we have argued elsewhere, this assessment approach is promising for many reasons, including scalability through the use of multiple choice questions, potential to measure behavioral tendencies in realistic situations, and resistance to faking and other shortcomings often associated with self-rated items. Our efforts to develop such assessment tools will build on parallel research, including a current project that involves generating and validating large back of situational judgment test (SJT) questions and online assessment platform focused on global engineering competency [28]. While the existing pool of scenarios all focus on doing technical work across countries and cultures, the present study would extend this work through creation of new scenario prompts that focus on other kinds of boundaries, e.g., organizational, knowledge, demographic, etc. Ultimately, we see considerable potential for creating and deploying a suite of high quality, validated assessment tools that can be used to measure the boundary spanning capabilities of engineering students and practicing professionals, including to detect possible changes over time related to both work experiences and targeted interventions. Through these efforts to relate research and practice, we hope to contribute to broader

efforts and initiatives that aim to prepare engineers for the current and future realities of professional practice.

ACKNOWLEDGMENTS

This material is based upon work supported by the National Science Foundation under Grant No. 1254323. The authors also wish to thank James Huff, Mary Pilotte, Julia Thompson, and Julie Trenor for their contributions to the ideas and work presented in this paper. Finally, we thank our interviewees, without whom this research would not be possible.

Pivot Thinking

Predicting Entrepreneurial Intent among Engineering Students and Faculty using Problem Solving Style Preference

Mark Schar

Mechanical Engineering - Design
Stanford University
Stanford, CA USA
mfschar@stanford.edu

Abstract— This research explores the concept of “pivot thinking” or the ability to pivot between domain specific problem solving heuristics, and the impact of this cognitive trait on entrepreneurial career intent. A review of popular problem solving heuristics is presented for comparison purposes. The research sample includes engineering and science-trained students and faculty ($n = 114$) and measures both business skill self-efficacy and cognitive problem solving style using a four-factor psychometric instrument called the Herrmann Brain Dominance Indicator (HBDI). Results show that both higher levels and a balance between problem solving styles of analytical-factual (Factor A) and conceptual-intuitive (Factor D) predict entrepreneurial intent. Business skill self-efficacy is also an important predictor of entrepreneurial intent with emphasis on understanding business finance and communication skills. The implications of this research on engineering and entrepreneurship education are discussed.

Keywords—*pivot thinking, macro pivot, micro pivot, entrepreneurship, entrepreneurial intent, problem solving style, domain specific heuristic*

I. INTRODUCTION

Over time certain domains of thinking have developed to serve the particular type of problems encountered by those domains. Art and design domains have developed problem solving heuristics that meet the needs encountered in the production of art or the design of goods and services. The field of engineering has developed an engineering problem solving heuristic; business problems lead to a business problem solving heuristic, and so on for many domains of expertise.

In teaching and apprenticeship within these domains, problem solving is often taught as a unique, domain-specific heuristic. For example, engineering students are trained in the “engineering problem solving process” and rewarded for following this process in homework and on exams. Research tends to support this approach, showing that successful problem solving is enhanced when domain specific knowledge is coupled with a domain specific problem solving heuristic to solve domain specific problems [1]. The challenge, of course, is when students (or faculty) cross over domains, into areas of new domain knowledge that require new domain specific problem solving heuristics.

Fortunately, students with knowledge of domain specific problem solving heuristics often have a range of alternative,

nascent problem solving heuristics acquired through their lifetime of experience. These alternate problem solving heuristics are rarely or never their first choice for problem solving but may be recruited and developed with practice. When a person shifts their fundamental domain specific problem solving heuristic, typically to meet the requirements of a new domain, it is termed pivot thinking.

Pivot thinking may be a particularly valuable skill for engineering students considering a career that spans a variety of domain specific problems – such as technology entrepreneurship, which bridges the domains of engineering and business. There has been little research done of the pedagogical techniques that encourage pivot thinking and even less is known about the connection between pivot thinking and entrepreneurship.

II. COGNITIVE PROBLEM SOLVING STYLE

Cognitive style is a well-researched psychological construct representing how a person thinks. The study of cognitive styles define “individual differences in preferred ways of organizing and processing information that cut across the personality and cognitive characteristics of an individual” [2]. Researchers such as Witkin et al. characterize cognitive style as simply “individual differences in the way people perceive, think, solve problems, learn, and relate to others” [3].

Individual cognitive styles are acquired and reinforced through life experiences such as education and work. Kozhevnikov states that “cognitive styles can be viewed as distinctive patterns of adjustment to the world that develop slowly and experientially as a result of the interplay between basic individual characteristics and long-lasting external requirements” [4]. These “distinctive patterns of adjustment” frequently align with domains of knowledge and practice, such as engineering or business or music, and they tend to attract individuals with cognitive styles that have a propensity for these patterns.

Individual cognitive styles (ICS) often lead an individual to a domain of study or practice where that particular cognitive style is effective at problem solving, as shown in Fig. 1. For example, individuals who have an individual cognitive style that favors mathematics may gravitate toward science or engineering domains of knowledge and practice. In the teaching and apprenticeship of these domains, distinctive

patterns are often reduced to domain specific problem solving heuristics that are reinforced, practiced and rewarded which can lead to students whose cognitive styles are more similar than different. Once a student is skilled in a domain specific problem solving heuristic there may be little incentive and even less ability to employ an alternative problem solving heuristic.

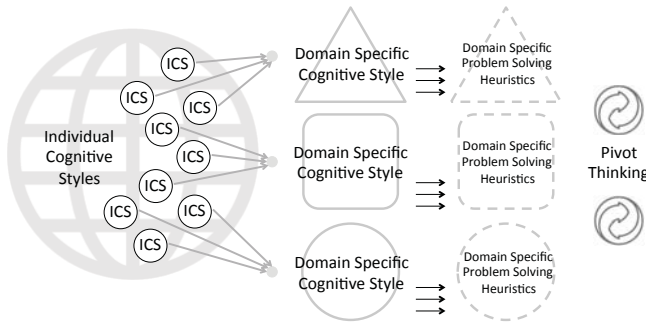

Fig. 1. Pivot Thinking Theoretical Framework

III. DOMAIN SPECIFIC PROBLEM SOLVING HEURISTICS

Problem solving heuristics are often codified, defined and taught within a specific domain of practice. In a typical, post secondary learning environment student are likely to specialize in one domain and seek to become expert in its problem solving heuristics. An engineering student will likely become proficient in engineering problem solving heuristics, and in some cases may be exposed the problem solving heuristics of other domains.

An overview of selected domain specific problem solving heuristics typically found in a post secondary learning environment is shown in TABLE I.

TABLE I. DOMAIN SPECIFIC PROBLEM SOLVING HEURISTICS

Domain	Heuristic Theme	Problem Solving Tools	Outcome
Engineering Problem Solving	Analyze your way forward	Equations, Analytics	Single point best answer
Business Problem Solving	Optimize your way forward	Maximizing, Satisficing	Single point sufficient answers
Design Problem Solving	Build your way forward	Empathy, Prototyping, Iteration	Multiple possible novel answers
Artistic Problem Solving	Feel your way forward	Qualitative, Experiential	Multiple possible balanced answers
Research Problem Solving	Logic your way forward	Deduction, Induction, Abduction	Internally consistent answer

A. Engineering Problem Solving

As plainly stated by the *National Academy of Engineering in The Engineer of 2020: Visions of Engineering in the New Century*, “Engineering is problem recognition, formulation, and solution”[5]. Post secondary, entry-level engineering education often includes a description of the “engineering way” to solve problems, with notable examples such as the NSF funded Dartmouth Project for Teaching Engineering Problem Solving [6] or the popular mechanical engineering statics textbook by Sheppard and Tongue [7]. The Sheppard and Tongue model of engineering problem solving is shown in Appendix A-1.

Most engineering problem solving heuristics begin by encouraging the problem solver to understand the problem solving goal, then moves through a roughly linear process of defining assumptions and selecting the appropriate formulas or equations to solve the problem. As a result, engineers are taught to “*analyze your way forward*,” seeking a single point answer that can be checked/confirmed with the original problem statement. This problem solving heuristic values showing the process as much as the answer, and correctness is often confirmed by drawing a box around the answer in summation. This heuristic is most valuable when both the problem and problem space are well defined and a specific answer is required that can be verified.

B. Business Problem Solving

Roger Martin, in his book *Playing to Win* [8], describes the essence of successful business strategy as “*a set of choices about winning*.” These choices often fall into the rubric of “*must win*” challenges and “*good enough*” trade-offs. Nobel laureate Herb Simon noted that organisms in nature, when seeking food, rarely seek the optimal answer, rather they “*satisfice*” or seek a good enough solution [9]. Driver et al. describe the tension between maximizing and satisficing in business as “*dynamic decision making*” [10] and display this on a utility curve as shown in Appendix A-2.

Business school students are taught this heuristic as part of strategic decision making and it is often summarized as the “*80/20 rule*” where a decision that captures 80% of the possible benefit from a solution for 20% of the investment required to execute the solution is a good outcome. Students optimize their way forward, examining the tradeoff between maximizing and satisficing. In entrepreneurship, this heuristic is often expressed as “*the hedgehog concept*,” defined by Berlin quoting the Greek poet Archilochos [11] and popularized for entrepreneurs by Jim Collins in the book *Good to Great*. [12] This heuristic, “*the fox knows many things, but the hedgehog knows one big thing*,” suggests its best to do one thing better than any competition while satisficing on everything else.

C. Design Problem Solving

This problem solving heuristic addresses the concept of “*wicked problems*” as popularized by Rittel and Webber [13] and Buchanan [14]. Rittel and Webber describe problems found in the domains of science and engineering as “*tame problems*” where “*the mission is clear*” and it is known “*whether or not the problem has been solved*.” (p160) By contrast, design problem solving, which Rittel calls “*wicked problems*,” have no clear path to solution, no understanding of when a successful answer is achieved and are often a symptom of another, higher-level problem. Over the years, many design problem solving heuristics have been developed, often under the banner of “*design thinking*,” and a representative version of this heuristic is shown in Appendix A-3.

The design problem solving heuristic incorporates empathy for the user (or customer) while prototyping and rapidly iterating through possible solutions. In this heuristic, the problem solver is encouraged to “*build your way forward*” and in the process often discovers many, novel solutions to the problem. However, unlike engineering or business problem

solving, there is no sense of “the best” answer or even an answer that is sufficient, only answers that are possible. It has also been said that “*the three most important words in design thinking are – change the problem,*” [15] meaning that within this design problem solving heuristic is the ability to change the problem statement completely as a way to achieve a novel or superior solution. This kind of problem solving flexibility is not often taught to engineering or business students.

D. Artistic Problem Solving

The French impressionist painter Claude Monet, during the period of 1889-1891, painted a 25-canvas series that has come to be known as “*Haystacks*” [16] The subject of these paintings were the harvest haystacks near his home near Giverny, France and this systematic, thematic repetition has come to represent the heuristic of how artists solve problems. Monet painted the haystack at various times of day, in varying weather, and in different seasons as a way to build knowledge – conceptual and experiential knowledge.

The artistic problem solving heuristic is explored in Hilary Austen’s book, *Artistry Unleashed* [17] where she describes an artist’s tension with balance between gaining mastery of the medium and the inherent search for originality, as shown in Appendix A-4. Austen explains:

Working with artistry means grappling with the interplay between mastery and originality in practice and on an ongoing basis. In this effort, you will find yourself working your way from one extreme to the other, passing through happy moments of perfect balance that can be expressed in what you do, make, and say. (p67)

The artistic problem solving heuristic encourages practitioners to “*feel your way forward,*” using qualitative tools and emphasis on the experiential, resulting in a “*balanced*” answer. Austen describes this balance as the “*continuous oscillation between mastery and originality*” which are “*places artists pass through*” rather than a final destination. The artist gains knowledge in the problem solving process: directional knowledge that motivates the artist, conceptual knowledge that structures artistic learning and experiential knowledge that shape the artistic medium to produce results. The artistic problem solving heuristic has no notion of a correct answer or best answer, only a balanced answer.

E. Research Problem Solving

The final domain specific problem solving heuristic likely encountered by a student on the typical post secondary campus is that of research problem solving. In this heuristic, the practitioner is encouraged to “*logic your way forward*” using the classic tools of deductive, inductive and abductive reasoning. The goal is an answer that is internally consistent with the parameters set by the process. An example of the research problem solving heuristic is shown in Appendix A-5.

Krathwohl refers to this research problem solving heuristic as a “*chain of reasoning*” and describes it as “*the context in which the researcher works*” [18]. Research problem solving begins with a thorough of previous work in the area, the adoption of a theoretical framework or model. This is followed by a statement of the research question, followed by a

description of the research design and methodology. Data is collected and analyzed, then formed into conclusions which bridge to the next step in the study process. Again, there is no correct answer, no best answer, only answers that are internally consistent with the research process.

IV. PIVOT THINKING

Psychologist and psychometrician Raymond Cattell put forward a theory that individual cognitive differences are result of an individual's lifelong pursuit of neurocognitive advantage [19]. Cattell believed that individuals are born with a unique fluid intelligence capability to solve particular problems. As they go about life solving problems, they acquire crystallized intelligence that helps solve those same problems more successfully [20]. In turn, the individual seeks more of the problems they solve successfully and acquires more of the successful problem solving skills. Cattell refers to this as cognitive “*investment theory*” where an individual gravitates toward problem-solving situations where they have skill and have experienced success in the past.

The challenge, of course, is when a problem solver encounters a problem that does not easily yield to their default heuristic. For example, when the product design engineer encounters consumer preferences that value aesthetics over performance or the social entrepreneur discovers that their product solution is not compatible with socio-economic needs of their target user. In each case, the successful problem solver must *pivot to another domain specific problem solving heuristic* – something called a **pivot**.

Nobel laureate Daniel Kahneman and his research partner Amos Tversky established that humans tend to be “*cognitive misers*” when problem solving, meaning that they rely on their default heuristics and jump quick, intuitive (and often incorrect) answers [21], [22]. In his recent book, *Thinking, Fast and Slow* [23], Kahneman explains the dual system of thinking embraced by most cognitive scientists. System 1 is “*fast thinking*” and results in the ability “*to perceive the world around us, recognize objects, orient attention, avoid losses, and fear spiders.*” (p22) System 2 is “*slow thinking*” and involves “*the conscious, reasoning self that has beliefs, makes choices, and decides what to think about and what to do.*” (p21)

Pivot thinking is a form of System 2 thinking yet it is more; it occurs when a problem solver shifts or changes the domain specific heuristic that guides System 2 thinking. When the use of a default heuristic involving both conscious and reflective reasoning fails to yield a successful answer, the problem solver initiates a macro pivot to an alternative heuristic system. This happens when the engineering student turns to a design problem solving heuristic or the business student reaches an artistic problem solving heuristic to find a successful answer.

There is evidence that very few people can easily accommodate a macro pivot. Researchers in the field of “*heuristics-and-biases*” use an instrument to measure this cognitive shift called the Cognitive Reflection Test (CRT) [24]. This three-question, open answer, correct/incorrect instrument that measures respondents’ tendency to reflect on problem solving strategies inherent with System 2-type thinking. In a

recent study, 56% of respondents got no answers correct, indicating the difficulty in shifting System 2 thinking, while only 7% of respondents got all three correct, showing how rare pivot thinking is within the general population [25].

At some point, the problem solver engages in a micro pivot, switching from divergence to convergent and back to divergence throughout the problem solving process. This micro pivot can happen second-by-second, minute-by-minute or day-by-day. It is not clear what triggers a micro pivot and this is a fertile area for additional research, unfortunately outside of the scope of this study.

V. RESEARCH QUESTION

The purpose of this research is to better understand the role of pivot thinking and the impact it may have, if any, on entrepreneurial intent. Therefore, the Research Question guiding this study is:

Among engineering trained participants, does the ability to “pivot think” or shift between domain specific heuristics predict entrepreneurial intent?

VI. RESEARCH SAMPLE

The sample for this for this research includes a total of 114 participants, collected over the 2013-2014 academic year.

A. Undergraduate Engineering Students ($n = 31$)

These participants were enrolled in a one-quarter design-build class during Spring 2014 at a private, western US university. The mean age was 20.3 years, 84% were engineering majors, 13% were science majors, and 52% were female.

B. Masters-Level Engineering Students ($n = 43$)

These participants were enrolled in a three quarter capstone design-build class during 2013-2014 at a private, western US university. The mean age was 23.6 years, 100% were engineering majors, and 52% were female.

C. Engineering Faculty ($n = 40$)

These participants were selected to take part in a 10-week entrepreneurial training experience during Fall 2013 at a private, western US university. All participants were faculty in engineering and science programs at a range of Polish universities. The mean age was 35.2 years, 95% were PhDs, 55% were engineering-trained, 32% were science-trained and 27% were female.

VII. MEASURES

A. Measure of Career Intent

This measures is the dependent variable for this research. During the first week of their classroom experience undergraduate and masters-level students were asked about their career intention using the question, “Looking into your future, over the 5 years from your graduation how likely are you to do any of the following?” Engineering faculty was asked the same question without the words “from your graduation.” The choices included *founding a company, working for a small business/start-up, medium or large size US-based business, multi-national global business, government*

and *non-profit*. Responses were collected using a 5-point Likert scale of likelihood ranging from Very Unlikely (1) to Very Likely (5) with (3) as neutral. This question was adapted from a longstanding alumni survey instrument. (28, 29)

B. Measure of Business Self-Efficacy

During the first week of their classroom experience respondents were asked about their confidence to perform in a series of business-related skills. This item was drawn from previous studies on engineering. (30) The question was “How confident are you in your ability to do each of the following at this time?” The eight choices included *recognizing a good idea, financing a new business, selecting a marketing approach, negotiating prices with a supplier, leading a team of people, and promoting accomplishments*. Responses were collected using a 5-point Likert scale of confidence ranging from Not Confident (1) to Extremely Confident (5) with (3) as neutral. The self-efficacy ratings of business-related skills showed high reliability ($\alpha = .88$), so the items were averaged to give an so the items were averaged to give an overall pre-and-post business skill self-efficacy score.

C. Herrmann Brain Dominance Indicator (HBDI)

Problem solving preferences is measured using the Herrmann Brain Dominance Indicator (HBDI). Ned Herrmann, a long-term General Electric executive, was interested in the thinking and problem solving preferences. Herrmann’s belief was that most people have one of four thinking styles that is a result of their training and life experiences. Some people have are overwhelmingly dominant in one style, while others balance thinking styles into what he calls “whole brain” thinking [26], [27] The HBDI has been in use for over 30 years and has collected 1.4+ million records. The HBDI is judged to be both a valid and reliable psychometric instrument. (33, 34)

The HBDI is a 120-item preference instrument, measuring respondents’ preference for certain types of cognitive problem solving processes. It results in a four-factor model with two opposing modalities. The four factors are (A) Analyzing, (B) Chronological, (C) Interpersonal and (D) Imaginative, as shown in TABLE II.

TABLE II. HERRMANN BRAIN DOMINANCE FACTOR DESCRIPTION

Factor	HBDI Style	Behavioral Characteristics	Typical Vocations
A	Analyzing	Logical, Factual, Technical, Analytical, Quantitative	Engineer, Financial Manager
B	Chronological	Structured, Sequential, Organized, Detailed, Planned	Operations, Accounting
C	Interpersonal	Emotional, Empathetic, Sensory, Social, Relational	Sales Manager, Nursing
D	Imaginative	Visual, Intuitive, Conceptual, Innovative, Holistic	Strategic Planner, Marketing

In *The Whole Brain Business Book*, [27] Herrmann links each of these factors with a series of behavioral characteristics (p23) and to typical vocations (p31). He defines this in terms of dominance by one cognitive style factor over the other factors:

“As dominance of one [factor] over its partner develops through life experiences, the degree of that dominance becomes evident from the mental preferences the person exhibits.” (p17)

Fig. 2. HBDI Factors and Technical Entrepreneurship

Herrmann devotes an entire chapter of *The Whole Brain Business Book* to the problem solving preference styles of the entrepreneur. Herrmann's data indicates that entrepreneurs are not "whole brained" in their approach to problem solving, rather he reports a Factor D dominance, as shown in Fig. 2.

Herrmann further distinguishes between "technical entrepreneurs" who have balanced scores between Factor D and Factor A (formula 1) and "general entrepreneurs" who have balanced scores between Factor D and Factor C preference (formula 2). This study was conducted among engineering students and faculty, so "technical entrepreneurship" should be evident in the relative balance between Factor D and Factor A scores.

$$\text{Factor}_{AD} = |\text{Factor}_A - \text{Factor}_D| \quad (1)$$

$$\text{Factor}_{DC} = |\text{Factor}_D - \text{Factor}_C| \quad (2)$$

D. Data Analysis

For the data analysis we conducted one-way analysis of variance (ANOVA) using Tukey posthoc tests with a significance reported at the $p < .050$ level. The Pearson product-moment correlation coefficient (r) was used to report correlations with significance determined at the $p < .050$ level. Multivariate linear regression generated fitted models using the least squares approach with significance determined at the $p < .050$ level. All analysis was done in R [28] with a variety of package components [29]–[31].

VIII. RESULTS

A. Career Intent

Career Intent scores (measured on a 1-5 "likelihood" Likert scale) showed the highest career interest in working for a small business (3.84) and the lowest career interest in working for a non-profit organization (2.62), as shown in TABLE III. Career interest in founding a start-up was above average (3.43 with 3.00 being neutral) and not significantly different that career interest in working for a medium-large US business (3.59) or a multi-national global business (3.49).

TABLE III. CAREER INTENT SCORES AND CORRELATION

	Career Intent	Mean	SD	$p <$	d	r
1	Founding a Start-Up	3.43	1.29	Base	Base	Base
2	Small Business	3.84	1.02	.000	.35	.54
3	M-L US Business	3.59	.98	.349	.14	-.23
4	Global Business	3.49	1.17	.912	.01	-.08
5	Government	2.84	1.22	.001	.59	-.04
6	Non-Profit	2.62	1.04	.000	.81	.00
Bold – significant $p < .05$ Cohen's d medium effect size $> .30$ Pearson's Product Moment Correlation Coefficient - r						

Not suprisingly, correlation analysis shows a significant negative correlation between career interest in founding a start-up and working for a medium-large US business ($r = -.23$) and a lesser, non-significant negative correlation with career interest in global business.

B. Business Skill Self-Efficacy

Business self-efficacy scores (measured of a 1-5 "confidence" Likert Scale) showed a significant advantage for participants interested in founding a start-up, as shown in TABLE IV. The eight business skills measured factored into two groups, Operational Skills ($\alpha = .81$) and Interpersonal Skills ($\alpha = .70$). Interpersonal Skills (3.62) showed a significant advantage over Operational Skills (2.75, $df(113)$, $t(14.44)$, $p < .000$, $d = 1.18$) indicating a greater confidence in working with others than in their operational business skills. Of note, the lowest scoring self-efficacy measure was "finance a new venture" (2.21) significantly lower than any other Operational Skills measure.

TABLE IV. BUSINESS SKILL SELF-EFFICACY SCORES

	Total (n = 114)		Start-Up (n = 60)				
Business Skill	Mean	SD	Mean	SD	Diff	$p <$	d
recognize an idea	2.94	.96	3.22	1.01	.28	.082	.28
finance a venture	2.21	1.08	2.70	1.08	.69	.005	.45
marketing approach	2.74	1.05	2.97	1.06	.23	.174	.22
supplier pricing	2.99	1.15	3.25	1.14	.26	.159	.23
estimate cost	2.86	1.02	3.13	1.02	.27	.094	.27
Operational Skills	2.75	.79	3.05	.80	.30	.017	.39
lead a team	3.75	.85	4.08	.72	.33	.007	.42
communicate ideas	3.79	.88	3.95	.89	.16	.258	.18
promote self	3.32	.95	3.57	.83	.25	.070	.28
Interpersonal Skills	3.62	.69	3.87	.61	.25	.016	.38
Business Self-Efficacy	3.07	.69	3.36	.65	.29	.008	.42
Bold – significant $p < .050$ Cohen's d medium effect size $> .30$							

The sample was split by participants who expressed career intent to found a company (4 or 5 rating on the career intent measure) and those who did not (1, 2 or 3 rating), resulting in a sub-sample of 60 respondents who expressed some level of interest in founding a company. This entrepreneurial sub-sample was significantly different in two business skill self-efficacy areas from the overall sample – "financing a venture" (2.70 vs. 2.21) and "lead a team" (4.08 vs. 3.75) – that are two skill areas important to entrepreneurial success.

C. HBDI Scores

The HBDI Factor Scores (range from 0 to 100, with the mean at 50) were significantly higher for the problem solving style preference Factor A (58.8) and Factor D (61.8) than for Factor B (35.1) and Factor C (32.6), as shown in TABLE V.

There were no significant differences between problem solving style preference Factors A and D or Factors B and C.

TABLE V. HBDI SCORES AND CORRELATION WITH CAREER INTENT

HBDI Factor Scores	Mean	SD	Career Intent Score - <i>r</i>	
			Start-Up	M-L US
A – Analytical, Factual	58.8	27.5	.08	.16
B – Sequential, Structured	35.1	26.2	-.20	-.13
C – Social, Empathetic	32.6	25.8	-.14	-.16
D – Intuitive, Conceptual	61.8	27.3	.21	.01
Indicators				
[A-D] Technical Entrepreneur	42.1	25.1	-.19	-.09
[D-C] General Entrepreneur	35.5	24.4	.25	.14
Bold – significant $p < .050$				
Pearson's Product Moment Correlation Coefficient - <i>r</i>				

Entrepreneurial career intent scores were significantly, negatively correlated with the Factor B score ($-.20, p < .04$) and significantly, positively correlated with the Factor D score ($.21, p < .02$). This indicates that the more interested a participant was in founding a start-up the lower they scored on Factor B (associated with a preference for sequential, structured problem solving) and the higher they scored on Factor D (associated with a preference for intuitive, conceptual problem solving). Recall, there was a strong, negative correlation between career intent scores for “founding a start-up” and “working for a medium-large US company” (see TABLE III.) Unlike, entrepreneurial career intent scores, there were no significant correlations between HBDI problem solving style preferences and medium-large US company career intent scores.

Importantly, there was a significant negative correlation ($-.19, p < .04$) between entrepreneurial intent scores and the [A-D] Technical Entrepreneur indicator (a measure of the balance between Factor A and Factor D scores with a lower score indication more of a balance). This supports Herrmann's assertion that technically oriented entrepreneurs will have higher Factor A and D scores and these scores will tend to be balanced between each other, indicating an equal preference for both analytical, factual and intuitive, conceptual problem solving styles. There is also a strong, positive correlation ($.21, p < .01$) between the [D-C] General Entrepreneur indicator and entrepreneurial career intent scores mean these technically trained participants show greater difference (less balanced) in Factor D and C scores and do not resemble the General Entrepreneur profile described by Herrmann.

D. Multivariate Linear Regression Models

The determinants that may predict entrepreneurial intent were evaluated with multivariate linear regression. The dependent variable was the career intent measure “founding a start-up”, a continuous Likert variable from 1 (Very Unlikely) to 5 (Very Likely). A total of 17 independent variables were incorporated into the modeling process – 8 business self-efficacy (BSSE) measures, 7 HBDI Factors scores and indicator variables, and the demographic variables of age and gender. Step-wise linear regression was used to optimize model fit while reducing the number of variables. The resulting model is referred to as “Best Fit Model.”

TABLE VI. LINEAR REGRESSION MODELS OF CAREER INTENT

Dependent Variable:	Best Fit Models							
	“Found a Start-Up”				“M-L US company”			
	<i>B</i>	<i>SE</i>	<i>t</i>	<i>p</i> <	<i>B</i>	<i>SE</i>	<i>t</i>	<i>p</i> <
Factor A	.01	.00	2.22	.028	.01	.00	2.24	.027
Factor D	.01	.00	3.23	.002				
[A-D] Indicator	-.01	.00	-1.72	.089				
“finance a venture”	.43	.10	4.15	.000	-.28	.09	-3.14	.002
“promote self”	.19	.12	1.58	.118	-.20	.11	-1.78	.078
Age	.03	.01	2.35	.021				
<i>Adjusted $r^2 = .37, p < .000$</i>								
Factor B					.21	.11	1.97	.052
Factor C					.01	.00	2.08	.040
“communicate ideas”					.01	.00	2.55	.012
<i>Adjusted $r^2 = .19, p < .000$</i>								
Bold – significant $p < .050$								

There were six variables that combined to have the best fit with entrepreneurial intent, as shown in TABLE VI. The HBDI Factor A and Factor D were significant predictors and the balance indicator ([A-D], where the lower the score the more balanced) was important, which suggests that these two problem solving styles are not only essential but must be in balance in terms of preference allowing the problem solver to readily pivot between these two different styles. In terms of business skill self-efficacy, “finance a venture” is a significant predictor and “promote self” and important predictor of interest in an entrepreneurial career, which seems consistent with this career path. Finally, age is a significant predictor, with older participants more likely to be interested in an entrepreneurial career. Overall, this model had a excellent fit (adjusted $r^2 = .37$) and was statistically significant ($p < .000$). These variables did a poor job of predicting career intent of working for a medium or large US business, the career option with the highest negative correlation with entrepreneurship, with a significantly lower model fit (adjusted $r^2 = .11$).

By contrast, career intent of working for a medium and large US business was predicted by a different set of variables. All HBDI Factor except Factor D were significant or important model contributors and this suggests that conceptual and intuitive problem solving are less important styles to participants with this career intent. The business skill self-efficacy measure, “communicate ideas” with “finance a venture” were both significant predictors, while age was not.

IX. DISCUSSION

The results of this research suggests that the ability to pivot or shift between problem solving styles, particularly analytical problem solving (HBDI Factor A) and intuitive problem solving (HBDI Factor D), is an important predictor of entrepreneurial career intent among engineering students. Pivot thinking is then defined as both a preference for a problem solving style and balanced preference with other problem solving styles. Importantly, entrepreneurial career intent suggests an emphasis on different problem solving styles than a corporate career path with more weight placed on conceptual and intuitive problem solving.

Business skill self-efficacy also plays a role in career intent. It seems that the more a student knows about money and finance, the more likely they are to be interested in entrepreneurship. Communication skills was an important contributor to career intent, either in the ability to promote personal accomplishments or enroll others in ideas.

A limitation of this research may be the implicit assumption underlying the measurement of “pivot thinking” where a balance in cognitive problem solving style preference is the indication of a “pivot thinker.” In fact, it is only evidence of balance, perhaps the precursor to the act of pivot thinking, but not an indicator of the actually shift in problem solving heuristics. The measurement of a heuristic problem solving shift requires different research tools.

Another important limitation of this research may involve the sample cohorts. While the participants were largely from the field of engineering the age range was significant, spanning from undergraduate engineering majors to senior engineering faculty (mean 27 years, range 19 to 60 years). It is possible that sampling from this wide range of cohorts in very different stages of life development, may have skewed results toward “older” participants who are at the stage of their career where entrepreneurship is a more attractive career option.

Finally, these results suggest important changes for the approach on engineering education. Engineers pride themselves on being problem solvers, when in fact, they may only be solving a narrow range of problem types. Engineering education would benefit by incorporating greater emphasis on problem identification and the teaching of a range of heuristic problem solving approaches. The broad incorporation of engineering ethics case study education (“ethical problem solving” is a discrete heuristic, see Harris et al. [32]) is an example of this that can be extended to other domains like business, design and artistry. This type of pedagogy will not diminish engineering education, rather it will enhance it.

ACKNOWLEDGMENT

This research would not be possible without the support of Ned Herrmann who introduced me to the concept of problem solving styles 30+ years ago and Anne Herrmann-Nedi who continues the work today. This work has benefited from the advice, counsel and support of my research partners, Dr. Sheri Sheppard, Dr. Shanon Gilmartin, Dr. Brian Knutson and Elizabeth Schar. Finally, a very special thank you to Dr. Hilary Austen who has been both an inspiration and motivation to complete this work.

    EK --> DK
    CK --> DK
  
```

The diagram illustrates the research workflow, showing a central cycle of activities. The central cycle is labeled "Work Flow" and is represented by a circular arrow. Surrounding this central cycle are eight ovals, each representing a stage of the research process. The stages are arranged in two columns. The left column includes "Previous Research", "Theory, Rationale", "Questions, Models", and "Research Design". The right column includes "Link to Next Study", "Conclusion", "Statistical Analyses", and "Data". A dashed arrow points from "Link to Next Study" back to "Previous Research", indicating a feedback loop. A solid arrow points from "Data" to "Procedure", indicating the flow of information from data collection to the final procedure.

West Texas A&M University
Canyon, Texas USA
kleitch@wtamu.edu and ebutler@wtamu.edu

Abstract – Starting a new engineering program in the 21st century that fulfills ABET 2000 requirements is a major undertaking. In this paper, the authors will discuss the process of implementing a new civil engineering program at West Texas A&M University in Canyon, TX (in the Amarillo metropolitan area), starting with planning, offering initial discipline-specific courses in Fall 2010, graduating the first cohort of students in 2013, and concluding with an ABET accreditation visit in Fall 2014. This process includes the development of a suitable curriculum using existing and new courses, development of the new civil engineering specific courses and laboratories, the senior design experience, assessment, and final preparation for an ABET accreditation visit. The discussion of the curriculum includes general education, mathematics, applied sciences (chemistry, physics, and biology), general engineering, and civil engineering specific courses is discussed. In particular, emphasis on the unique approach to the senior design capstone experience is described here. Engineering course outcomes are mapped to a modified Bloom's Taxonomy and to ABET 2000 Outcome 3 a through k. A new program must also meet the requirements of regional and community stakeholders and fit with the unique service population in the greater Texas Panhandle region. West Texas A&M University is also on the verge of becoming a Hispanic Serving Institution (HSI, 25% or more of enrolled population) and is seeking to improve participation of women and underserved populations in STEM fields, such as with engineering. An overview of the process of preparation of the ABET self-study is described, including development of assessment tools necessary to determine the effectiveness of the new engineering program. Lessons learned and future improvements for the civil engineering program at West Texas A&M University are discussed.

Keywords – ABET, accreditation, ASCE, civil engineering, curricula, Bloom's Taxonomy, Body of Knowledge, Hispanic Serving Institution, senior design, WTAMU

I. INTRODUCTION

West Texas A&M University (WTAMU) is one of eleven universities comprising the Texas A&M System, enrolling nearly 9000 undergraduate and postgraduate students. In cooperation with local and regional stakeholders, WTAMU established undergraduate programs in mechanical (2003), civil (2010), and environmental engineering (2012). These programs were joined with existing engineering technology and computer science programs to form what is now the School of Engineering and Computer Science (ECS). ECS has expanded to over 600 students as of Fall 2014, of which over 500 are engineering and engineering technology majors. It is expected that ECS will enroll approximately 700 students in these majors in Fall 2015. Growth has been rapid but the school still maintains a very hands-on and personable approach to instruction with faculty instructing all lectures and laboratory courses.

ECS enrolls about 50% of its students through transfers from partner institutions such as Amarillo College [1], South Plains College [2], and Lubbock Christian University [3]. The transfer credits align fairly closely with the pre-engineering program at WTAMU. This corresponds roughly with the requirements of an engineering associate's degree program. This policy also ensures that upper division engineering students will thrive in their program of choice because they know that the basic engineering, math, and science courses are foundational to what they will be expected to do in their junior and senior undergraduate years of study. WTAMU requires that at least 39 credit hours of junior and senior level courses be taken in residence at the university in order to earn a degree from the institution.

In order to move from the pre-engineering to the civil engineering program, a student must complete the fundamentals of engineering, drafting, chemistry I and II, calculus I and II, statics, and dynamics courses with a GPA of 2.75 or greater, whether taken at the partner institution and/or at WTAMU.

It is also of note that in addition to having a large

transfer contingent is that about 50% of students are first-generation college students. Furthermore, the university population is nearing the threshold (23% vs. 25% required) of becoming a Hispanic-serving institution (HSI) [4,5], reflecting the population diversity of the state of Texas and the surrounding service area. The university has a border-state tuition rate [6] (WTAMU defines border states as New Mexico, Oklahoma, Colorado, and Kansas) that has attracted students from these areas due to favorable costs and desirable university majors, such as those in ECS.

The engineering faculty at ECS includes five full-time mechanical engineering, two full-time civil engineering faculty, two full-time environmental engineering, one shared full-time civil/environmental engineering faculty, one full-time engineering technology faculty, and one full-time engineering instructor. Between these faculty, all required general engineering, required general civil engineering, and elective civil engineering courses can be covered. Two of the mechanical, the two civil, and the one shared civil/environmental engineering faculty are licensed professional engineers. The two environmental engineering faculty are EITs and working toward gaining professional licensure. The civil and environmental engineering faculty function as a unit within ECS in regard to their respective programs since they are interdependent on one another and form a natural grouping within the ECS hierarchy.

It is important to note the state of professional licensure because ABET and ASCE prefer that civil engineering faculty to be licensed in order to teach any course with significant *design* content, typically reflected in the course title and catalog description. This will also be important for the environmental engineering program, as ASCE is a major stakeholder in that discipline as well.

The balance of this paper will review the development of the civil engineering program at WTAMU, the first senior design experience, preparation for accreditation, and future changes and conclusions.

II. PREVIOUS WORK

It is helpful understand how other programs have responded to creation and accreditation of new engineering programs in the 21st century. As the population of the USA and Texas in particular grows, there is growing demand for engineers as well. The Texas Office of the State Demographer notes that the 2015 population of 27 million will grow to somewhere between 31 million (no migration, natural growth only) to 54 million (migration following 2000-2010 US Census trends) [7], spurring a strong demand for Texas institutions of higher learning to graduate more engineers. In particular, civil engineers are at the forefront of development, construction, and maintenance of the infrastructure that society is dependent upon.

One of the oldest civil engineering programs in the USA is that at the United States Military Academy at West Point (USMA), which coincidentally has been at the forefront of civil engineering education innovation. In particular, Drs. Stephen Ressler, Alan Estes, Karl Meyer, and others that have been associated with USMA have spurred this innovation out of necessity, as they need to quickly train engineering instructors in order to educate the men and women of the US Army to practice civil engineering, oftentimes under wartime conditions. They have graciously passed along this wisdom through the highly regarded ASCE EXCEED (Excellence in Civil Engineering Education) seminar series [8].

In particular, Drs. Ressler, Estes, and Meyer plus Dr. Tom Lenox from ASCE have spent significant effort in tying the ABET 2000 Outcome 3c [9] and ASCE Body of Knowledge (BOK) 2 [10] to contemporary civil engineering education [11-15]. In short, Appendix H of the BOK 2 neatly ties the ABET 2000 3c Outcomes a-k that many engineering faculty are familiar with to the requirements for the civil engineering discipline in the 21st century. These references validate the process that WTAMU has gone about to pursue accreditation for the civil engineering program. Ressler [11] also validates the need to add biology to the WTAMU civil engineering program, discussed in the next section on curricula.

One reference of note by Lambrechts [16] describes the process of elevating a civil engineering technology program to a full civil engineering program. This change was initiated due to the National Council of Examiners of Engineers (NCEES) adopting ASCE's Policy 465 and its associated BOK 2 (summarized in its Appendix H) [10], further emphasizing the requirement to follow ABET 2000 Outcome 3c plus additional requirements for the education of civil engineers for the 21st century. It is in this light that WTAMU has formulated its civil engineering curricula, described in the following section.

III. WTAMU CIVIL ENGINEERING CURRICULA

The development of the civil engineering curriculum must be consistent with ABET 2000 [9] and ASCE Body of Knowledge 2 Appendix H [10] criteria as well as institutional and community stakeholders. The resulting civil engineering curricula at WTAMU resemble that at other ABET aligned programs.

Similar to other institutions, the civil engineering program is constrained to operating within requirements for general education coursework (English, speech, history, government, arts, etc.) as well requirements for basic science (chemistry, physics, and biology), mathematics (calculus I-III and differential equations), general engineering (fundamentals of engineering, drafting, statics,

dynamics, mechanics, etc.), and specialized civil engineering coursework. A degree checklist for the BS civil engineering degree may be found at the online WTAMU online catalog [17].

WTAMU operates on the semester credit system, the dominant system in the USA at this time. Engineering courses are typically offered in fall, spring, summer I, and summer II semesters. Like other similar engineering programs, it is designed for full time students to be completed in approximately four years with a total of 127 semester credit hours.

It should be noted that the academic year 2014-2015 degree checklist shows a total of 126 semester credit hours. Why is there a difference of 1 credit hour versus the checklist? The reason is that effective in academic year 2015-2016, the checklist will replace the 3-credit *EVEG*, *MENG*, *GEOL*, *CS*, *OR ET ELECTIVE* with a 4-credit biology course. This was in direct response to feedback from the ABET accreditation team that visited WTAMU in October 2014. It was an easy change to implement and puts the civil engineering major in better alignment with ABET and ASCE requirements for applied sciences. It is of note that currently enrolled students are already being required to take the biology course, regardless of catalog year. It is substitutes for the aforementioned elective.

In regard to civil engineering discipline specific courses, the curriculum is designed to provide at least one foundational course in all six traditional subareas (structural, transportation, construction, environmental, geotechnical, and water resources) of the civil engineering discipline. Some of these courses are cross-listed with the new environmental engineering degree program such as the introduction to environmental engineering, fluid mechanics, and hydrology and hydraulics courses.

The civil engineering program has five courses (two shared with environmental engineering, noted with *) with specific laboratory components: introduction to environmental engineering*, surveying, civil construction materials, geotechnical engineering, and fluid mechanics for civil and environmental engineers*. For the first two years of operation, the civil engineering program used the mechanical engineering fluid mechanics course but this course lacked material in regard to open channel flow, essential for the follow on hydrology and hydraulics course. The civil/environmental engineering fluid mechanics course is a 4-credit lecture/laboratory while the mechanical engineering fluids course is a 3-credit lecture/laboratory.

There are three required upper level civil engineering courses. Of these, one must be structural design (ex: steel or concrete design), one is design of any type in regard to any subarea of the civil engineering discipline, and one is a general course in any subarea of the civil engineering

discipline, directed study, or internship. It is possible that one or both of the non-structural electives may be a course shared with the environmental engineering discipline.

IV. SENIOR DESIGN CAPSTONE

The first civil engineering senior design experience was in summer session 2013. The reasoning for a summer session was to ensure that among the seven participating students, most if not all would have completed coursework in all six traditional subareas (structural, transportation, construction, environmental, geotechnical, and hydrology) of the civil engineering discipline.

This first senior design project entailed the design of an outdoor civil engineering laboratory. The project was linked to the ABET 2000 Outcome 3c and modified Bloom's Taxonomy described in the section of this report in regard to preparation for accreditation.

Seven students participated in the course. The students arranged themselves in six subarea teams, each of which had at least three students involved. This means that any one particular student was part of two or more of the smaller subarea teams. One student was chosen by the other students to be the project leader, who in turn organized meetings and met with the three faculty members that were in charge of the course.

The students had approximately seven weeks to design the outdoor civil engineering laboratory. At first glance, that may not sound like enough time, but most of these students were taking only this one course in summer. It was much like a 40-hour-a-week job in scope, a fairly reasonable and realistic scenario for the students.

Students were responsible for weekly meetings and work summaries that were submitted to the faculty in charge. Along with evaluation of an interim report with presentation and a final report with presentation, peer and faculty evaluation forms were completed for all seven students. This allowed for a final grade to be assigned to each student for his or her performance in the course. Six students were deemed to have passed with a grade of C or better. While it may sound harsh for the seventh student deemed below this threshold, it is very important for program integrity and the safety of the public that a student performing below an acceptable level not graduate until he or she demonstrates the high level of competence required in the civil engineering discipline.

The senior design project was very important from the standpoint that the graduation of the first cohort of civil engineering students triggered the year-long process for ABET accreditation of the program. An honest assessment of this project, the students, and the faculty involved is necessary for the integrity and growth of the program.

V. PREPARATION FOR ACCREDITATION AND RESPONSE

All programs undergoing the accreditation process must submit a self-study. The self-study consists of information that describes the program in details as outlined by the ABET 2000 criteria. The self-study consists of nine different criteria. Self-study materials were to be prepared by the program and submitted by the 1st of July 2014. Faculty from the civil and environmental engineering programs met frequently during the months of May through June to prepare the self-study. An excellent view from the evaluator standpoint describes this preparation process, stating that a program really only gets one chance to make a good impression and that involvement of faculty and documentation are key for gaining or maintaining accreditation¹⁵.

In addition to the self-study, faculty were also required to prepare materials for the accreditation visit. There were two major components—course binders and senior design videos. The course binders consisted of materials from selected courses taken by civil engineering students. The binders consisted of sample work (i.e. homework, exams, quizzes, and design projects) for the accreditation reviewers. The sample work was assessed by faculty to determine how well the student met metrics as discussed by the civil and environmental engineering faculty. Copies of the two senior design final presentations were placed on flash drives for the reviewers upon request. Videos of the senior design presentations were also made available for review as well.

The assessment metrics were tied directly to ABET Outcome 3c a-k with achievement tied to a modified Bloom's Taxonomy at a freshman, sophomore, junior, or senior level. The levels of achievement, in order of increasing difficulty are: *knowledge* - recall and organization of facts and figures; *understanding* - comprehending the meaning of facts and figures; *application* - being able to utilize appropriate formulas and principles to determine a problem solution; *synthesis* - being able to break a problem into components and solve by application of basic principles without reliance upon example problems; and *design* - making something that is new and unique with little reliance upon examples.

The ABET accreditation site visit occurred in October 2014. The reviewers were provided access to the self-study materials, met with faculty and administrators, and conducted focus group sessions with current civil engineering students. The comment and response period is currently on-going at the time of this writing in June 2015. It is anticipated that the conclusion of this process will occur during the summer of 2015.

VI. FUTURE DIRECTIONS AND CONCLUSIONS

Engineering curricula continues to evolve in regard to stakeholders, technology, business, society, and other outside factors. Developing new engineering programs in the 21st century requires input from these factors and a willingness of faculty to adapt and change in order to develop the problem solving skills that engineering students will need.

The lessons learned in the first senior design and initial ABET site visit have been adapted and refined in the second and third cohorts of civil engineering graduates from the WTAMU School of Engineering and Computer Science.

The civil engineering faculty decided to implement a continuous improvement program, rather than waiting until the year before an accreditation cycle to gather assessment data. Courses will be on a regular cycle for assessment to address problems and change curriculum more quickly, as needed. Making continuous improvement a part of the ECS culture will ensure the best education for engineering students.

The October 2014 ABET visit affirmed the good aspects of the civil engineering program and spurred the faculty to move quickly to address deficiencies, especially to implement a third required science with biology, even before the comment and response period is complete. The new environmental engineering program will also directly benefit from the learning process, much like the civil engineering program learned from the first WTAMU ECS accredited program in mechanical engineering.

Newer programs such as the ones at WTAMU have great flexibility in devising and implementing engineering education. Established programs can learn from and share best practices with these newer programs. In any case, the criteria of ABET and the ASCE Body of Knowledge give guidance in regard to what education of engineers in the 21st century should address and the feedback to continually improve and innovate.

Abstract—This article has probed an innovative conversion from micromouse competition to a systematic curriculum design that integrates practice with theory. Micromouse competition is an event where small robot mice are designed to solve a 16x16 maze. The process includes multi-disciplinary knowledge such as electrical and computer engineering, mechanical engineering and algorithm design. Limited by the competition rules, micromouse is easy to learn but difficult to master, which provides a high suitability with the teaching processes of foundation courses of embedded system for undergraduate students. This paper elaborates the emphasis, difficulties and innovation of the conversion process, of which the core is student engagement. In the class, students must take part in the whole micromouse design progress to comprehend the interactive method of hardware and software of embedded devices and strengthen the ability of applying professional skills. Students are required to participate in the entire micromouse building process, including welding, assembling, environment building, debugging and finishing the competition in groups. This curriculum focuses on training students' research interests, competition skills and teamwork spirit. Final examination scores are mainly based on each group's ranking in the final round, and technology innovators will be given appropriate incentives.

Keywords—Micromouse; Academic competitions; Innovative teaching; Practice course

I. INTRODUCTION

Micromouse is a science and technology competition project which began in late 1970s. It quickly swept the world after the birth. "Principles and Practice of Micromouse" is an innovation practice course designed based on the micromouse competition for the undergraduate students. As a device of mechanical and electrical integration, participating in the development process of micromouse can train the students' ability of innovative practice. Theoretical knowledge is applied in practical operation in this curriculum, which is mandatory for electronic engineering students. Moreover, the micromouse contains a wide range of disciplines. Therefore, systems integration capability and academic vision expanding are also concerned in this course.

In simple terms, micromouse competition is an event where small robot mice could solve a 16x16 maze (Fig. 1). It needs to

complete several tasks such as maze searching, path memorizing and maze solving. Winner is the fastest one [1].

Fig. 1. Standard maze for micromouse competition.

II. ADVANTAGES OF MICROMOUSE

The reason why micromouse is introduced to classroom and applied to undergraduate practice teaching is that micromouse provides a high suitability with the teaching requirements of electric and electronic majors in many aspects. The coverage of the knowledge points is the first reason.

Micromouse must have the following capabilities to complete the competition tasks [2].

- Stable and fast walking
- Accurate judgment
- Path memorizing
- Maze solving ability

In order to satisfy these requirements, the design of micromouse have to involve several subjects including circuit design, motion control, mechanical design, sensor applications, algorithms optimization and programming. These hardware and software design skills are just necessary for an electronics engineer. Based on the study of Williams, A, B [3], it can significantly improve students' technical level by using robots in engineering teaching. The process of micromouse design can show a basic development process for electromechanical systems to students clearly, and exercise their comprehensive ability of professional skills.

Secondly, micromouse possesses a simple structure and clear mandate. So it is relatively easy to understand for tyros. The students can achieve a simple control for this mobile robot through a unified basic teaching mold. In the same time, micromouse is a racing competition. Under the premise of accomplishing basic tasks, the pursuit for better performance

and better algorithm is almost a never-ending improvement direction. The characteristic of easy to learn but difficult to master ensures good compatibility with students in different stages and different abilities in the classroom.

Thirdly, combination of theory and practice is one of the most important features of the experimental curriculum. Students can achieve the real-time transformation from the voids theoretical knowledge to practical application ability by micromouse platform. This conversion process is visualized. Students can clearly observe how their modifications impact the operation of the micromouse,

Last but not least, electrical and electronic major generally use experimental box or development board as the platform for experimental courses. Compared with this, micromouse has incomparable advantages in interests, competition and teamwork. Moreover, since this course grew out of a competition, it can be considered an example of "gamification" of learning. Dominguez Adrian's research [4] shows that this teaching method can effectively increase student motivation and engagement. Once the students get interested in the curriculum, the purpose of their study could be transformed from getting good grades into meeting their own interests. Obviously, it will be beneficial to both class atmosphere and teaching effectiveness.

In summary, as a teaching platform for experimental course, it has an ideal performance in coverage of expertise, friendliness of the development process, practical ability and interests. Based on the above analysis, micromouse is boldly introduced to the undergraduate teaching. A practice curriculum named "Principles and Practice of Micromouse" has been opened in the past two years.

III. TRANSFORMATION FROM THE CONTEST TO CLASSROOM

Although the micromouse possess a natural advantage as a teaching platform, but it was developed for a technology competition after all. Its original organization and participation process have a large difference from classroom.

In the university, participations in science and technology competition mostly start from the students' own interests. Loose organization and participation mode result in the lack of competition documentation and process standards. At the same time, the goal of competition is generally simple and clear, so most students focus only on the performance but show little interests in principles. The lack of theoretical knowledge has become a very common phenomenon.

But different from technology contest, classroom has a broader audience and more stringent requirements. The classroom content must be systematic and theoretical with standard teaching documents, presentation slides, etc. The teacher should lead the classroom, act as technical heritage links, teach theoretical knowledge and basic operation and guide students to complete practical tasks. Teaching methods should be universal and reproducible. In order to improve the time efficiency, appropriate performance standards should be developed with some specific procedure.

A. Course preparation.

Because of the difference between micromouse contest and classroom, lots of course preparation should be completed beforehand, including micromouse modules subdivision, routines splitting and process standardization (Fig. 2.).

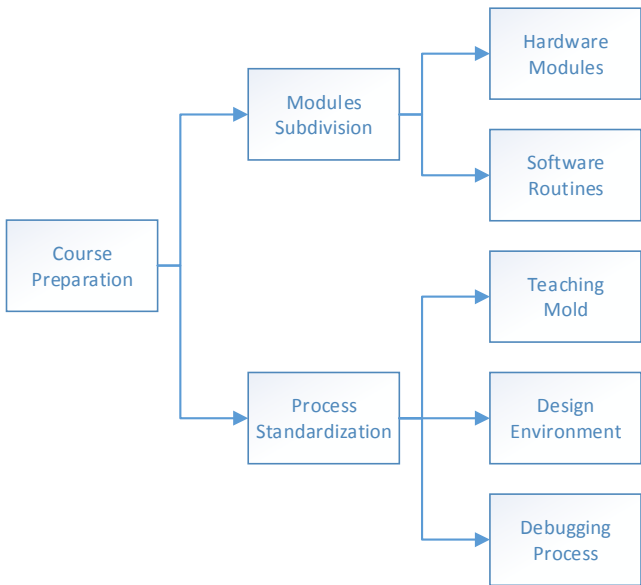

Fig. 2. Course preparation for *Principles and Practice of Micromouse*.

In the process of participating in contest, participants generally pay more attention to the overall performance and parameters of the micromouse. Someone even just focus on the most important adjustment of sensors and motors, but never note the structure, principle and function of other modules. This approach is understandable for a contest with short process and clear purpose. But as a practical course, competition process needs to be manifested in the form of academic hours. Therefore, such modules subdivision must be completed at first.

The first is the division of hardware modules. The micromouse is subdivided into the following modules based on functional clustering [5].

- Power: Provide the power to maintain the operation of the micromouse, including the power supply circuit and a battery.
- Control module: It is the control core of micromouse, including a micro-controller and its minimum system.
- Motor driver: All motor behavior of micromouse is controlled by this module, which consists of two motors and a drive circuit.
- Sensor: Detect the operational status and the external environment of micromouse by six infrared sensors.
- HCI: Display status information for assisting in debugging. Various buttons, lights, and LED digital display tubes are contained therein.

- **Interface:** Provide several common communication interfaces including serial, SPI and JTAG.
- **Mechanical structure:** Various mechanical devices are used to assemble the components into a complete micromouse.

This division is based on progressive approach to display micromouse's composition, theory and application methods. The development and debugging process of an electromechanical system is presented through this division.

The routine splitting should be also completed in the course preparation. Based on the above modules division, the original complete program is split into multiple subroutines for different modules. Each routine corresponds to only one or a few simple tasks, which can show the different functions of each module and their relationships more clearly and directly.

Moreover, because the micromouse competition with a high degree of openness almost has no constraints for micromouse design, the present micromouse are vastly different in hardware structure, development environment, design philosophy and debugging method. In terms of an undergraduate course, such characteristic is not friendly enough. So a series of standardized work is very necessary for micromouse.

- **Standard teaching mold.** Combined with available micromouse technology [6], a number of standard micromouse for classroom are completed prior to commencement (Fig. 3.). Unified batteries, chargers, emulators and related auxiliary debugging device are fully equipped at the same time (Fig. 4.).
- **Standard design environment.** Type, version, and installation procedures of IDE software, device drivers and related link library files are ordained.
- **Standard debugging process.** Adjustment of each module is provided with a standard template with detailed regulation steps. These templates can effectively reduce the difficulty of the entry in the early courses.

Fig. 3. Standard micromouse PCB board.

Fig. 4. Micromouse Curriculum Kit.

Standardization process does bring a lot of benefits to the classroom according to the teaching experience acquired during the past two years. First of all, students may encounter roughly the same faults in the unified debugging process. This facilitates problem solving. Then, a detailed "manual" is probably the friendliest 'Getting Started' for the novice. And it can avoid some of improper explorations to waste valuable class time or even the damage of teaching equipments. Sum up, teaching process standardization makes limited teaching resources to maximize utilization which greatly enhance the teaching efficiency.

B. Realization in classroom.

To enable students to understand how an electromechanical system containing the design of software, hardware and mechanical components is designed from scratch, the entire course is divided into several parts as hardware assembly, environmental construction, parameter adjustment, algorithm optimization and real competition (Fig. 5.).

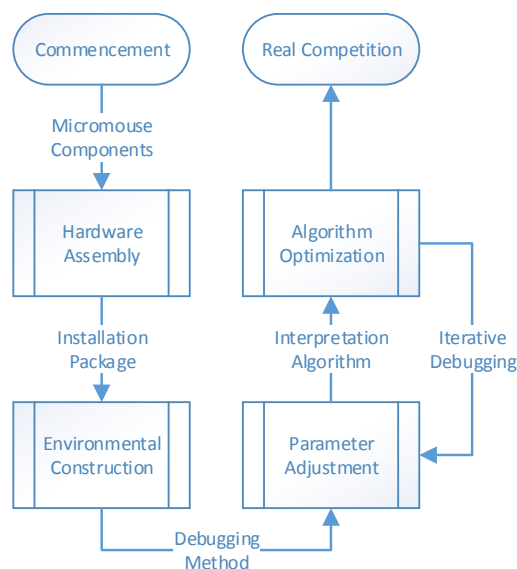

Fig. 5. Course preparation for *Principles and Practice of Micromouse*.

- Hardware assembly

At the beginning of the course, students get just some scattered parts, rather than a directly available micromouse. They are asked to weld and assemble these parts together into a complete micromouse based on the BOM and assembly drawings by themselves. Of course, this micromouse would accompany them to complete all the subsequent courses.

- Environmental construction

Before the micromouse commissioning work begins, a series of software installation and configuration must be completed on the computer. In this part of the course, the teacher would instruct students to install the driver of emulator, C language compiler (IAR Embedded Workbench 32K Free version) and some of the libraries used to support the work of the core controller, etc. The reason why software installation should be taught as a dedicated part is that different computer operating systems express different compatibilities for the software. The installation process may give rise to various problems. Uniformly solving these problems in the class can effectively improve the efficiency of the classroom.

- Parameter adjustment

After the hardware assembly and development environment building are done, the course officially entered into the commissioning phase. It is very difficult and inefficient to modify the program logic directly for people new to micromouse. Students are provided with a basic version of the operating procedures in the beginning. This program is only able to complete the most basic tasks with inefficiencies. A variety of control parameters in the program are required to make the appropriate adjustments due to the tiny differences in hardware. The design purpose of this part of the course is to guide students to develop an understanding of micromouse by modifying the values in the program. After this phase of training, students have been able to skillfully use the IDE software programming. And they may also be very clear for the general debugging method and debugging steps. Their micromouse can successfully complete a simple maze task in a more stable state.

- Algorithm optimization

In addition to a body with stable operation, micromouse also needs a smart brain to help itself perform complex calculations and solve the maze. This part of course would surely involve the program logic modifications. To complete this part of classroom tasks, students need to have a clear understanding about the overall structure of the program. And mathematical knowledge learning in other courses may be used to optimize the calculation method legitimately. It can be said that this part is the most essential part of the whole curriculum which can help students bring up code reading capability,

programming capability and conversion capability from the theoretical knowledge to practical application.

Of course, with the modification of program logic, the control parameters may also need to be amended accordingly. These processes are closely linked. And iterative improvement is necessary. Each element should be taken into consideration in the latter part of debugging.

- Real competition

As a contest-based curriculum, the best way to inspect the outcome is contest ranking. Moreover, this example of "gamification" of learning do needs a clear indicator to measure students' learning outcomes. So, all teams will be scheduled for a complete micromouse contest in the last class of each semester. The competition process is strictly enforced in accordance with the standard rules.

For the sake of fairness, the competition maze map and the order of appearance were determined by lot before the game started. Then the maze should be built on the spot. Each team played the game according to the order of the draw with three competition opportunities or fifteen minutes at most. The game used a laser sensor to detect the timing. The team which finished the game with the shortest time was the winner

The final results of this competition would account for a pretty big proportion of the student's course grade evaluation.

IV. TEACHING METHODS

The main content of this course is to show the general process of electromechanical systems design with micromouse as an experimental platform. Through the hands-on experiments, students can gain a profound understanding of how software and hardware are combined into a specific functional electromechanical system. Team is the basic unit of this course. The core concept of the curriculum is to create an atmosphere of good teamwork, healthy and interest-driven competition, and encourage innovation.

In the teaching process, every three students are teamed up as a group. They will work together to complete the teaching tasks in the whole semester. As some tasks cannot be completed by a single person, team members must learn to communicate and collaborate. They will face the competition assessment together in the end of the semester. Moreover, since the final competition rankings will largely determine the grades, in order to get a good score, students must defeat other competitors instead of an examination paper. Improving learning motivation by the sense of competition is the significance of this teaching model.

The interest-based classroom climate is another major driving force in independent study. Appropriate started difficulty allows students to adapt to the classroom content quickly. As the modular, progressive and visualization target division, students can get a great sense of accomplishment by completing each task, which can help student maintain

continuous enthusiasm. All teaching equipments are assembled, kept and maintained by the students themselves. The sense of belonging and responsibility is also able to motivate students to maintain interest and participate into the class activities.

Although the neat process facilitates the classroom a lot, students' divergent thinking is locked out, too. Conservative strategy may be able to achieve better competition results. But in such a practice classroom, the new ideas and methods with some bright spots are the most exciting. In order to encourage innovation, all reasonable unique improvements had been used as an important indicator of the final score.

The most important is that these ideas are not stuck in the theoretical design stage, but have truly happened in every classroom lesson.

V. TEACHING ACHIEVEMENT SUMMARY

In the process of teaching practice, students have completely experienced the whole development process of electromechanical systems from hardware assembly and hardware and software debugging to real competition. Theoretical knowledge has been vividly embodied by the micromouse platform. In teaching content, the works such as hardware debugging, software development and algorithm optimization can effectively train students' abilities of system integration and engineering practice.

In teaching methods, group collaboration, fixed allocation and reasonable milestones are used to mobilize the enthusiasm of independent learning and research interests while cultivating

teamwork and competition sense. Through this classroom form, the students have maintained a high degree of enthusiasm in the classroom. And great teaching effectiveness can be achieved.

By training in this course, the proportion of students to complete the end contest is 100%. The students from this course have obtained excellent results in *2014 Beijing Micromouse Competition*. On the basis of the original micromouse technology, multiple students innovative practice projects have been derived, some of which have applied for patents.

Abstract— An information technology (IT) tool that can guide STEM educators through the complex task of course design development, ensure tight alignment between various components of an instructional module, and provide relevant information about research-based pedagogical and assessment strategies will be of great value. A team of researchers is engaged in a User-Centered Design (UCD) approach to develop the Instructional Module Development System (IMODS), i.e., a software program that facilitates course design. In this paper the authors present the high-level design of the IMODS and demonstrate its use in the development of the curriculum for an introductory software engineering course.

Keywords—instruction design; outcome-based education; semantic web-based application; user-centered design

I. INTRODUCTION

Felder, Brent and Prince [1] have made a strong argument in support of instructional development training for engineering faculty. This argument, which cites among other reasons: shortfalls in graduation rates, changing demographics and attributes of the student body, and modifications in the expectations of graduates; can be extended to encompass all STEM fields. Furthermore, studies show that for 95% of new faculty members, it takes four to five years, through trial and error (the most common method of gaining expertise in teaching), to deliver effective instruction [2]. While there are a number of options available to faculty for receiving instructional development training (i.e., training focused on improving teaching and learning), most share similar format, features, and shortcomings. For example: workshops, courses and seminar series, the most common program structures, are often offered at a cost to the institution, department or individual attendee; delivered face-to-face at specified times; and accessible to a restricted number of persons. Even when interest is high, these factors can become obstacles to participation.

Outcome-based Education (OBE) is a result-oriented approach where the product defines the process. The learning outcomes guide what is taught and assessed [3], [4]. This approach contrasts the preceding “input-based” model that places emphasis on what is included in the curriculum as opposed to the result of instruction. There is a growing demand and interest in faculty professional development in areas such as OBE, curriculum design, and pedagogical and assessment strategies.

In response to these challenges and needs, a group of faculty

researchers from two south-western universities have undertaken a project to design and develop the Instructional Module Development System (IMODS) that will facilitate self-paced instructional development training while the user creates his/her course design with the added benefits of being free to all who are interested, accessible almost anywhere through a web browser, and at any time that is convenient.

Additional key features of the IMODS are as follows:

1. Guides individual or collaborating users, step-by-step, through an outcome-based education process as they define learning objectives, select content to be covered, develop an instruction and assessment plan, and define the learning environment and context for their course(s).
2. Contains a repository of current best pedagogical and assessment practices, and based on selections the user makes when defining the learning objectives of the course, the system will present options for assessment and instruction that align with the type/level of student learning desired.
3. Generates documentation of a course designs. In the same manner that an architect’s blue-print articulates the plans for a structure, the IMODS course design documentation will present an unequivocal statement as to what to expect when the course is delivered.
4. Provides just-in-time help to the user. The system will provide explanations to the user on how to perform course design tasks efficiently and accurately. When the user explores a given functionality, related explanations will be made available.
5. Provides feedback to the user on the fidelity of the course design. This will be assessed in terms of the cohesiveness of the alignment of the course design components (i.e., content, assessment, and pedagogy) around the defined course objectives.

In this paper the authors present the high-level design of the IMODS and demonstrate its use in the development of the curriculum for an introductory software engineering course. The rest of the paper is organized as follows. Background material for this research project is presented in section 2. Section 3 presents the high-level design of the IMODS software system. Section 4 presents a case study that demonstrates the use of the IMODS framework in the development of an introductory software engineering course. The paper concludes with future work and acknowledgements.

II. BACKGROUND

A. Related Work

To justify the need for the development of IMODS we conducted a competitive analysis to determine the strengths and weaknesses of tools and approaches currently used to support course design and related training. The tools and approaches that were evaluated were categorized into five groups based on primary functions and features.

Knowledge/Learning Management System (KMS/LMS):

This group contains a number of proprietary and open-source solutions that are delivered either as desktop or web-based applications. These tools mainly facilitate the administration of training, through the (semi-) automation of tasks such as: registering users, tracking courses in a catalog, recording data, charting a user's progress toward certification, and providing reports to managers. These tools also serve as a platform to deliver eLearning to students. In that context, their main purpose is to assemble and deliver learning content, personalize content and reuse it.

Examples: Blackboard, Moodle, Sakai, Canvas, WeBWorK, and Olat

Educational Digital Libraries: These tools contain collections of learning and educational resources in digital format. They provide services that support the organization, management, and dissemination of the digital content for the education community.

Examples: National Engineering Education Delivery System (NEEDS), National Science Digital Library (NSDL) and Connexions

Personalized Learning Services: There are a number of e-learning tools that leverage semantic web technologies to support personalized learning services for their users with an ontology based framework [5]. Some of these tools function by initially profiling the learner and then, based on that profile, identifying the best strategies for presenting resources to them. They can also provide feedback to instructors on student learning, so improvements to the content and structure of the course can be incorporated. For many of these tools the ontology framework is used to bridge learning content with corresponding pedagogy; however, they seldom address assessments and learning objectives. **Examples:** Content Automated Design and Development Integrated Editor (CADDIE), Intelligent Web Teacher (IWT), LOMster [6], and LOCO-Analyst [7].

Understanding by Design Exchange (UbD Exchange): This is a software framework based on Wiggins's and McTighe's Backward Design principle [8] that is used for designing curriculum, assessments, and instruction, and integrates K-12 state and provincial standards in the design of units [9]. It provides a form-based user interface to fill in the details of the course unit that is being designed.

Professional Development Workshops, Courses & Seminars: Face-to-face training sessions in teaching and learning that are facilitated by experts in the field of instructional design.

Examples: National Effective Teaching Institute, Connect Student Learning Outcomes to Teaching, Assessment, and Curriculum, Content, Assessment and Pedagogy [10].

Our search identified very few tools and approaches that contained features or functionality that explicitly facilitated the design of course curriculum. Of these tools few of them facilitated the generation of design documentation and feedback to the user on the fidelity of the design. These are two key deficiencies that IMODS will address.

B. IMODS Framework – PC³ Model

The IMOD framework adheres strongly to the OBE approach and treats the course objective as the spine of the structure. New constructs (not included in the models previously discussed) are incorporated to add further definition to the objective. The work of Robert Mager [11] informs the IMOD definition of the objective. Mager identifies three defining characteristics of a learning objective: Performance – description of what the learner is expected to be able to do; Conditions – description of the conditions under which the performance is expected to occur; and the Criterion – a description of the level of competence that must be reached or surpassed. For use in the IMOD framework an additional characteristic was included, i.e., the Content to be learned – description of the factual, procedural, conceptual or meta-cognitive knowledge; skill; or behavior related to the discipline. The resulting IMOD definition of the objective is referred to as the PC³ model [12].

The other course design elements (i.e., Content, Pedagogy, and Assessment) are incorporated into the IMOD framework through interactions with two of the PC³ characteristics. Course-Content is linked to the content and condition components of the objective. The condition component is often stated in terms of pre-cursor disciplinary knowledge, skills or behaviors. This information, together with the content defined in the objective, can be used to generate or validate the list of course topics. Course-Pedagogy is linked to the performance and content components of the objective. The types of instructional approaches or learning activities used in a course should correspond to the level of learning expected and the disciplinary knowledge, skills or behaviors to be learned. The content and performance can be used to validate pedagogical choices. Course-Assessment is linked to the performance and criteria components of the objective. This affiliation can be used to test the suitability of the assessment strategies since an effective assessment, at the very least, must be able to determine whether the learner's performance constitutes competency. Figure 1 shows a visual representation of the IMOD framework. Learning domains and domain categories defined by Bloom's revised taxonomy [11] are used to describe learner performance. Learning domains are categorized into Cognitive, Affective, and

Psychomotor, which are further classified under various Domain Categories (Remember, Understand, Apply, Analyze, Evaluate, Create). Each Domain Category has performance verbs associated to it. Learning objective in the PC³ model is described in terms of Performance, Content, Condition, and Criteria. Performance is described using an appropriate action verb from revised Bloom's taxonomy based on the learning domain and domain category.

Criteria: Learning objective assessment criteria are categorized as quality, quantity, speed, and accuracy. Criteria for learning objectives are described in terms of one or more of these categories with a criteria value defined or determined later when the assessment is defined.

Knowledge Dimensions: The revised Bloom's taxonomy introduced an additional dimension called the knowledge dimension that was categorized as Factual, Conceptual, Procedural and Metacognitive.

Topic Prioritization: The IMODS framework uses a prioritization framework that classifies topics and subtopics of a particular course as one of the following:

- Critical
- Important
- Good to know

Achieving the right mix of the three levels of learning (priorities) is essential to planning a good course.

PC³ Model

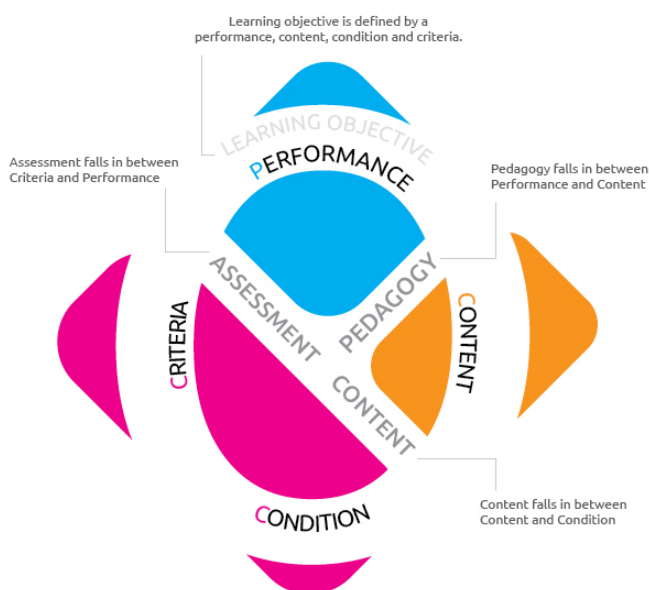

Figure 1: IMODS Framework - PC³ model

C. User-centered design methodology

The IMODS system is being developed using a user-centered design (UCD) methodology, as opposed to technology focused, methodology [13]. This approach is well suited for the project given the high cognitive nature of outcome-based course design tasks, and the high levels of interactions required between the user and the system to not only facilitate the development of course designs, but to help users build an

enduring foundation of knowledge, skills and habits of mind about curriculum development.

UCD is an emerging design method that focuses on both operational and technical requirements by observing and understanding user needs and wants, as well as by prototyping and testing software throughout all phases of software lifecycle. It enables the capturing and resolution of any mismatches between users and software early on. The main objective of UCD is to allow for a closer match between users and the software, leading to a more intuitive interaction. As a design process, it also has the objective of reaching that goal in the most resource-efficient way, in terms of time and cost through careful planning and execution [14].

The UCD process can be divided into five main phases: Plan, User Research, Design, Develop, and Measure. Thus far, the research team has completed the user research and design phases of the UCD process. In this respect, 4 focus group sessions were conducted with prospective users of IMODS to gather insights on how faculty approach the task of designing a course. At the beginning of each session all participants were asked to fill an electronic background survey that collected demographic information, primary areas of interest in teaching and research, time spent on teaching, number of courses taught per year (at both undergraduate and graduate levels), and number of new courses developed (both at undergraduate and graduate levels). Participants were also asked to fill an electronic questionnaire about curriculum design tools that they currently use to create and manage their courses (e.g. preparing syllabi; communicating with students; developing teaching materials; preparing, assigning, and delivering grades, etc.). The results of this phase were published in ASEE 2014 and FIE 2014 [15], [16]. The results from the focus group helped identify the key features of the software system; an ontology that defines the relevant terms of the domain and identifies their specific meaning as well as the potential relationships between them; and mental model, which is a tool to improve understanding of the user needs and activities. Figure 2 shows the ontological concepts and relationships between concepts as a hierarchy. Figure 3 shows the mental model that depicts an affinity diagram of similar activities organized sequentially into 9 towers in the upper half with detailed relevant activities in the lower half.

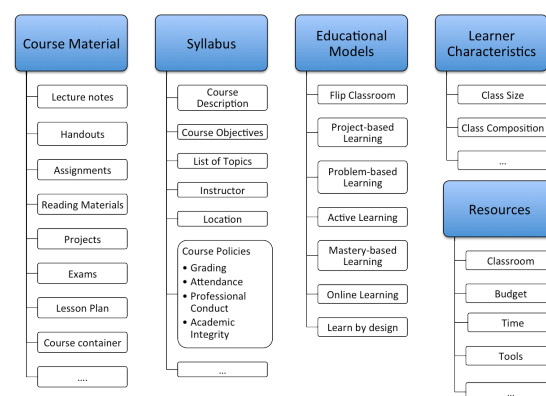

Figure 2: IMODS Ontological Concepts and Relationships

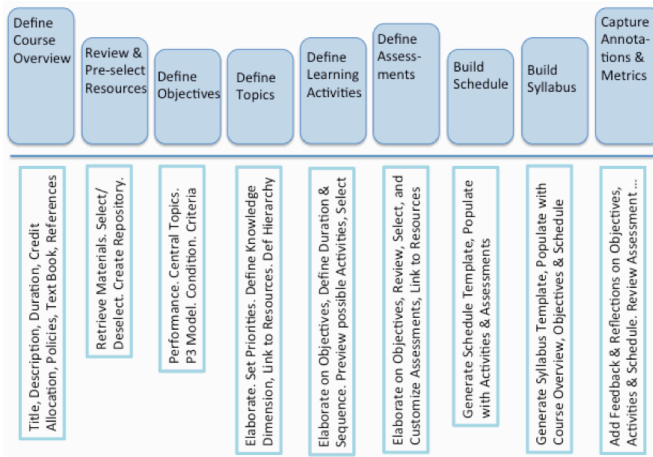

Figure 3: Mental Model

III. HIGH-LEVEL DESIGN OF IMODS

One of the biggest challenges of software design is to make sure the user has sufficient understanding to use the application successfully and accomplish the required tasks. Our User-centered design approach followed two main phases:

A. Conceptualization Phase

After the user research provided a relatively clear idea and understanding of domain- and user needs, this initial design phase provides a high-level design with concepts identification, conceptual modeling and early prototyping. During initial conceptualization and high-level design, we focused on Brainstorming sessions and contextual analysis to build an initial concept of the application. We gradually consolidated it into a set of requirements on flip charts and PowerPoint slides. The main goal of high-level design is to plot down schematic ideas and steps into visual graphs and models; an early blueprint. We started by investigating different options and providing design alternatives to make sure we have a broad view before identifying a good design. Doing this early on, at high-level, sketchy, paper-based only, and without going into details help provide several solution alternatives at a very low cost.

The IMODS system is conceptualized such that a course design is centered around the learning objectives of the course defined by the instructor (user) as shown in Figure 4. Learning objectives are directly associated with the course content, assessments, and pedagogical activities as defined in the PC³ model (Figure 5).

Figure 4: IMODS System Overview

The Learning Objectives component of the IMODS system was conceptualized with its various components based on the PC³ model as shown in Figure 5.

Figure 5: IMODS Learning Objective Overview

Then as we planned and executed the testing, we were able to directly ask the user to work on a “Criteria” within “learning objectives”. Our dual purpose is to let the user know that those are two concepts of the IMOD, as well as knowing the structural relationship between them.

B. Development Phase

In order to validate that we were proceeding in the right direction, we ran a series of usability tests on the application. We chose between multiple good designs instead of focusing on only one early on. The high-level design sketches were discussed with the users to make sure what they said in unstructured dialogs and vague ideas and imaginations can now be concretely captured in design artifacts for further validation and clarifications [17]. Our main goal was to evaluate the simplicity and clarity of the application structure to allow for an easy-to-recognize mental model. A mental model can be loosely defined as the user perception of the application. The opposite is the developers’ perception of the application. While the latter one is the actual structure that developers use to build the application, typically as their interpretation of the requirements, the user mental model is not necessarily the same. With the fact that users don’t normally have access to the actual structure of the application, or detailed and prolonged access to the application to know any of its internal structure, they can only perceive what’s exposed to them from the UI, and can build an “imagination: of what the application structure might look like. In ideal situations, this “imaginary” structure should match the actual structure build by developers. In reality, though, it is rarely the case. A discrepancy or vagueness on the user mental model (we can call it a delta) is typically present and expected. The problems arise when this delta is large, indicating an application whose structure is not comprehensible by the user. We have identified 2 tools that are most suitable for this project in this phase.

C. Tools

Navigation Model is one of the essential methods of design that we used. A significant challenge in complex software is not the contents of each screen, but how the user mentally build a mental view of how all screens are connected (like a city road map), and how to navigate between hundreds of screens to accomplish their task. In this regard, we have developed an effective technique, elastic prototyping, an implementation of a participatory design to help designers and users build a navigation model together, greatly reducing time and effort needed. Figure 6 shows the navigation model for the primary application. Figures 7 and 8 show the navigation model for new user registration and user login. One of the

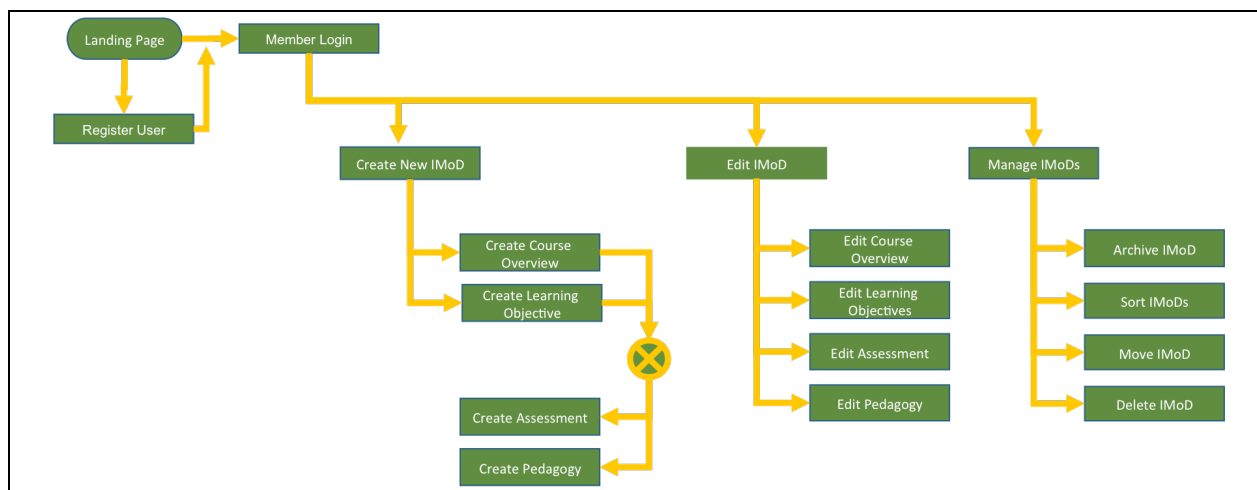

Figure 6: Primary IMODS Application - Navigation Model

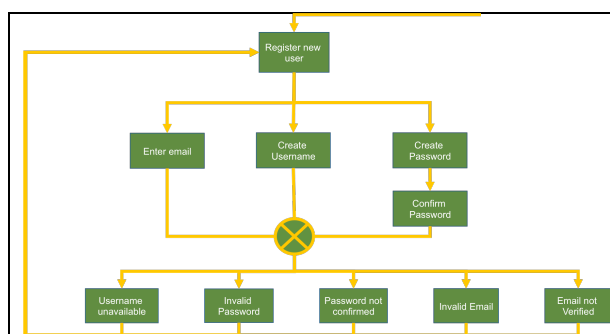

Figure 7: New User Registration - Navigation Model

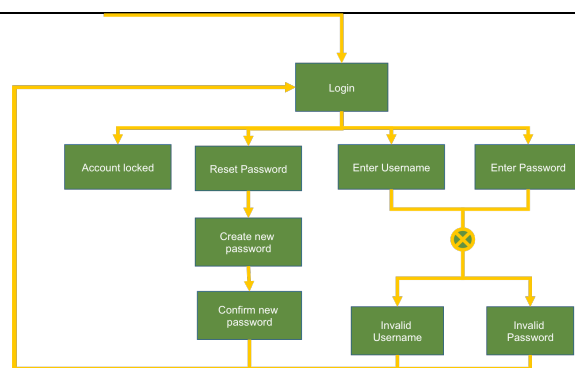

Figure 8: User Login - Navigation Model

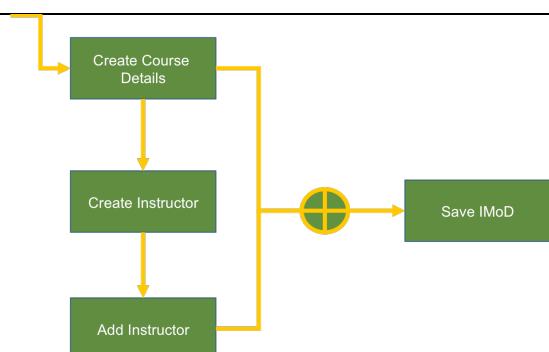

Figure 9: Course Overview - Navigation Model

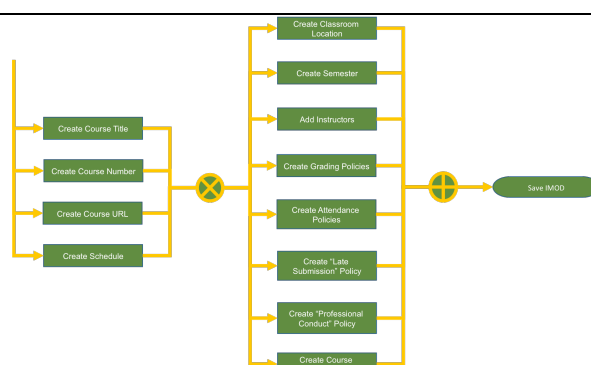

Figure 10: Course Details - Navigation Model

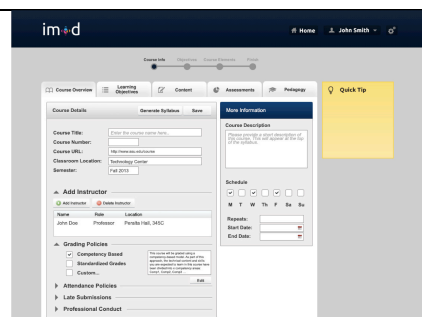

Figure 11: Course Overview Mockup

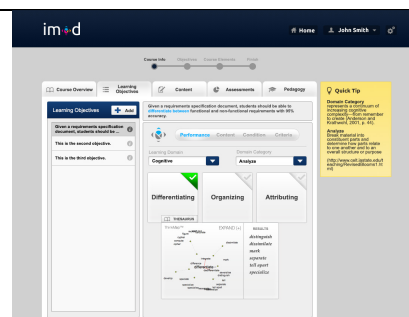

Figure 12: Learning Objectives Mockup

main components of course design is describing course overview information that includes data about course title, description, schedule, instructors, course policies, etc. Figures 9 and 10 show the navigation model for course overview data entry. In a similar manner navigation model for other screens of IMODS that are used for design of Learning Objectives, Content, Assessments, and Pedagogy were created.

Prototyping (PT) is extensively used in UCD to visualize and validate all otherwise vague ideas and unclear expectations at low cost and high effectiveness. We focused on three main categories of prototyping: Paper (low-level) PT, low-fidelity electronic (medium level) PT, and high-fidelity, detailed PT [18]. Paper prototypes are very inexpensive and help us capture several initial ideas and concepts, and validate them. After explaining their needs, users often change their minds when they see them on paper. Therefore multiple paper PT sessions gives a head start in validating what users actually mean and need. After initial concepts, design ideas and directions were identified, we moved into a medium fidelity prototyping stage where we provided a sketchy visualization of key screens without contents and gradually validated them and added initial contents. Figures 11 and 12 show the user interface mockups of Course Overview and Learning Objective components of the IMODS system

D. System Architecture

The development phase of the project included identifying appropriate technologies to be used for the development of the IMODS semantic web application, design of the back-end database schema, installation and configuration of the server-side and client-side technologies, and development of the user interface screens for login, registration, index, and creation of an instructional module and the connectivity of these web pages with the backend database. An Agile software development methodology called Scrum is being used for the development of this project. Scrum is an iterative and incremental framework for managing product development. The technologies chosen included Groovy on Grails, an open source, full stack, web application framework for the Java Virtual Machine. It takes advantage of the Groovy programming language and convention over configuration to provide a productive and streamlined development experience. Grails uses Spring Model-View-Controller (MVC) architecture as the underlying framework. MVC is a software architecture pattern that separates the representation of information from the user's interaction with it. PostgreSQL was chosen as the database management system. It is a powerful, open source object-relational database system with more than 15 years of active development and a proven architecture that has earned it a strong reputation for reliability, data integrity, and correctness. Git was chosen for source code version control. It is a distributed revision control and source code management (SCM) system with an emphasis on speed.

E. Testing

For the testing phase of the project, we opted to not have a complete discovery test, where the user would be asked to do a blind discovery of the application without any prior knowledge [19]. That would be a simulation of a completely novice user without any application background. Instead, we decided to test for an average user with some level of knowledge about the application structure. The reason is that we already have a concrete navigation model, and we can typically bring it to any user's attention in few minutes to help them in building a correct navigation model. That is one of the main advantages of using the navigation modeling method. Currently our research team is working on software development and testing phases of the project.

IV. CASE STUDY

The IMODS framework was applied to design an introductory software engineering course titled "Software Enterprise I: Personal Software Process" in B.S. in Software Engineering program. This section describes the use of IMODS – PC³ model for course design.

A. About the Course

Software Enterprise I: Personal Software Process is a sophomore course in the Software Engineering program that introduces software engineering and object-oriented software design principles using a modern programming language. Students are introduced to Software Engineering, Software Life Cycle models, Object-Oriented Programming, Personal Software process, Effort estimation, effort tracking, defect estimation and defect tracking. Students learn personal software process for individual professionalism, time and defect estimation; yield and productivity. A project-based pedagogical model is used for delivery of all our courses in Software Engineering program. Students in this course worked on a game project using Java programming language.

B. Learning Objectives

Learning objectives of this course were defined using the PC³ model. The course has 6 objectives that are categorized under Performance, Content, Condition, and Criteria as shown in the Table 1. The objectives are as follows:

- *LO1:* Design a software solution using Object-Oriented Design principles of encapsulation, information hiding, abstraction, inheritance, and polymorphism
- *LO2:* Develop a software solution in an object-oriented programming language employing standard naming conventions and making appropriate use of advanced features such as exception handling, I/O operations, and simple GUI
- *LO3:* Use object-oriented design tools such as UML class diagrams to model problem solutions and express classes and relationships such as inheritance, association, aggregation, and composition

- *LO4*: Use personal software process for individual development productivity through time estimation and tracking
- *LO5*: Use personal software process for individual development quality through defect estimation and tracking
- *LO6*: Demonstrate teamwork

Table 1: Learning Objectives based on PC³ Model

Objective	Learning Domain	Domain Category	Action Category	Action/Word Performance	Content	Criteria	Condition
LO1	Cognitive	Create	Plan	Design	Software Solution, Object-Oriented Design principles, encapsulation, information hiding, abstraction, inheritance, polymorphism	Quality (DPA**)	At completion of this course, student will be able to
LO2	Cognitive	Create	Produce	Develop	Software Solution, Object-Oriented programming language, standard naming conventions, Exception Handling, I/O operations, simple GUI	Quality (DPA**); Speed (DPA**)	At completion of this course, student will be able to
LO3	Cognitive	Apply	Implement	Use	Object-oriented design tools, UML Class diagrams, Modeling problem solutions, Classes, Relationships between Classes, Inheritance, Association, Aggregation, Composition	Quality (DPA**); Speed (DPA**)	At completion of this course, student will be able to
LO4	Cognitive	Apply	Implement	Use	Personal Software Process, Individual Development Productivity, Time Estimation, Time Tracking	Accuracy (85%)	At completion of this course, student will be able to
LO5	Cognitive	Apply	Implement	Use	Personal Software Process, Individual Development Quality, Defect Estimation, Defect Tracking	Accuracy (85%)	At completion of this course, student will be able to
LO6	Cognitive	Apply	Implement	Demonstrate	Teamwork	Quality (DPA**)	At completion of this course, student will be able to

** DPA Determined Per Assessment

C. Content

The list of Content topics and subtopics are listed in Table 2. For each topic the knowledge dimension and topic priority is defined. This information is used to find assessments and instructional activities that best fit for delivering a topic.

Table 2: Content Topics based on PC³ Model

Content Topic	Content Sub-Topics	Knowledge Dimension	Priority
Object-Oriented Design Principles	Encapsulation	Factual (F), Conceptual (C)	Critical (3)
	Information Hiding	Factual (F), Conceptual (C)	Critical (3)
	Abstraction	Factual (F), Conceptual (C)	Critical (3)
	Inheritance	Factual (F), Conceptual (C)	Critical (3)
	Polymorphism	Factual (F), Conceptual (C)	Critical (3)
	Software Solution	Conceptual(C), Metacognitive (M)	Critical (3)
Object-Oriented Design tools	Modeling Problem solution	Procedural (P), Metacognitive (M)	Critical (3)
	UML Class diagram	Procedural (P)	Critical (3)
	UML Use Case Diagram	Procedural (P)	Important (2)
Object-Oriented Programming Language	Exception Handling	Factual (F), Conceptual (C)	Important (2)
	I/O Operations	Factual (F), Conceptual (C)	Important (2)
	Simple GUI	Factual (F), Conceptual (C)	Important (2)
	Standard naming conventions	Factual (F), Conceptual (C)	Good to know (1)
	Time Tracking	Factual (F), Procedural (P)	Critical (3)
Personal Software Process	Time Estimation	Factual (F), Procedural (P)	Critical (3)
	Defect Tracking	Factual (F), Procedural (P)	Critical (3)
	Defect Estimation	Factual (F), Procedural (P)	Critical (3)
	Teamwork	-	Metacognitive (M) Important (2)

D. Assessments

Assessments chosen for this course include a mix of both formative and summative assessments. The PC³ model aligns assessments chosen for the course with the learning objectives by checking compatibility of learning domains, performance, and criteria requirements. Table 3 provides the list of assessments with their corresponding learning domain

category, knowledge dimension, and criteria type that each method is suitable for.

E. Instructional Activities

Pedagogical activities used in this course are listed in Table 4 along with the knowledge dimension and learning domain category that they are suitable for. The list of activities includes a mix of lectures, lab activities, Q&A discussions, and problem solving activities.

Table 3: Course Assessments

Assessment	Type	Domain Category	Knowledge Dimension	Criteria
Programming exercise (write formal code)	Formative	Understand, Apply, Analyze, Evaluate, Create	Conceptual, Procedural	Speed, Quality, Accuracy
Partially guided programming exercise	Formative	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural	Quality, Accuracy
Guided Lab exercise	Formative	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural	Quality, Accuracy
Quiz	Formative	Remember, Understand	Conceptual, Factual	Accuracy, Speed
Project	Summative	Understand, Apply, Analyze, Evaluate, Create	Conceptual, Procedural	Quality, Accuracy
Exam	Summative	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural	Quality, Accuracy

F. Results

Software Enterprise I: Personal Software Process course in the Software Engineering program in School of Computing, Informatics, Decision Systems Engineering (CIDSE) at Arizona State University was designed using the IMODS – PC³ model and offered as a face-to-face section (with 82 students) as well as an online section (with 87 students) by the same instructor (one of the co-authors). Using the IMODS framework ensured the alignment between various course elements and thereby ensuring high-quality course design.

Table 4: Course Pedagogical activities

Instructional Activities	Domain Category	Knowledge Dimension
Lectures (Face-to-Face, Audio, or Video)	Remember, Understand	Conceptual, Factual
Problem Solving	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural
Partially Guided Programming exercise	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural
Active Reading	Remember, Understand, Apply	Conceptual, Factual, Procedural
Programming Assignment	Understand, Apply, Analyze, Evaluate, Create	Conceptual, Procedural
Guided Lab Exercise	Understand, Apply, Analyze, Evaluate	Conceptual, Procedural
Q&A Forum	Remember, Understand	Factual, Conceptual

Alignment between various course components:

The framework supports the checking of alignment between course assessments and learning objectives. The course assessments are linked to the performance and criteria elements of the learning objective as shown in Figure 1. The framework supports the checking of alignment between course instructional activities and learning objectives. The course pedagogical activities are linked to the performance and content of the learning objective as shown in Figure 1.

Topic Prioritization:

Use of the PC³ model ensured a balanced distribution of the topics under Critical, Important, and Good to know as shown in figure below.

V. FUTURE WORK

Following the high-level design phase of the project, the next step will be software development and testing of IMODS. We will conduct usability testing of the prototype with instructors and solicit feedback using surveys, observation, and user interviews. The feedback will be incorporated into the iterative software development lifecycle model. The scope of this project will also include the evaluation of its novel approach to self-guided web-based professional training in terms of: 1) user satisfaction with the documentation of course designs generated; and 2) impact on users' knowledge of the outcome-based course design process.

ACKNOWLEDGMENT

The authors gratefully acknowledge the support for this project under the National Science Foundation's Transforming Undergraduate Education in Science, Technology, Engineering and Mathematics (TUES) program Award No. DUE-1246139.

Global vs. Local - Experiences from a Distributed Software Project Course Using Agile Methodologies

Outi Sievi-Korte, Kari Systä
Department of Pervasive Computing
Tampere University of Technology
Tampere, Finland

Gjøvik University College
Gjøvik, Norway

Abstract—Global software engineering (GSE) has become common in the software industry. Distributed development work comes with many challenges, especially related to communication and coordination. Thus, it is essential to also teach and prepare the new population of software engineers to be aware of – and familiar with – these hurdles. We addressed this need by arranging a joint (agile) software project course between universities in Finland and Norway. We had three teams – one with students from both countries and two with students from the Norwegian university only. The students were given a teacher mentor, a handbook on agile practices and state-of-the-art tools for project management and software development. Apart from monitoring the teams' progress, we also collected data from emails, questionnaires, student reports and interviews during and after the project. The main lesson learned is that the global and local teams are mostly facing the same challenges - especially when it comes to team building, clear project roles, and communication and management issues. Ultimately, our results show that the challenges were harder to solve by the global team and that not solving challenges in a timely manner had more serious consequences.

Keywords—global software development, agile, student teams

I. INTRODUCTION

Global software engineering (GSE) has become increasingly popular in the industry during the past 15 years [1]. Software components are outsourced to subcontractors around the world, but also the main developer companies have distributed their development to several countries in order to leverage the benefits of a wider pool of skilled resources, lower costs and proximity to the customers. Thus, the development teams themselves have become distributed, with team members working from different locations, having to face temporal, cultural and geographical distances and the challenges they bring on a daily basis [2]. These challenges have significant effects on the project process and outcome, and thus it is necessary to begin preparing the software engineers of the future - the current students at universities - for these challenges in advance and to teach them methodologies that can be used when facing them.

There is a growing trend towards teaching global software engineering in a setup where software projects are developed in distributed teams. Following several experience reports and viewing the increasing need to give students hands-on practice with working in a distributed team, Tampere University of Technology (TUT) (Finland), and Gjøvik University College

(GUC) (Norway) embarked on a joint mission to set up a software engineering project course to reach this objective. TUT had already been running a software engineering project work course for 20 years on the Master's level where the topics came from the industry, while the Master's students in Gjøvik have had their software engineering project in their Bachelor studies.

There were two main drivers for covering global software engineering in a project format rather than in a traditional software engineering course: firstly, and most importantly, we wanted the students to get a hands-on experience in addition to more theoretical introduction to global software engineering. Secondly, we found it easier to organize the teaching activities at the two universities when students worked in projects.

The structure of the paper is as follows: in the next section, we will discuss existing studies on teaching globally distributed software projects. We will then present the setup for our course - the background of the students, the course arrangements (practicalities and implementation of Scrum methodologies), provided tools and description of the assigned project for the students. In section IV, we will describe the project process, and compare the local teams' process to that of the distributed team, especially concentrating on the challenges the distributed team faced. In section V we discuss our findings, backed up by data collected from different sources, and then in Section VI draw our conclusions.

II. RELATED WORK

As is the case for GSE in general, the number of experience reports from teaching GSE have increased significantly in the past decade, since the first experiences from teaching a distributed student project was published already in 1998 [3]. Monasor et al. [4] performed a systematic review on the topic in 2010, and found six types of proposals regarding teaching or educating in global software engineering: learning environments, e-learning approaches, simulators, teaching GSE in the classroom, training GSE in the classroom, and teaching GSE in the company. In this context, a project work in truly distributed teams is considered training in the classroom, so we will focus on existing studies in this category.

The longest running course on GSE seems to be DSD (Distributed software development course), organized by University of Zagreb (Croatia) and University of Mälardalen (Sweden), which has been running since 2003 [5]. The course consists of

introductory lectures (5 weeks) and project work (3 months). During the years, factors affecting student motivation [5], factors to consider when choosing a project for the team [6], and the role of customer have been investigated within the context of the DSD course [7].

The largest GSE course, in turn, appears to be the DOSE course [8]; the 2012 instance of which was organized between 12 universities in 11 countries, each group having members in 2-3 countries [9]. As the previous implementations of the course had revealed that communication, coordination and management roles were challenging for the students, the instructors experimented with a playful competition that would actually act as a pedagogical tool to teach how meaningful the role of project management and working communication methods are in a distributed course.

Recently, Agile methodologies have also been brought to GSE courses. Damian et al. [10] discuss the initial findings of using Scrum in a course distributed between Finland and Canada. These results are further examined by Paasivaara et al. [11]. In the Finnish-Canadian course, the Scrum policies were monitored very strictly, and several practices for supporting GSE were also established. Students reported good outcomes on learning GSE, and showed an innovative spirit to find ways of establishing methods for frequent and fluent communication, which is essential in both GSE and Scrum.

Scharff et al. [12] have also studied the difficulties students have in adhering to Scrum policies in GSE, and have concluded that due to the nature of GSE, there were problems such as unexpected absences of developers, no regularity in doing Scrums, sprint planning was done late, and retrospective and sprint demo were not prepared.

Our work gives a new angle to existing studies by being able to present a realistic comparison between local and distributed teams. Our students had the exact same setup, project descriptions and schedule, and thus we (and the students) are able to analyze the difficulties that were specifically due to the nature of GSE for the distributed team. Additionally, we have used Scrum, and there are still only few experience reports on how distributed Scrum works in student projects. Furthermore, the students were expected to implement a working piece of software from start to finish.

III. SETUP

In the past TUT have been running two project courses. One course has been implemented already since 1991 [13] and the name of the current version is Project Work on Pervasive Systems. During latest years we have also course Demola Project Work that has more innovation and start-up aspects. It was decided to offer the course as a parallel version of the existing project course at TUT, i.e., students could choose if they wanted to participate on the traditional software project course or the GSE project course. For Gjøvik students the project was offered as a separate course by the name "Global Software Development". The Gjøvik semester structure only enabled the course to last for 3 months (beginning of September to beginning of December), while the traditional TUT course lasted for almost five months. To enable same schedule for all students we condensed the GSE version at TUT to last for only three

months. Although the international version took a shorter time, overall effort in terms of working hours was planned to be about the same. The fact that all groups ended up doing the same project made it possible to compare the processes and performances of local teams to the globally distributed team in a systematic way.

A. Student selection

In Tampere University of Technology, 111 students had initially signed up for two project courses called Project Work on Pervasive Systems, and Demola Project Work. We sent an invitation to all those students to consider the international course, and we received 10 initial contacts from students. These students were then asked to provide background information of their experience in different programming languages, software projects in practice, and what kind of studies they had completed. We had to send these questions, because not all of the students had software engineering as a major subject and we wanted to gain insight on the background and motivation of the interested students. Some of the students decided to drop at this phase, while some decided to postpone the project course to next year because they did not have enough background knowledge, yet. Some students also discovered that the more intensive version of the course did not fit to their schedule, and wanted a version where the amount of work is spread to a longer period. After discussing with the teachers a couple of students withdrew themselves because they were in too early a phase in their studies and could not contribute properly. At the end, only two actually joined the course. They were both international students, and had both motivation and skills. Both of them have passed courses on programming and on software engineering processes.

In Gjøvik, the course was made compulsory for students in the Web, Mobile, Games track of the Master of Applied Computer Science program. The course runs in the third semester of the two-year master program and was brand new in the program. The 13 Norwegian students were all registered as full time students on this Master's program track; 7 students having their bachelor degree from GUC, while the remaining students were students from Ukraine, Russia, and China. All students had a Bachelor's degree in computer science (CS) with at least 20 ECTS in SE projects.

Most of the students had some familiarity with Scrum and Agile methodologies prior to the GSE course: 40% of the students reported that they had practical experience in Scrum, 40% reported that they were familiar with the methodology but had never actually used the methodology, and the remaining 20% had no familiarity with Scrum.

B. Course arrangements

1) Practicalities

The course began on September 5th, and lasted until December 5th. The course was divided into 4 sprints, and after each sprint, a 4-hour long seminar was arranged. During the kick-off seminar (before the first sprint), the staff presented the provided tools and the project handbook. The project handbook was prepared for the students to specify explicitly the Scrum practices the students were expected to follow. It also con-

tained information about the tools and the reports required from the students. Other seminars acted as sprint demonstration, review and retrospective events for all the groups, as they presented their progress to the course staff and students and discussed their difficulties and successes. Additionally, relevant topics were presented by the staff.

After the kick-off seminar, the course staff provided the students with an opportunity for team building in a voluntary session. The distributed team chose to have a separate, independently arranged, team building session where they discussed their hobbies and such.

In addition, Gjøvik had invited two senior developers from the industry with extensive experience from working in global teams to share their experiences with the students. These senior developers also participated in the planning of the course to ensure that the project handbook and the chosen tool set were up to date with regard to software development industry practices. Student groups were also assigned mentors to assist them during the project (mentoring is discussed in more detail in a later section).

The students were required to produce three types of deliverables:

- Running software
- Scrum artifacts (backlog, sprint backlog, sprint retrospective, and system documentation)
- Project reports

2) Scrum policies

As discussed above, the students were provided a project handbook explaining Scrum policies, and the groups were thus instructed to familiarize themselves with the contents of the handbook and to make sure that they run the project according to the handbook. The handbook introduced Scrum and included several links to resources on the web describing Scrum in more detail. The handbook further described the mandatory project roles, the required Scrum artifacts, the definition of done, and the required meetings. Finally, the handbook had a short chapter on working in global teams. Groups were required to select a Scrum Master and a Product Owner from the group members. The groups were also encouraged to appoint a Build Master who would be in charge of the development tools. Groups were expected to have meetings at least twice a week.

3) Tools

Gjøvik provided the students with an extensive set of state-of-the-art tools for project management and collaboration. The tools were chosen based on the recommendations given by the two senior developers from the industry, as the tools are common in the corporate world. Atlassian Confluence [14] was used as a wiki for the course, and the teams were given their own spaces for sharing material and discussions. The project groups also used the wiki for the system description they were required to write. In addition, the teams were given access to Atlassian Jira [15], where they were expected to manage the tasks and issues as the development progressed and to log their working hours.

The tool set was to a large degree the same for all projects: A version management server for Git [16] repositories was provided and Apache Maven [17] was chosen as the tool for managing the software build process. The backend parts of the applications were developed as Java applications implementing a RESTful interface [17] and running on Apache Tomcat [19] using MySQL [20] as the database. The teams chose different client side strategies. One team chose to develop a thick Java Swing client. The second team chose to develop a native Android application. The third team chose to develop an application to run inside a web browser.

4) Groups and project description

The students were divided into three groups. Group assignment was based on the students' response to a questionnaire in which they described their programming and management experience and interests respectively. As there were only two TUT students participating, we decided to assign them to the same project group so that all students had also some local team mates. These were the three groups:

1) The members of the (local) Baldr project were three Norwegians, one Chinese, and one Ukrainian student. The group's mentor was one of the senior developers from the industry. In the group members' self-evaluation only one's programming experience was only based on schoolwork, while others also engaged in extra-curricular activities or had professional experience.

2) The members of the (local) Freya project were two Norwegians, one Chinese and one Russian student. The group's mentor was the Norwegian professor. In the group members' self-evaluation three group members' programming experience was only based on schoolwork, while one also engaged in extra-curricular activities and one had professional experience.

3) The members of the (global) Kvasir project were two Norwegians, and a Ukrainian student located in Norway and two Iranian students located in Finland. The group had one of the Finnish professors as mentor in Tampere and one of the senior developers from the industry as a mentor in Gjøvik. In the group members' self-evaluation three group members' programming experience was only based on schoolwork, while one also engaged in extra-curricular activities and two had professional experience.

When reporting experience in Java programming, group members from Baldr and Freya had on average the same level of proficiency, while members from Kvasir group reported slightly lower levels of Java knowledge. In JSP/Servlet technologies Baldr's group members' knowledge was slightly below average, Freya's merely adequate, and Kvasir's the highest of all groups (due to one professional expert).

The students were given a choice of three different topics. All the teams, however, ended up choosing the same topic - an educational trivia game. One team initially chose a different topic, but found it too vague, and then changed to the game topic as well. A two-page project description was given to the students suggesting features for the game play. The document also suggested features for defining questions and answer alternatives and for quiz management. Students were expected to put down at least 275 hours each on the project. The size of the

suggested project was larger than what we expected the students to deliver, thereby challenging the student teams to order features according to perceived importance to the users. The project did not require any special programming skills beyond what an average CS student should have acquired after four years into a CS program.

IV. PROJECT PROGRESS

A. Seminars

The course started in the first week of September. During the course, five seminars were organized in total at intervals varying from two to four weeks apart. The purpose of the seminars was partly to introduce relevant topics (the first four seminars only) and partly to have the students demo their progress and to summarize their sprint retrospectives (the latter four seminars only). Each seminar was held in a room with video conferencing facilities, and both universities were involved in providing content to each seminar. The topics of the first four seminars were:

- Introduction to the project handbook and the project management and the development tool set. The students were also given suggestions for team formation activities.
- Working globally; communication challenges and Conway's law.
- Estimation and (OO) metrics; common issues regarding project startup.
- Beyond school projects: commercial software development projects and open and free software development projects.

Students would be given the floor first to present their progress, after which, the course staff gave presentations on the listed topics. The fifth seminar was reserved solely for review and retrospective.

B. Communication issues and team formation

Not surprisingly, all teams had issues in team formation and communication. As mentioned above, teams were supposed to select the Scrum Master and Product Owner. This process lasted longer for the distributed team than for the collocated teams. It turned out that making such selection is far from obvious if the team members do not know each other and cannot communicate face-to-face. There was a clear difference in how quickly and easily the local teams were able to solve the team formation issues compared to the global team. Earlier projects have shown that physical meetings at the beginning of project are beneficial [1]. Although the course organizers discussed bringing the students of the distributed team together for a physical meeting, it was not implemented due to financial and resource constraints. Our experience confirms the assumption that a distributed project would be more successful if the team can have a physical meeting, too.

The performance of the distributed team was further worsened by the fact that one of the team members refused to install and run Skype on his personal computer. The team there-

fore ended up spending a significant effort deciding whether the team should use Skype or IRC as the chat tool. When choosing the IRC solution, the team also lost a means for seeing each other while communicating.

The third, and maybe the biggest problem, was related to implementation of Scrum practices. All teams would have benefitted from having Scrum ceremonies and well-managed backlog items. The distributed team would have benefitted from those practices most. The implementation of the Scrum practices also took longer time for the distributed team. At the end, it was clear that a simple set of three questions: "What did you do yesterday?", "What will you do today?", and "Are there any impediments in your way?" contributed to trust within the team in addition to improving visibility. However, it took some time and help from the team mentors to learn the value of the Daily Scrum. The distributed team had also difficulties in implementing the daily Scrum meetings due to lack of face-to-face contact and due to mismatching schedules. To overcome these challenges the distributed team decided to use a shared notebook in Confluence tool and set a deadline by which every team member should write an answer to the standard questions. Apparently, this alternative worked and the team members reported that they really checked the content of the shared notebook late in the evening.

C. Mentoring

As already mentioned, each local team had one mentor. The global team, however, had two mentors, one in Tampere and one in Gjøvik to make sure that each both parts of the distributed project had a local mentor. The mentors kept an eye on the group activities and progress. The teams were told that they could invite mentors to their project meetings on demand.

Local teams did not require much help from the mentor, and the teams just reported about the progress. However, the distributed team needed help from mentors several times. Mentors had to help the team in team formation, and explain to the team how important certain Scrum practices are and how they can solve the current issues of the team. Mentors also had to work together in assessing the status of the team. The help from mentors concentrated on teamwork and organization of the work. No help was needed in technical or software development areas.

D. Deliverables

1) Code

The students were asked to deliver running of software. As already mentioned, they were requested to develop a server providing a REST API implemented in Java. The students were free to choose the front-end technology, but selected Java-based application server. Most students were lacking deep Java server experience and were therefore having some problems developing a working server solution. There were no significant differences between the local and the global teams in terms of delivered software.

There was one observable difference between one of the local teams and the global team when it came to adapting to similar challenges in the team organization. Both teams had assigned two team members to work on the server side but expe-

rienced that the server side development was lagging behind. The local team decided to add a third developer to do server side development when they became aware of the problem. The global team, however, had decided to split work so that the Tampere team members worked on the client side while the Gjøvik team members worked on the server side. This way of organizing the project simplified coordination of the server and the client side activities, when both parts were progressing as planned. It turned out, however, that this way of splitting work was not so good when the server side developers, due to unforeseen resource issues and technical complexities, failed in progressing as planned. There was no server side expertise in Tampere that could be used to assist the Gjøvik server team. The Tampere client side team had developed “their part” but could not sign it off completely since it could not be integrated on tested with the server side and was therefore frustrated with the teamwork as a whole.

2) Documents

The students were expected to document their backlog issues and working hours with Jira. They were also expected to document larger discussions in Confluence. In practice, Jira and Confluence were used scarcely. The main reason, according to the students, was that there were several new tools they needed to learn to use and they felt that they had too little time to learn them all. The students claimed that it would take too much time to learn to use two tools properly. The distributed team, however, did use Confluence as a batch-mode tool for sharing notes from daily scrums.

Additionally, students had to submit two reports at the end of the project: A group report (one per group) and an individual report (one per student). In these reports, the students briefly described the project and the product they had developed. In addition, the students were required to reflect on the experiences and learnings. The team report included descriptions of the developed software, project organization, used tools and conclusion. The personal report was more about time spent in various tasks and about personal learnings.

V. RESULTS AND DISCUSSION

In the following, we will discuss issues particularly regarding team formation and project execution based on the data collected from observations, emails and students’ reports. Some participants of the distributed team were also interviewed in Spring 2015. We will also reflect on our own part of how the offered learning experience could have been improved.

A. Team formation

The distributed team clearly had more difficulties in getting organized work started. The team did also recognize this issue and wrote in their final report “Roles within the project should be clearly defined. In the first sprint, our roles were not clear, and each member had slightly different understanding of what he/she supposed to do.” In a later interview, the members also reported that lack of knowing each other’s skills and other background caused problems during first half of the project.

Although we discussed the opportunity to bring the distributed team to the same physical location, that plan was not implemented. The team formation clearly suffered from that

decision, which was also noted in the end-report of the team: “It would be beneficial for distributed teams to meet up in person during the project kickoff. The team could meet up for a two to three day seminar where the project would be outlined and the basic backlog created.”

We proposed that the distributed team should run a networked game to help team formation, but the team did not use this opportunity. In the later interview, we discovered that the students did not understand the need and motivation for such a game session.

B. Project execution

Based on the outcomes of the projects and the data we collected from the teams’ reports, we may evaluate the differences between the local teams and the distributed team.

Firstly, we can compare the used hours on the project. In Table 1, we present the relative percentages of how teams used their time and the total number of hours they put into the project. Note, that not all students provided such detailed estimation of how they spent their working hours, and so estimation is made based on the data at hand.

TABLE 1. GROUPS' WORKING HOURS

	Development and testing	Learning tools and techniques	Project management (incl. meetings)	Other	Total (h)
Baldr (local)	55%	23%	25%	2%	1521
Freya (local)	44%	24%	29%	3%	1485
Kvasir (distr.)	34%	37%	21%	8%	1545

From Table 1 we can see that the distributed team used a significantly larger amount of time learning the tools and techniques. This is partially because several members from the distributed team reported limited experience with Java, so learning that programming language and libraries took them far more time than more experienced teams. Another reason may be that the distributed team was not able to set up a common session for learning the tools and techniques. A third reason may be that everybody tried to learn everything because the team did not have a clear idea of how to divide work in the beginning. For example, the Product Owner from local team Baldr reported spending a day from 9 AM to 10 PM with his teammates, helping them with programming issues, and that overall their pair programming was very efficient. Local team Baldr also stated in their report that “We also helped each other understand the tools“. This kind of collaboration would have been much more difficult for the distributed team.

From the reported hours, we can also see that the distributed team used less time on project management and meetings than the other teams. The Scrum Master of the distributed team states in her final report that “We knew that being distributed will be a very challenging task for us, so we put very many efforts on solving these problems. However, as it could be seen from group presentations, our problems were similar. Miscommunication, cultural differences, language barrier and

TABLE 2. GOOD PRACTICES

	Good practices	Problems	Changed practices during project?	Other observations
Baldr (local)	XP/Pair programming	Initial project selection had to be abandoned. Work distribution.		"If our team had been a distributed team, we expect that most challenging issue would be building communication, and understanding how each member works."
Freya (local)	Face to face kickoff meeting. Regular meetings in person. The idea of using Scrum was good for this project.	Time estimation for tasks. Dependencies between tasks, availability of group members (when needed to ask about the tasks/implementation). Scrum process was difficult to follow due to conflicting timetables.	Technical solutions to support Maven and Jenkins.	Ensure a face-to-face kick off meeting in the start of the project. Ensure the process should be known by each member in time. Be aware of the cultural change.
Kvasir (distr.)	Regular meetings. Clearly defined roles. Agreed and well-defined distribution of work.	Estimating required work effort was difficult. IRC as communication channel did not work, mostly due to communication and cultural differences.	During the 4th sprint communication practices were changed/improved. A shared Notebook was used to collect Scrum meeting notes. More effort put to updating Jira and Confluence. Increasing number of shorter meetings, group members staying online. Sitewise working sessions.	"It would be beneficial for distributed teams to meet up in person during the project kickoff. During the early planning, it is crucial for all members to understand each others' ideas and visions for the project. This can prevent several misunderstandings later on."

different personalities do happen in ordinary teams, but distributed trying harder to solve them, and thus, can be even more effective."

The observations by the mentors and from students' end reports all indicate that communication was the main challenge faced by the distributed team. Due to lack of face-to-face time, the team had to use communication tools. Due to different personal preferences and communication styles, it was hard to find a common set of tools and common ways to use them. In the end, the project chose IRC as the main communication tool, which meant that the team members did not have any means to see the faces of the members from the other location, apart from the video-based seminars.

Overall, it seems that during the first two sprints the distributed team was not able to work efficiently and spent time in learning the needed technologies, and the actual outcome was a result of very hard work during the last two sprints. We suspect that one reason for low percentage of less reported time for management is late team formation since from the reports it can also be seen that the time spent in initial confusion has not been reported anywhere.

In Table we have collected the groups' experiences from their reports. All groups were asked to report what practices worked for them, what did not work (or where they had problems), what changes they made to their practices during the project, and generally what kind of observations and suggestions they would have based on their experience. Notably, the good practices reported in Table 2 by the local teams are such that would have been difficult for the distributed team to adopt.

Nevertheless, the biggest problem encountered for all teams was the same - estimating the time it takes to complete tasks. The second biggest problem for the local teams was work distribution, and more specifically the dependencies between tasks. The distributed team, in turn, reported that their roles distribution (including the roles of developers to back end and front end) worked well, and they did not find as many difficulties between task dependencies.

In Table 3, we have collected individual students' experiences from their final reports. The students were asked to reflect on their learning experiences, what was the best and weakest thing in their project, what they might have done differently, and other aspects they experienced in the course. The students had very different styles for reporting. In Table 3, we have collected those comments that mostly relate to the learning process and to different aspects of a distributed project. From the table we see that all three teams emphasize the importance of communication. It is clear that the lack of an established communication infrastructure for the distributed team was a major hindrance. The team spent time on agreeing on the tools to use and ended up with a solution that did not proved audio/video communication. The teams also seem to share many of the other experiences.

The one issue that is highlighted by the distributed team only is the cultural issue (cultural difference, respect for each other, language differences). None of the other teams mentioned this issue even though they were all multi-cultural teams. It is likely that cultural issues are easier to solve when the team is physically collocated than when it is distributed.

TABLE 3. STUDENTS' EXPERIENCES

	Primary lesson learned	Best part of project	Other comments
Baldr (local)	Working with less experienced developers. Dealing with uncommunicative and unavailable group members. Building a structured workflow. Task distribution. Importance of communication.	Experience, preparing for the future. "letting us figure things out ourselves".	Weakest part was getting to know and using the management tools. Possibility to have face-to-face meetings made the tools less important. "if I had earlier understanding of culture, habits and complexity of some parts of work, I would do proper planning and change development process."
Freya (local)	Team work, agile methodology, tools. Team building takes time. Communication is important. Time must be spent on project management. How distributed development works. Flexibility of Scrum. Completing small tasks is most efficient. Meeting with the team is a great advantage. Need for good communication, good tool stack and project documentation routines key when dealing with cultural difference.	Working in a team. Process. Overall development framework. Producing an actual product using Scrum.	Communication is a necessary part of team work and cannot be overlooked though some people would rather just product code instead of spend time in meetings. Face-to-face meetings and Skype overruled Confluence and Jira due to ease of use. Team members need to know each other well to be effective. Team members' varying background in Scrum effects the Scrum master's workload. "Now, we were a team composed of different cultures, background and experience, and although we weren't distributed, I got a greater sense of what it means to work on a "real world" project."
Kvasir (distr.)	Communication channels. Respect of other cultures and avoidance of stereotypes. Fast response to others. Using Jira as a main tool (Others can keep track of your done, current and future work). Using Confluence as a formal expression of a topic (it can be logged easily in the future). Several problems in distributed teams are similar to problems that appear in regular teams. Misunderstandings are common when not using face-to-face communication. "Miscommunication, cultural differences, language barrier and different personalities do happen in ordinary teams, but distributed trying harder to solve them, and thus, can be even more effective."	Learning how to communicate, respect each other, enhance tolerance, work in a group, learning new things from others and so on. Learning roles in the Scrum methodology. Developing the client part of the application. Division of work.	Live audio and video should be preferred over text only. Overall productivity not too different from local teams. All teams had similar challenges. Deciding roles by ourselves was difficult, too much freedom hindered the project setup. Misunderstandings delayed development. "The weakest part of the project is probably the slow start of communication from the very beginning. If good communication had been in place early, more time could have been spent productively, resulting in a better product. The communication affects all parts of the project planning, which then affects the final product."

C. Reflection

In a normal company environment, the organization guides and helps team formation. The teams are not asked to select critical roles such as product owners. In addition, teams typically have organic growth - which means that teams are not built from solely people that do not share any past experience. In this course set-up, the teams were asked to self-organize and the teams were built from scratch. The distributed team had to adapt to shortcomings in this respect since self-organizing without physical meeting is more difficult and the students from different sites did not know each other in advance.

Although principles of Scrum can be explained in 15 minutes, it cannot be fully learned in such a short time. In addition

to telling the rules of Scrum, therefore, the students should get some "hands-on" experience and learn the reasoning behind the Scrum practices. Thus, the theoretical knowledge about Scrum is best learned by the help of more experienced persons. In our course, all students had about a similar knowledge about Scrum, but the distributed team would have benefitted more from adopting Scrum from the very beginning. Thus, we believe that the first sprint should have been run by the teacher mentor who should play a more active role but still not solve the problems on behalf of the students.

The project was run in autumn 2013 and in retrospect, we recognized a few problems that we wanted to fix for 2014. Those issues and planned solutions were:

Issue: Too few people from Tampere volunteered to international version. We thought that one reason was lack of company contact - local version worked in collaboration with local industry.

Solution: We asked our partner companies to indicate which topics welcome international team. Three topics out of 37 welcomed international teams.

Issue: Students had to learn many tools during the first sprint and create many things "from scratch".

Solution: Having a separate "sprint zero" of two weeks just for learning the tools by the means of an example project.

Unfortunately, for 2014 we got even less volunteers since all Tampere students preferred the traditional local option. Once the traditional project course had ended, we asked students their reasons for not selecting the international version as an additional question in our standard feedback system. The answers we received can be summarized as follows:

Clearly, the biggest reason was the extra complexity and "hassle" the students expected. Twelve (12) responses included a comment on generic complexity of the set-up.

The second area of concern was related to team dynamics. In a few cases, a group of students wanted to work together, or there was at least a wish to work with students that were familiar already. Nine (9) responses included that element.

In addition, five (5) students also expressed concerns of communication explicitly. Tighter schedule was mentioned five (5) times and fear of more work four (4) times. Uninteresting topic was mentioned only five (5) times. Three (3) responses indicated that they had considered but in the end selected differently.

This feedback shows that the students are well aware about the issues of GSE, but did not want to take the challenge as it was seen as extra work or hassle. The summary also shows that the organizing the GSE course as a separate course might work better than having it running as an alternative way to the traditional project course. In the future we should try an option where two local teams collaborate, but are different Scrum teams.

VI. CONCLUSIONS

Our experiments show that if an agile team is distributed, it faces more problems compared to local teams. Our project therefore supports the recommendation that agile teams should be colocated. In addition, we have learned to run a distributed project course that can teach the students valuable lessons in project management and distributed development. We have also discovered that very similar recommendations that literature - like [19] - recommend to actual projects work for project courses, too. The recommendations include:

- Organize face-to-face meetings every now and then, at least in the beginning.
- Pay attention to team formations and provide help for that. Self-organization does not work.

- Provide good and standardized communication tools. For the team it will take long to bootstrap communication tools.

The end reports and the later interview showed that the students have learned well the issues and challenges of global software development.

ACKNOWLEDGMENT

The authors would like to thank all the students participating on the course and all other personnel involved.

[‡]Federal University of Alagoas – Alagoas, Brazil

Abstract—This paper presents a framework for building mechanisms for automatic analysis of introductory programming exercises. This framework consists of a structure that provides the combination of different types of analysis mechanisms, providing the configuration of various families of analyzers. One of these analyzers is based on a tree inclusion mechanism that verifies whether a particular structure (i.e. combination of language constructs) is contained in a solution. For evaluating our proposal, we conduct a study with 232 submissions from two introductory programming classes. The results indicate the following groups of students: one group that failed on syntactic and functional correctness stages; eight groups that submitted solutions with similar structure. Finally, the results provide evidences that is possible to identify different templates of correct solutions.

Keywords—Computer Science Education, Introductory Programming; Code Analysis.

I. INTRODUCTION

Learning to program, especially in introductory classes, has been defined as a complex task and, therefore, has been the subject of several studies, including being labeled as one of the greatest challenges in computer education [1]. Typically, the introductory classes have a large number of students, and consequently exercises. On that point, provide feedback in a timely manner shown an extremely onerous task, causing overload on the lecturer [2].

In this context, some tools have been used to provide automatic verification of solutions and immediate feedback, reducing the lecturer workload. Usually, the Online Judges verify the syntactic and functional correctness of a solution based on the application of a set of test cases (e.g., [3], [4], [5]). However, this approach takes into account only the performance on these

tests, and does not provide a more detailed information about the solution. Thereby, the traditional tools are not able to identify less suitable solutions and, either, to suggest improvements in student code.

About this aspect, it is possible to highlight a number of initiatives that are beyond the rule and have different analytical perspectives about a programming solution. The work of [6] uses a set of software engineering metrics to analyze the quality of the built program. The work [7] uses metrics of structural similarity and one analyzer to verify the occurrence of certain control structures. The work [8] uses an approach that aims to train students' ability to find errors in a program.

In this work, we present a framework for building code analyzers. This framework consists of a structure that allows the combination of different types of analyzers (e.g., Syntactic, Functional, Similarity, Constructs, among others). We designed this mechanism based on two complementary views: the conceptual view uses a multi-criteria decision-making technique called Valuated State Space [9]; the computational view uses the Decorator Pattern for building different configurations of analyzers (e.g., a syntactic analyzer combined with a functional correctness analyzer and a structural similarity analyzer) [10].

To evaluate our proposal, we present an analysis of solutions from two classes of introductory programming course at Federal University of Alagoas. In this study, we analyze solutions of one activity that correspond to the concepts of variables, inputs, output commands, operators and expressions. We analyze each one of the solutions using a set of structures. Thus, we expect to identify both the least appropriate correct solutions, which uses unusual buildings, as the most appropriate correct solutions, which uses a set of ideal and concise constructs.

The results suggest a set of students who have syntactic and functional correctness errors; a set of students who present structurally redundant solutions; and a group of students who submitted highly concise solutions.

The remainder of this paper is structured as follows: in section 2 we present related work, in particular work that use some kind of approach to analyze codes; in section 3 we present our proposal with the conceptual model and the computational model; in section 4 we present the configuration of our experiment; in section 5 we present and discuss the results of the experiment; finally, in section 6 we present our conclusions.

II. RELATED WORK

For the related of work related we focus on approaches that presents some differential with relation the centered only in verification of inputs and outputs. For those approaches, we aim to evidence its limit and possibility front to framework here proposed.

The work of [6] utilize a set of metrics of software engineering for analyze the quality of the solution. Differently of our approach, the authors do not use other type of analysis. However, the approach based on metrics of quality shows interesting and could be integrated to our framework in order to increase the coverage of mechanism of analysis.

The work of [7] present a mechanism that combine a structural analyzer (i.e., similarity analyzer) and an analyzer of constructs. This approach use the idea of combine different analyzers to provide a more embracing verification. However, one of the differentials of our framework is the conceptual basis defined by the Valuated State Space technique, and the logic architecture that allows easy extension and reconfiguration of analysis mechanisms

The work [8] uses an approach that aims to train students' ability to find errors in a program. The works of [11], [12] use an approach based on peer review to training the students analytical skills. Such work could be further integrated into our framework and thus would provide a wider range of tools for teaching programming.

III. PROPOSAL

Our framework is based on the composition of different types of code analyzers (e.g., syntactic analyzer, functional correctness analyzer, structural analyzer, construct analyzer, among others). This arrangement aims to provide a more

comprehensive analysis, because it allows the verification of different aspects of a code. Thus, we will present three complementary visions to this framework. The conceptual model aims to define the basic concepts of the analysis mechanism, basing its operation on a multi-criteria decision-making technique called Valuated State Space [9]. The tree inclusion model aims to define the basic concepts of the constructs analyzer, basing its analysis on a graph theory approach [13]. The computational model aims to define an architectural foundation for the framework, highlighting its extension points through the use of a set of Software Design Patterns [10].

A. Conceptual Model

Conceptually a programming problem consists of two distinct elements: a set of statements that should provide a clear and objective instruction of the problem to be solved; and a set of constraints, which define the criteria that must be complied in the proposed solution. Such criteria may define a set of allowed programming languages, a set of unit tests, a set mandatory language constructs, a set of reference solutions etc.

In this context, a set of analyzers aims to verify whether a solution violates a restriction of the problem. Each analyzer is defined by a function that determines the level of conformity between a solution and a particular restriction, where the maximum value represents maximum conformity and the minimum value represents minimal conformity.

Definition 1: Let P and S , respectively, a problem and a solution, there is a set of mechanisms that analyzes attributes of this solution. These mechanisms are defined by $A : P \times S \rightarrow \{a : 0 \leq a \leq 1\}$, where each $a \in A$ denotes a particular analysis mechanism.

To quantify the analysis we use a technique known as Valuated State Space [9]. In this technique, a decision maker (e.g., an expert in programming) determines a level of influence for each analyzer (e.g., a gradual scale of 0 to 5). Thus, each analyzer might present different degrees of influence in the resulting score.

Definition 2: Let A a set of mechanisms for analysis, there is a level of influence for each analyzer. The levels of influence are defined by $L : A \rightarrow \{l \in \mathbb{N} : 0 \leq l \leq n\}$, where each $l \in L$ denotes the level of a particular analyzer and the constant n denotes the maximum value of the scale.

The set of levels represents a more intuitive weighting scheme; however, it is necessary to relativize these values, to define a

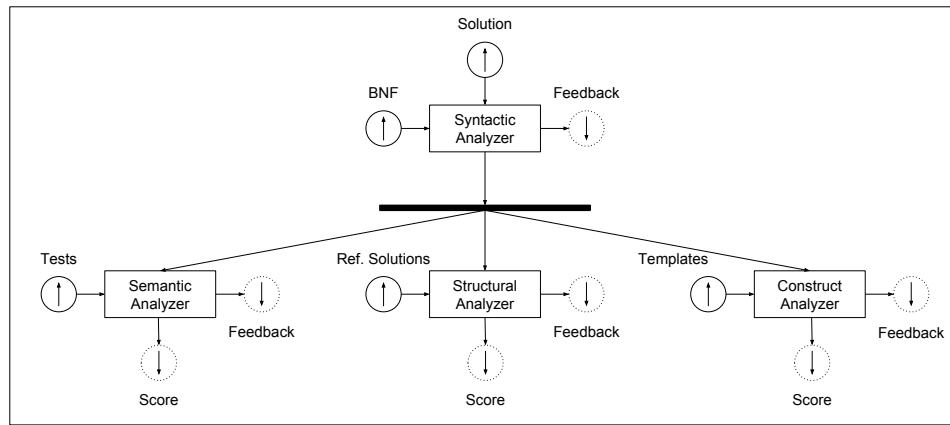

Fig. 1. Conceptual Architecture: the structural analyzer utilizes similarity metrics to compare a proposed solution with a set of reference solutions; the constructs analyzer uses graph theory techniques to determine whether a given solution satisfies a particular combination of constructs of the language; each analysis generates a score and a feedback that can be used by students and lecturers.

resulting score in the range between 0 and 1. Therefore, we define a set of weights to measure this resulting score.

Definition 3: Let L the set of levels, there is a weight for each of its elements. The weights are defined by $W : L \rightarrow \{w \in \mathbb{R} : w = l/\text{sum}(L)\}$, where each $w \in W$ denotes the weight of an analysis mechanism and sum denotes the summation of the elements in L .

To obtain the resulting score, we compute the product of the powers. From this combination we obtain the resulting score, where each of the analyzers present its “contribution” to the final score.

Definition 4: Let P and S , respectively, a problem and a solution, a function $\text{score} : P \times S \rightarrow \{s \in \mathbb{R} : s = \prod a(P, S)^w\}$ aims to assign a score that results of the combination of each mechanism of analysis $a \in A$ and its respective weight $w \in W$.

In short, this mechanism has the function of analyzing a particular solution from different perspectives, providing a more comprehensive view and extracting a score based on criteria defined by a human expert.

B. Computational Model

To build the computational model we used an architectural style based on Pipes and Filters. This architectural style defines a set of elements (filters), and a processing flow (pipes), allowing different configurations of the elements. As illustrated in Figure 1, the analysis mechanism defines the parser as the initial element of the process and, from this, branches the

process through the other analyzers.

To model the structure of analyzers we use the Decorator Pattern, which aims to attach additional responsibilities to an object (see Figure 2). This pattern defines an abstract entity to represent the common features between the various types of analyzers.

To build the Syntactic Analyzer we combine two design patterns: Builder Pattern, which aims to abstract the parsing mechanism and consequently the construction of the Abstract Syntax Tree; Composite Pattern, which aims to compose objects into structures to represent an Abstract Syntax Tree. The combination of these two patterns defines an extension point to abstract the programming language used in the solution.

To build the Filter Analyzer we use the Template Method Pattern, which aims to define the skeleton of an algorithm allowing its subclasses redefine certain steps without changing its structure. In this sense, it defines an extension point that delegates the responsibility of verify the conformity between the solution and the restrictions of the problem.

Finally, we use other Patterns to provide some desired features. The Strategy Pattern encapsulates traversal tree algorithms, which are used in structural analyzers, and constructs analyzers. The Factory Pattern defines a central point for the creation of traversal algorithms. The Collecting Parameter stores the information obtained from the execution of the analyzers in order to provide feedback to the user.

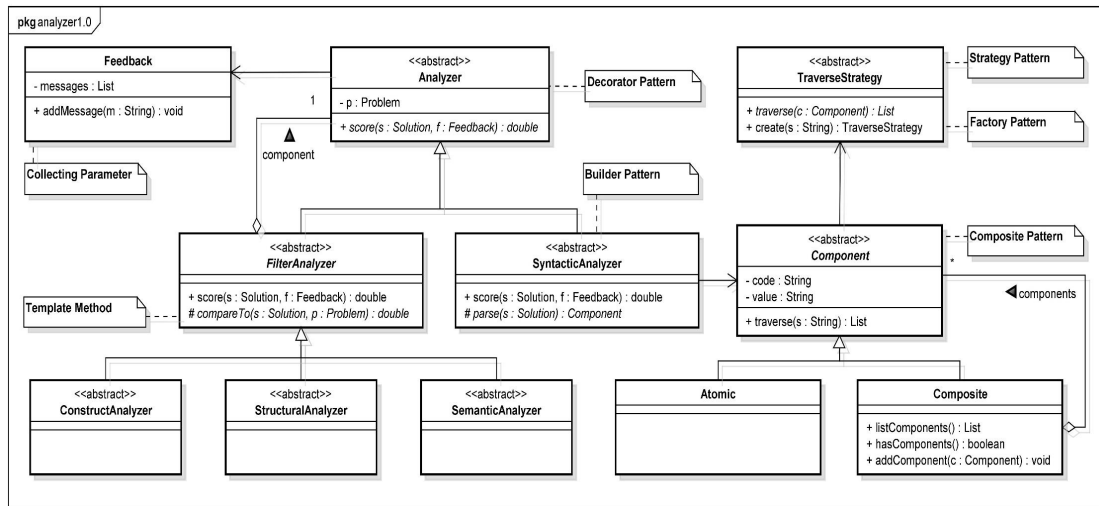

Fig. 2. Logic Architecture: the abstract Analyzer represents the common features between the various types of analyzers; the Syntactic Analyzer defines a specific analyzer, which will be the basis of all the analysis process; the Filter Analyzer defines an extension point for creating filters, which might be attached to the Syntactic Analyzer

IV. EVALUATION

To evaluate the framework we made an initial study with codes submitted by students from 2010 and 2013 classes of Introductory Programming from the Information System course at Federal University of Alagoas, Brazil. Methodologically, we define this study based on the following sections.

A. Planning and Execution

We analyze 232 codes submitted in one homework of the course. In this homework, the students must be able to create a program to calculate the value of an account based on price and quantity of each item consumed. We define each solution as an experimental unit of the study and define the following variables:

I : Submission	(ordinal with $1 \leq x \leq 232$)
D_1 : Syntactic Score	(continuous with $0 \leq x \leq 1$)
D_2 : Correctness Score	(continuous with $0 \leq x \leq 1$)
D_3 : Constructs Score	(continuous with $0 \leq x \leq 1$)
D_4 : Structural Score	(continuous with $0 \leq x \leq 1$)

For the execution of the study we use an instance of the framework that contains the following combination of analyzers: Syntactic Analyzer based on Python 3.x, standard language used in the discipline; Structural Analyzer based on the similarity metric known as Levenshtein Edit Distance

of [14], to analyze the similarity with the reference solution provided by the lecturer; and Constructs Analyzer based on the technique known as Tree Inclusion [13], to analyze compliance with a predefined control structures.

In this study, we do not use the correctness analyzer, considering that the lecturer did not define a standard format for input or output data. Therefore, we perform a manual inspection to establish that score. In addition, we define the constructs analyzer with only one template based on the constructs of the reference solution (i.e., a set of assignments followed by an expression to calculate the total bill). As we are analyzing the programs, we will introduce other templates if necessary.

V. RESULT AND DISCUSSION

The results of the study are summarized in Figure 3, Figure 4, Table I and Table II. Considering these results, we start a discussion in order to highlight the following aspects:

Syntactic Analysis: the results show a low number of students ($7 \leq x \leq 15$) who cannot overcome the syntactic barrier. A manual inspection revealed several types of syntactical problems: solutions described in the algorithmic language; solutions containing the records of the interactive mode of Python; solutions described in older versions of language Python; other more basic syntactic errors, for example, errors in the use of variable identifiers.

Correctness Analysis: the results show a low number of students ($9 \leq x \leq 14$) that cannot overcome the barrier of

Fig. 3. Analysis of Submissions (Syntactic x Correctness): the lower bars represent the number of solutions that have failed in the parser; the top bars represent the amount of solutions that failed in the correctness analyzer; and the higher rates represent the percentage of solutions which failed in one of the two analyzers.

Fig. 4. Analysis of Submissions (Structural x Constructs): the central indices represent the average similarity for submissions of a group; the lower indices represent one standard deviation below the mean; and the lower indices represent one standard deviation above the average.

correctness. A manual inspection revealed several types of errors: misunderstanding of the problem statement; misunderstanding in the use of variables; misunderstanding in the use of expressions.

Constructs Analysis: the results show about eight different types of solutions. The solutions can be summarized from the most concise (Group 1) to the less concise (Group 8). The most concise solutions have only the necessary operations for data entry and only one arithmetic expression to perform the calculation. The solutions least concise solutions have more

input operations than the necessary, more variables than the necessary, and that expression is break in up to four other expressions.

Structural Analysis: the results show an average rate of compliance with the reference solution ($0.3 \leq x \leq 0.6$). These results corroborate the formation of groups of students and show that the solutions of first group are more similar to the expected solution. However, the eighth group present the least similar to the reference solution and have a set of unnecessary structures.

TABLE I. ANALYSIS OF SUBMISSIONS: GROUPS OF SUBMISSIONS

Template	Constructs

	id = input()
	id = id * number
	id = input()
	id = id * number
	id = input()
	id = id * number
	id + id + id

In summary, our study provided evidence that is possible to identify various types of unexpected behavior in the solutions, for example, use of old versions of language, use of non-expected structures, use of redundant constructions, among others. Conventional analyzers might not notice such features, given that they generally perform only syntactic and functional correctness verifications. In addition, our framework allows the configuration of different types of analyzers (e.g., plagiarism analyzer, cyclomatic complexity analyzer, readability analyzer) and new versions of existing analyzers (e.g., new similarity metrics for comparison).

VI. CONCLUSION

We presented the design of a framework for building analysis mechanisms for introductory programming solutions. In this framework, we define a conceptual model based on the Valuated State Space technique, and a computational model based

TABLE II. ANALYSIS OF SUBMISSIONS: GROUPS OF SUBMISSIONS

on Software Design Patterns.

About the results is important to emphasize the identification of different groups of students, among which can be highlighted: students with problems the syntactic and correctness level; students with problems using control structures; and students with problems in building solutions that maintain a minimum level of compliance with the expectations of the subject lecturer.

Finally, we expect present a contribution to the introductory programming area. In this sense, we planning to developed new types of analyzers and perform further studies in order to ensure greater coverage of the approach.

Abstract— For many engineering students, freshman programming represents one of the hardest courses for them to master. Unlike other science fields, few students are routinely exposed to programming in the K12 system. This can make the freshman programming course daunting. However, in the field of software engineering, success in this area is vital, as success in nearly all future courses requires mastery of this skillset.

In the engineering field, we find that many students are visual learners. These students learn best by seeing, and they can perform very well in the classroom with the appropriate usage of teaching styles. However, when it comes to providing feedback to students on submitted assignments, the main method employed is the written comment, which is not conducive to visual learners. From a faculty member's standpoint, this makes sense, as it is the simplest form of feedback. However, written feedback is often ineffective at improving student performance, as many students simply do not read the comments because the students feel they are not relevant to their performance. This can be compounded in the freshman year, as students are still learning what is meant to be an effective college student.

At higher levels, an alternative feedback mechanism, namely asynchronous multimedia feedback, has shown great promise. In lieu of written feedback, students are provided feedback for software engineering exercises through the use of a short video made via video capture. The video captures in multimedia format the instructor's perceptions and actions when grading a given assignment. The video shows, in real time, what the instructor saw, whether it is a program crashing or the successful operation of the program. Furthermore, it provides the instructor the ability to potentially fix simple blatant errors and see the instructor's debugging strategy. The article describes the pedagogical foundation for the technique, specifics of the technique used, student perceptions of the technique, and an assessment of the learning gains from using such a method in an introductory freshman programming course. In general, students are shown to prefer the technique versus traditional grading, and a statistically significant improvement in overall outcomes for the experimental course is shown to exist. A statistically significant correlation between the watching of videos and outcomes is also shown.

Keywords—asynchronous feedback; video feedback; assessment; grading

I. INTRODUCTION

Students receive many forms of feedback throughout their college experience. Feedback has been shown to be the single

most powerful influence on student success [1]. Hounsell states:

"It has long been recognized, by researchers and practitioners alike, that feedback plays a decisive role in learning and development, within and beyond formal educational settings. We learn faster, and much more effectively, when we have a clear sense of how well we are doing and what we might need to do in order to improve." [2]

With appropriate feedback, students are able to master the material. Without appropriate feedback, mastery can be a daunting task. Appropriate feedback must meet many different criteria. First and foremost, it must be applicable to the student [3]. It must be delivered in a timely fashion: taking too long to provide the feedback to students means they have forgotten the purpose for the assignment or have lost interest in the assignment because they have moved on to other things. Feedback must be appropriately engaging to the student as well, for if the feedback is not engaging, then the student may not read the feedback, defeating its purpose. Lastly, the feedback must be relevant to the assignment and the needs of the student [4].

The traditional form of feedback provided to most students is the written comment [5]. Traditionally, faculty marked up hard copy reports, commenting on coding style, algorithms, and other issues. This was then returned to the student at the next meeting. While newer techniques can be employed, for example, marked up pdf files or typed comments in code submissions that are returned electronically, the main feedback is still in the written format. This approach, the traditional written comment, generally is ineffective, as it is a static monologue between the instructor and the student [6]. Research has shown that feedback can be more effective when conveyed in a variety of modes [6].

In past studies, it has been shown that for many problems, other types of feedback can be more effective. In some areas, verbal feedback has become common. Traditionally, verbal feedback has been employed more in a mentorship role. However, modern technology allows it to be used in the more traditional classroom environment. Reference [8] provides details of a program in bioscience whereby feedback was given to students' as mp3 files. Students felt the feedback was of better quality, easier to understand, had more depth, and much more personal than traditional feedback. There also was a greater emphasis on developmental aspects of learning with this method. Reference [9] shows that students overall favor

audio feedback, especially those in the undergraduate population and those with learning disabilities.

In the computing field, the next natural advancement beyond verbal feedback is multimedia feedback. With multimedia feedback, feedback is provided to students through a short video recording the events which transpired during a grading session. In the case of computer programs, this may be program crashes which the students didn't expect, test cases which resulted in unexpected behavior or code that may or may not compile as submitted. The video provides irrefutable evidence to the student of these scenarios, which again leads to more effective feedback [6].

II. PREVIOUS WORK

Previous work on asynchronous multimedia feedback has looked student impressions of the technique as well as provided high level analysis of its effectiveness. Reference [10] provided details on a pilot study of a tool, ASSET, which allowed staff to create video feedback to students, and showed

that the technique was advantageous to both students and staff, as it addressed many of the common problems of feedback. References [11] and [12] again provided a qualitative assessment on the impact on students of video feedback, indicating that students felt that the technique was highly individualized, supportive, and motivating, as well as clearer and more detailed than traditional methods. Reference [13] first looked at the overall process and examined student's thoughts on the process, and showed similar results to [10]. Overall, students were found to like the process, and based upon self-reported data, did watch the videos. References [14], [15], and [16] expanded upon this by with further analysis through short Likert surveys of student sentiment toward the process and also expended the analysis across multiple courses at different institutions. Reference [17] compared lab performance across different years based on whether or not multimedia feedback was employed as a grading technology, and demonstrated that there were gains in lab scores in the year which employed asynchronous multimedia feedback. It also further confirmed that students preferred asynchronous multimedia feedback.

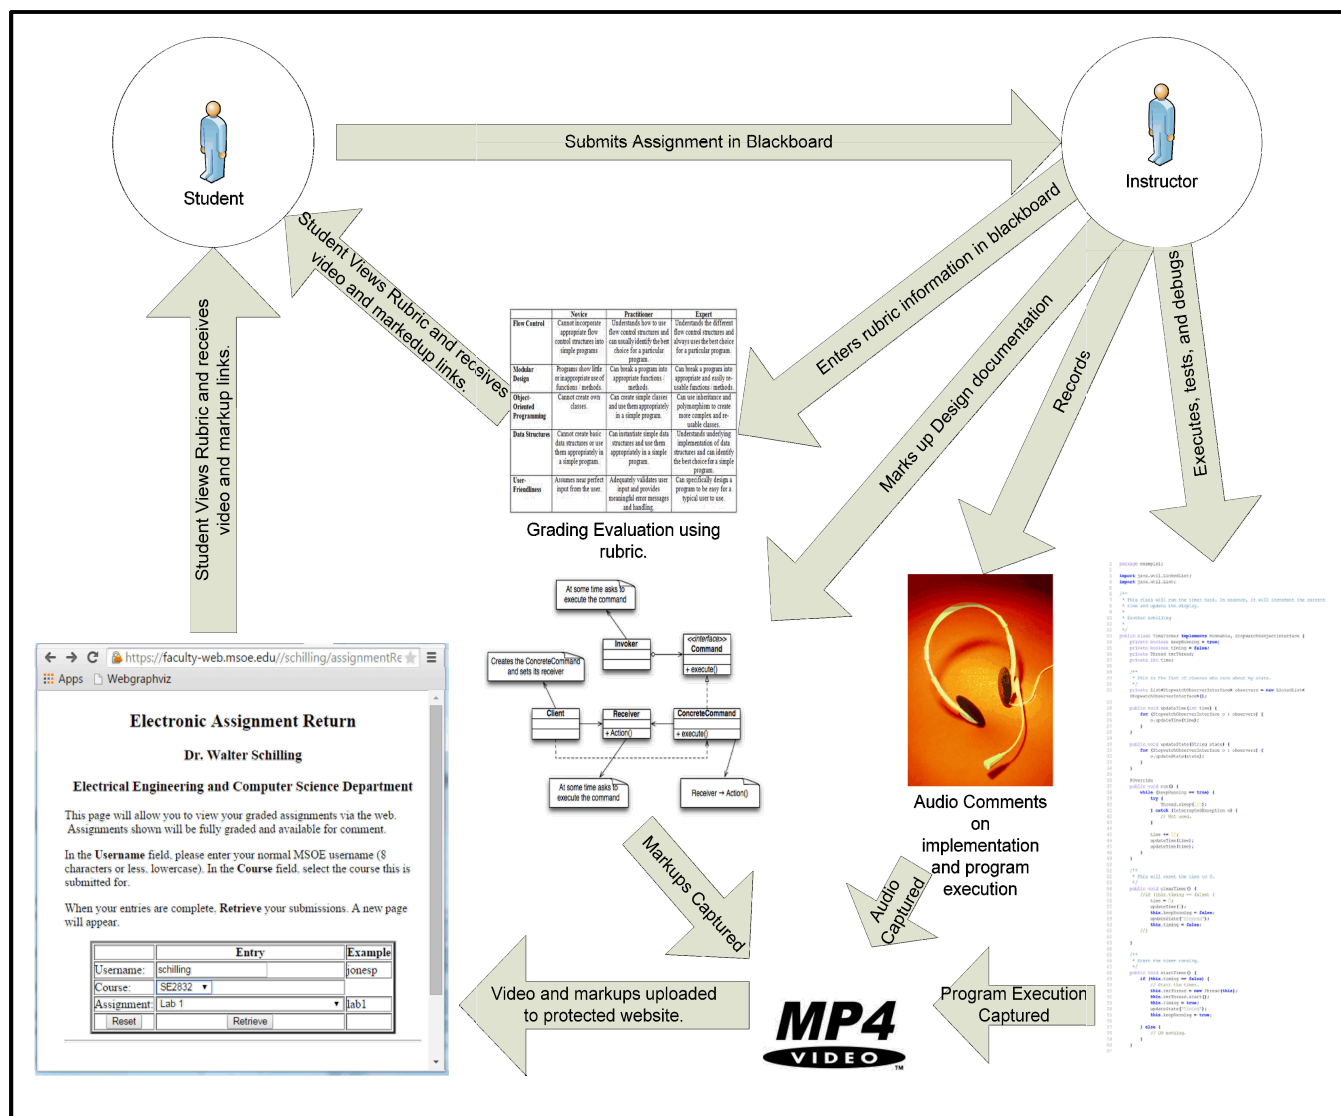

Figure 1: Asynchronous Multimedia Feedback Process

III. AN OVERVIEW OF ASYNCHRONOUS MULTIMEDIA FEEDBACK

Multimedia grading uses many of the same production techniques as the flipped classroom, in that the instructor creates a video during the grading session, excepting that the video is customized to each student or student team based on submitted work, and the focus of the video is to provide targeted meaningful feedback to the student rather than to introduce a new concept. This is, in some manner, more difficult than the traditional usage of videos, as the traditional usage of videos requires the instructor to carefully design the video to maximize all students' learning whereas this approach generates a customized video for each student or team.

The process, shown in Figure 1, begins with a traditional assignment. In this particular case, students uploaded Java implementation code and a lab report to the Blackboard course management system. The instructor then downloads these files and grades them. In grading, the programs were actually compiled and executed on the instructor's machine. While this was occurring, the instructor's screen was captured using a screen capture program (Microsoft Expression in this example). The screen capture program also captured audio narrative of the grading session. This video would capture any program crashes, execution failures, or other problems with program execution in real time. Additionally, the instructor was able to provide a verbal critique of the source code, commenting on code commenting styles, structural issues, and other problems. In certain cases, it was also possible for the instructor to fix simple mistakes in implementation, demonstrating to the student how their submission could be improved with simple corrections.

At the end of the grading session, a grading rubric was filled out which calculated a numeric score for the submission. The videos were post-processed offline and uploaded, along with marked up pdf files of lab reports, to a secure website. When students logged into the course management system, they were provided with both the numeric score for the assignment as well as a link to the files in the secure website.

While this approach may seem to overwhelm the instructor, the overall impact on grading versus traditional approaches was not found to be significant. Reference [14] indicates that there was less than a 5% difference in grading time when compared with traditional approaches.

IV. EXPERIMENTAL OVERVIEW

Previous work has left many questions unanswered. While [6] did show improvements in lab outcomes, data was not available to normalize the cohorts, potentially introducing bias into the results. The other papers mainly focused on student sentiment and included self-reported results of students watching videos. The other papers also focused on upper classmen, and while meaningful, research has shown that retention is highly correlated with the freshman experience. Thus, it would be very useful to have information related to freshman performance, as if the technique increases engagement it is also likely to aid in improved retention.

The goal of this experiment was to attempt to judge the impact of asynchronous multimedia feedback on freshman programming students. The goal was to numerically measure differences in achievement between students who were taught in a "traditional manner" as well as students who received asynchronous multimedia feedback. Additionally, a goal was to directly measure whether the students watched the videos and correlate the performance in class with watching the videos. A final goal was to reaffirm student sentiment that this approach is a worthwhile approach. While the last objective is duplicative of the previous work, the fact that the previous work has focused on upper classman makes the sentiment of freshmen particularly important to understand.

To do this, a cohort of students in the second freshman programming course was studied. This cohort excluded students who had not taken the first programming course in the previous quarter, students who were retaking the second programming course due to poor performance in previous offerings, and students who had received either advanced placement or transfer credit for the first programming course. By defining the cohort in this manner, it was possible to eliminate as many variables related to previous preparation as was possible, as all of the students received the same training going into the second course.

At MSOE, all students enrolled in the freshman programming courses take a common final exam at the end of the quarter. The final, drafted by all instructors teaching the course, is carefully designed to match the daily course outcomes and coverage for the given quarter. Grading is also distributed amongst faculty teaching the course, in that no single faculty member grades an entire student's exam. Rather, faculty members are responsible for grading one or more problems on the exam, and the final exam score is obtained by summing the subscores of individual problems from the faculty members grading those problems. This mechanism, initially intended to improve grading efficiency, also avoids instructors injecting bias into the scoring of the common final exam.

Given that the cohort of students being studied had taken the common final exam the previous quarter, it was possible to use this exam as a normalizing factor for the control and experimental groups. While not perfect as an assessment tool, the exam offers a non-biased mechanism to assess student learning as of the end of the first course, and given the nature of the study, also serves as a pre-requisite assessment for the second course.

To determine whether or not students watched the videos, a secured website was instrumented to provide a log of when students' accessed the feedback videos as well as what items were viewed. This was obtained for all students in the experimental class, and thus allowed student achievement for students to be compared versus the number of videos watched. This data, however, did not include the exact same cohort as the first portion of the experiment. Rather, all students enrolled in the experimental section were compared, not just those who had taken the preceding programming course during the previous quarter. This increase, however, does not introduce bias into the experiment.

Table I: Final Exam Initial Analysis

	All Students			Students in Studied Cohort		
Final Exam Score	Mean Score	Median Score	Standard Deviation	Mean Score	Median Score	Standard Deviation
First Programming Course	78.18%	82.50%	14.90%	82.78%	84.50%	9.38%
Second Programming Course	77.04%	79.00%	12.66%	75.35%	77.00%	12.61%
Delta	-1.14%	-3.5%	2.24%	-7.43%	-7.5%	3.23%

Lastly, to judge student sentiment toward the process, a simple Likert survey was given to all students enrolled in the experimental section. This judged what they felt about the course as well as provided for free-form comments on the technique. From this, student sentiment toward the process was to be assessed.

V. INITIAL PERFORMANCE ANALYSIS

The first aspect to address was to assess the validity of the cohort studied versus all students who had taken the courses. To analyze this, the mean, median, and standard deviations for the exam (shown in Table I) were analyzed. This data showed that there was a small but significant difference between the scores of all students who took the first exam and students who took the first exam and were in the studies cohort. This difference, however, had a logical source. The cohort, by definition, excluded students who did not pass the first programming course, as they were not enrolled in the second course due to a prerequisite issue. Thus, it would be expected that the overall average for all students who took the final would be slightly lower than those in the cohort. On the second exam, there is a small but insignificant difference between the cohort group and all students who took the exam. This small difference is caused by high achieving students who had AP credit and transfer credit who took the second exam but not the first, resulting in a slight bias toward all students versus the experimental cohort.

With the validity of the cohort established, the next aspect to address in the data was the performance of the cohort overall between the first course's final exam and the second course's final exam. In this case, non-normalized scores were used. On the first final exam, the scores were approximately 7.5% higher than on the second final exam. Additionally, there was less

deviation in scores on the first midterm exam.

This difference can be attributed to several factors. First and foremost, by definition, the cohort excluded students who did not pass the first programming course. Thus, the performance on the first exam would be higher because the lowest scores on the first midterm would be excluded from the study cohort. Additionally, some decrease in performance is expected, as the second course is a more difficult course than the first course.

With the cohort group established, the cohort group was broken into two groups, an experimental group and a control group. This division had effectively occurred during registration as students were randomly distributed to the different sections based upon scheduling and registration times. Four sections, deemed the control group, were taught by different faculty members, and a fifth section, the experimental section, was taught by a fifth faculty member. Three of the five instructors had taught the course before, while two of the instructors were new to the course (including the instructor teaching the experimental section.) The courses were taught to the same list of outcomes and used common lab assignments. Faculty members met weekly as a teaching team to discuss course status and impediments to success. Faculty members also shared exam materials for midterms, though exams were not identical outside of the final exam.

The first analysis that was conducted was to determine if there was an initial bias in the scores of the experimental group or the control group on the final exam for the first programming course. The raw data, given in Table 2, was analyzed for the control group and the experimental group. Even though there was a slight difference in the mean score, among the students in the study groups, there was no statistically different performance between the students in the control group ($N=56$, $M=82.10$, $SD=14.64$) and the

Table 2: Final Exam Initial Analysis without normalization

	Raw Control Group Data (n=57)			Raw Experimental Group Data (n=14)		
Final Exam Score	Mean Score	Median Score	Standard Deviation	Mean Score	Median Score	Standard Deviation
First Programming Course	82.10%	83.50%	14.64%	85.50%	86.00%	5.50%
Second Programming Course	73.50	75.00%	12.51%	82.86%	87.00%	9.36%
Delta	-8.60%	-8.50	-2.13%	-2.64%	1.00%	3.86%

experimental group (N=14, M=85.50, SD=5.50), $t(68)=1.21$ $p \geq .05$ CI_{.95}= -2.21 to 9.01. Therefore, we fail to reject the null hypothesis that there is no difference in performance between the experimental and control groups. The control group did exhibit a slightly larger variance in performance versus the experimental group, but it also was a larger group as well.

Being unable to detect any statistical differences between the performance of the control and experimental groups on the final exam from the first course, analysis then moved onto the second exam. This exam, conducted at the end of the second programming course, was also analyzed for performance differences. Among the students in the study groups taking the second exam, there was a statistically different performance between the students in the control group (N=56, M=73.50, SD=12.62) and the experimental group (N=14, M=82.86, SD=9.71), $t(68)=2.52$ $p \geq .05$ CI_{.95}= 1.86 to 16.01. Therefore, we are able to reject the null hypothesis that there is no difference in performance on the second exam between the experimental and control groups.

VI. ANALYSIS OF VIDEO VIEWERSHIP

A second answer that this study desired to answer was whether or not the students actually watched the videos, and what impact this had on their success in the class. References [13] and [14] indicated, through student self-feedback, that a majority of students watched most of the videos. However, this was self-reported data, and the problems with self-reported student data are well known. Subjects tend to report what the researcher would like to see, as well as tend to report positively on their own abilities, knowledge, beliefs, and opinions [17], [18]. Furthermore, since the data regarding video viewership was collected at the end of the quarter, there is a chance that the students did not remember specific details of their viewership. This fallibility of memory is a concern raised by cognitive scientists with self-reported data [18].

To analyze this data, we started by looking at the difference in time between when the assignment was first released to students via the learning management system and when the students first viewed the video feedback. On average, our results found that 65% of the videos were viewed in their entirety an average of 1.35 days after the assignment was graded and returned to the students. This ranged from a high

Figure 2: Scatter plot of Videos watched versus exam score

of 76.4% on the first video to a low of 52.9% on the last video. The majority of videos were either watched on the day they were returned or the next day. However, given that most assignments were returned around 18:00, one can safely state that the majority of the videos were watched within 30 hours of being returned. Several students actually watched parts of the video more than once. This second viewing was often found shortly before the next assignment was due, indicating that the students were potentially reviewing feedback before submitting the next assignment.

From this analysis, we believe that we can conclude that the students felt that the feedback was received in a timely fashion. The fact that students believed that feedback was received in a timely fashion was further collaborated by the results of Likert survey, where 90% of students strongly agreed with the statement "The professor provided helpful feedback on student assignments and exams."

This data, in general, appears similar to that which was self-reported by students in the previous works [13] [14].

A second goal of this analysis was to determine if there was a relationship between viewership and performance on the final exam. Figure 2 shows a plot of the number of videos watched versus the performance of students on the common final exam for the course. Due to the small number of videos, the data could not be compared using traditional linear regression approaches. Instead, correlation was analyzed using Spearman's Rank-Order Correlation. The data set was found to have a weak but significant correlation coefficient $\rho(15)=.49$, $P=0.042$.

This relationship, while present, can not necessarily prove causality. From the research, it is not possible to determine if the students did better in the course because they watched the videos or if they watched the videos because they were students who were more concerned about obtaining adequate feedback in the class.

VII. ANALYSIS OF STUDENT SENTIMENT ABOUT ASYNCHRONOUS MULTIMEDIA FEEDBACK

The last analysis attempted to duplicate the results of previous papers in showing that students viewed feedback from the videos in a positive fashion. In [14] and [17], students were asked on a Likert survey if they preferred video feedback to traditional feedback in computer courses. In this paper, for the courses most similar to this course, the majority of students agreed or strongly agreed with this statement. In an Operating Systems Design Course, 92% of students either agreed or strongly agreed with this sentiment. In the Introductory Programming course, 70% of students either agreed or strongly agreed with this sentiment. In the case of the introductory

programming course, even though the technique was only used for one class, it was viewed as successful by students.

For this research, students again were asked to rate their sentiment on a Likert scale whether or not they felt that video grading helped in their understanding of the lab material. The overwhelming response of the students enrolled in the course was positive, as is shown in Table 3. While not asking exactly the same questions as those that were asked on previous surveys, the sentiment expressed by the students is very similar.

Students also expressed strong support for video grading in their comments on the survey. Sample comments received include those shown in Figure 3. As in the previous works, video grading is viewed very positively by students who seem to feel that the feedback is very helpful for them in their academic endeavors.

VIII. CONCLUSIONS AND FUTURE WORK

This paper has analyzed the impact of asynchronous multimedia feedback (video grading) on freshman programming students in the second quarter of programming. Through three different measures, the effectiveness of the technique was investigated.

The first investigation involved establishing if there was a difference in performance between students who were enrolled in a section of programming which used asynchronous multimedia feedback and other sections which did not. Based upon a common final exam from the first programming course, the sections were shown to not have a statistical difference in average scores on the first course's final exam. However, a statistically significant difference was found at the end of the second course. While this does not imply causality with asynchronous multimedia feedback, a correlation is present.

The second investigation involved determining if students watched the videos. Using logs from the secured website, it was found that the majority of students did watch videos in a timely fashion after they were returned. Most videos were watched within less than 30 hours of them being made available to students. More importantly, a weak but statistically significant correlation was found between final exam scores and the number of videos watched by the students. Again, while correlation does not indicate causation, the finding is interesting nevertheless.

The third investigation reaffirmed the findings of previous publications that multimedia feedback is highly valued by students and aids in their understanding of grading. This was shown through both Likert surveys as well as voluntary free form comments from the students.

Table 3: Likert Analysis Video Grading Sentiment expressed by students.

Statement: I felt that video grading helped my understanding of lab assignments and lab grading.				
Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
83.3%	8.3%	8.3%	0%	0%

- The personal review videos for labs were extremely helpful in seeing what went wrong and what worked when the professor was grading the labs.
- Videos were a great feedback tool for labs
- I like the visual and textual feedback on the labs to know what to improve from lab to lab.
- Video grading is by far one of the best things any professor does, absolutely love it.
- Feedback on labs is excellent. Providing a video is especially helpful.
- The lab grading was amazing
- (Video Grading)Yes, keep doing this. It is awesome.

Figure 3: Sample student comments on Video feedback from student surveys

In terms of future work, there is much that can be done to try and better understand the cognitive aspects of asynchronous multimedia feedback. Certainly the literature indicates that the technique will be successful because it touches on many of the problems of traditional feedback. However, from the work we have done, we do not fully understand why students view the technique so positively. We believe that this technique may show more empathy toward students as well as providing a more dynamic approach. However, this does not explain why it is successful.

We also need to delve further into what makes for successful feedback with this technique. While the video lengths in this work varied, they generally were short, between 4 to 6 minutes each. At some point we know that students will lose interest in the feedback and not watch, but we do not know from our work what really the most effective length is. As it is with the flipped classroom, there may be a significant relation between learning effectiveness and length.

Abstract—In recent years, professionals in different fields have become able to do programming by using simplified software tools, as a consequence of this they are becoming able to understand programming in a general or “panoramic” way. This understanding is not evaluated by current programming abilities testing methods such as written paper tests or practical programming. This paper proposes a *Programmed Visual Contents Comparison Method* to assess programming ability, and additionally, a testing system based on this method. With this method, by comparing 2 displayed images and interactive animations produced by programming samples (a *question*) a subject must decide which one of the programs is more difficult to build with programming than the other, or, if the difficulty is similar for both of them. The validity of the method is confirmed by comparing the ability reported by programming teachers with the results of an experiment performed with a testing system.

Keywords—Computer science education; Programming Training; Student Assessment; Graphic Design; Software Engineering

I. INTRODUCTION

During the last two decades, software development has changed drastically, more and more people not involved in professional software development have become able to do programming and new resources to make programming easier have been created. For example: several amounts of code samples and tutorials are being uploaded to the web and used through copy-pasting; a large amount of algorithms are constantly being converted into libraries and made widely available, so to find the best-suited function within libraries has become an important task; and several visual software development tools and languages, where the programming code is hidden and it can be applied with “just a click” are being developed.

In addition to those changes on programming development, the background and learning modes of people using programming in their jobs or careers have diversified as well. Software developers are taught to use code samples and libraries to do programming as a complement to the traditional “write code from scratch” perspective, while graphic designers are learning programming through authoring tools and visual-based programming languages; additionally, game designers

are learning the principles of both of the mentioned professions at the same time. As a consequence of these changes, both developers and designers may have changed their way of planning and structuring a programming project and solving programming issues, developing what we think is a *panoramic* way of learning and applying programming.

This paper proposes a Programmed Visual Contents Comparison Method to evaluate programming ability. With this method, from a pair of images produced by programming samples (questions) a student must decide which one of the programs is more difficult to build with programming than the other, or, if the difficulty is similar.

We examined the validity of this method by comparing the ability reported by programming teachers at a technical school with the results of an experiment performed using a web testing system based on the proposed method.

On Section II of this paper, we explain what *Panoramic Understanding of Programming (PUP)* is by taking graphic designers as a particular case. Section III describes the *Programmed Visual Contents Comparison Method*, Section IV introduces and explains the characteristics of the performed experiment, Section V presents the results of our experiment, and, in Section VI we present an analysis of how well this method can evaluate programming ability.

II. BACKGROUND OF THE STUDY

A. Panoramic Understanding of Programming, the Case of Graphic Designers as Programmers

We think is appropriate to explain what *PUP* means by using the specific case of graphic designers since they have started to be more and more involved in programming tasks and have been receiving programming education for the last 10 years approximately, thus acquiring a special, different understanding on programming.

In Graphic Design courses it is becoming usual to include programming classes together with graphic software tools instruction; programming for designers is usually taught by following a basic curriculum summarized from IT courses, but fixing the topics according to the resources available on the

This work was partly supported by JSPS KAKENHI number 15K010168.

tools [1], or externally in additional libraries, probably code snippets or extensions.

When a designer deals with a software tool almost always deals with new methods or “tricks” to use a programming language through an interface. Ko et al. consider that, with visualization tools for programming, “*learners [do] not face barriers in understanding data itself, but in trying to act on data (such as how to create or modify it)*” [2].

For example: a popular web authoring tool used by designers to program with HTML (HyperText Markup Language), CSS (Cascade Styling Sheets) and JavaScript among other programming languages is Adobe Dreamweaver [3]; this tool has several snippets and pre-made objects that can be dragged into a visible template of a web page, and supposedly will work at execution time but sometimes they do not. Besides, there are many “tricks” to make appear specific pieces of code or to control diverse processes; these tricks usually require a long sequence of mouse clicks, searching around the tool menus or the interface and dealing with programming code directly.

Considering that a graphic designer is an end-user programmer, or a person who needs to use programming in his projects but is not entirely dedicated to that [4]; by using these tools he will consequently solve programming problems recursively: by trial and error, by pulling in and taking out those code snippets and pre-made objects, by possibly trying out a few lines of code he could have found online; in the end by *sketching* code [4] [5], that he himself has built without having any idea if it is optimal or standard-compliant, not even how many hidden bugs it will have.

Sketching code allows graphic designers to transform the knowledge they acquire on programming, an external matter, into something more related with their visual nature; so they generate a new *panoramic* kind of programming understanding merged with design concepts [1] [4].

A graphic designer expects some of the skills he assumes as fundamental related with the appropriation of objects (for instance: drawing, diagramming, getting to know physical characteristics like: color, form, texture) and scenarios or stages where to explore the relation between objects (things), space, and environmental factors, to be available when programming; but they cannot find any of this in programming code. They lack the understanding of “code” as “objects” because they do not have anything holding up their perception.

Ozenc et al. refer to this as the *immateriality of software* [5]; so through sketching a designer tries to bring materiality to code; regarding this aspect, Ozenc et al. mention that:

“Most designers explore materials in a studio or workshop where they (...) play with a material to develop tacit knowledge (...). However, designers cannot easily play with the material of software making the development of tacit knowledge much more difficult.” [5].

B. A Contrast with Programmers’ Programming Understanding

Programmers on the other hand only get to know and become aware of software graphic elements when they deal with subjects like: User Interface Programming, Web development, or Multimedia (Sound or Video). But unlike designers, they do not do programming by *seeing* but by *reading*; they manage languages so they need to be aware of syntax, coherence and particularly, errors; they focus on code patterns and coding style to “catch the bug”.

Regarding this aspect LaToza and Myers state that:

“In coding activities, developers select among various strategies to answer the questions necessary to complete their tasks (...). When exploring code, developers seek information, make decisions about which structural relationship to traverse to find information.” [6].

Programmers then, make relationships between structures instead of objects, they cannot perceive things like color, or shape but they decipher code and, to do that, they apply *strategies* instead of *sketching*, and their Affordance is on the identification of patterns inside the code. From knowing how an application is supposed to behave (pattern) they can rebuild or modify a program, this only through constant testing of the previous and own (new) code; in this respect LaToza and Myers state that:

“As developers gain expertise in programming, they also gain knowledge about typical code idioms and patterns (...). When developers know how an application is supposed to behave, they can use this knowledge to answer some questions about the code.” [6]

III. PROGRAMMED VISUAL CONTENTS COMPARISON METHOD

A. Basic Concept

This method is based on the comparison of 2 displayed images and interactive animations produced by programming samples that, for our purposes we call a *question*; if a question is showed to the student taking the test, he is requested to decide which one of the samples is more difficult to build with programming than the other, or, if the difficulty is similar for both of them.

The correct answer for a question is defined by a main programming structure we called *programming concept*; basically, the student needs to identify this concept in order to provide an answer, and the most difficult sample of each question is built based on this programming concept.

Considering this approach, we warn the student to answer each question looking at them from a programming point of view, in other words, to think about each question using any experience and knowledge he could have on programming, as little as it could be, regardless of the tools or programming languages he could know. The following question examples will allow us to explain more in detail this aspect:

Fig. 1. Question based on the *Nested Iteration* concept

The concept for the question displayed on Fig. 1 is *Nested Iteration*, and the correct answer for this question would be *the difficulty is similar* since both samples were built by using a nested loop changing only the number of squares to be drawn.

We would expect programming experts and programmers with ability in simplified programming languages based on libraries and graphic objects only (e.g. Processing) to answer that *the difficulty is similar*, since *Nested Iteration* is applied in similar ways regardless of the programming language.

Students with an ability limited to graphic tools will surely select one of both samples since they don't necessarily use or know about *Nested Iteration* therefore are most likely unable to identify the concept.

Fig. 2. Question based on the *Hidden Line Removal* concept

The concept for the question shown on Fig. 2 is *Hidden Line Removal* and its correct answer is the sample on the left marked with (1); those students answering correctly would surely know what *Hidden Line Removal* is and how it is applied on the programming sample.

Programmers whose ability is based on simplified programming languages only would answer *the difficulty is similar* since the same image can be obtained easily with languages like Processing by using a single function changing some of its parameters, but, they would probably misunderstand the difficulty of each sample because they certainly wouldn't know what is the content of the function applied, or what kind of algorithm is used to perform the *Hidden Line Removal*.

In the same way, people having an ability limited to graphic software tools, would probably answer based on what is shown on the pictures and could assume that both samples can be performed with the same tool on a specific software.

B. Sample Selection

Several programming concepts were selected from programming books oriented to designers and developers; having as main criteria: its level (beginners to experts), if it is

representative of programming in general and/or if along those books the concept is studied by graphic and game designers, as well as by developers and programmers [7] [8] [9] [10] [11]. The chosen concepts were, respectively: Bezier Line, Nested Iteration, Coordinates Storage and Recalling, Erasing and re-drawing, Boundary detection, Easing, Timer, Area delimitation, New position according to previous position, Change through time, Animation using trigonometry, Picture Pixel Management, Recursion, Lists, Empty Area Recognition and Hidden Line Removal. In total 16 questions were prepared.

C. Questions' Degree of Difficulty

We designed the whole set of questions to have two kinds of difficulty for each one: first, the difficulty of associating images with programs; to surpass this difficulty, we consider that the subject answering the questions probably needs to:

- Understand what is each sample doing (how is it moving? what's happening?).
- Identify what elements each program is using to do what it is doing (if there is a movement on the sample, how is it structured on the program?).
- Understand how the objects the program is using are working together to give that (visual) result (for example how a circle is connected with the movement it is doing).

Second, the difficulty of associating the programs with the programming concept; to surpass this difficulty we think the subject probably needs to:

- Think about, and/or recall from his own knowledge and/or experience:
 - What kind of programming structure or concept can be used to achieve this movement or effect?
 - What is the main effect of each of those structures? (The subject probably asks himself: if we apply that structure to something, what is the result? And, is that result coherent with some of what is currently happening on the pictures?).
 - How many programming structures or concepts he can apply into the objects appearing on the screen, and how many ways of application does they have (alternative uses).
- Identify which is the main concept for each sample (what is the more relevant programming concept?).
- Compare both main concepts, for both samples.

Following this line of thought, we classified the set of 16 questions into three types: first, questions having a difficult image-program association, needing more knowledge on images and/or graphic software tools management (Type A); second, questions having an easily identifiable image-program association but needing a deeper knowledge on programming to perform the comparison between programs and the connection with the concept (Type B); and third, questions with both characteristics, where both kinds of knowledge will be needed (Type C).

D. Programmed Visual Contents Comparison Testing System

Based on the proposed method we built a web testing system where the set of 16 questions was displayed. This system was made by using current web standards; Questions' contents were developed using *Processing.js* and, the interface and database were developed using current programming languages such as: *JavaScript*, *MySQL* and *PHP*.

The answering method was built to be straightforward, having a unique question: "If you were to make any of the previously displayed samples using a programming language, which one do you think is the most difficult?" and four answer options: "sample 1", "sample 2", "Both have the same difficulty" and "I don't know". During the test the student must choose only one answer, then click on a "submit" button to store it on a database and pass to the next question. Fig. 3 shows an example of how a question is seen on screen.

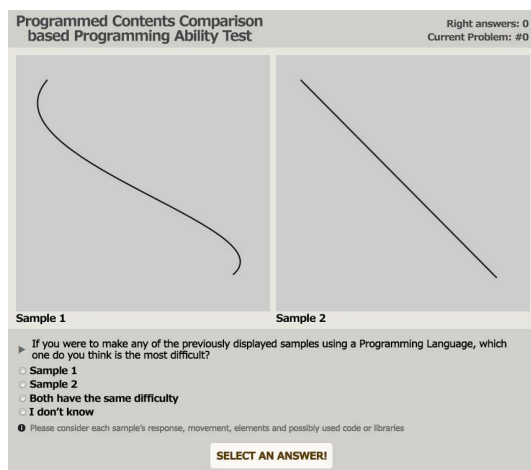

Fig. 3. Example of a question on the Web Testing System

The test is thought to be carried on sequentially (one question after another) and in one try, the time needed to answer one question is considered to be 30 sec. to 1 min. Table I shows the displaying order of the test questions, and the programming concept of each numbered question.

TABLE I. DISPLAYING ORDER OF TEST QUESTIONS INCLUDING THEIR PROGRAMMING CONCEPT AND TYPE

Question Number	Type	Programming Concept
#1	A	Bezier Line
#2	B	Nested Iteration
#3	A	Coordinates Storage and Recalling
#4	A	Erasing and re-drawing
#5	C	Boundary detection
#6	C	Easing
#7	B	Timer
#8	C	Area delimitation
#9	B	New position according to previous position
#10	C	Change through time
#11	C	Animation using trigonometry
#12	A	Picture Pixel Management
#13	C	Recursion
#14	B	Lists
#15	B	Empty Area Recognition
#16	B	Hidden Line Removal

In addition, at the end of the test, a report with user's answers per question compared with their respective correct answers is displayed; and following this, the test subject has the opportunity to answer a brief questionnaire about the whole test experience.

IV. EXPERIMENT

We wanted to know if the programming ability of students of different fields and level could be evaluated with this method; for this purpose we performed an experiment with 4 groups of students whose ability in programming was already known. This experiment mainly consisted of: doing the test using the Testing System and answering the final questionnaire.

The programming ability of these student groups was reported by their programming teachers who we gathered together to share their results and to make them know in detail what the experiment consists of and how their report was to be utilized.

The ability reported by these programming teachers (from now: *the report*) was compared with the results of our experiment; in this sense three kinds of results are the outcome of this comparison: *Questions matching our assumption*, *Questions mismatching our assumption but having a significant difference*, and *Questions mismatching our assumption and having a small or no significant difference*.

A. Student Groups Characteristics

According to the report, the students groups differentiated each other by their field of study and curriculum related with programming and/or graphic software tools in the following way:

The first group: Graphic Design (GD) has a curriculum that includes classes where Graphic Software Tools for Photo Edition, Illustration, Desktop Publishing and 3D Modeling are taught together with Web Coding and Web Design. This group studies only programming languages oriented to Web (HTML, CSS, JavaScript).

The second group: Game Software (GS) studies several programming languages such as: C (and its derivatives: C++ and C#) and Java besides of Game Design related subjects such as: Graphic Design Principles, Character Design, 3D Modeling and Animation. Additionally, their curriculum includes subjects on Application Programming Interfaces such as DirectX and OpenGL, Web related languages, Algorithm Theory and Mathematics. Graphic Software Tools are used mostly on Game Design classes.

The third group: IT and Software (IT) has a curriculum including subjects on programming languages such as: C, Java and Assembler, that are studied together with Algorithm Theory and Web back-end programming and networking. It does not include classes about graphic software tools or visual/graphic related programming languages.

This report indicated also a subdivision in levels of knowledge for IT. The group was divided into two sub-groups: IT-1 and IT-2. It also pointed out that IT-2 had more

knowledge on programming than IT-1, since they have received preparation for IT tests such as the JITEE (Japan Information Technology Engineers Examination).

B. Assumption Based on the Reported Programming Ability

Based on the report, and using the questions types we specified previously for the method on section V, our assumption on the results for our experiment is summarized in Table II.

TABLE II. ASSUMPTION ON ANSWERS TO THE TEST QUESTIONS PER GROUP PER TYPE ACCORDING TO THE PROGRAMMING ABILITY REPORTED

	Type A	Type B	Type C
GD	●	×	×
GS	●	●	●
IT-1 and IT-2	×	●	×

Conventions

●	Group with high score
×	Group with low score

According to the report, Type A questions are to be best answered by GD and GS, due probably to GD's knowledge on Images Management and/or Graphic Software tools; IT's knowledge on this area is little to none.

Type B questions are to be best answered by IT and GS, due to their deeper foundations on programming; they are capable of managing programming concepts from their base while GD manage those concepts only through Graphic Tools, possibly without having a conceptual base of what kind of programming structure is.

Finally, Type C questions are to be best answered by GS, because this is the only group who learn both Programming and Graphic Tools at the same time.

For IT-1 and IT-2, even when both are supposed to answer better the same type of questions (Type B), the report mentions that IT-2 has a higher knowledge in programming than IT-1 so we expected IT-2 to have a better correct answers average than IT-1.

V. RESULTS AND COMPARISON TO FIND SIGNIFICANT QUESTIONS

Here we describe how significant questions were found by comparing the difference on correct answers' percentage between groups. The amount of answers per option per question were compared with the correct answer for each question to obtain the amount of correct answers per group for each question and for the whole test per student. Being unequal groups, we had to establish the percentage of correct answers per question for each one of the groups, Table III shows the percentage of the total of correct answers and average for each question per group, highlighting questions with high and low scores.

TABLE III. PERCENTAGE OF CORRECT ANSWERS PER QUESTION HIGHLIGHTING THOSE WITH HIGH AND LOW SCORES PER GROUP

	Type A				Type B						Type C						Avg
	#1	#3	#4	#12	#2	#7	#9	#14	#15	#16	#5	#6	#8	#10	#11	#13	
GD	88	72	44	66	31	44	72	63	41	25	88	81	34	19	16	53	52
GS	90	64	31	69	74	54	67	72	44	51	62	85	41	5	26	84	57
IT - 1	63	56	37	39	66	41	66	49	27	41	71	80	37	20	20	63	48
IT - 2	76	56	56	36	80	28	72	68	60	40	64	80	48	20	24	84	56

Conventions

High Score

Low Score

By using the correct answers percentages, we could establish difference per questions between the four groups by comparing: GD with IT-1 and IT-2; GD with GS, GS with IT-1 and IT-2 and the two IT subgroups.

Having the differences on the correct answers for each group we could see which questions had a significant difference; considering these as representative we performed an F-test of equality of variances and a two tailed T-test to confirm the validity of the difference for each representative question.

Table IV shows the difference on correct answers' percentage between the groups highlighting the questions having a significant difference for, at least one of the performed comparisons, those are our representative questions.

TABLE IV. SIGNIFICANT DIFFERENCE ON PERCENTAGE OF CORRECT ANSWERS VERIFIED THROUGH T-TEST PER GROUP COMPARISON PER QUESTION, HIGHLIGHTING REPRESENTATIVE QUESTIONS

Questions without Significant Difference

The result for each representative question belonging to each one of the types previously determined, was compared with our assumption; Table V shows which questions' result matched our assumption and which ones had other outcomes. Each question has its own particularities regarding measurability and optimization that will be discussed in the following section.

 Result mismatching the assumption

VI. ANALYSIS AND DISCUSSION ON THE METHOD'S APPLICABILITY

A. How Well Can This Method Evaluate Programming Ability?

In this section, three types of representative questions (see Table V) will be discussed: those whose results matched our assumption, those not matching our assumption but considered useful to assess programming ability and those having only one significant difference and whose results mismatched our assumption; additionally, we consider necessary to do some remarks about non-representative questions.

1) Representative Questions whose Results Matched our Assumption

As shown on Table V, results for representative questions #1, #2, #12 and #16 matched our assumption, these questions are considered valid to assess programming ability. To this respect we want to quote questions #2 and #16, used as an example in section III-A.

TABLE VI. NESTED ITERATION (#2) QUESTION - ANSWERS FOR EACH GROUP (PERCENTAGE)

	Sample 1	Similar	Sample 2
GD	25	31	44
GS	3	74	23
IT-1	12	66	22
IT-2	12	80	8

Table VI shows the percentage of answers that students from the four groups gave to question #2, which concept is: *Nested Iteration* (see Fig. 2) and belongs to Type B.

As we stated in section III-A the correct answer for this question is *the difficulty is similar*, which was selected by a 31% of GD, a 74% of GS, a 66% of IT-1 and an 80% of IT-2. These students found out that, using *Nested Iteration* both the first and the second sample can be performed with the same difficulty while GD didn't perceived this issue, seemingly, their programming ability doesn't reach this level.

We consider worth mentioning that a 44% of GD a 23% of GS and a 22% of IT-1 selected *sample #2* as the right answer, while a 25% on GD and a 12% on both IT-1 and IT-2 selected *sample #1*. These students probably considered the difficulty of both samples based more on screen presentation issues (scale, distance between objects, visual impression) than on how they were programmed. For instance: some GD students could have thought the second sample was the most difficult because it had more squares than the first one, then involving more steps if performed using a software tool; or, for the first sample's case, some students probably thought that the squares' size or scale needed to be calculated.

TABLE VII. HIDDEN LINE REMOVAL (#16) QUESTION - ANSWERS FOR EACH GROUP (PERCENTAGE)

	Sample 1	Similar	Sample 2
GD	25	22	53
GS	51	15	34
IT-1	41	25	34
IT-2	40	24	36

Table VII shows the percentage of answers that the four groups gave to question #16 which concept is *Hidden Line Removal* (See Fig. 1) and belongs to Type B.

As we said in section III the correct answer for this question is *Sample #1* and a 25% of GD, a 51% of GS, a 41% of IT-1 and a 40% of IT-2 selected this answer. These students found out that the first sample contained the *Hidden Line Removal* concept. The programming ability of GD almost certainly wasn't enough to figure out the difference between the two samples, neither to identify the concept.

We may assume that those students who answered *the difficulty is similar*, namely, a 22% of GD, a 15% of GS, a 22% of IT-1 and a 24% of IT-2, probably have a programming ability limited only to simplified programming languages, therefore not familiar with the *Hidden Line Removal* algorithm; they were able to associate both samples only to the simplified functions used to do these samples on those languages. For example: by using *Processing*, through a *for* loop and the *ellipse* and *fill* functions both samples can be done and modified in their size, color and filling.

2) Representative Questions whose Results mismatch our Assumption but Useful to Evaluate Programming Ability

By looking at Tables IV and V we can see that questions #5, #10 and #13 have more than one significant differences on the comparisons between groups, but they didn't match our assumption.

We discussed and analyzed the results for questions #5 and #13 together with the group of teachers in charge of the four groups to establish to what point they could be useful. Since question #10 was one of the three questions obtaining the lowest score (see Table III) we thought more appropriate to include it in the group of non-representative questions instead.

Fig. 4. Appearance of: *Boundary Detection* (#5) question

Question #5, *Boundary Detection* (See Fig. 4) belongs to Type C. For the first sample, if the mouse pointer hovers over the circle, the background turns black; for the second sample, if the moving circle (replacing the mouse pointer) touches the border of the static circle the background turns black.

TABLE VIII. BOUNDARY DETECTION (#5) QUESTION - ANSWERS FOR EACH GROUP (PERCENTAGE)

	Sample 1	Similar	Sample 2
GD	4	8	88
GS	9	29	62
IT-1	12	17	71
IT-2	12	24	64

We initially considered the correct answer for this question to be *Sample 2* and an 88% of GD, a 62% of GS, a 71% of IT-1 and a 64% of IT-2 guessed our assumption, but in fact, the second sample has other ways to be programmed. For example: and the answer would change to become *the difficulty is similar* if the second sample changes to contain a bigger invisible circle placed around the centered one, so when the moving circle intersects it, the background turns black just when the borders of the visible circles apparently touch each other.

This issue makes the question not valid to measure *PUP* related with the *Boundary detection* concept but, looking at the results from students answering *the difficulty is similar*, namely: 8% of GD, 29% of GS, 17% of IT-1 and 24% of IT-2 we can see that a significant percentage of GS and IT-2 students somehow perceived the similarity between the two samples; this aspect led us to think that they probably went deeper to think about the difficulty of the algorithm of both samples to compare them.

Having this into account, even when this sample resulted inappropriate to measure *PUP* related with *Boundary Detection*, we considered it useful to identify student's potential algorithmic skills.

Fig. 5. Appearance of: *Recursion and Repetition* (#13) question

Question #13, *Recursion and Repetition* (see Fig. 5) belongs to Type C, the first sample changes according to a recursive algorithm when the user clicks over; the second sample draws two crossing lines in the position where the click is performed.

TABLE IX. *RECURSION AND REPETITION* (#13) QUESTION - ANSWERS FOR EACH GROUP (PERCENTAGE)

	Sample 1	Similar	Sample 2
GD	53	16	31
GS	84	5	11
IT-1	63	10	27
IT-2	84	6	10

The correct answer for this question was *Sample #1*, GS and IT-2 obtained a comparatively high score of 84% both, while IT-1 obtained a 63% and GD had a 53%.

IT-1 and GD had almost the same percentage of people selecting *sample #2*, and little difference between the percentage of those selecting *the difficulty is similar*; while for GD this kind of results can be supposed, for IT-1 this could be a sign of their ability level difference with IT-2, some students on IT-1 are probably lacking the ability to identify the common pattern of a recursive algorithm or haven't studied it yet.

Furthermore, each time the student clicks a mouse on any of the samples, the picture changes; in other words the number and position of clicks affects the visual impression of each sample, this could have affected his answer too.

3) Questions whose Results Mismatched our Assumption Useless to Evaluate Programming Ability

Questions #4, #7, #14 and #15 had only one significant difference and their results didn't match our assumption; these questions are not useful to evaluate programming ability.

Within this set, questions #7, #14 and #15 were *interactive* (affected by clicks or mouse movement); this interactivity was programmed together with the code containing the concepts to be evaluated, and in some cases it was more difficult that those concepts; additionally, these questions were lacking enough instructions or guidance about how to operate them. The following example will provide details regarding this issue.

Fig. 6. Appearance of: *Timer* (#7) question

Question #7, *Timer* (See Fig. 6) belongs to Type B, the first sample draws a point on mouse coordinates every frame; the second sample draws a point each 400 milliseconds only when the mouse almost stops or is really slow.

TABLE X. *TIMER* (#7) QUESTION - ANSWERS FOR EACH GROUP (PERCENTAGE)

	Sample 1	Similar	Sample 2
GD	20	36	44
GS	15	31	54
IT-1	39	20	41
IT-2	18	54	28

The correct answer for this question was *Sample #2*, and even when the 44% of GD, the 54% of GS and the 41% of IT-1 guessed this answer, but the difference in the percentage of answers between the groups is minimal. Probably the lack of appropriate instructions and the fact that the response of this sample depends on the slow movement of the mouse, made some students think the answer was different.

An additional issue to have into account with this question is that, even when we implemented the second sample to have a timer (and to be the most difficult), the first one also has a timer: the frame rate, and the mouse makes evident from the moment that it enters the sample's area that this frame rate works as a timer, so that could have been confusing as well.

4) Non-representative Questions

Table IV indicates that questions #3, #6, #8, #9 and #11 didn't have any significant difference on the comparison of correct answers between the four groups, these questions are not valid to evaluate programming ability. Additionally, as it

was mentioned in the previous subsection A-2), question #10 belongs to this group too.

For questions #3, #6, #9 the four groups had high percentages of correct answers (see Table III); we think these questions compared samples containing difficult concepts (see Table I) with samples evidently easier or too basic; in other words, the difficulty level difference of the compared samples for these questions was too obvious; probably, even students without *PUP* could have answered right.

On the other hand, questions #8, #10 and #11 had low percentages of correct answers (see Table III); these questions were ill-made, most likely because they contained additional concepts on the same level or more difficult than those evaluated, or the programming samples were too similar.

B. Questions' Programming Level and Difficulty

One of the main aspects that affected the results for all groups is the definition of *difficulty*. Even when in section III-C: *Questions' degree of difficulty* we defined it, in many cases students couldn't identify what was the main difficulty for each one of questions; this lead us to think that this definition is not complete, however those students having the ability to perceive the difficulty for the valid questions answered correctly. For future tests and questions we need to find a way to make clear each question's *difficulty*.

In the aforementioned section III-C we also established that the level of the programming concepts is the main selection criteria, having as a reference a somewhat wide range going from concepts studied on a programming beginner level to expert level concepts. We originally thought that the correct answer for each one of the questions could be one and only one, but we omitted the possibility of each one of these questions to be answered by people with different knowledge levels, thus having different ideas of programs that can be harder or easier for each one of the samples, this could lead them to think different correct answers. In this sense, our criteria for choosing the right answer is still weak, we need to define what kind of answers per level can emerge for different (future) questions.

In the same way, those questions whose results matched our assumption are a reference of the necessary level to answer a specific question with a specific concept; having this in mind, we can consider to test other concepts, of other levels with other difficulty with the same question, to measure other abilities on a later stage.

CONCLUSION

In this paper we propose and describe a *Programmed Visual Contents Comparison Method*. Through the use of this method in an experiment we were able to evaluate the programming ability of four groups of students from different fields and levels of knowledge.

We could understand as well that the assessed programming ability is related with *PUP*, and the level of the person who answers, the definition of difficulty and how the programming samples are built and paired to form a question define how well this method can evaluate programming ability.

In the same way we were able to find other kinds of programming abilities used by the students to answer the questions of our method; those abilities, even different to the ones we wanted to assess, are also related with a Panoramic Programming Understanding.

This method can be used in the future with other kinds of samples and other kinds of programming concepts to obtain more results regarding abilities related with *PUP*.

Additionally, results from the questionnaire performed at the end of the test showed a positive feedback regarding the test system. The majority of the students from the four groups recognized that this test allowed them to evaluate their own ability on programming, and that this test was more enjoyable than a paper based ability test. This feedback will be used in future stages of this research as criteria to modify questions and the testing system in general.

ACKNOWLEDGMENT

We would like to thank all the Professors and Students from the College of Computing of Kobe Institute of Computing who through their participation and collaboration made possible the realization of this project's experiment.

Abstract— Online programming discussion forums are popular trouble-shooting and problem-solving sites for programmers and learners to reach out for help. The massive volumes of forum threads harbor tremendous amounts of information, but at the same time increase the complexity of search and navigation. In this work, we make use of programming discussions' syntactic, semantic and social features to model content associated with learning activities based on the ICAP learning framework. Our main goal is to detect *useful* content for learning programming in a large scale of questions and answers, while at the same time experiment with an artificial intelligence approach to detect learning-inductive content. We build regression models based on the defined constructive learning activities. Results reveal a *passive-proactive* learning behavior in an online programming discussion forum. The findings also reconfirm the value of programming discussion content, disregarding the crowds' approval. The automatic detection of constructive learning activities from programming discussions can be a helpful classifier in identifying relevant educational resources. Overall, this project contributes to our understanding on analyzing and utilizing mass programming discussion content for online programming language learning.

Keywords— *learning activity; engagement activity; discourse analysis; programming language learning; constructive learning; discussion forum; programming; semantic modelling; learning assessment.*

I. INTRODUCTION

Online programming discussion forums are popular trouble-shooting and problem-solving sites for programmers and learners to reach out for help. For instance, StackOverflow¹ harbors large amounts of social and gamified Question and Answers (Q&A). This and similar kinds of programming discussion forums provoke the engagement and response rate of knowledge providers, resulting in vast popularity and tremendous amount of valuable information [1]. Just in the span of two years since its foundation in 2008, more than one million questions and 2.5 million answers have been posted [2]. As this amount of information continues to grow, the complexity of navigation has also increased. The scale and types of content are often very diverse in terms of user background, coverage of topics, post volumes, post-response turnaround rates, etc. It becomes a typical "open corpus"

challenge, where content sources are diverse and usually unbounded; therefore, it is challenging to estimate learners' knowledge and further provide personalized support. To tap into this reservoir of knowledge, it is increasingly important to innovate automatic methods to discern the quality and *usefulness* of content to facilitate programming learning in cyberspace.

Learning programming is a challenging task and involves a variety of cognitive skills. Discussion technologies have been successfully applied with Intelligent Tutors and have demonstrated that students can learn from a wide range of dialogue-based instructional settings, such as dialogic-based tutors, asynchronous discussion forums, etc. [3-8]. However, it is not yet clear how people learn programming from such free, open and fast-growing online communities (homework-help sites, discussion forums for MOOCs courses etc.). Recently, studies from Learning Science/Computer Supported Collaborative Learning (LS/CSCL) show an alternative instructional context by *learning from observing others learn* [3] and is considered a promising learning paradigm [4]. It suggests that passive participants (such as lurkers who consume content without contributions) can still learn by reading the postings-and-replies exchanges from others due to the constructive responses in the content [9]. Such a *learning-from-observing* paradigm addresses a major limitation on development time in ITSs & liberates the domains from procedural skills to less structured fields. Nevertheless, verifying students' learning activities usually relies on qualitative human-coded methods (i.e. domain expert judges), which is typically difficult to scale. Furthermore, it is challenging to keep persistent traces of current knowledge prediction. Thus, the challenge motivates us to investigate automatic methods for identifying learning activities and associated content from large scale programming discussions.

In this project, we aim to study automatic methods for identifying *useful* content to learn programming from a discussion forum. Our assumption is that online programming learning activities in discussion forums are quantifiable. We hypothesize that identifying learning-inductive content in large scale programming discussions will prevent learners from searching for a needle in the haystack and reading a mess of new detail. In the context of programming learning, can we successfully model users' learning activities in such a large-scaled open corpus environment? To what extent can we

¹ <http://stackoverflow.com>

capitalize the learning activity: reading others' constructive dialogues voluntarily and engage in some sort of learning activity afterwards? The rest of the paper is structured toward answering these research questions. We begin with reviewing two streams of related work: online support for programming learning and learning from discussion forums. We then present the methodology, detail features extraction exploring, and describe how we model learning activities in an online programming discussion forum. Finally, we discuss the findings and summarize the study.

II. LITERATURE

A. Online Support for Programming Language Learning

There is a great deal of research addressing the issue of developers switching between activities like searching for relevant code and collecting code and other information [10]. These tools are designed mainly to extract relevant information from the web to assist in current coding tasks and save time spent navigating through codes when gathering information. Some examples include navigational shortcuts to the code in IDE [11] leveraging version history data in predicting code changes [12], better use of API [13] and integration of web search or recommend source code examples in the developing environment [13-15]. Additionally, with the rise of web 2.0, we also see a variety of technologies (blogs, tags, wikis, recommenders etc.) emerging, such as online collaborative programming (social coding in GitHub), Q&A websites, crowdsourcing suggestions, etc. [1, 16, 17]. However, almost all of these tools are targeted at problem-solving augmentation, reducing coding cognitive overhead when coding. Utility features enhancement (i.e. collaboration) and supporting learning activities are less emphasized.

Using code examples is not only a common practice for programmers to reduce development efforts in solving task-specific problems, but they are also frequently used in teaching or offered in programming textbooks as problem-solving practices and strategies [14, 18]. Worked examples have been extensively studied since the early 90's and frequently adopted in math, physics, computer programming etc. up until today [19, 20]. We believe that large scaled online discussion forums should go beyond the merits of traditional discussion technology offers: collaboration and communication. We argue that the fragments of code in online discussions and various code solutions in Q&A provide monumental learning opportunities. For instance, similar or different solutions are constantly exposed to learners for comparing and contrasting, which help students identify what is important in a problem, identify different features of code, and paint a road-map to the problem [21, 22]. Multiple pieces of code can allow a novice construct patterns and schema [23], while even erroneous worked examples may assist learning in various levels [24].

B. Learning from Discussion Forums

Over the decades, discourse analysis on discussion forums has been carried out through various formats, network analyses, topical analyses, interactive explorers, knowledge extraction, etc. [25-29]. Due to calculation complexities (since linguistic features rely on computer processing power), most

of these in-depth analyses were performed offline [30]. As a result, the lesson learned could only be applied in the next iteration of system development. Recently, however, we have begun to see some studies that focus on dynamic support for users [31]. Yet, there has been no conclusive or comprehensive technological support, nor systematic studies to date on large-scale discussion forums that associate with students' learning. With the rapid growth of free, open, and large user-based online discussion forums, it is essential, therefore, for education researchers to pay more attention to emerging technologies that facilitate learning in cyberspace. For instance, Wise, Speer, Marbouti, and Hsiao [32] studied an invisible behavior (listening behavior) in online discussions, where the participants are students in a classroom instructed to discuss tasks on the platform; van de Sande [33] and Sande & Leinhard [34] investigated online tutoring forums for homework help, making observations on participation patterns and the pedagogical quality of the content; Hanrahan, Convertino & Nelson [35] and Posnett, Warburg, Devanbu, & Filkov [36] studied expertise modeling in a similar sort of discussion environment; Goda & Mine [37] quantify online forum comments by time series (Previous, Current & Next) to infer the corresponding learning behaviors.

III. METHODOLOGY

In order to research automatic methods for identifying *useful* content to learn programming from a discussion forum, we select a single programming language domain, Java, based on our expertise and interests. We experiment and study the content corpus from StackOverflow site due to the openness, popularity, and availability. There are three types of posts: question, accepted answer, and answers. Often times, there is more than one "correct" answer, especially for code review questions [2]. Even though quality indicators (votes, acceptance, favorite) point to the correctness of a possible solution, readers have differing backgrounds and varying degrees of previous knowledge which influence which answer is the best for that particular individual. Therefore, these quality indicators may not be universally applied to all users. For example, an accepted answer may be too dense for a novice to grasp. Therefore, this project is set out to research artificial intelligent methods to evaluate content quality that provokes learning in large scale programming discussions.

According to ICAP (Interactive, Constructive, Active, Passive) learning activity framework, "learning activities" are a broader and larger collection of instructional or learning tasks, which allow educational researchers to explain subtle engagement activities (invisible learning behaviors) [4, 9]. The framework examines comparable learning involvement, where *Interactive* modes of engagement achieve the greatest level of learning, followed by the *Constructive* mode, the *Active* mode, and finally, at the lowest level of learning, the *Passive* mode. This will allow us to predict learning outcomes and estimate knowledge transformation. In our project context, "replying to a post based on co-constructed content" is an interactive activity; constructing meaningful posts that require cognitive thinking is a constructive activity; shallow posts content or interactions are active activities; search, browse and read

content without contributing to the content are passive activities.

Our goal is to be able to identify useful content that provokes learning. We aim to detect all the constructive content to encapsulate users' learning. Thus, we focus on identifying the constructive activities in this project. Based on the framework, constructive learning activities include the following possible underlying cognitive processes: *inferring, creating, integrating new information with prior knowledge, elaborating, comparing, contrasting, analogizing, generalizing, including, reflecting on conditions, explaining why something works*. According to these cognitive processes, we build a constructive lexicon library to capture comparing & contrasting words, explanation, and justification & elaboration words. We then adopt a comparative opinions mining technique and extend the constructive lexicon, which was originally used in sentiment analysis for detecting and comparing product features in reviews [38]. For example, comparative or superlative adjectives and adverbs, such as *versus, unlike, most etc.*, are included in our lexicon. We then modify an arguing lexicon to extract explanation, justification & elaboration words [39]. We focus on the *assessment, emphasis, causation, generalization, and conditionals* sentence patterns and include WH-type and punctuation features in generating associated constructive lexicons. For instance, "in my understanding...", "all I'm saying is..." (*assessment*), "...this is why...(emphasis)", "...as a result...(causation)", "...everything...(generalization)" and "...it would be...(conditionals)" are merely a few examples.

To automatically identify useful content that might elicit learning, we construct a model to capture quality of the content that signals constructive behavior. We define the value to provoke learning as *constructiveness* based on the constructive lexicons mentioned above. We then analyze forum content and extract features. We consider three dimensions of features that cover the knowledge sphere for an online programming learning: 1) Syntactic features, 2) Semantic features, and 3) Social aspects features. Table 1 presents an overview of the features categories.

Table 1: Generic Feature Groups

Features Groups	Descriptions
Syntactic features	Statistics based on text readability, post length, code length, the amount of information the post carries, overall post readability.
Semantic features	Semantics of an answer and its similarity or coherence to the semantics of its corresponding question post and polarity.
User and social features	User characteristics (reputation and number of badges ²); social features include the user interactions with the posts, such as votes and favorites.

Programming discussion forums include a mixture of natural languages and programming languages. To represent both languages' complexities, we focus on extracting generic

features, instead of specific linguistic components. For instance, we leverage a modern opinion mining technique to analyze post polarities, which is commonly used in analyzing product reviews (i.e. amazon product reviews, restaurant reviews, movie critiques, news, etc.) or detecting spams. The polarity analysis is usually used to detect good or bad quality of the content. For a product, the majority of extreme opinions may be representative on product quality. In a discussion forum, a *negative-opinionated post* may not necessarily mean that it is a bad post. It can indicate the dis-association between question and answer; it can also suggest emphasis on contrary cases, instead of pinpointing on correct solutions (trial and error; learning from mistakes; erroneous example).

IV. FEATURE ENGINEERING

Our features collection specializes features, which are usually generally applied to social media platforms, to specifically detect useful content in not only programming, but also other discussion forums. We provide both the generic applications of these features in Table 1 and describe each feature in detail and how we made them domain specific.

A. Syntactic Features and Readability Metrics

Syntactic features capture the surface level, exterior characteristics of the text and any accompanying code that may provide insight into identifying constructive content. The following features are included:

- *Post length*, counts the number of words in the text. We hypothesize that answers with higher post length include more constructive learning behavior.
- *Code length*, counts the number of lines of code. We hypothesize code examples will increase constructive learning since more explanation is likely to follow, which is a constructive learning activity.
- *Informativeness*, measures the novelty of terms in a post compared to another post. Not only did we measure the informativeness of an answer compared to other answers of the same question, but also the informativeness of an answer compared to its corresponding question. We assume informativeness to be an indicator of constructive learning since it detects posts which are more informative. To ensure that domain-specific informativeness is detected, each post (p) is parsed to only contain words (w) found in the index or glossary of domain related textbooks or websites and is calculated as follows:

$$\Sigma_{w \in p} tfidf(w, p) \quad (1)$$

- *Readability metrics*, measure the difficulty in the understandability of text using various characteristics of the text, such as the Gunning Fog³ index, which uses syllables and the Coleman Liau⁴, which considers the number of characters. We assume a lower readability index indicates a post is easier to understand and thus easier to learn from.

² Stack Overflow utilizes gamification mechanism, which allows community members to vote and gain badges in reflecting community status (i.e. gold, silver, bronze, etc.)

³ http://en.wikipedia.org/wiki/Gunning_fog_index

⁴ http://en.wikipedia.org/wiki/Coleman-Liau_index

B. Semantic and topical features

Semantic and topical features measure characteristics of a post beyond the surface level and text structure by taking the meaning of the text into consideration. Concepts from both the text and code are also derived to gain insight on the actual topical features of the post.

- *Code concept count*, counts the number of concepts in the code accompanying an answer using a programming language parser [40]. We assume that a higher concept count indicates more learning conducive content.
- *Code concept entropy*, measures community code concept focus through code topic distribution. The program code parser [40] is used to obtain semantics from the code accompanying a post. We assume code concept entropy to be an indicator of learning since people often seek code solutions in programming discussion forums. We define entropy as the following where u is the user who authored the post, t is a topic, and n is the number of topics.

$$Entropy(\hat{u}) = -\sum_{j=1}^n p(t_{i,j}) \log_e p(t_{i,j}) \quad (2)$$

- *Post entropy*, measures community topic focus through post topic distribution. These topics are extracted by Topic Facet Modelling (TFM) algorithm from the post texts into corresponding sets of topics [41]. TFM is a modified Latent Dirichlet Allocation (LDA) probabilistic model, capable of automatically detecting content semantics in conversational and relatively short texts. We assume topical focus has an effect on the constructiveness of a post's content, since a low topic focus indicates high focus. Post entropy is calculated in the same manner as code concept entropy as described above.
- *Overall Sentiment*, subtracts the number of words that express negative sentiment from words that express positive sentiment. It is based on a list of positive and negative sentiment words in English [42]. In order to make the lexicon domain specific, words from Oracle's Java glossary were removed. We assumed overall sentiment may influence whether or not an answer is accepted. We further break down overall sentiment by considering positive and negative sentiment as separate features, since a more comprehensive sentiment analysis may give further insight into effects of sentiment on learning.

$$Sentiment = \#(PosTerms) - \#(NegTerms) \quad (3)$$

- *UMass Coherence*, measures the coherence between an answer and its question. It is measured as a pairwise score to represent how much a word in a post triggers the corresponding concept [43]. In order to make coherence domain-specific, we parse each post to only contain words from a lexicon of stemmed words from domain-specific glossaries and indexes. We assumed that a more coherent answer would most likely be accepted.

$$score_{UMass}(w_t, w_p) = \log \frac{P(w_t, w_p)}{P(w_p)} \quad (4)$$

C. User characteristics and Social Features

Social features include all the user and system interactions, which can also promote forum participation through gamification.

- *Votes*, are used to evaluate the quality of post content using up or down votes by community democracy.
- *Reputation*, measures community trust of a user based on prior activities on the site as well as up-voted posts.
- *Status*, of a user is measured through the number of badges earned. The score represents the amount of contribution and work done in the site community. i.e. Gold indicates important contributions; silver indicates strategic questions or answers; bronze shows rewards for participation.
- *Favorite*, is the number of bookmarks by the community. We assume that this may indicate learning inductive content in post and may even aid in filtering poor questions.

Table 2: Features Overview

Feature	Description
Syntactic Features and Readability Metrics	
Post length	Number of words in the post
Code length	Number of lines of code
Informativeness	Novelty of words in a post compared to another post
Readability Metrics	Understandability of text
Semantic and Topical Features	
Code concept count	Number of code concepts
Code Concept entropy	Code topic distribution among all codes to measure community code topic focus
Post entropy	Post topic distribution
Overall Sentiment	Positive and negative sentiments of the content
UMass coherence	Coherence score between the text of a post with another
User Characteristics and Social Features	
Vote	Community democracy evaluation of content quality
Reputation	Community trust measurement
Status	The accumulated scores on user profile to symbolize the amount of work done in the community.
Favorite	Number of saved bookmarks by the community
Dependent Variable	
Constructiveness	The number of constructive word counts based on the constructive lexicon described above

V. EVALUATION

According to the engagement activity framework reviewed above, we constructed the learning activity model based on the features identified. We then further analyzed the forum content to examine the validity of the findings from the results discovered from the model.

A. Data Collection

We sampled one year (year 2013) of forum posts under topic Java from StackOverflow site through the StackExchange API. Stack Exchange

(<http://stackexchange.com>) is a question and answer website network for various fields. The data pool was selected from the top 9 frequently tagged questions due to the fact that most of the posts in this section contained at least one accepted answer. It allowed us to build a baseline on the answer quality according to crowdsourced votes. There is a total of 16,739 posts, which includes 3,725 questions and 13,014 answers, 3,718 of which are accepted answers.

B. Model Learning Activity Analysis

To capture whether the observed assumptions on the features would account for the variation in user engagement prediction, we performed a logistic regression analysis. The full model was able to successfully predict *constructiveness* at 0.001 level, *adjusted-R*² = 0.6514. We tested the goodness of the models reserving 20% of the observations for testing with 10-fold cross validation and selected a final model. The full model is reported in Table 3.

Table 3: The logistic regression model on Constructiveness

Feature	Coefficient

Significance codes: 0***, 0.001**, 0.01*, 0.05(.)

We found that there are significantly more constructive words within Accepted Answers ($M = 0.827$, $SE = 1.334$) than Answers ($M = 0.583$, $SE = 1.005$), $p < 0.01$. This result confirmed that the answers accepted by the crowd not only agreed as correct solutions among the best available answers, but also contained higher constructive information. Accepted Answers also showed a positive correlation between user favorites and the amount of constructive words ($r = 0.0781$, $p < 0.01$), but we did not see such correlation between Questions/Answers and the amount of constructive words. This result is not surprising. This indicates that the community tends to bookmark useful Accepted Answers, but not Questions nor Answers. However, we found the community provided as many votes to Answers and Accepted Answers, no matter how constructive the content was. This observation was very interesting and revealed that the community may not bookmark the Answers as frequently as they do to Accepted Answers, but it did show the effort to screen the Answers and

provide votes to them. Table 4 summarizes all the significant differences between Accepted Answers and Answers.

C. Deeper Content Analysis

From the learning activity model analysis, we learn that there are learning opportunities in utilizing discussion forum content that is not limited to the crowd accepted content only. To further understand why and how people can benefit from the content (not just the Accepted Answers, but also the Answers), we analyzed the forum content. We further divided the content into two categories, Easy & Difficult (based on whether the topic is covered in CS1 or CS2 courses). Easy topics include *Classes*, *Objects*, *Loops*, *ArrayLists* etc.; difficult topics contain *Inheritance*, *Recursion*, *Multithreading*, *User Interfaces* etc. We found that easier content had slightly higher constructive words than difficult content, but the difference was not significant. It is understandable that simpler problems may be easier to provide examples and tougher problems may require more effort to justify the answers. However, we found that among Answers, users bookmarked and up voted more in difficult content when the content also had more constructive words. But we saw no such pattern in Accepted Answers or in Questions. This again shows important evidence that the users in the community spend effort in locating relevant information to themselves, even if the answers are not accepted by the crowd. These results suggest that there is a *passive-proactive* learning behavior, in which users did not simply read the Accepted Answers, but also read the Answers and further performed some sort of action (up voted, bookmarked etc.) These findings also suggest that detecting constructive content can be a helpful classifier in discerning relevant information to the users, and in turn provide learning opportunities.

Table 4: Mean and standard deviation of all features. Significance is highlighted in bold.

	Question	Accepted Answer	Answer
Syntactic Features			
Post length	89.02±67.11	84.47±76.61	58.86±61.3
Code length	45.29±88.46	39.49±81.37	15.8±43.2
Informativeness	-	0.777±0.828	0.672±0.706

Status – Gold	21.34±81.25	19.706±66.59	10.485±28.76
Status – Silver	31.48±59.81	112.97±492.7	77.42±349.49
Status – Bronze	46.83±75.78	162.57±644.1	116.07±461.1
Favorite	5.92±19.72	-	-

D. Topic Difficulty and Content Type across Constructiveness Predictors Analysis

Based on the topic difficulty distinctions described in the previous subsection, the pairwise comparisons of content types across all constructiveness predictors are reported in Table 5.

1) The effects of topic difficulty levels with syntactic features:

a) *Accepted Answers have an overall higher informativeness:* this confirms that they have more novel terms compared to the question. Since domain-related novelty was measured, it can be assumed that more domain-related constructive learning occurs. However, the average informativeness values of Answers are not too far behind, confirming their importance in also delivering novel information.

b) *Accepted Answers consist of more complex words:* The readability metrics of Gunning Fog and Coleman Liau are very similar between Accepted Answer and Answers, however there are more complex words in Accepted Answers than Answers, which may indicate that accepted ones were more composed and phrased formally with more complex words.

c) *Syntactic features differ between Accepted Answers and Answers on different topic difficulties:* Both post length and the length of the accompanying code are significantly higher in Accepted Answers than Answers. Accepted Answers delve into more detail and may provide various alternative solutions to a question, leveraging constructive learning. It is not surprising that post length, code length, and readability scores are lower for easier topics than more difficult topics since easier topics do not require as much explanation and depth as harder ones.

2) The impacts of topic difficulty levels with semantic features:

a) *Accepted Answers cover more concepts:* Code concept count and code entropy for Accepted Answers are significantly higher than Answer values. This can be due to the reason that people often turn toward programming discussion forums in search of code solutions; relevant code solutions are then more likely to be accepted. This also relates to the fact that Accepted Answers have a higher code length, which can increase the probability of more concepts being covered.

b) *Accepted Answers are more coherent with Questions:* Code concept count, code entropy, and domain-related UMass coherence are also significantly higher in Accepted Answers, which is not surprising, since the answer most coherent to the question is most likely going to be accepted. However, this does not discredit other answers, since they can also present learning inductive material not entirely coherent to the question.

3) The impacts of topic difficulty levels on social features:

Easier topics tend to have more votes and favourites than difficult ones. This indicates that using system interactive features (vote or favourites) may reach a limit in identifying useful content when the topics get tougher. This supports the

assumption that programming discussion forums may attract novice programmers more and reinforces the importance of intelligent content filtering assistance.

Table 5: Pairwise comparisons of topic difficulty and all constructiveness predictors

Easy/Difficult Question			Accepted Answer	Answer
Syntactic Features				
Post length	E	73.07±51.71	71.45±65.3	50.76±55.53
	D	96.54±72.04	90.59±80.66	63.56±63.93
Code length	E	43.81±94.89	36.05±75.05	13.99±29.5

VI. DISCUSSIONS

In this paper, we modeled constructive engagement activities in an online programming discussion. In order to identify learning-inductive material from such platforms, we built a constructive word lexicon based on constructive learning activities underlining cognitive processes described in the ICAP learning activity framework. We then performed logistic analysis and selected a model, which was able to explain 65.14 % of users' engagement activities. Deeper analysis confirmed that the crowd perceived Accepted Answers as more likely to contain more constructive words. Moreover, users had more up vote interactions with Answers and Accepted Answers disregarding the quantity of constructive words. Furthermore, they especially bookmarked and up voted more in difficult Answers when the content also

had more constructive words. In addition, in the semantic content analysis, we found higher topical focus of the program codes in Answers in the discussion forum. This again demonstrated the value of discussion forum content, no matter whether or not the crowd approves the content.

All these findings combined together supported the existence of *passive-proactive* learning in large-scaled online discussion forums and confirmed that content of discussion forums is a valuable asset for learning, disregarding the acceptance by the crowd. They also suggested that detecting constructive content could be a helpful classifier in discerning relevant information to the users, and in turn providing learning opportunities. For instance, we can optimize learning opportunities in the open corpus large-scaled discussion forum by identifying and ordering content based on the quality and constructiveness, which may result in better efficiency for mass *passive-proactive* users (as opposed to the traditional layout of the content, which is ordered by content quality and reversed chronological order). Similarly, the value of the Answers in the massive amount of discussion forums should be harnessed and better utilized. For example, relevant Answers can be recommended to learners, instead of Accepted Answers.

VII. LIMITATIONS & FUTURE WORK

We recognized two major limitations during the exploratory modeling process. 1) We currently only considered the constructive learning activity, while neglecting other activities, such as *Interactive* learning. Learning is complex. Therefore, all sorts of learning activities can be intertwined among the same context. 2) The current model considered limited social features to capture users' profiles. We believe that a learning-inductive post should also take into account the content poster's expertise, rather than just the amount of activities in the community. Therefore, in the future, we plan to integrate other learning activities associated with constructive ones and conduct more rigorous evaluation in modeling forum posters' expertise. Moreover, we are currently testing innovative learning analytics interfaces, which present personalized views, sequencing, and summaries to assist users to make better use of the massive content from discussion forums. More exhaustive user studies have been planned to evaluate the effectiveness of this predictive model.

Gauging Influence in Software Development Teams

Allen Marshall Rose Gamble

{allen-marshall, gamble}@utulsa.edu

Abstract— Agile software development teams are generally small, focused groups that require highly motivated members operating in a high-trust environment. Through interactive communication and collaborative work, team members can influence project outcomes both directly and indirectly. One method to examine influence is in terms of communication and control flow among team members when sharing a communication medium and artifact development tools. There currently exist several approaches for characterizing team communication using social network analysis. However, these approaches require modification to be applicable for measuring control flow influence in small teams. In this paper, we discuss the methodology and results of an influence study in which we analyze data generated by student teams in a capstone Software Engineering course. We develop three metrics to measure direct and indirect influence among team members, taking into account the temporal order of interactions and the small size of the teams studied. We correlate the influence metrics with grades, existing participation metrics, and team evaluation scores. The results suggest that our influence metrics correlate to a team member's perceived role on the team, measures of team communication and levels of task performance. This suggests that instructors can recognize the levels of influence exerted by team members by examining team communication and control flow, allowing for mediation prior to product development milestones.

Keywords—Computer science education; agile software development; collaborative work; social network analysis; centrality

I. INTRODUCTION

The role of influence in team dynamics has been studied from multiple perspectives, such as the response to leadership [1], the allowance of diversity in problem solving approaches [2-3], and the impact of perceived status and likeability on individual performance [4]. In a classroom setting, understanding how influence is manifested and perceived by team members can allow for early mediation. If negative influence from a team member is evident, individual and team meetings can help bring awareness and correction. If a member exerts positive influence and is perceived as a leader or role model for the team, then watchfulness may be needed to ensure adequate participation by all members.

The objective of the research is to devise an influence measure that can serve as a predictor of team performance characteristics. We use communication and control flow as an influence indicator among team members as they share a dedicated communication medium and multiple artifact

development tools. The resulting sociometrics developed in this study are based on the concepts of centrality and centralization from social network analysis [5]. *Centrality* is a number that quantifies some type of "importance" of a node in a social network. *Centralization* is a numerical measure of how evenly centrality is distributed over the nodes in a network. If a social network has a high centralization, this means that most of the centrality is concentrated in a relatively small group of nodes.

The main research question we seek to answer is: *Can social network analysis algorithms be applied in small team assessment to accurately quantify influence and predict aspects of product outcomes, individual performance, and peer assessments?* Section II overviews studies in influence, provides an overview of centrality and centralization, and briefly describes the communication medium used by the teams in this study. Section III describes our methodology, including the processes used to build and analyze influence network graphs based on each team's recorded actions. Section IV describes the study parameters and correlation results. Section V provides discussion and conclusion.

II. RELATED WORK

A. Influence Studies

Status and sentiments are two major factors that have been researched with respect to determining the expectations to task ability among collaborative team members. This expectation can translate into one team member influencing the behavior of another in a positive or negative way. Status is defined as the prestige a person has because of a valued social distinction. Sentiments involve the relationship of liking or disliking a team member. They may be expressed in the form of expressive patterns or gestures that are manifested in social settings. Research in understanding the interplay between sentiments and status can provide reasons for team interventions to reduce any negative effects on group behavior. Bianchi [4] crafts a set of actor-partner studies to examine the interplay between advisor-decision maker and neutral-negative sentiment. Each study participant was informed that they could not directly view their partner and did not know that their partner was a computer program. With respect to influence, the results indicate that the partner's approval is more important when an actor is fully responsible for the outcome of the team and less important if there is dislike.

Goh and Wasko [3] explore the roles of leadership as a form of influence on how resources are allocated to members on a virtual world team. Abstractly these resources may include expertise, task load balancing, or planning aid. Using a massive, multiplayer online game, they found that there is a leader-member relationship that impacts performance. Notably, the higher the quality of the relationship, the better the resource allocation. However, they also found only partial support for a relationship between the level of quality and the level of trust and performance. The possibility exists that virtual world teams may not have the same social connection to other team members as teams that can meet face to face.

Santos, et al. [6] examine organizational strategy and communication flow and channels as influencing factors for knowledge sharing. Their goal was to study these factors in terms of how the companies used agile methods. Using survey data, they showed that extensive communication with multiple channels fostered knowledge sharing across teams, which also had a significant association with a company's experience using agile methods.

B. Centrality and Centralization

There are many metrics used to compute centrality and centralization. Two existing centrality metrics which are relevant to our study are *degree centrality* [5] and *Katz centrality* [7]. Degree centrality is a metric in which each node's centrality is equal to the number of direct connections it has with other nodes. In a directed graph, degree centrality might consider only incoming or outgoing connections, depending on what the graph models. Katz centrality is a metric that considers all paths that exist in a network (including those that follow the same edge multiple times), and assigns each path a weight which degrades exponentially with path length. If we let $L(p)$ denote the number of edge traversals in a path p , the weight of p is

$$w_{\text{Katz}}(p) = b^{-L(p)}$$

where $b \geq 1$ is a parameter. The centrality of a node is then the sum of the weights of all paths that start at that node. If we let V denote the set of nodes and P_{ij} denote the set of all paths from node i to node j , then the Katz centrality for node i is given by

$$\sum_{j \in V} \sum_{p \in P_{ij}} w_{\text{Katz}}(p)$$

Since the number of paths in a network is often infinite, this sum may not converge if b is too small.

In this study, we use slightly modified versions of two existing centralization metrics. One simple centralization metric is the population variance of the observed centrality values [5]. If we let $C(i)$ denote the value of some centrality metric for node i and let \bar{C} denote the mean observed centrality, the variance is

$$\left(\sum_{i \in V} (C(i) - \bar{C})^2 \right) / \|V\|$$

Another centralization metric is *Freeman's centralization index* [5]. This metric is computed by finding a sum of differences representing the amounts by which the most central node's centrality exceeds each other node's, and dividing the sum by its theoretical maximum. If we let C^* denote the maximum observed centrality, the value of Freeman's centralization index is

$$\left(\sum_{i \in V} (C^* - C(i)) \right) / S$$

where S is the maximum possible value of the numerator sum

$$\sum_{i \in V} (C^* - C(i))$$

Note that Freeman's centralization index is always in the range from 0 to 1.

C. Communication Medium

In prior studies, we have examined learning indicators [9] and performance metrics [10] using a collaborative project management tool, SEREBRO [11]. We developed SEREBRO in 2008 as part of an NSF Creative IT program [12] and have used it as courseware in Software Engineering classes since 2009. It was used in Introduction to Psychology classes for further studies on self-regulation from 2011-2013.

Fig. 1 shows the interface of SEREBRO as it relates to a forum post. The forum is structured as a set of trees where each root (circle) is a brainstorm node to start a conversation and the triangles are agree (point up) or disagree nodes (point down, not shown). The lightbulbs mark posts the user has not yet viewed. Hovering over a node on the graph displays the post, and clicking on it allows the user to agree, disagree, or comment to add a child post. The tabs at the top of Fig. 1 show that the user is in the Sprint 1 milestone under the topic Meeting 6. To the left of the interface is the listing of project management modules. These include a wiki and an SVN version control repository.

SEREBRO has an embedded event tracking system that assigns events to users whenever they post, change the wiki, upload files, or commit to the SVN. We use the SEREBRO forum and wiki data, along with other event logs from Git (for version control), Google Drive (drive.google.com), and Lucidchart (www.lucidchart.com), to build our influence networks, as described in Section III.B. In the Software Engineering courses used in this study, team members are required to use these tools for all electronic communications. Thus, untracked interactions such as email and text messages are discouraged.

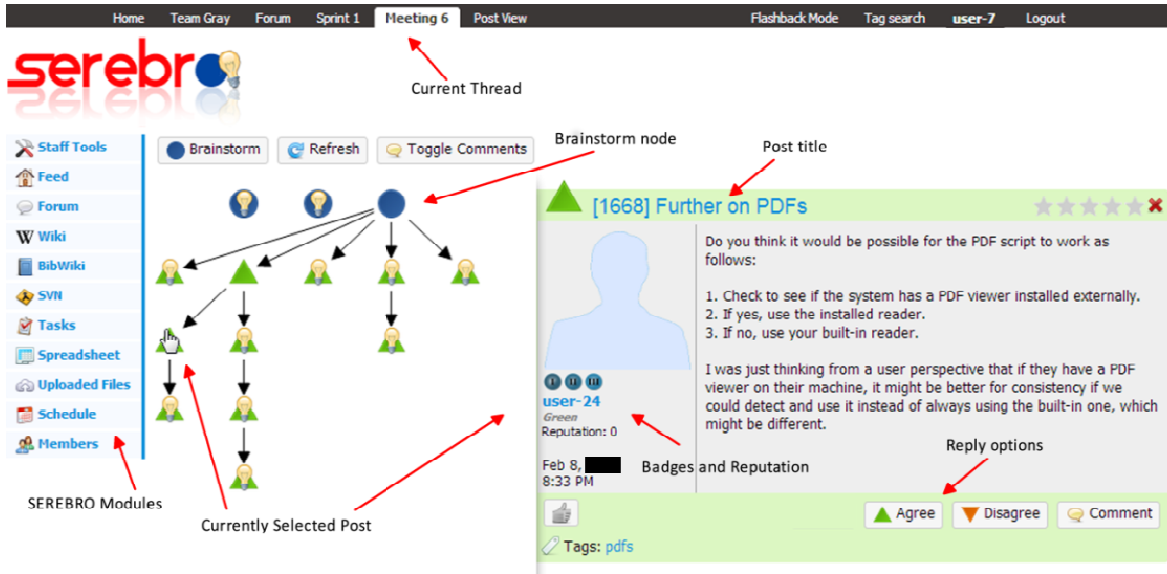

Fig. 1. SEREBRO Forum Interface

III. METHODOLOGY

When reviewing existing social network analysis techniques, we generally found that these techniques model the network as a simple graph, where an edge between two nodes indicates that a connection or interaction was observed between those nodes (e.g., [1], [5], [8]). Since our study focuses on small teams, in which any given pair of members will likely share a direct interaction at some point, this type of model would tend to produce a clique very often. Without some way of modeling the number and type of interactions, this leaves little potential for differentiating the influence levels of different team members.

Another limitation of a standard graph-based model is that it does not provide information about the timing of interactions. The lack of timing information could be problematic for our purposes. For example, if person *A* interacts with person *B*, who then interacts with person *C*, it seems reasonable to suspect that *A* may have exerted some indirect influence on *C* through *B*. However, if the interaction between *A* and *B* had taken place after the interaction between *B* and *C*, no indirect influence from *A* to *C* would be possible. Since one of our goals is to develop sociometrics that take indirect influence into account, it is desirable to use a model that can distinguish between the above two scenarios. To this end, we developed a modified graph model, described as follows.

A. Network Model and Metrics

In our model, the influence network contains *member nodes* representing the human team members, as well as *artifact nodes* representing shared documents and code repositories. The graph contains an edge for each influence event tuple that we recorded (as described in Section III.B.). Each edge is directed from the node responsible for the influence to the one receiving the influence, and edges are marked with time stamps indicating the time of the influence event. Since there can, of course, be many observed influence events between two nodes, our graph can include multiple edges from one node to another.

We developed three centrality metrics to use in this study. One

metric is similar to Katz centrality [7], but with a few modifications. First, since the network can contain multiple edges from one node to another, there can be multiple paths following the same sequence of nodes. Paths that visit the same node sequence but use different edge sequences are considered distinct. Second, our metric only considers paths that are monotonically increasing in time. This ensures that indirect influence will not be considered when the ordering of events makes it impossible. It also ensures that only finitely many paths will be considered, which means centralities will be defined even when *b* is small. Third, we include an optional *path length limit* parameter L_{max} ; paths containing more than L_{max} edges are assigned zero weight and thus ignored. Fourth, our metric ignores paths that start and end at the same node. This is because we are primarily interested in the influence a node has on other nodes, rather than any indirect influence a node may have on itself. Fifth, our metric includes *normalization* of centrality values so that the centralities of all member nodes sum to 1.

To express this metric formally, let V_M denote the set of member nodes, and let PT_{ij} denote the set of monotonically temporally increasing paths from node *i* to node *j*. Furthermore, let

$$w_{Exp}(p) = \begin{cases} 0, & \text{if } L(p) > L_{max} \\ b^{-L(p)}, & \text{otherwise} \end{cases}$$

for each path *p*, and let

$$I_{Exp}(i) = \sum_{j \in V_M - \{i\}} \sum_{p \in PT_{ij}} w_{Exp}(p)$$

for each node *i*. w_{Exp} is a weighing function giving the weight of each path, and I_{Exp} gives the centrality values before normalization. The normalized centrality is then

$$C_{Exp}(i) = \frac{I_{Exp}(i)}{\sum_{j \in V_M} I_{Exp}(j)}$$

We developed another metric C_{poly} in which path weights degrade at a polynomial-like rate rather than an exponential rate. The metric is

the same as above, except that the weighing function w_{Exp} is replaced with

$$w_{\text{Poly}}(p) = \begin{cases} 0, & \text{if } L(p) > L_{\max} \\ (L(p))^{-a}, & \text{otherwise} \end{cases}$$

where $a \geq 1$ is a parameter.

The third centrality metric we used is C_{Direct} , a form of degree centrality based on outdegree. This metric can be defined the same way as C_{Exp} , with w_{Exp} replaced by

$$w_{\text{Direct}}(p) = \begin{cases} 0, & \text{if } L(p) > 1 \\ 1, & \text{otherwise} \end{cases}$$

Note that the use of C_{Direct} is practically equivalent to assigning influence values by simply counting the number of direct influence events from a given team member. As such, this metric is not novel; it was included as a baseline to determine whether our other metrics gain any advantage by considering indirect influence.

Since we are primarily interested in the influence of human team members, we also modified existing centralization metrics to consider only the set V_M of member nodes. Note that, despite being ignored in the centralization computations, artifact nodes do have a meaningful impact on centralization due to their use in computing the centralities of member nodes. The modified variance centralization metric is

$$\left(\sum_{i \in V_M} (C(i) - \bar{C}_M)^2 \right) / \|V_M\|$$

where \bar{C}_M is the average centrality over all member nodes. The modified Freeman centralization index is

$$\left(\sum_{i \in V_M} (C^* - C(i)) \right) / S_M$$

where S_M is the maximum possible value of the sum in the numerator. For all three of our centrality metrics, the most centralized scenario possible is one in which one team member has centrality 1 while the others have centrality 0. In that case, the sum in the numerator reaches its maximum value:

$$S_M = \|V_M\| - 1$$

In addition to trying the above centrality and centralization metrics with various values for the parameters, we experimented with different ways of building the influence network. In our first approach, we included edges for all the influence event tuples that we had recorded (see Section III.B.). In another approach, we omitted all direct communication edges between team members, so that only influence events involving artifacts were considered. In a third approach, we omitted all edges starting or ending at artifact nodes, so that only influence arising from interpersonal interactions was considered.

B. Constructing the Networks

Because the teams were formed with a common goal and had approximately the same foundational training, we hypothesized that those team members that would assert themselves as leaders would

also influence the team through their collaborative actions. To construct our influence networks, we compile a set of influence events based on the communication among team members and the control they exert over artifacts. Each event was encoded as a 3-tuple corresponding to an edge in the network. The tuple set is described below.

Direct naming. If user A names user B in a SEREBRO forum post with a request to perform a task or a suggestion as to how to perform a task, then A influences B at the time, t , of the direct naming of B in the forum post, resulting in tuple (A, B, t) .

Direct use. If user A names user B in a post at time t in reference to evaluating or using something B produced, then B influences A , resulting in tuple $(B, A, t - \varepsilon)$, where $t - \varepsilon$ is a time that precedes t by a small amount, such that no tuples will have timestamps between $t - \varepsilon$ and t . The subtraction of ε is done so that, if a single post involves both direct naming and direct use, the direct use will appear first in the temporal order. We believe this is appropriate, as the actual influence implied by direct use presumably occurs before the associated forum post.

Deliberate response. As shown in Fig. 1, the forum is structured in a manner such that a conversation is held by a tree within a larger topic. If user A posts and user B responds in any way that reflects the content of A 's post and is within the same forum topic, then A influences B , resulting in a tuple $(A, B, t - \varepsilon)$, where t is the time of B 's post.

User/wiki interaction. If user A edits a SEREBRO wiki page at time t , then a tuple (A, W, t) is produced, where W is the wiki's artifact node. Furthermore, if the previous person to edit the wiki was someone other than A , then a tuple $(W, A, t - \varepsilon)$ is produced. The rationale for recording influence from W to A is that A presumably would have to read the wiki page before editing it if A was not the previous editor.

User/codebase interaction. In this study, each team used one or more Git repositories hosted through either GitLab (gitlab.com) or Bitbucket (bitbucket.org). If a Git repository G contains a commit with author A and commit time t , and that commit is an ancestor of G 's master branch at the end of the associated 3-sprint project, then a tuple (A, G, t) is produced. For each parent of A 's commit that does not have A as its author, a tuple $(G, A, t - \varepsilon)$ is produced. Multiple identical tuples may thus be generated when a commit has multiple parents; these are treated as distinct.

Google Drive and Lucidchart interaction. In addition to SEREBRO and hosted Git repositories, each team used one or more shared Google Drive and/or Lucidchart documents. Due to the nature of the Google Drive and Lucidchart Web interfaces (which upload changes frequently and automatically even when the changes are minimal), we suspected that recording a tuple for each uploaded change would result in a disproportionately large number of tuples associated with these artifacts. To avoid this, we generated tuples based on small intervals of time in which users actively edited documents. These *activity blocks* were estimated as follows. Wherever a document's event log indicates that a user A made two edits less than 30 minutes apart, user A is assumed to have been editing the document in the time between those edits. User A is also assumed to have been active at the single point in time corresponding to each recorded edit (possibly producing some single-point editing

intervals). Each contiguous interval of active time, including any single-point intervals, is split into 5-minute activity blocks. (The interval's last block may be less than 5 minutes long. Any active interval shorter than 5 minutes becomes a single block.) Then, if user A has an activity block for document D that starts at time t , a tuple (A, D, t) is generated. Additionally, if one or more other users were active with respect to D between the current block's starting time and the starting time of A 's previous block for D , one tuple $(D, A, t - \epsilon)$ is generated.

IV. ASSESSING INFLUENCE

A. Study Parameters

The preliminary study reported here involved 19 students separated into 5 teams with 3 to 4 people per team. Each team's work was separated into 3 sprints, each having its own milestones, grades, and peer evaluations. Considering each sprint and student separately, our data covers a total of 57 evaluation points. The teams are in a realistic setting, with a product customer, and work collaboratively both face-to-face and asynchronously through SEREBRO. Teams collaborate on code development through shared Git repositories that replace SEREBRO's SVN repositories used in previous years. While they have consented to the study of their data, they are not acting primarily as study participants, but as actual team members with a common product goal. Sprints last an average of 5 weeks.

For each team, we generated 3 sets of influence tuples corresponding to the 3 development sprints. This allows us to compute centralities separately for each sprint, resulting in 57 data points for each centrality metric and 15 data points for each centralization metric. For each sprint, we also calculated some of the performance metrics assessed in [10]. We believe the Influence metric from this previous study was too narrowly based on event counts. We re-term this metric as *Event Proportion* here to avoid confusion. The performance metrics for Contribution and Impression from [10] are repeated below.

Contribution. *Contribution* measures quality of meeting check-ins on the SEREBRO forum for each sprint according to Subject Matter Expert content evaluation and rating [10]. The meeting check-ins simulate a daily Scrum meeting with modifications for an educational setting. Users are expected to (1) state what they did since the last check-in, (2) state what they are doing for the next check-in, (3) state what impediments they have or evaluations of other team members they have performed, and (4) be on time for posting. A sprint averages 12 meeting check-ins with each check-in worth 15 points. There are sometimes bonus points awarded if an individual completes all requirements for all check-ins during the sprint.

Impression. *Impression* measures the average evaluation rating for 20 qualities in a team survey regarding each individual's perceived performance during a sprint [10]. The general qualities are the same for each sprint, but some of the questions are presented differently given the goals of the sprint. The survey requires individuals to report on the performance of each team member (including themselves) with a rating from 0 (no performance) to 10 (exceedingly high performance) for each quality. The questions common to all sprints are listed below.

- Q1. Participated in online and face-to-face meetings
- Q2. Responded to team activity in a timely manner

- Q3. Contributed project ideas that were implemented
- Q4. Contributed to document artifacts creation and/or review
- Q5. Set the standard for team performance
- Q6. Completed all tasks assigned at agreed upon timeline
- Q7. Organized the requirements, user stories, and Sprint Backlog
- Q8. Communicated project and instructor expectations well
- Q9. Performed design based tasks effectively
- Q10. Initiated and maintained required documents
- Q11. Worked with team to create overall product vision
- Q12. Delegated tasks appropriately

Qualities that relate to status or sentiment among team members in terms of perceived reputation and follow-through, and embody project and team influence, are included in questions 2, 3, 5, 6, 11, and 12. We target these questions in the correlation results presented in Section IV.B. For each question and sprint, we assigned each team member an *Evaluation Question score* equal to the average of all scores assigned to that user (for the given question) in surveys from the given sprint.

Event Proportion. *Event Proportion* measures the number of events an individual performs relative to the number of team events for a given sprint. The events we counted for this metric consist of SEREBRO events, Git commits, and activity blocks for Google Drive and Lucidchart documents.

Sprint Grade. A team grade is assigned for each sprint based on the timely hand-in of the team work products which generally include design documents, code, project documentation, artifacts such as images created for a web application, and presentations. All team members received the same team grade as an initial score. Individual grades are produced by incorporating participation in meeting check-ins, attending mandatory team meetings, and the team evaluation. If the team evaluation goes below certain levels and there is general agreement among the team, the individual affected receives a percentage of the team grade. The individual grade is recorded as the Sprint Grade for the study.

For purposes of statistical analysis, the Contribution, Impression, Sprint Grade, and Evaluation Question scores were normalized for each sprint/team. That is, for each sprint/team, each of these metrics was multiplied by a normalization factor so that the metric's values across team members sum to 1. This was done to compensate for any overall performance differences among teams. Without normalization, we believe these differences would negatively impact the meaningfulness of our correlation analysis, since our centrality metrics only attempt to measure a team member's influence relative to other members of the same team.

B. Results of Correlation

As mentioned in Section III.A., influence networks were constructed three ways: (1) *All* – using event tuples from forum posts and artifacts, (2) *Artifacts* – using only artifact tuples (thus ignoring direct communication within teams), and (3) *Forum* – using only forum tuples (thus considering only direct communication within teams).

We examine the linear dependence among our influence centrality metrics and the normalized Sprint Grades, Evaluation Question scores, Impression scores, Event Proportions, and Contribution scores. We use the Pearson correlation coefficient (Pearson's r) to determine

what correlations exist between influence centrality metrics and other performance measures. Correlation values are calculated using sum of squares. Critical values are chosen based on a two-tailed test with 55 degrees of freedom, corresponding to the 57 evaluations examined.

We experimented with a broad range of metric parameters. In Tables I, II, and III, we show the results obtained using C_{Direct} , C_{Poly} with $a = 2$; and C_{Exp} with $b = 2$, $b = 5$, and $b = 10$. In all cases shown, L_{max} is set to infinity. These tables show the obtained correlation values for *All*, *Artifacts*, and *Forum*, respectively, as defined above. Cells in the tables are highlighted to show significant results as follows.

- $p > 0.05$ (low confidence), $|r| < 0.261$; white cells
- $p \leq 0.05$ (95% confidence), $|r| \geq 0.261$; blue cells
- $p \leq 0.01$ (99% confidence), $|r| \geq 0.339$; tan cells

1) Correlation Results – All Event Tuples

Reviewing Table I, the degree centrality metric, C_{Direct} , strongly correlated with several performance measures. The correlation with event proportion is particularly strong. This is to be expected, since C_{Direct} is equivalent to a normalized event count. The correlations with peer evaluation questions 1-5 and 10-11, as well as with Impression and Sprint Grade (both of which depend on evaluation scores), suggest that team members were able to accurately assess the direct work occurring within their teams.

The polynomial decay metric, C_{Poly} , had no correlation with sprint grade, but did correlate with 3 of the 6 targeted questions. C_{Poly} had a slightly higher correlation with question 11 than the other sociometrics.

Of most interest for our research is the exponential decay metric, C_{Exp} , which correlates well with our target questions (particularly with $b = 10$) while taking the possibility of indirect influence into account. This metric's correlations with evaluation questions are fairly similar to those of C_{Direct} , with the exceptions of questions 4, 6, and 10. Notably, questions 4 and 10 are both closely related to documents. This may indicate that indirect influence is less important in document creation than in other aspects of team functioning, or that our methodology for deriving document editing events, primarily the timings set for the activity blocks in Google Drive and Lucidchart documents, needs further refinement. C_{Exp} appears to be the best predictor for question 6, which measures team members' reputations for completing assigned tasks on time.

The overall lack of correlation with questions 8 and 12 indicates that, when all events are used, the communication authority exhibited by team members is not captured well by the influence centrality values.

2) Correlation Results – Artifact Event Tuples

For the most part, Table II exhibits the same patterns as Table I, although the correlations are generally weaker. The similarity of the *All* and *Artifacts* cases suggests that, in the *All* case, artifact event tuples may have had excessive impact on the sociometric values, overwhelming the effects of the discussion-based tuples. This is further supported by the strong contrast with Table III (in which only the forum was considered), and indicates a possible need for modifications to the way artifacts are incorporated in the *All* case.

TABLE I. CORRELATION RESULTS – ALL EVENT TUPLES

	C_{Direct}	C_{Poly} (a=2)	C_{Exp} (b=2)	C_{Exp} (b=5)	C_{Exp} (b=10)
Sprint Grade	0.393	0.236	0.265	0.301	0.330
Q1	0.412	0.232	0.288	0.334	0.347
Q2	0.438	0.206	0.264	0.324	0.357
Q3	0.427	0.280	0.356	0.411	0.440
Q4	0.363	0.082	0.034	0.020	0.058
Q5	0.495	0.345	0.401	0.440	0.471
Q6	0.247	0.207	0.270	0.312	0.319
Q7	0.231	0.043	0.029	0.013	0.009
Q8	0.242	-0.027	-0.091	-0.160	-0.142
Q9	0.156	0.097	0.033	0.000	0.008
Q10	0.278	0.021	0.0431	-0.073	-0.048
Q11	0.316	0.327	0.3241	0.301	0.289
Q12	0.179	0.071	0.079	0.051	0.049
Impression	0.400	0.284	0.320	0.336	0.352
Event Proportion	0.902	0.294	0.380	0.556	0.659
Contribution	0.397	0.277	0.245	0.225	0.252

A few differences between Tables I and II are notable, particularly with respect to C_{Poly} with $a = 2$ and C_{Exp} with $b = 2$. C_{Poly} no longer correlates significantly with Contribution or question 3 but now correlates with question 1. C_{Exp} with $b = 2$ no longer correlates significantly with Sprint Grade or question 2. We do not have a satisfactory explanation for these changes, but we note that the associated changes in r seem fairly small. In all cases where significant correlations are lost or gained between Tables I and II, the insignificant correlation is within 90% confidence ($p \leq 0.1$, $|r| \geq 0.220$). Therefore, we hypothesize that these differences are due to coincidence. Further experiments with more teams would be needed to test this hypothesis.

3) Correlation Results – Forum Event Tuples

Table III has the most interesting results. When artifact tuples are omitted, all of the sociometrics shown have highly significant correlations with questions 1-3 and 5, as well as Sprint Grade and Impression. Significant correlations with questions 6 and 11, as well as Contribution and Event Proportion, are also present for all metrics. Higher correlation with Contribution is to be expected, as Contribution scores are heavily dependent on forum activity.

Notably, C_{Exp} with $b = 10$ has larger r values than C_{Direct} for *all* of the performance measures. This provides support for our hypothesis that influence metrics can gain predictive power through the consideration of indirect influence. Admittedly, some of the differences in r values are quite small, suggesting a need for further study of how indirect influence may be gauged.

TABLE II. CORRELATION RESULTS – ARTIFACT EVENT TUPLES

	C _{Direct}	C _{Poly} (a=2)	C _{Exp} (b=2)	C _{Exp} (b=5)	C _{Exp} (b=10)
Sprint Grade	0.364	0.219	0.240	0.264	0.289
Q1	0.383	0.264	0.307	0.311	0.309
Q2	0.408	0.211	0.260	0.2900	0.312
Q3	0.384	0.260	0.321	0.367	0.396
Q4	0.361	0.073	0.031	0.001	0.036
Q5	0.465	0.356	0.398	0.409	0.430
Q6	0.191	0.242	0.282	0.280	0.270
Q7	0.245	0.034	0.032	0.009	-0.004
Q8	0.247	0.005	-0.063	-0.143	-0.135
Q9	0.160	0.071	-0.002	-0.031	-0.019
Q10	0.306	-0.015	-0.071	-0.096	-0.067
Q11	0.288	0.351	0.347	0.299	0.270
Q12	0.160	0.049	0.066	0.032	0.024
Impression	0.369	0.284	0.303	0.302	0.311
Event Proportion	0.879	0.311	0.383	0.543	0.643
Contribution	0.375	0.259	0.230	0.205	0.220

C_{Exp} with $b = 5$ and $b = 10$ correlate with question 12, while Tables I and II show no significant correlation with question 12 for any metrics. This is understandable, as question 12 relates to task delegation, which is more likely to occur through discussion than to be recorded in artifacts. C_{Exp} has also gained significant correlations to question 4, where in Tables I and II the r values were extremely low. This is difficult to explain, since the correlation between C_{Direct} and question 4 is much *smaller* in Table III compared to the other two tables.

Also note that for questions 4 and 12, C_{Exp} with $b = 5$ and $b = 10$ have stronger correlations than C_{Direct} (which gives the least consideration to indirect influence) as well as C_{Poly} with $a = 2$ and C_{Exp} with $b = 2$ (which have the slowest path weight degradation and thus give the most consideration to indirect influence). This indicates that, for some predictive purposes, it may be important to avoid both underestimating and overestimating the amount of indirect influence. Further research is needed to determine how one might choose the best parameters for sociometrics given an intended application.

It should also be mentioned that our correlation analysis remained consistent with results presented in [10]. Given the data from the current study, which uses multiple teams, semesters, and instructors, Impression strongly correlated with both Event Proportion ($r = 0.429$) and Contribution ($r = 0.764$), and Event Proportion strongly correlated with Contribution ($r = 0.429$).

We also performed analysis of correlation between our centralization metrics and other measures relating to teams as a whole, such as team size and overall team grade. The goals of this analysis were to determine whether team size affects a team's level of

centralization and whether more centralized teams tend to have higher or lower performance than less centralized teams. We found very few significant correlations, so the numerical results are omitted here. However, it is worth noting that, in the *All* and *Artifacts* cases, both the Freeman and variance centralization metrics correlated negatively with team size (with at least 95% confidence) for C_{Exp} with $b = 10$. It is possible that the lack of meaningful results is due to the small sample size; since these metrics apply to teams rather than individuals, only 15 data points were available for the analysis.

TABLE III. CORRELATION RESULTS – SEREBRO FORUM EVENT TUPLES

	C _{Direct}	C _{Poly} (a=2)	C _{Exp} (b=2)	C _{Exp} (b=5)	C _{Exp} (b=10)
Sprint Grade	0.370	0.366	0.375	0.409	0.401
Q1	0.386	0.345	0.362	0.409	0.408
Q2	0.393	0.355	0.378	0.431	0.426
Q3	0.421	0.388	0.409	0.433	0.433
Q4	0.253	0.200	0.212	0.270	0.273
Q5	0.480	0.480	0.523	0.551	0.529
Q6	0.380	0.324	0.318	0.369	0.380
Q7	0.165	0.221	0.219	0.229	0.211
Q8	0.149	0.185	0.204	0.195	0.176

Q11	0.333	0.357	0.356	0.355	0.348
Q12	0.261	0.230	0.244	0.280	0.277
Impression	0.445	0.433	0.450	0.483	0.475
Event Proportion	0.416	0.322	0.326	0.409	0.422
Contribution	0.337	0.346	0.352	0.375	0.367

V. DISCUSSION AND CONCLUSION

A. Potential Threats to Validity

As our data were gathered in a real class setting and students were not enrolled primarily as research subjects, some anomalous situations occurred which we had to work around. In one case, there was a 4-member team in which one member stopped working and attending meetings early in Sprint 1, and later withdrew from the class. We chose to exclude this team member from analysis to reduce the risk of producing a statistical outlier. The team was treated as a 3-member team, and the small amount of activity by the omitted member was ignored as if it were influence from outside the team.

We also encountered a situation in which a team member moved from one team to another between Sprints 2 and 3, but later made a small commit to the previous team's Git repository. This commit had one child and one parent. In tuple generation, the child commit was treated as if it were a direct child of the anomalous commit's parent, and the anomalous commit was ignored.

Another potential issue is the complex dependency of events in different sprints, due to the fact that most teams keep the same members across sprints. Students are evaluated and graded separately for each sprint, but the separation is likely imperfect. For instance, a poor grade in one sprint might motivate higher performance in the next, and team members might develop status and sentiments in one sprint that could affect their interactions and peer evaluations in later sprints. It is possible that influence may manifest itself differently in different sprints based on how long team members have worked together. However, we believe that there was significant independence in the communication and collaborative activities during each sprint, as well as evaluations of team members, to justify the use of the data.

B. Conclusion and Future Work

The correlation results from this study support the hypothesis that social network analysis can be applied in small teams to make predictions about the likely performance of individuals. Thus, social network analysis may provide a useful way for instructors, supervisors, or team members to monitor the performance of individuals in an agile software development team, and detect potential problems.

One key result from the study shows the benefits of assessing the frequency and content of communication among team members. Given Table III's correlation values, influence appears to be manifested most among forum posts. While an instructor needs artifact-based events to track and grade a student's project engagement and outcome, having access to team communication provides a clear mechanism to assess who is exerting influence on the team. Self-reporting team evaluations provides additional insights into a student's perception of a team member and their own role on the team. Table III also provides some evidence that the consideration of indirect influence based on the timing of interactions may improve predictions.

One goal for our future work is to repeat our analysis with a larger data set having at least 200 samples. A larger sample may provide more detailed information about the behavior of our sociometrics.

Other important directions for future research include seeking ways to automate the construction of influence networks (thus making our metrics much easier to apply in practice) and determining how artifacts can be more effectively incorporated into our analysis.

marja.kankaanranta@jyu.fi

Abstract — This paper presents perspectives on adaptive web-based learning environments, their tasks, functions, techniques and methods. The main categories, types and layers of adaptive learning systems as well as different forms of feedback used in these environments were examined. The significance of feedback becomes emphasized in learning environments because it helps to plan the student's learning path, provide information about their progress, note the important information and guide the student along the learning process. This work introduces an evaluation framework for the analysis of game-based learning environments by the main criteria used in adaptive learning games. The analysis is focused on various learning environments, specifically applications and games for English language learning. The analysis results in an evaluation of 23 game-based learning environments and applications that are developed for the purposes of English learning. The relationship between the feedback types and areas of English learning is presented.

Keywords — *adaptive learning system; game-based learning environment; feedback system; English-learning games*

I. INTRODUCTION

In recent years, there has been a growing interest towards utilizing adaptive intelligent technologies in creating learning environments for enhancing more personalized education. The use of these technologies contributes to improving the quality of education, as well as reducing the time required for mastering learning content. Learning environments that adjust themselves according to the needs and abilities of individual users or groups of users are called adaptive learning systems.

Adaptive learning systems allow organizing content, identifying the way to learn according to learner's knowledge and use assessment results to provide personalized feedback to each learner [1]. Adaptation of the learning process implies a change in the sequence of the studied topics and visual representation of each viewing page. The quality of the educational process in web-based learning systems depends on the use of adaptive technology, methods and built-in mechanisms.

This paper provides a short review on existing adaptive game-based learning systems, specifically concentrating on English language learning. The use of game-based learning in English language learning has spread on a wide area including games and applications that may be used, for instance, for vocabulary and grammar learning, pronunciation and listening comprehension, and it has been proved to improve learning [2], [3], [4]. However, as the previous studies reveal, research in the area of feedback in applications and games has not yet been conducted to a large extent and at the same time the amount of students hoping to improve their language skills by

using e-learning tools is increasing. As Belotti F. et al. [5] point out, technology and various tools can be used to provide a learner with assessment and feedback without the presence of an instructor or a teacher.

The problem of assessing the quality of adaptive learning system, the problem of choosing technologies and methods for constructing such adaptive systems, as well as determination of the causes of low efficiency of learning are relevant for the development of such systems.

Despite the fact that significant results have been achieved in the area of adaptive learning systems, including practical ones, there are not any defined evaluation criteria and optimal components for these systems, nor are there any specific requirements for the construction of logical and structural models for these systems. In order to build a good quality adaptive game-based learning system, developers have to understand the main criteria for the evaluation of these systems.

This paper consists of five sections. Section 2 presents general information about adaptive learning systems and their division according to types, methods, technologies, features and levels. Section 3 opens a discussion about the meaning of feedback in game-based learning environments, especially focusing on English learning. Section 4 presents a design of evaluation framework for adaptive English learning game-based environments and criteria for this evaluation. Section 5 concludes the paper by presenting results in 23 evaluated game-based learning environments according to feedback types. It presents feedback types used in different English learning areas, addressed in selected game-based learning environments, and the relationship of English learning areas to the types of feedback.

II. CONTEXT OF THE ADAPTIVE LEARNING SYSTEM

A. Adaptive Learning and Adaptive Learning Systems

According to Gifford T. [6] adaptive learning is a method that is centered on "creating a learning experience that is unique" for every individual learner through the intervention of computer software. Adaptation in learning can be viewed from several different aspects: adaptation to the current needs of particular learner; adaptation to a particular learner's state; adaptation to a chosen specific field for studying and adaptation to a specific task.

According to Sonwalkar N. [1], adaptive learning systems are technological systems that are capable of adapting and learning depending on received input signals. Intelligent adaptive learning observes each decision a student makes and

adapts the student's learning pathway (or produces many personalized learning paths, which are specifically designed to a student's unique needs).

The goal of an adaptive learning system is to individualize learning so it becomes possible to improve or stimulate student's performance gain. According to Weber G. [7] the system is able to "enhance the individual learning process with respect to speed, accuracy, quality and quantity of learning". Adaptive learning systems are intended to identify what a student does and does not understand, identify and provide content that will help the student learn it, assess again, help again, etc., until a defined learning goal is achieved [8].

Adaptive distance learning systems have a number of advantages, the main ones being: providing opportunities to choose student's own path of learning; differential approach to learning based on the fact that each learning experience and knowledge in one area that determines the degree of understanding of the new material is different; increasing objectivity and knowledge control efficiency of the student; individualization of learning activities; and increasing motivation and activation of cognitive activity of students.

B. Types, Technologies, Methods, Levels and Features of Adaptive Learning Systems

Earlier research has indicated that adaptive systems can be defined according to their types [8], utilized technologies [9], [10] methods for building these systems [11], [12], [13], [14], levels [8] and features [15], [16].

The main types of adaptive learning systems are simpler adaptive systems and those that are algorithm-based [8]. Simpler adaptive systems are based on rules and are more content-oriented. They are easier to understand in terms of functionality; however they are less adaptive to individual needs of students. Here is an example of a system flow: the system asks the user a question, and if the answer is correct, it continues to the next one. If the given answer is incorrect, the system helps the user by displaying additional information, e.g. a hint, same learning material repeated, additional learning material, explaining the matter in a different way, etc. Algorithm-based systems are based on advanced mathematical formulas and machine learning concepts. These systems are more complex. Such systems may make use of educational data mining and advanced analytics to deal with big data, and employ complex algorithms for predicting probabilities of a particular student being successful in learning particular content.

There are two main technologies utilized in the design of adaptive systems: Adaptive Hypermedia Systems and Intelligent Tutoring Systems [10]. Adaptive Hypermedia Systems include adaptive presentation and adaptive navigation support. Intelligent Tutoring Systems include curriculum sequencing, intelligent solution analysis and problem solving support.

Adaptive and intelligent technologies can significantly improve the quality of distance education systems. Adaptive presentation can improve the usability of course material. Adaptive navigation support and adaptive curriculum sequencing can be used for full control over the course and to aid in selecting the most appropriate information and regulations. Problem solving support and intelligent solution analysis can significantly improve the quality of software requirements, and make teachers' work easier.

Many techniques and methods have been utilized in the development of adaptive learning systems [11], [12], [13], [14]. The main methods include the data-based inference method (case-based reasoning, machine learning, collaboration filtering), theory-based inference method (Bayesian networks, Naive Bayes analysis, fuzzy logic, Dempster-Shafer theory of evidence) and decision-making methods (influence diagrams, decision theoretic planning). Some of the techniques are using learning style (MBTI, Kolb's, Felder-Silverman, and The Vark) and some are using technologies based on Semantics (ontologies, agent-based, etc.).

The levels of adaptivity are determined according to the complexity of a system. Verdugo D. and Belmonte I. [4] present five levels, which differ in regard of complexity and features.

Level 1: Students complete a quiz after reading the material and the system provides feedback informing the student on whether or not the given answer was correct.

Level 2: Same as in Level 1. In addition, the system provides some explanations detailing why some answers were incorrect, as well as presenting a link to the material for a review.

Level 3: Same as in Level 1. Furthermore, the system gives a recommendation about the material to read. In the next quiz, the system will add the questions that have been answered incorrectly in the previous section to see if the student has mastered the material. Students can track their progress on the dashboard.

Level 4: The student studies learning material and then completes quizzes on it. Based on the results, the system provides an individualized learning plan that aims to fill any possible gaps in the student's knowledge. After completing the plan, the student completes another quiz to see whether he or she has made progress.

Level 5: A student is given a problem, and asked to fill in the gaps for each step along the way to a solution. Feedback is given right after each step or after the whole quiz. The feedback is based on the analysis of the steps the student has taken, compared to the most effective methods for solving such a problem. The system then selects the next question based on student's readiness.

The features of adaptive systems describe and provide relevant content and support, and guide the learner through the adaptive learning system and the accompanying courses [15]. The author divides such features into the following five categories according to the functions that a system can have.

- Pre-test: when the system begins with an assessment of current knowledge and skills. This assessment gathers information about personal learner characteristics, which include prior knowledge on the subject domain.
- Pacing and control: when a learner has control over certain aspects of the system, such as controlling the speed with which the content is presented, or the order in which the content is presented, among others.
- Feedback and assessment: when the system evaluates learner's progress and gives feedback according to his/her performance. Feedback can be presented as correct/incorrect responses, or the system can recommend material, resources and suggest some possibilities for additional practice.

- Progress tracking and reports: when the system can save the user's profile with his/her progress, and the user has a possibility to start from where he/she left off. System can also generate some periodic progress tracking according to individual progress.
- Motivation and reward: when the system includes gamification elements to motivate its users. This can involve rewards (points, stars, badges) for passing levels, and its aim is to advance the users' performance and achievement.

According to Paramythis A. and Loidl-Reisinger [16], there is one extra feature that could be used for defining adaptive learning systems. This feature is about understanding the student's requirements and preferences.

III. THE MEANING OF FEEDBACK IN GAME-BASED LEARNING ENVIRONMENTS

A. Feedback Types and Formes Used in Game-based Learning Environments

The significance of feedback becomes emphasized in learning environments and games because it helps to plan the student's learning path, provides information about his/her progress, notes the important information and guides a the learner through the learning process [17], [18]. In games and learning platforms, feedback can improve learning and help the learner to make decisions about his/her learning strategy, while also increasing the learner's motivation [19]. Breuer and Bente [20] (as quoted by Bellotti et al., 2013) state that incorporating the elements of assessment into games makes assessment more invisible and enables a more thorough use of the medium itself.

In the definition of Mory E. [21], feedback is any message that is generated in response to a learner's action, usually after the learner has completed a particular task or function. It implies that there is an "interactive flow between the learner and the system, coming from some information collected or generated by the learner and coming back to him as an output after some processing".

There are many existing studies based on categorization of feedback. Table 1 presents the number of feedback types [22], [23], [24], [25], [26] and their description.

According to the provided descriptions of each feedback type in Table 1, it could be argued that informative and conformational feedbacks are closely related to each other. These types of feedback only provide information on whether the answer is correct or not. Likewise, instructive and corrective feedbacks are also closely related, because they provide corrections and instructions on how to get the correct answer. Explanatory and elaborative feedbacks are also concentrated on similar things, providing explanations of why the answer provided by the user is wrong. Information-based and point-based feedbacks are closely related, because they provide the accuracy and quality of answers in levels of mastery, progress bars, cumulative points, etc.

Taking into account that some of the feedback types have the same functions, this study used a combination of feedback types, specifically informative, corrective, explanatory, diagnostic, point-based, consequence-based and interactional feedbacks provided by Kinzer C. et al. [22], McNamara et al. [23], Kapp K. [24] and Mackey A. [25]. These types are related to the features used in adaptive learning games and applications in area of English learning.

TABLE I. FEEDBACK TYPES

Author	Type	Description
Kinzer C. et.al. [22]	informative	provides information on results, does not explain why the results are right or wrong.
Mory E. [21]	informative	is focused on self-regulation, related to the context where learning takes place.
McNamara et. al [23]	information-based	is concentrated on providing the accuracy and quality of answers and actions including immediate corrections, delayed corrections, level of mastery achieved on specific content.
McNamara et. al. [23]	point-based	can be conveyed in the form of cumulative points, progress bars, and levels.
Kapp K.[24]	conformational	indicates the degree of "rightness" or "wrongness" of a response, action, or activity. Feedback immediately informs the learner if he or she did the right thing, the wrong thing, or if it was somewhere in the middle. This feedback doesn't tell the learner how to correct the action.
Mory E. [21]	instructive	is related to the knowledge domain. It provides instructions on how to get right answer.
Kapp K. [24]	corrective	guides a learner with instructions. If the learner did the wrong thing, he or she will be prompted, guided, or pointed toward a more appropriate action. Corrective feedback informs the learner that their response was incorrect and provides knowledge of the correct or desired response.
Kapp K.[24]	diagnostic	provides diagnosis about incorrect answers. It defines why the incorrect response was chosen, corrects those common mistakes through the feedback.
McNamara et. al [23]	consequence-based	is a type where the system reacts to the user's responses or actions by changing the system path (paths of actions taken by the system).
Kinzer et.al. [22]	elaborative	provides more information about why an answer was wrong and what has to be done to correct an error.
Kapp K. [24]	explanatory	works as corrective feedback but it also includes relevant information about why an answer is correct or incorrect. It provides a rich explanation to a learner for effective encryption of knowledge.
Mackey A. [25]	interactional	provides the receiver of the feedback with corrective feedback based on learner's utterances, for instance, on pronunciation or articles. Used frequently in language learning applications and games

B. Game-based learning in English Learning and the Significance of Feedback

In order to analyze various English learning applications and games, it is important to understand the underlying processes normally associated with language learning. As we think about language learning as a process, we normally associate certain features to it: listening, reading, speaking and writing. Of these four, the first two are receptive skills, which

normally precede the following two productive skills, speaking and writing. Johnson K. [26] notes, however, that these skills are frequently intertwined, e.g. a learner working on a writing exercise can benefit from previous speaking exercises. Learning grammar and vocabulary are also frequently connected to mastering a foreign language.

There are, however, more thorough ways of categorizing the skills involved in foreign language learning and acquisition. Johnson K. [26] has divided the process of learning a language, basing the division on an earlier model by Canale, M. and Swain, M. [27], into three various parts: systemic competence, sociolinguistic competence and strategic competence. In order for a person to master a language properly, he/she has to be familiar with the various sounds in the target language, the rules that apply to that specific grammar and the lexis, that is, the vocabulary or words of the language. These components form an important ground for further knowledge of language learning. The sociolinguistic competence, on the other hand, entails the cultural norms that one has to take into account when speaking a certain language. This area of language includes, for instance, the codes of being polite in a specific culture language wise. The last one, strategic competence, and covers a language user's ability to handle situations where the right type of vocabulary, for instance, is not found.

At this point it is important to mention that the focus of the present study is on foreign language learning and acquisition which diverges itself from the process of the natural first language acquisition [26]. As explained by Krashen S. and Terrel T. [28] language learning follows certain paths and learners typically acquire certain language features in a certain order. According to the natural order hypothesis, grammatical morphemes, for instance, are acquired in a highly organized manner by children and adults with progressive from preceding articles, irregular past forms and possessive forms [28].

Many studies conducted in the field of English learning with games and applications give proof that they improve learning outcomes for students. Aghlara L. and Tamjid N. in [29] discovered in their study aimed at Iranian, six- to seven-year-old girls that vocabulary of animals, family members, numbers and colors was acquired more efficiently with a software game than with traditional teaching tools, such as blackboards and flash cards, which was explained by the increased motivation of children playing the game. Verdugo D. and Belmonte I. in [4] also share the same result with children's listening comprehension. They studied six-year-old Spanish learners and concluded that the children learning with digital stories improved their skills in listening comprehension more compared to those learning with traditional methods. Verdugo D. and Belmonte I. in [4] mention the more focused way of learning and individual learning pace as key elements that favor the use of digital stories as a form of developing learners' listening comprehension. Vocabulary acquisition and learning with applications and games has been examined in many studies. Cobb T. and Horst M. in [3] studied the word acquisition process with a vocabulary training system and they concluded that with the use of the system in language learning, significant results were achieved. During a two-month period, participants learned the amount of vocabulary that in a normal classroom setting is achieved in one to two years. Aghlara and Tamjid [29] share this result and they further state that vocabulary, in addition to the increased speed of learning, is also retained longer in the memory of a learner with online games compared to the traditional classroom environment. Yip F. and Kwan A. in [30] imply that the enhanced learning experience created by a mobile English vocabulary learning

system is explained by a more personal and flexible learning method.

Games and applications for learning may include various elements for signaling how a player has succeeded in it. The most common, and perhaps the most simple, form of receiving feedback in educational English learning games is to signal the right and wrong answers, for instance, by giving awards for correct answers. Aghlara L. and Tamjid N. in [29] studied a game for English vocabulary learning which offers confetti for every right answer whereas a wrong answer will be delivered in the form of a squashed tomato. Scoring is another popular method of providing feedback for learners [31]. With scoring, learners are able to see how others have succeeded in the game but most importantly they are being informed of which aspects are the most significant in the learning process. Michael D. and Chen S. in [32] have studied the effect of an automatic scoring system in an application for rehearsing English pronunciation. The benefit of such system is that a teacher is not required to provide a learner with corrections but the feedback is provided automatically by the system. This type of a feedback mechanism is able to provide the learner with feedback, for instance, on mispronounced phones. This type of a mechanism is able to tackle areas such as spectral match, phone duration, word duration and speech rate in foreign language learner's pronunciation [33]. Chen C. and Chung C. in [31] studied vocabulary learning with a personalized mobile English vocabulary learning system that uses the collected information to improve the learning process. The idea of the system is to first to determine the learner's vocabulary skills with a pre-test after which the learner is able to proceed to the actual learning process based on the test results. A learner is first provided with a rehearsing mode of the targeted vocabulary, which is followed by a test mode. The learning process is stored in a personal portfolio showing the learner the progress with the vocabulary. The improved learning with the system is connected to the system's ability to recommend a learner with appropriate vocabulary.

As language learning is a complex process, the feedback and assessment techniques utilized in the games and applications should support a learner to acquire and master areas in language learning, such as vocabulary, grammar and pronunciation. Sandberg J. et al. [34] summarize that such support could be provided to a learner by offering more difficult content (such as words) more often, providing feedback that goes deeper than just pointing out the correct and wrong answers (e.g. explanations), taking in the information and knowledge a learner already possesses on the subject, and offering a learner with formative targets and assigning new study objects based on the results.

IV. RESEARCH METHODS AND DESIGN

A. Procedure

Previous studies used criteria for the evaluation of learning systems mostly from the perspectives of technology and education. Yip and Kwan [35] used two criteria for the evaluation of educational websites: an educational perspective and a technical perspective. Educational perspective concentrated mostly on information quality, and technical perspective concentrated on navigation, consistent look of the websites and the use of multimedia-like enhancement. Wood [36] discussed in his work desirable criteria related to technical features of vocabulary websites, such as animations, sound components, hints or clues, multimodal presentation of information, and online definitions for the words. Cowan [37]

suggested to use criteria such as relevance, peer interaction, continuous motivation and minimum equipment.

As for the evaluation of adaptive learning systems, the criteria that has been used [38], [39], [40] has been based on evaluation of input data, inference, adaptive decision, total interaction, predictability, privacy, controllability, breadth of experience, unobtrusiveness, timeliness, aesthetics, necessity, consistency, etc.

In order to make an evaluation framework for the adaptive learning applications and games in English learning, we used criteria that is based on defining adaptive learning systems and feedback types in those systems. In this study, we concentrated on various areas of English learning, age level, adaptive system features which were based on combining features discussed in Section B of Chapter 2 with features of feedback, types of feedback, levels of adaptivity and types of adaptive learning systems. The analysis is not based on the techniques and methods of adaptive learning systems, but mostly on the features of these systems for defining types of feedback and levels of adaptivity.

B. Description of Evaluated Game-based Applications for English learning.

In order to reach a sufficient amount of games and learning solutions for the evaluation process, many searchers were executed through Google. Searching in Google was considered to provide us with the broadest selection of English games. The following search terms were used: "games for English learners", "best apps for English learning", "best apps for learning English grammar", "best apps for learning English vocabulary", "applications for English language learners" "online games for English language learner", "best applications for language learning", as well as "adaptive learning in English language teaching", "adaptive games for English learning", "intelligent learning games for English learning", "smart games for English learning", and "intelligent learning applications for English learning".

Games and learning solutions were also selected based on their availability, namely whether they were free of charge for users. There were many web-based applications; some of which could be used on tablets or mobile phones. The applications that clearly did not include gaming aspects or that did not give learners the opportunity to exercise their language skills were excluded from the evaluation. Various sites were then browsed through in order to discover whether there were games that frequently surfaced after which they were included in the study.

In the following phase, 23 games were selected for the evaluation process. Both applications and games were included in the study, in order to construct as comprehensive a picture of the various feedback features as possible. Applications and games were selected in a way that they represent different aspects to language learning, covering areas from systemic and sociolinguistic competence, as explained by Canale M. and Swain M. [27] to the four significant skills of language learning, those of reading, writing, listening and speaking. The analysis included altogether 23 English learning applications or games ranging from colorful vocabulary games for preschool children to more comprehensive individualized learning paths for adult learners. Many of the applications and games could be used for several educational levels; three were targeting preschool children, nine primary school students, 17 junior high school students, 15 high school students and 16 adult learners. The applications and games were also selected to cover the

various language proficiency levels from beginner levels to the more advanced proficiencies. 15 of the applications and games included the beginner level, 18 the intermediate level and 15 the advanced level.

C. Criteria for the Evaluation Framework

For the analysis of the selected English learning games and applications, a table was created, in which evaluation criteria such as application name, area of English learning, grade, level of knowledge, learning system features, types of feedback in those systems, levels of adaptivity and types of adaptive systems was used.

Areas for English learning, such as grammar, vocabulary, reading, writing, listening, speaking and culture, were listed. Preschool, primary school, junior high school, high school and adult learners were used in the analysis of grade/age. Such levels as beginner, intermediate and advanced were used in the analysis of level of knowledge.

For the analysis of adaptive system features we used a list of features according to our research in Section 2:

- 1) *Checking the right or wrong answer:* the system simply tells the user if the given answer is correct or not.
 - 2) *Providing hints:* the system gives hints if a user is struggling.
 - 3) *Providing explanation:* in the case of an incorrect answer, the system explains why the answer is incorrect.
 - 4) *Understanding the users' requirements and preferences:* the system asks questions about the user's hobbies, preferences and goals.
 - 5) *Progress tracking and reports:* the system can track the user's progress and the user can see it on his/her dashboard.
 - 6) *Updating information according to user's actions:* the system changes the material to be learned according to the user's progress.
 - 7) *Diagnosis of the users' mistakes:* the system detects why the answer were answered as wrong.
 - 8) *Having a live discussion with a tutor:* this could be with a native speaker or with a tutor.
 - 9) *Pre-test:* the system conducts a pre-test to detect the user's level of knowledge and to provide recommendations.
 - 10) *Pacing and control:* the option to control speed, select a level, change courses, etc.
 - 11) *Providing recommendations:* when the system recommends what material to study.
 - 12) *Motivation and rewards:* the system provides rewards for the user, which can be used to move to next levels or when competing with other users.
 - 13) *Creation of learning path:* the system creates an individualized learning plan.
- The first eight features are related to feedback type recognition. In our study, we used seven types of feedback:
- 1) *Informative feedback:* includes feature 1.
 - 2) *Corrective feedback:* includes feature 1 and feature 2.
 - 3) *Explanatory feedback:* includes feature 1 and feature 3.
 - 4) *Diagnostic feedback:* includes feature 1 and feature 7.

- 5) *Point-based feedback*: includes feature 1 and feature 5.
- 6) *Consequence-based feedback*: includes feature 1 and feature 6, also not obligatory is feature 4.
- 7) *Interactional feedback*: includes feature 8.

Rule-based and algorithm-based systems were used as types of adaptive systems. Five different levels were used for adaptive systems according to our research in Section 2.

Level 1 includes feature 1 (checking right or wrong answer).

Level 2 includes feature 1 (checking right or wrong answer) and feature 3 (providing explanation).

Level 3 includes feature 1 (checking right or wrong answer), feature 11 (providing recommendations), feature 5 (progress tracking and reports) and feature 6 (updating information according to users actions).

Level 4 includes feature 1 (checking right or wrong answer) and feature 13 (creation of learning path).

Level 5 includes feature 1 (checking right or wrong answer) and feature 7 (diagnosis of users' mistakes).

V. RESULTS AND DISCUSSION

23 game-based environments and applications that included different types of feedback were analyzed in the paper.

After the analysis of the selected applications, we also found other criteria which could be taken into account, such as: collaboration (ability to learn together with someone), mobility (users could use applications on tablets, not only on computers), having how-to videos with explanations, having a discussion area, etc.

The applications and games in the present study can be categorized into four sections: applications and games for grammar (5 out of 23), vocabulary (8 out of 23), speaking (pronunciation) (2 out of 23) and applications that include multiple language learning goals (8 out of 23).

In addition, a deviation of main and second areas of English language learning was applied. Main area has number "1" for the analysis. Secondary areas have number "2". If a system does not include a specific area, it is signaled with a "0". According to Table 2, there are 12 applications that have grammar as one of the main areas of English learning. 16 applications have vocabulary as one of the main areas of English learning. Ten applications have reading as one of the main areas of English learning. Seven applications have writing as one of the main areas of English learning. Nine applications have listening as one of the main areas of English learning. Seven applications have speaking as one of the main areas of English learning. Zero applications have culture as one of the main areas of English learning, but seven applications have culture as secondary area of English language learning.

According to the number of features in applications (discussed in Section 4), we detected the types of feedback that each system uses and the level of adaptivity in these systems. The level of adaptivity 1 is more common (appears 12 times out of 23) because it is a more simple one. Level of adaptivity 2 appears 8 times out of 23 and level of adaptivity 3 appears 3 times out of 23.

Other levels need to have more features. The most common feedback types are informative feedback and point-based feedback. Diagnostic feedback does not appear in the list of

analyzed applications. This type of feedback appears more in high-level adaptive learning systems.

TABLE II. SURVEY OF THE ENGLISH LEARNING AREAS AND THE FEEDBACK TYPES USED IN THOSE AREAS

Application (game-based environment)	Grammar	Vocabulary	Culture	Reading	Writing	Listening	Speaking	Type of feedback
Grammar up	1	2	0	2	0	0	0	3,5
Practice English Grammar	1	2	0	2	2	0	0	3,5
Grammaropolis	1	2	0	2	0	2	0	3,5
British council's learn English grammar	1	2	0	1	2	0	0	1,5
IKnow!	0	1	2	2	2	2	1	2,5
PowerVocab Word Game	0	1	0	1	0	2	0	2, 5
Knowji	0	1	0	2	2	2	2	1,5,6
Bitsboard	0	1	0	2	2	2	0	2,5
Arcademics	2	1	0	2	0	0	0	2,5
Quizlet	2	1	0	2	2	0	0	1
Speaking pal	0	2	2	2	0	2	1	1,5
Hawina	0	1	2	2	0	2	1	1,5
Duolingo	1	1	2	2	1	1	1	3,5,6
Busuu	0	2	0	1	2	1	0	1
The interactive grammar of English	1	2	0	2	0	0	0	3,5
Rosetta Stone	1	1	2	2	1	1	1	1,5,7
LinguaLeo	1	1	2	1	1	1	0	1,6
SHAIEEx	0	1	0	1	0	1	0	1,6
Agnitus Personal Learning Program	0	1	0	1	2	2	0	1,5,6
Scootpad	1	1	0	1	1	1	1	2,5,6
Voxy	1	1	2	1	1	1	2	1,5,6,7
Babbel	1	1	0	2	1	1	2	2,3,5
Livemocha	1	1	2	1	1	1	2	3,7

As an experiment, we analyzed the relationship of English learning areas to the types of feedback. As shown in Table 2, one game or application can have several areas of English learning and several feedback types.

In Table 3, the relationship between the English learning area and the feedback types is presented in percentages, knowing the total amount of applications and the frequency of feedback type in a selected area.

We discovered that there are similar features in applications targeting the same types of language skills. In English learning areas like grammar, vocabulary and reading, the most common type of feedback is informative and point-based. Vocabulary also has corrective feedback. In the English learning areas such as writing, listening and speaking all feedback types are almost equally presented (but with the frequency under 6) except of diagnostic feedback. As culture is not a very popular area of English learning, it has a low frequency of informative, explanatory and point-based feedback in secondary area of English language learning.

TABLE III. RELATIONSHIP BETWEEN THE ENGLISH LEARNING AREA AND THE FEEDBACK TYPES, %

Area	Type of feedback						
	informative	corrective	explanatory	diagnostic	point-based	consequence-based	interactional
Grammar	17,4	9	30	0	44	17,4	13
Vocabulary	35	26	13	0	12	30	13
Reading	26	9	4,3	0	21,7	21,7	8,7
Writing	13	8,7	13	0	21,7	17	13
Listening	21,7	8,7	8,7	0	21,7	21,7	13
Speaking	17,4	4,3	8,7	0	26	13	13
Culture (only for secondary area)	4,3	0	4,3	0	4,3	0	0

Informative feedback is basically incorporated into each application and game that we examined in our analysis, and it typically takes the form of simply signaling a learner with either a correct or an incorrect answer. Corrective feedback is almost identical with informative feedback also entailing the part of informing a learner about the correctness of the answer (explicit correction). There are examples where the right answer is simply explicitly stated to a learner. Alternatively, the system briefly shows the correct answer after which a learner corrects the answer accordingly. Metalinguistic feedback, also a part of corrective feedback, on the other hand, is in one application interpreted to represent a situation that points out the incorrect parts for a learner without actually stating how to correct it. One application we analyzed included a clarification request that was a part of a speaking exercise. Examples of explanatory feedback typically include a brief explanation following the wrong (sometimes also the correct) answer. Some of the grammar specific applications and games analyzed have explanations about grammar rules that are not necessarily connected to exercises or games. Each of the applications and analyzed games incorporated at least some elements of point-based feedback in the form of cumulative points, progress bars or levels or a combination of the three. Interactional feedback is rather difficult to analyze

since it can be interpreted in many ways. Naturally all of the applications and analyzed games include some interactional elements such as instant information about the correctness of the answer. There are, however, some applications that allow a learner to discuss the learning process with other users therefore making the learning experience even more interactional.

Most of the English learning applications have multiple learning goals; therefore, it is difficult to separate the various language areas from each other. Furthermore, in many cases, the applications are not targeted for a specific group but they offer a creation of a personalized learning path.

CONCLUSION

In this article, we presented a short review on adaptive web-based learning environments and applications according to their tasks, functions, techniques, methods and levels. We examined feedback, which is an important feature of all adaptive learning systems. According to the selected adaptive game-based environments and applications based on English learning, we found some similarities in feedback types according to a specific English learning area.

The main problem in analyzing the contents and various feedback features of English learning applications and games is that at most times they are complex systems targeting multiple language learning goals simultaneously. Therefore, it is rather difficult to divide the applications based on any one area of language learning, e.g. grammar or vocabulary. Instead, the trend in the applications for English learning at present time seems to be the aim to provide a language learner with a personalized learning path that leads a learner from the beginning steps of language to the more advanced levels.

According to our results, we can say that the more complex feedback types the system has, the more adaptive it will be. Therefore, it is very important to know which types of feedback to use while creating adaptive learning systems with high level of adaptivity. Feedback is an important feature of the adaptive learning systems since it can help to guide users. They can see how they are progressing and what needs to be improved. If there are any problems with answering questions and a learner is struggling, embedded feedback should provide hints and explanations to support the learning process. When a learner has some incorrect answers, the system should include the same questions in the next lessons to see if a learner can solve the task according to provided instructions and learned material.

The findings from the present study function as important guidelines for the developers of various applications and games for English language learning. The users of the applications and games will also get some ideas to select the best tools to guide them in the language learning process.

Abstract—In addition to a high technical level and performance in their discipline, engineers of the 21st century require a high level of general or transferable skills that allow them to excel in their work environment. Engineers at the University of Antioquia in Colombia are no strangers to this situation, which is why the University has decided to face this new condition through the inclusion of activities in courses that support the development of these skills. Part of these activities includes the transformation of the traditional evaluation scheme for Radiofrequency Circuits course in Electrical and Telecommunication Engineering programs. This transformation has been performed taking advantage of the LMS (Learning Management Systems) platforms, web and mobile application and game-based learning techniques. The development of innovative practices that can leverage information and communication technologies is one of the major challenges in education. This paper shows the design of an online game-based assessment and training strategy. The new assessment and training tests were designed to help students improve their learning outcomes on the course topics; meanwhile, they promote development of general or transferable skills such as the ability to solve problems in complex situations and working under pressure.

Keywords—Assessment strategies; Game-based learning; LMS; Mobile applications; Professional performance; Transferable skills; Web applications

I. INTRODUCTION

Engineers at the University of Antioquia, Medellín, Colombia, have been characterized by a high technical standard. However, due to high professional competition and they work for society, engineers must not only be people with great disciplinary knowledge, but also be integral professionals. Since 2005, the University of Antioquia has been developing several investigations about the lack of comprehensiveness on professionals, which has led to the restructuring of undergraduate engineering curriculums. With the curricular changes, the program added the use of virtual platforms in some courses, and also has promoted the development of student transferable skills that improve their professional and personal performance [1, 2, 3].

The Radiofrequency Circuits course, which is taught at the undergraduate level in Electrical engineering and Telecommunications Engineering programs at the University of Antioquia [4], is a deepening course in wireless

communications area and is offered when the student has completed 70% of the courses on his career. The course is divided into two parts, one part is theoretical and the other one is a laboratory. Traditionally, the theoretical component assessment has been evaluated through 6 tests, using traditional strategies such as paper based tests and writing home works.

The University has been using during the last 10 years virtual platforms to support the student learning process, including assessment modules of these platforms, which simulate the behavior of paper based tests made in the classroom. Since 2014, the program, has been designed a strategy to develop new assessments schemes, changing some of the traditional assessments to game-based training and assessment schemes that not only assess knowledge of the course topics but also allowed improving transferable skills of students.

This article presents the design of a training and assessment tool, and is organized as follows: Section II presents an overview of Game-Based Assessment Scheme and transferable skills; the Section III shows the new approach of evaluation schemes in Radiofrequency Circuits course assessment; and Section IV presents the proposal study and finally the conclusions are stated.

II. TRANSFERABLE SKILLS AND GAME-BASED ASSESSMENT SCHEME

Since the late 20th century, society has professionals with technical or disciplinary skills, and also skills that include values and attitudes that enable them to confront and solve important new century problems [2]. The transferable skills are those skills that are transversal to many activities, common to different professions and related to aptitude, knowledge and values of people [5]. These transferable skills are part of the 21 century skills [6, 7].

Studies have found a relationship between the transferable skills development in people and their subsequent educational and labor outcomes. People, who develop transferable skills on their education, has better academic results and better attitudes and behavior in several situations [6, 8], and are more effective when use this abilities in a specific contexts [9].

These competences could be developed using new assessments schemes. There are various techniques with which one student can learn about a topic and at the same time

develop transferable skills. According to several studies, traditional tests formats such as multiple choice, essay or short answers are not completely appropriate to evaluate academic concepts and to improve transferable skills. Therefore the use of alternative assessments schemes becomes necessary [10].

For students, the assessment is important because it allows them to follow their progress and it also provides valuable information to teachers to give feedback to student, this information could be used to motivate them to keep learning. The assessment can relate the skills that the teacher hopes to teach with student expectations. Thus, a good assessment reflects good teaching [11]. A good assessment allows the teacher to know what students have understood, so the teachers can modify the way to reach the learning objectives based on this information [12, 13, 14].

Good assessment methods have to include the following characteristics: evaluate what is intended to measure, predictive validity of future behaviors and should motivate the student to work hardy in challenging scenarios [12, 13]. Assessment should be an engagement for the learner, help to improve persistence and 21th century skills, relevant for students and teacher, and provide a personalized learning environment [15].

However generally the real life problems are different from the ones students solve in their classes. This may be because real life problems do not have a standardized solving method; it needs collaborative systems, experience, diverse knowledge and especially transferable skills [16].

For that reason the teacher has the responsibility to change the traditional class assessment into one that reduces the gap between the traditional education and the real-world challenges. Alternative assessments methods involve real-world applications and ask students to create, produce, solve problems and develop their critical thinking. These assessments involve new strategies to accomplish learning outcomes [11, 14, 17].

Game-based assessment can help students to construct knowledge through trial and error, solving challenging problems that motivates students to learn intrinsically. Student can work or observe real life situations, motivating the need to reach the goals and improve their persistence [18, 19]. Digital learning environments can provide a meaningful assessment to students, where they can learn and play in scenarios where they have to improve several competences, like academic, social and personal. The really important point is to develop assessments that lead students to use their knowledge and combine it with other skills to solve different problems [12, 13].

With the Game-based assessment it is possible to transform a boring or stressing assessment into one that evaluates the knowledge and also can be enjoyable. Assessment with games, is a strategic option, because students have an inherent attraction to games, are part of their lives and “win the game” is one of the most valuable rewards. Shute and Ventura, Zapata Rivera and Bauer and DiCerbo [12, 14, 19] presents cases of success in game-based learning, where students develop class activities simulating games and finally acquire specific academic knowledge and transferable skills.

Bokyeong, Hyungsung and Youngkyun [20], present three strategies for learning with games that allows the students improve transferable skills: The self-recording which includes writing, modeling, thinking aloud, listening and speaking activities. Osman and Bakar [21] describe a method where the student is not only a player but also becomes in a playmaker. This is known as collaborative game making. Its importance lies in that students can make part of creating a game, where they can learn the class subject, inventing meaningful games and allows them to develop transferable skills, as critical thinking, creativity, innovation, problem solving and team work.

III. PROPOSAL ASSESSMENT SCHEME IN RADIOFREQUENCY CIRCUITS COURSE

Being in a technological age, it is necessary to potentiate and take advantage of information and communication technologies ICT. There are several Learning Management Systems LMS like Moodle, Canvas, Sakai, Blackboard, Desire to Learn [22, 23, 24, 25, 26] among others, all of them includes modules that allows interoperability and flexibility for assessment and training process [27].

The technological architecture includes the integration of services through standards such as LTI (Learning Tools Interoperability), Tin Can API (XAPI), XML- Moodle [28, 29, 30] and using the LMS and mobile apps as interfaces of interaction for students. The figure 1, shows the interaction between users and modules of the system.

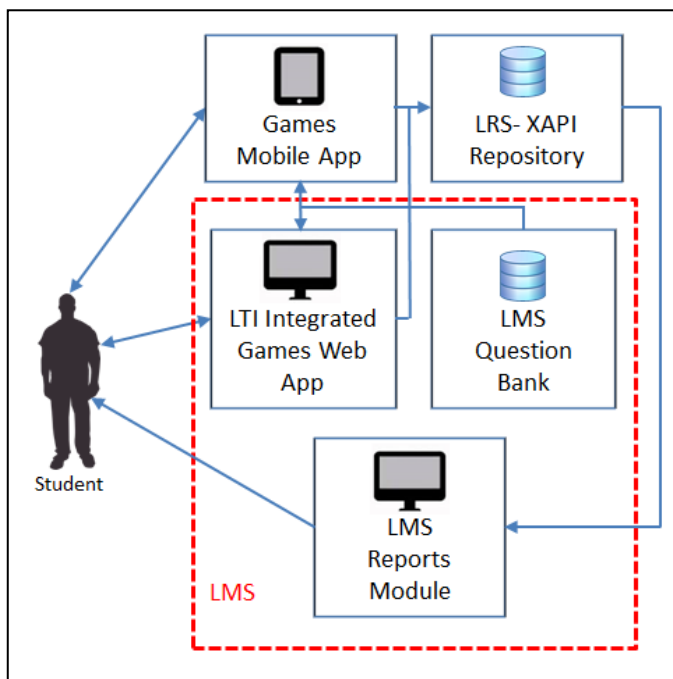

Fig. 1. User interaction with system modules.

The games for Radiofrequency circuits course are being developed in a web and mobile application versions. The web application could be integrated to LMS platform via LTI standard or could be used directly in Android devices like cell phones or tablets. These applications use the LMS question

banks as inputs for all games. In both cases (LMS integrated web and mobile application) the interactions will be stored in the LRS (learner record store) and the results of interactions could be included into student LMS reports. Figure 2 and 3, shows mobile app Mockup.

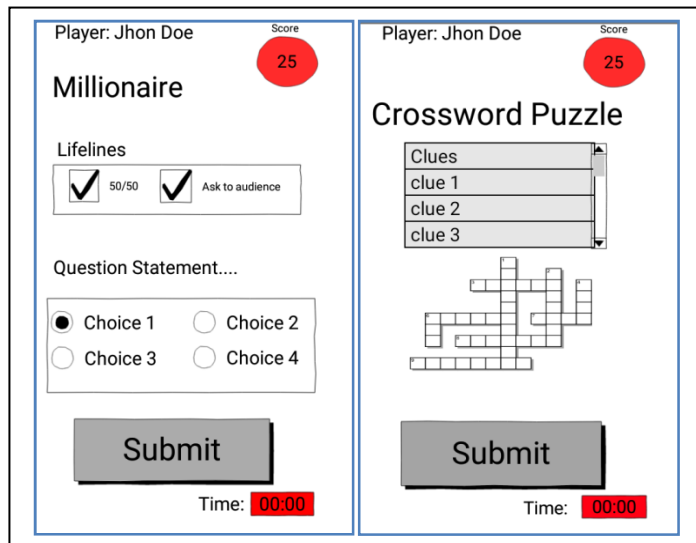

Fig. 2. Mobile app Mockup of Millionaire And Crossword Puzzle

Fig. 3. Mobile app Mockup of What happens if? and Cause-effect problems

The games were divided into four groups: Trivia Games, Word Games, Prediction and Decision making. The style of question planned for different games includes multiple-choice questions, short answer and essay. Games are different each other according to particular intentions, some of them are focused in development of solving problem skills, while others have the goal of improve the agility of giving solution to a complex situation when time is a limited resource. The difficulty level of each interactive game has direct correspondence with the skills level defined in the course topics. These games are aligned with transferable skills like: decision making, working under pressure, problem solving, willingness to learn, self-motivation and analytical thinking.

Descriptions of each game, type of question used for develop them and an example of real question that will be used in the Mobile app Mockup (see figure 2 and 3) are:

- Trivia game: Millionaire. The aim of the activity is answer a series of questions, where each new level of questions increases difficulty. If the student answer correctly, (s)he goes to the next question. The student has 1 minute to answer each question. The activity has two types of lifelines: 50-50 where the platform deletes 2 wrong answers and ask the public, where the student can go to an internet page using hyperlink and consult the question during 30 seconds. The type of questions used to develop the game was: Multiple choice questions. The student can decide not continue with the game on any moment, but (s)he cannot answer the question before leaving. Example:

If you have a circuit with $R_S = 10 \text{ ohm}$ and $R_L = 50 \text{ ohm}$, which coupler do you use?:

- Resonant Coupler
- Coupler type T
- Coupler type L
- Coupler type π

Helps:

- 50 – 50
- Ask the audience (consult internet)

- Word games: Crossword Puzzle: the activity presents a track to student and (s)he should interpret it and write the concept that is reference. The student has 30 minutes to develop the activity. On this game, short answer questions were used. Example:

5. (Across) RF output power and DC power ratio.

- Prediction of future events: “What happens if?”. In this activity, a real life or laboratory situation is presented to the student, then (s)he have to predict what happens later. On this game, the student has 5 minutes to write the answer. Multiple choice questions, short answer question and essay were used. Example:

What happened if you are in a laboratory with a BJT mixer circuit and you change the transistor for another with higher transconductance. If the initial mixer has a low amplitude output, what would you think is the amplitude of the mixer with the new transistor?

- Decision making game: Cause – effect problems. The activity presents a series of real life situations, where the student should make a decision. These decisions affect subsequent situations, and then the activity has multiple ways of solve it. The student has 2 minutes to take each decision. If the student does not choose any answer, the game will end. Type of questions used: multiple choice or short answer questions, according to the previous response. Example:

You have a video transmitter with 3 blocks: an oscillator, a low signal amplifier and a power amplifier. If the central frequency should be 56.92 MHz and the output amplitude 1.92V, but the oscilloscope shows 51.87 MHz and 1V and you use T band-pass couplers, you can:

- a. Change the output T type coupler of the power amplifier.
- b. Change the T type coupler between the low signal amplifier and the power amplifier.
- c. Change the value of the mechanical capacitor of the oscillator.
- d. Change the T type coupler of the low signal amplifier.

Currently, there are platforms that offer the possibility of bring training and evaluation processes through trivia games in different areas of knowledge. Kahoot and Duolingo [31, 32] are examples of mobile applications where questions can be created and solved through a playful interaction. One of the important contribution of the proposed scheme is that allows to link the gaming environment used by students and the formal on-line environment used for learning, commonly LMS platforms. This integration favors the monitoring and reporting processes in terms of time investment and student results on their gaming sessions. And also it helps to take advantage of the 70% of informal learning or experience learning that occurs outside the classroom, that when is mixed with 10% of formal learning, best results are expected to achieve in the course [33, 34].

Moreover, there are two reasons for using this evaluation scheme based on games. The first reason is based on the investment of time of students in interaction with course concepts involved along levels or stages of games. The second reason is to propose an additional learning challenge to student, because traditional methods of education generate some level of challenge, but games generate the additional addictive and engaging component. This motivates the player to achieve progress and increasing their score of previous attempts; this is commonly known as persistence. The evaluation scheme can transform an assessment moment in a learning process based on training and experimentation, allowing the existence of formative assessment and feedback schemes and even more, a development of transferable skills.

IV. STUDY PROPOSAL

The system will be used in the second semester of 2015 in the radiofrequency course to probe if the use of the new scheme of training and assessment can improve the student's motivation and scores on the course, and moreover if can help to develop some transferable skills. The course will use the game-based assessment system in each test, and a training session will be done before every quiz and laboratory practice. The periods of training with the system correspond to the periods in which each topic is taught. The students assessment

scores will be measured according to the number of clear levels, scores obtained on the games and time required.

At the end of the semester the student scores will be compared with the scores of the past courses that have used traditional assessments methods. And also a survey will be applied to know the perception of the students about the proposed scheme and transferable skills improvement. Some questions of the survey are:

1. If you compare the training and assessment games proposed with the traditional training and assessment, you would say proposed games are:
 - a. More entertaining but does not allow me to acquire knowledge
 - b. More entertaining and allow me to acquire knowledge
 - c. Equally entertaining and acquire the same knowledge
 - d. Less entertaining but allow me to acquire knowledge
 - e. Less entertaining and not allow me to acquire knowledge
 2. Will you consider investing more time training with the games proposed that in traditional homework?
 3. Do you think that using the training and assessment games helps you to acquire transferable skills?
 - a. True
 - b. False
- Which? _____

V. CONCLUSIONS

Implementation process imply high technical skills like: design and implementation of web and mobile applications, integration of web services through educational standards and LMS management, which requires a multidisciplinary work.

The game-based training and assessment strategy proposed have the potential to be implemented in other undergraduate courses.

The development of more games and activities could help to mapping other transferable skills like: team work, communication skills, co-operation among other, that are not included on this version of the system.

Abstract—Living in the world that is rapidly changing and is strongly interconnected with digital technologies puts a lot of pressure on K-12 students' teachers. Although, today's K-12 students are surrounded by technology and computers from the day they are born, they also must learn the basic principles of computer science in order to be adequately equip for their future jobs. However, Science, Technology, Engineering, Mathematics and Computer Science (STEM-C) fields are too wide and too complex for only K-12 schools to participate in the teaching process. In this paper we thus present how high education institutions can cooperate with elementary and secondary schools in STEM-C education process of K-12 students. We will share two good practices for allowing K-12 students to learn STEM-C related topics that have been implemented in Puerto Rico and Croatia. The objective of both projects is to establish a pipeline for K-12 students to go to colleges, and from colleges to graduate schools. The paper will present the impact of the program on the pre-college and university community of Puerto Rico, as well as the results of outreach activities conducted in Croatia.

Keywords—K-12 students, early research experiences, STEM-C fields, learning programming through "playing" computer games

I. INTRODUCTION

According the U.S. National Academy of Engineering and National Research Council the Science, Technology, Engineering, Mathematics and Computer Science (STEM-C) fields are too wide and too complex for one single educational institution to cover all areas [1]. It is thus of vital importance to combine the strength and knowledge of various institutions in order to achieve successful education of students in STEM-C fields. The academia and other high educational science institutions, as well as research laboratories, have the knowledge and resources that elementary and secondary schools lack of. In this paper we will show how K-12 students can benefit from simultaneously combining both "sides" of education.

As opposed to elementary and secondary schools that have very firm schedules and clear learning outcomes, after-/out-of-school STEM-C settings (i.e., informal education) can contribute towards K-12 students' development of interest and identity in STEM-C fields. In that way, already jam-packed elementary and secondary school curricula do not have to be extended or reorganized, and students can have a boost they need to consider STEM-C fields as an important part of their lives. Here we do not only want to make an impact on K-12 students that will work in STEM-C fields in future, but also on

every K-12 student as this knowledge will help them to cope with the challenges that will await them in their everyday lives.

Informal STEM-C education can be either a long term or a short term one. Both approaches have its advantages and disadvantages. For example, when K-12 students are involve in a long term after-/out-of-school STEM-C program then they get better understanding of how things work in this particular case and gain more extensive knowledge. However, they can experience only a limited number of opportunities as this approach is time consuming. Moreover, time constraints also affect educators who can provide these opportunities to only a limited number of K-12 students. On the contrary, when K-12 students are involved in short term programs then they can explore different types of programs and since they are short, more students can benefit from participating in them.

In this paper we will present both approaches and compare them in cases of K-12 students involved in programs run in Puerto Rico and Croatia. Namely, in Puerto Rico K 10-12 students are mostly involved in STEM-C long term research projects: (1) 16 weeks out-of-school program on Saturdays, (2) research mentoring process by undergraduates, (3) pre-college research symposium, and (4) 7 weeks summer research program at the US mainland research institutions. In Croatia K-12 students and their teachers are involved in shorter term programs: (1) K-8 students visit our research groups and departments where they play and learn how to code, (2) K 9-12 students do their own specific mini projects with their school teachers during a school year and then present them at our university, and (3) K-12 school teachers learn how to improve their approach to teach STEM-C concepts in a fun way.

The rest of the paper is organized as follows. In Section II we present related work and Section III describes two frameworks that are used to carry out STEM-C outreach activities: "SUZA - from school to science and the academic community" in Croatia and the Student Research Development Center (SRDC) in Puerto Rico. The SUZA program started in 2012, while SRDC has served as STEM-C outreach activity center in Puerto Rico for almost 15 years now. Furthermore, Section IV present short term out-of-school STEM-C activities, while Section V emphasizes our efforts made in long term outreach programs. Finally, Section VI comments on results that are obtained from our STEM-C outreach activities and Section VII concludes the paper.

II. RELATED WORK

Changes in STEM-C formal education are a "hot topic" across different countries in the world, although discussed differently by nations. Differences can be mostly seen in a case of level of integration of STEM-C and other fields. Some scholars are more keen on STEM-C taught using an integrative subjects approach, other consider STEM-C education to be the improved teaching of the separate subjects of STEM-C and many believe that it should be a combination of both of these approaches [2]. There are also some efforts made towards understanding challenges in developing a global curriculum [3]. However, no matter what their opinion on the level of integration is, it is widely accepted that STEM-C formal education needs to be complemented with the education activities conducted in informal STEM-C settings.

There is an extensive body of related work how universities and other research institutions can contribute to K-12 student's STEM-C education. Recently Steinmeyer has shown how to increase the reach of STEM-C exposure and education programs for high school students through the use of online environments [4] and Granchelli and Agbasi-Porter showed how intensive classroom lectures and hands-on activities can be used in their experiential STEM-C programs also for K 10-12 students [5]. Moreover, it has been shown that research is not only important on undergraduate level [6], but also on the high school level [7]. However, most of the studies are only concentrated on one STEM-C outreach activity (e.g., Kinect sensor [8], robots [9] or Arduino [10]) and are rarely focused on building pipelines [11].

In that sense, the contribution of this paper is threefold: 1) we propose a pre-college pipeline in which K-12 students participate at different stages of their pre-college education, 2) we introduce case studies of our STEM-C outreach activities in which we compare long and short term out-of-school STEM-C programs and 3) we distinguish among different goals for informal STEM-C education depending on student group ages.

III. FRAMEWORKS FOR STEM-C OUTREACH ACTIVITIES

All activities that are organized in Croatia are a part of a program called "SUZA - from school to science and the academic community" [12]. This program is the official popularization program of the University of Zagreb Faculty of Electrical Engineering and Computing in Zagreb, Croatia. We partner with the Institute of Electrical and Electronics Engineers (IEEE) Croatia Section and the student organization eSTUDENT with the support of two Croatian agencies: Education and Teacher Training Agency (AZOO) [13] and Agency for Vocational Education and Training and Adult Education (ASOO) [14]. The aim of SUZA is to increase interests of K-12 students and their school teachers in STEM-C fields by organizing different educational and popular science talks, presentations, workshops and organized tours.

All activities organized in Puerto Rico are grouped within Student Research Development Center (SRDC), which is a part of Ana G. Mendez University System (AGMUS) in San Juan, Puerto Rico. AGMUS became the model institution for excellence institution when received the first National Science Foundation (NSF) grant in 1985, following by others grants totaling over 30 million USD. One of the main objectives of

these grants was to establish a pipeline for pre-college from high school to college, and from college to graduate school for young economically disadvantage minority students from Metropolitan San Juan, Puerto Rico, interested STEM-C fields.

IV. SHORT TERM OUT-OF-SCHOOL STEM-C PROGRAMS

This section presents three short term out-of-school STEM-C activities, two of which were organized in Croatia and one in Puerto Rico. As mentioned earlier, activities organized in Puerto Rico are mostly, although not exclusively, a longer term and aimed to K 10-12 students, while activities in Croatia are mostly a shorter term ones and aimed mostly to K-8 students. Namely, as the vision of SUZA program is to ensure the feasibility of the mutually entangled priorities of high science and industrial leadership defined by the Horizon 2020 program through ensuring quality learning outcomes and professional guidance for the top students [15], in SUZA we want to (1) start early (i.e., include K-8 students), and (2) reach out to as many students as we can (i.e., in form of short term outreach activities). On the contrary, STEM-C outreach activities in Puerto Rico are more oriented towards pre-college students (i.e., K 10-12 students) helping them with their transition from a high school setting to a university life.

A. Scientific visits for K-8 students

K-8 students should be first introduced to the basic concepts in STEM-C fields in order to understand that this is an important part of our everyday lives [16]. Applying the described concepts, we organize K-8 student short visits to our research groups and departments followed by a programming class similar to the Hour of Code [17]. These short term visits are usually 2-3 hours long and follow the same format: K-8 students are first introduced to simple theory concepts that are behind things they are going to see (see Fig. 1) and then they can even try simple examples by themselves (see Fig. 2). Finally, they participate in a short programming workshop where they write their first codes (see Fig. 3).

Fig. 1. Our volunteers explaining basic theoretical concepts before showing the real-world examples of their research.

At our university in Zagreb, Croatia in total we have 12 departments where each department has different focuses and things to explain and show to K-8 students. For example at Department of Electroacoustic K-8 students learn about physical phenomenon related to sound propagation, visit so-called "deaf chamber" and experience a professional audio equipment in a controlled environment. They also learn about how dangerous it is to hear music very loudly and can "play" with some sound equipment.

Fig. 2. Experiencing "deaf chamber" and playing with sound equipment.

Last part of the visit is a programming workshop where K-8 students do a pair-programming with help of our volunteers and learn basic concepts of computer science with drag and drop programming [17]. Using this game-like approach, they learn repeat-loops, conditionals and basic algorithms.

Fig. 3. Learning basic programming concepts in pairs with help of our volunteers and earning certificates for successfully finishing the workshop.

B. Science fairs for K 9-12 students

K 9-12 students should have a basic knowledge about: (1) STEM-C in the modern world, (2) STEM-C concepts and practices, and (3) specific topics in STEM-C. They should first learn how to appreciate the breadth of computing and its influence in almost every aspect of modern life and should be aware of social and ethical impacts of their choices when using computing technology, both in their work and personal lives. Then, they should also learn how to clearly understand the application of computational thinking for tackling the real-world problems and how to work collaboratively to solve various problems using modern collaboration tools. Finally, K 9-12 students should be involved in projects-based work focusing on a single problem [16].

In contrast to short term programs that we organize for K-8 students where we want to make a first impact on student lives, by organizing short term programs for K 9-12 students we hope to help students to continue their interest in STEM-C fields. With that goal we help K 9-12 students to present outcomes of their work at a scientific fair. Fig. 4 shows

a student fair that was organized at our university for two years in a row and where more than 60 students and teams from almost 30 technical and vocational secondary schools in Croatia presented their work in front of their future professors and colleagues. Their work was judged by external team of university professors and research assistants and the best of them got awards for their achievements.

Fig. 4. Defending their work in front of judges.

C. Research symposiums for K 10-12 students

In Puerto Rico twice a year (i.e., in December and May) we organize AGMUS pre-college research symposium with the goal of emphasizing the importance of conducting research work starting already in pre-college years. Namely, at this event K 10-12 students present their research results in forms of professional posters or oral presentations. By doing so, K 10-12 students gain experience of communicating their scientific results using PowerPoint presentations and computer-generated posters (see Fig. 5).

Fig. 5. K 10-12 students at the poster session.

A typical structure of AGMUS pre-college research symposium includes: a poster session set up, breakfast, registration followed by an opening ceremony with a keynote speaker presenting motivational and state-of-the-art talk every time with a different topic (e.g., topics from robotics, computational chemistry, computational biology, modeling and simulation, software development, visualization and astronomy). Moreover, during the symposium K 10-12 students have opportunities to attend workshops for example in ethics, English and STEM-C fields.

The efforts of the students that showed the most outstanding performance are recognized at the end of the symposium during the closing ceremony when they are awarded the certificates (see Fig. 6). By presetting in this research symposium, pre-college students not only gain knowledge and practice how to present their work in front of others, but also do get feedback on their presentation performance as they are evaluated by professional judges (e.g., faculty members and/or specialists within the area).

Fig. 6. The awarded K 10-12 students.

All posters and oral presentations are in English, which is not their mother tongue, so they practice to present in a foreign language as well. Finally, in addition to the pre-college students who present their research work, other K 10-12 students who do not have any prior research experience are also invited to attend the symposium. By just attending, these students have the opportunity to see posters and presentations done by their peers that can give them a push to try the same in the following years.

Once when AGMUS pre-college research symposium finishes, we publish a special post symposium proceedings in which we include all presented posters and given presentations. Although this event can be seen as a short term one, it has long term positive effects on lives of students who participated in it as we encourage them to continue with their research activities and to participate in national and international research conferences. We also support them in their future years as young scientists by providing them with more information about the process of publishing in peer-reviewed journals [18].

D. Short term programs for K-12 school teachers

Within SUZA program we also offer K-12 school teachers in STEM-C fields educational workshops where they can learn how to present STEM-C topics in such a way that is understandable, interesting and attractive to "ordinary" people, especially youth (see Fig. 7). Namely, during their studies, future K-12 school teachers usually learn how to present the required content in a traditional ex-cathedra way. However, times have been changed and nowadays K-12 students want and expect more out of their education.

Fig. 7. Teachers listening to presentations.

This is also recognized by AZOO and ASOO agencies that are encouraging K-12 teachers in their life-long learning process. Not only school teachers are encourage to take additional "classes", but attending certain programs is even mandatory. That is why the aforementioned workshops entered the calendar of professional teacher conferences and are now

a part of the lifelong learning education and professional education offerings for K-12 school teachers in Croatia.

V. LONG TERM OUT-OF-SCHOOL STEM-C PROGRAMS

In this section we will present two types of longer term outreach activities designed for pre-college students. Both activities are organized in Puerto Rico. The first one is a pre-college research program organized in a partnership with institutions in Puerto Rico and US Virgin Islands during the school year, while the second one is a summer research program for pre-college students, undergraduates, and graduates organized in collaboration with some of the best universities and research institutions from US mainland and abroad (e.g., MIT, UCLA, UC Berkeley, University of Texas-El Paso, Carnegie Mellon University, Spanish Research Council).

A. K 10-12 student research program on Saturdays

The AGMUS pre-college research program is developed with NSF support who awarded us with the three grants: Modeling Institutions for Excellence, AGMUS Institute of Mathematics and Caribbean Computing Center for Excellence [19]–[21]. The main objective of the program is that K 10-12 students by attending Saturday research-oriented activities become more interested in STEM-C fields and afterwards enroll more easily to universities in the same fields. This is a longer term program that is run twice a year (i.e., during both fall and spring semesters) with total load of on average 64 hours per semester (see Fig. 8).

Fig. 8. Students involved in research programs run on Saturdays.

Students, while participating in research activities in STEM-C fields, are guided by their research mentors who are mainly undergraduate and graduate students. Research mentors provide students with knowledge and skills that they need to conduct their research. Namely, training that they get comprises of basic steps how to do research starting with how to make a literature review, format research hypotheses, what methods to use, how to get results and finally how to draw conclusions from their research.

They also learn about research protocols and safety, how to make a good plan for dissemination activities and the most importantly what the "real world" application of their research/science can be. Some of the examples of the previous projects are: (1) extrapolation of stock market data using MATLAB, (2) a study of Newton's law using Maple, (3) simulation of the Lorenz equation using an RK4 algorithm in C++, and (4) gamma ray burst associated with Supernova: a highly correlated physical sample.

B. Summer pre-college research program

Every summer for the last five years we have been organizing 7 weeks summer research program in which our partners were institutions in the US mainland and abroad (see Fig. 9). The list of partner institutions includes: MIT-Haystack, University of Vermont, University of Texas, El Paso, National Center for Atmospheric Research, North Carolina State University-Raleigh, Vanderbilt University, UCLA, UC Berkeley, Lawrence Berkeley National Laboratory, Lawrence Livermore National Laboratory, and Jagiellonian Observatory in Krakow, Poland.

Fig. 9. Summer pre-college research program flyers for 2012, 2013 & 2014.

The participants for this program are selected among the best performing students who attended our research programs on Saturdays during the given school year. The selected participants travel in groups of five, supervised by a chaperone, to one of the partner institutions where their mentors provide them education in the following core areas: (1) hands-on laboratory research, (2) computer-based research, (3) mentor/modeling, (4) career counseling and orientation, (5) professional growth, and (6) English language enhancement. A list of previous projects includes:

- Leg design for a praying mantis robot
- Visualization of molecular-dynamics simulations

- Tekkotsu support for the calliope platform
- An ontology on algorithms for high spatial resolution image interpretation
- Graphical display of search trees for transparent robot programming
- Teaching robotics in a three-dimensional visualization environment
- Development of educational data mining environment for the analyses of Moodle data
- Robot for support teaching parabolic trajectories
- Dog simulation behavior through the game of "catch"
- Effectiveness of a sensor-based video game system in the therapy of students with special needs.

During the program students spend on average eight hours per day, five days per week doing research-related activities under their mentor supervision. On weekends and holidays a chaperone, who is usually an undergraduate student, organizes cultural and social activities for them. Selected students are prepared and trained during a spring or fall semester prior to the summer one participating in research methodology seminars, English courses, and other professional development activities. Moreover, we help them with their travel and housing arrangements. Finally, as they move forward with their research we monitor their progress either via e-mail either by having weekly meetings on Skype or by telephone.

At the end of the summer experience, students have to make their posters and prepare oral presentations that they present both at their research sites while still there, and later one during a local research symposium held in Puerto Rico early in fall of the same year (see Fig. 10). The AGMUS research symposium is a two days event organized with the goal of bringing together pre-college, undergraduate and graduate students presenting their research projects in STEM-C fields [22], [23]. In addition to student research presentations, future participants can get an insight into summer research internship opportunities offered by major US research institutions such like MIT, UC Irving, Carnegie Mellon, University of Vermont, Princeton, University of Colorado, Boulder, UCLA, Washington University, St. Louis. The AGMUS research symposium finishes with an award ceremony where the best students are recognized for their posters and oral presentations and where they receive prizes from local industries and commerce.

VI. RESULTS OF OUT-OF-SCHOOL STEM-C PROGRAMS

We achieved great results both in short and long term outreach activities in STEM-C fields. Activities that we have organized in Croatia during the last two years made impacts on more than 500 K-8 and K 9-12 students all together. Our university was visited by K-8 students from 4 different elementary schools in Croatia: (1) more than 60 students visiting from elementary school "Kralj Tomislav", (2) more than 20 students from elementary school "Pavel Miskin", (3) more than 20 students from elementary school "Tin Ujevic", and (4) more than 10 students from elementary school "Stenjevec". On top of that we had more than 100 K-8 students participating in Hour of code workshops.

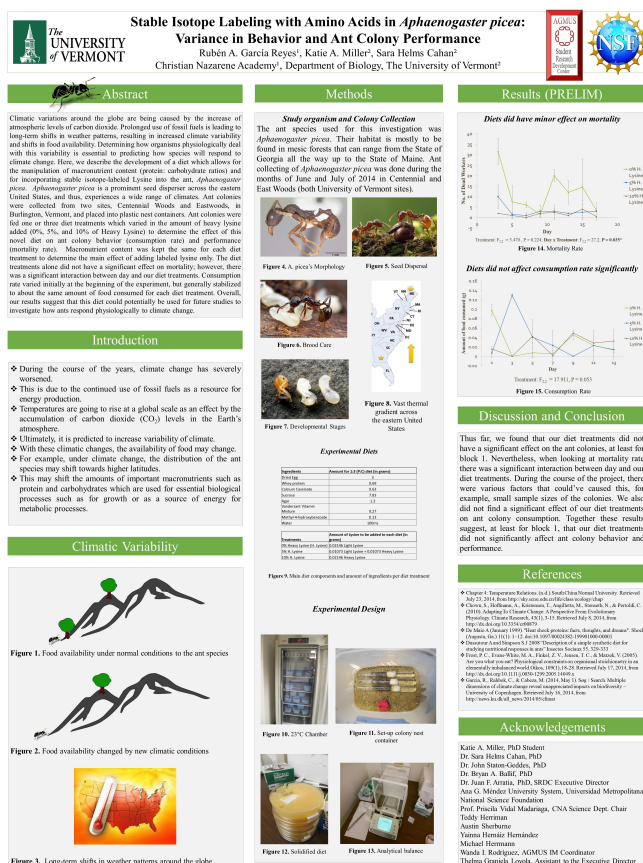

Fig. 10. An example of a scientific poster made by a pre-college student.

In addition to K-8 students, we also supported different activities for K 9-12 students. By organizing student scientific fairs and mini hands-on workshops, in total we hosted more than 210 K 9-12 students, where the full statistic is as follows: (1) more than 20 Swedish secondary school students, (2) more than 90 students participating at Student fairs 2013 and 2014, (3) more than 30 students visiting from Technical school "Ruder Boskovic", (4) more than 40 students participating in Scientific Saturday, and (5) more than 10 students visiting from Electrotechnical school. Finally, in collaboration with other popularization groups, initiatives and organizations in Croatia, we made impact on more than 540 not only students, but also other individuals interested in STEM-C fields.

In order to improve our program after each event that we organize we collect students' feedback. We rarely give to them specialized questioners, but rather support their creativity to express their opinion in a nonstructural and for them the most preferable way. In that sense, K-8 students expressed their opinions through their paintings (see Fig. 11), while K 9-12 students provided us with their feedback in form of a short written summary of their visit along with things that they liked or did not like. We took their feedback very serious and tried to improve our further activities based on the things that they did not like as much. Although our main goal is not only to promote our university, we are proud when students before leaving say: "See you in ten years!".

Fig. 11. A K-8 student giving us her feedback.

In partnership with public and private high schools across Puerto Rico and the US Virgin Islands for the last fifteen years we have impacted more than 4,550 K 10-12 students from 225 schools. The partnership with the Department of Education of Puerto Rico, and the Municipalities of the major cities and town of Puerto Rico and US Virgin Islands helped with the recruitment and selection of pre-college students for the research agenda. The model has a very successful track record of transferring almost 100% of the participants into college, and a rate of 85% of them into STEM-C fields. Fig. 12 shows outcomes of our activities that we organized for the last fifteen years. The blue colored bar denotes the number of project per year, while the orange one denotes the number of students participating in those projects.

The most important outcome of our long term project in Puerto Rico is the establishment of a pipeline from pre-college to college and from college to graduate school for STEM-C minority students from Puerto Rico and the Caribbean. During the last fifteen years we have witnessed to numerous successful examples of students who were involved in our projects. It can be either a short term success when for example technical papers that students write as a part of their summer pre-college research program are published in scientific journals or a longer term success when our students finish good universities and build a successful scientific career. In the rest of this section, due to the lack of space, we are going to mention only a few of them.

Fig. 12. Outcomes of outreach activities organized in Puerto Rico.

One of the successful short term outcomes was when the technical paper written by a student Andrea Boria who worked in the research project "Gamma Ray Burst Associated with Supernova: A Highly Correlated Physical Sample" under the mentorship of Dr. Maria Dianotti from the Jagiellonian Observatory in Krakow, Poland was published as a journal paper. Other longer term successful stories are in cases of Dr. Dalvin Mndez and Dr. Joshua Martnez, who are both from Puerto Rico. Namely, Dr. Dalvin Mndez, who entered our program as a 10-K student, finished an undergraduate program in Chemistry, Ph.D. in Computational Chemistry at Arizona State University and now is a Postdoc at Yale University. Dr. Joshua Martnez, who also joined our program in grade 10, finished his undergraduate program in Material Sciences at MIT, Ph.D. in Bio-Materials at Johns Hopkins University and now is a Postdoc at Oxford University, UK.

The list of universities where we successfully implemented our pre-college pipeline includes: the University of Puerto Rico-Mayaguez, MIT, the University of Texas-El Paso, Universidad Metropolitana, Universidad del Turabo, the University of Puerto Rico-Ro Piedras, the University of Puerto Rico-Humacao, Polytechnic University of Puerto Rico, Universidad del Sagrado Corazn, UC Irvine, UC Berkeley, the University of Virginia, Charlottesville, Howard University, Universidad Central del Caribe, Universidad Interamericana, the University of Vermont, Syracuse University, Tuft University, Cleveland State University, Boston University, Ohio State University, Georgia Tech University, the University of Maryland, Johns Hopkins University, the University of Kentucky, Pontificia Universidad Catlica de Puerto Rico, the University of Puerto Rico-Cayey, and the University of Puerto Rico-Bayamn.

To gather information about the outcomes of our activities, our students are always asked to complete an anonymous evaluation questionnaire. The evaluation questionnaire is usually a modified version of the Student Assessment of their Learning Gains instrument [24]. Due to lack of space, we are going to show only results from research program run on Saturdays in 2014. Of 65 participants who participated and completed the online survey, 24 (38%) were males, and 39 (62%) were females. In relation to education level, 21 (33%) were high school seniors, 18 (29%) were juniors, 8 (13%) were sophomores, and 12 (19%) were freshmen, and 3 were college students (5%). Most participants, 56 (90%) were Puerto Rican, 2 (3%) were White, 1 (2%) were African American, 3 (4%) reported "Other" race/ethnicity and one student did not report his/her race/ethnicity.

After finishing our program, participants reported substantial knowledge in relation to numerous scientific research-related variables. As illustrated in Fig. 13, over 70% of participants reported "great deal of knowledge/a lot of knowledge" in relation to all of the scientific research related-variables.

Fig. 13. Students' scientific knowledge and understanding of research.

Moreover, as expected, most participants (about 70%) reported "great/a lot" of skills in relation to many research/scientific related skills as shown in Fig. 14.

Fig. 14. Students' skills related to higher learning and scientific research.

Finally, as displayed in Fig. 15, over 80% of participants reported "great/a lot of interest" in relation to educational opportunities in STEM-C and over 80% of students reported interest in majoring in STEM-C and enthusiasm for research.

Fig. 15. Students' attitudes and interests in higher learning (Ph.D. in STEM-C), science, and research.

VII. CONCLUSION

As today we are facing very rapid changes in the way we are living (e.g., crowd-sourcing, crowd-owning), it is very hard to predict what future is going to look like. However, the thing that is very obvious is that jobs people (i.e., today's K-12 students) will have in 10-20 years are going to be more and more connected with digital technologies. In that sense, it is of vital importance to prepare today's students for the future challenges in the best way we can, i.e., by teaching them basic concepts of STEM-C fields. Without any doubt, this knowledge is going to be needed not only for people working in those fields, but also for other professions.

In this paper we presented two ways of introducing K-12 students to STEM-C fields: by involving them into short and long term programs. With the goal of promoting STEM-C fields, we have been organizing different scientific events both in Croatia and Puerto Rico. We showed that both approaches have their own advantages and disadvantages. Unlike the longer term activities, in cases of short term activities, we are able to include more students. However, with longer term activities we are able to establish a pre-college pipeline through which we are able to achieve more concrete results.

In our future work, we will try to benefit from both approaches by combining them together and by merging our two programs into the one. Namely, in two settings that we have today in Croatia and Puerto Rico we have either a pipeline that starts at a pre-college level or disconnected activities at lower levels (i.e., for K-8 students). In order to get better results, we would need to establish a pipeline that starts in elementary school and continues until the college level. However, to successfully implement this model, we would need every entity in the pipeline supporting lower levels. That would for example mean that high schools would need to be involved in outreach activities for elementary schools, and elementary schools would need to participate in STEM-C popularization activities for kindergarten students. Once when fully established, students who enter this pipeline will have a lower level risk of dropping along the way. Consequently, this would mean that we would have more students educated in STEM-C fields. Finally, by having more people educated in STEM-C fields, in future we will hopefully live in a more advanced and safe world.

ACKNOWLEDGMENT

The authors want to recognize the support of the National Science Foundation with the Model Institutions for Excellence grants: (DMS-9550504, DMS-9988401, DMS-0348742), AGMUS Institute of Mathematics (DMS-0822404), and Caribbean Computing Center for Excellence (CNS-0940522), the staff of the SRDC, the pre-college research mentors, the pre-college student researchers, and the administration of the Ana G. Mndez University System. Finally, this work was partially supported by research project "Managing Trust and Coordinating Interactions in Smart Networks of People, Machines and Organizations", funded by the Croatian Science Foundation.

Using Simulation Games to Teach Global Software Engineering Courses

Amir Zeid

Department of Computer Science and Information Systems
American University of Kuwait
Kuwait
azeid@auk.edu.kw

Abstract— Global software engineering is a growing field of research. The ability to develop software at remote sites provides means to utilize talents and skills in different parts of the world. Organizations and companies benefit from such diverse pool of developers. Recently, global software engineering courses started to be popular in academic settings to prepare generations of developers who can function in a professional way in such distributed setting. Courses are normally offered as part of computer science or software engineering degrees. There are different challenges pertaining to team members, environment and the interlacing factors like time zones, cultural diversity of team members, location barriers and gender issues. Simulation games have been used to teach classical software engineering courses. Simulation games can be used to illustrate and experiment with concepts like team management, performance and tool selection. SimSE is an educational simulation tool that provides graphical simulation environment to help students to practice anticipated challenges during software development. In this paper, we propose a model for distributed global software development simulation games. The model includes factors like time zones, cultural diversity of users (mainly Hofstede's culture dimensions are used), location barriers and gender issues. These factors will result in game triggers that may affect the development of the virtual project. The model is then implemented using the SimSE model builder. The game will be illustrated showing how it can be used in teaching global software engineering courses. The results will be verified using existing models.

Index Terms—Global Software Engineering education.

I. INTRODUCTION

Research in collaborative global software development (GSD) is mainly concerned with studying methodologies, tools, infrastructures, and other factors that influence distributed software development by culturally diverse teams. The main classifications of collaborative software development are: context, support, tasks interaction, teams, individuals and overreaching factors [1]. Typical problems in teaching global software engineering (GSE) courses include grading and aligning learning outcomes, securing proper communication and overcoming cultural barriers, different time zones and university calendars [2].

In the past 30 years, a considerable amount of literature has examined the definition and characteristics of culture, mostly from a person-task perspective. The most referenced research

of all literature on cultural dimensions in the context of global software engineering is that of Greet Hofstede, Project GLOBE, Trompenaars and Hampden-Turner and Hall [3]. Hofstede identified four major dimensions on which cultures may vary: Power Distance, Individualism, Uncertainty Avoidance and Masculinity. In subsequent years, Hofstede and his partners add two more cultural dimensions (Long-term versus short-term orientation (LTO) and Indulgence versus Restraint (IVR)) [4].

The general framework of our research aims to provide a longitudinal observation and documentation of distributed software development projects within an educational context. Over the period of 3 years, student teams at three sites (Kuwait, Poland and USA) will be assigned to collaborate in developing software projects. The projects and the student teams will change on an annual basis. The model simulates outsourcing in software development context. Many issues will be studied as the project progresses. Typically, the teams are enrolled in advanced software engineering courses (offered simultaneously at participating sites). The associated tools, risks and best practices will be investigated. We will choose a client from Kuwait for all experiments. We plan to run the experiments for 3 years (following similar previously reported experiments) to allow enough time for the evaluation of outcomes between the different phases.

The proposed simulation game is part of our research project. It can be used to teach and prepare students located at different sites about expected challenges in global software development. The simulations produced by the game should lead to improve the overall experience and minimize the risks and overheads. According to theories of diversity management, understanding the challenges associated with cultural differences at an early stage may help the workgroups to manage more effectively their cross-cultural communication and conflict management techniques. Based on the newly gained cultural understanding, the workgroups can come up with rules of interaction and reach a harmonization stage in which all groups are satisfied [5]. The main idea of the simulation game is to have three teams at different sites (one in Kuwait, one in USA and one in Poland) collaborate in developing software projects. The three sites belong to different cultures which may result in challenges. The goal of the simulation game is to help students understand

real challenges in global software development by trying different scenarios in the game.

The rest of this paper is organized as follows:

- Section 2 includes research background and literature survey.
- Section 3 includes related important issues to be included in the model.
- Section 4 discusses the simulation model and its components.
- Section 5 discusses how the model can be used in classroom.
- Section 6 concludes the paper and points to plans to future enhancements.

II. BACKGROUND AND LITERATURE SURVEY

SimSE model builder was used to implement the model. SimSE is an educational software engineering simulation environment that aims to bridge the gap between the large amount of conceptual software engineering knowledge given to students in lectures and the comparably small amount of this they actually get to put into practice [6]. SimSE provides a graphical simulation environment that helps students to practice and appreciate anticipated software development problems. Figure-1 shows a snapshot of the game [6]. The tool includes a model builder that can be used to construct games for different software development paradigms.

There are some other software engineering simulation games: SESAM [7], SimVBSE [8] and OSS [9]. Up to our knowledge, they do not simulate distributed software development using cultural models as a reference.

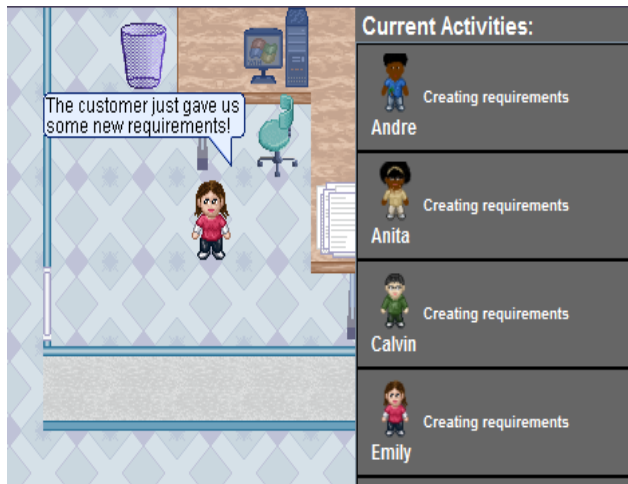

Fig. 1. Screen-Shot of SimSE tool.

A. Cultural Dimensions

Geert Hofstede conducted one of the well-known and most widely used studies about defining cultural dimensions. According to Hofstede, culture can be measured by six dimensions [10]. The following three dimensions are the most relevant measures to global software engineering [11]:

- Power Distance (PDI): This dimension expresses the degree to which people and society accept that power is not equally distributed. In societies with low power distance, people strive to equalize the distribution of power and demand justification for inequalities of power [10].
- Individualism versus collectivism (IDV): the degree to which people are attached to the group/tribe/family [10]. A society's position on this dimension is reflected in whether people's self-image is defined in terms of "I" or "we."
- Uncertainty avoidance (UAI): The degree to which people accept ambiguous and unknown future [10]. The fundamental issue here is how a society deals with the fact that the future can never be known: should we try to control the future or just let it happen? Weak UAI societies maintain a more relaxed attitude in which practice counts more than principles.

There are other cultural dimensions that will not be considered in our initial study. The remaining dimensions are [10]:

- Masculinity versus femininity (MAS): The masculinity side of this dimension represents a preference in society for achievement, heroism, assertiveness and material reward for success.
- Long-term versus short-term orientation (LTO): The long-term orientation dimension can be interpreted as dealing with society's search for virtue.
- Indulgence versus Restraint (IVR): Indulgence stands for a society that allows relatively free gratification of basic and natural human drives related to enjoying life and having fun.

Other efforts to define culture were reported. Examples include: Trompenaar's dimensions and Hall's dimensions [12]. The decision to base this discussion on Hofstede's dimensions is due to the fact that it is the most widely used cultural benchmark in the context of software industry since it was originally conducted at IBM. In next phases of research, other models and dimensions will be considered.

B. Global Software Development

Many empirical studies and literature reviews focus on the identification of challenges in collaborative work [13]. In the context of GSD in academia, there were similar projects that investigated possible challenges through experiments. The first project had two sites of software development (in multiple countries): one in Turkey and one in USA, while another experiment was done between USA and Sweden [14]. The clients in both experiments were from industry. During the first study, students from the US visited Turkey twice during the semester, once at the beginning of the project and once at the end. It was reported that time difference and language were among the major obstacles in performing the experiments [14]. The research group of Global Software Engineering at University of Victoria, Canada carried out several related research projects. One of the projects

investigated whether geographical distance continues to affect developers' collaboration in large teams that use development environments specifically designed to support collaborative distributed teams. Communication and response time were analyzed [15]. Another project at the same university developed an improvement to the original socio-technical congruence calculation in the literature. A metric that measures the strength of relationships between people and tasks, interdependent tasks and between project members was used [16].

Many efforts aimed at applying Hofstede cultural dimensions on global software engineering. Borchers suggested using three of Hofstede's cultural dimensions in the context of global software development [11]. Other research efforts argue that applying Hofstede's dimensions is not sufficient to study cultural factors in GSD [12]. Shah et al proposed using different cultural models instead of the dimensions of Hofstede [12].

C. Using Simulation in Global Software Development

The idea of using simulation to evaluate global software development projects was examined by Setamanit [17]. A hybrid simulation model was introduced [17]. The model includes fundamental factors, strategic factors and organizational factors. Fundamental factors include communication and coordination problems, cultural and time-zone differences. Strategic factors include development site, product architecture, task allocation and distribution overhead. Organizational factors include team formulation and team dynamics. The model has been verified and validated [17]. The model has been tested against ideal situation and real world cases [17]. In this paper, we will follow similar approach but we will add more details about the cultural differences using Hofstede dimensions. Our developed game simulation is verified using the simulation model of Setamanit [17].

III. ISSUES TO BE CONSIDERED IN THE MODEL

Learning outcomes of using the game partially cover the learning outcomes of the global software engineering course. In each category, the learning outcomes will be mentioned followed by a discussion of relevant issues to be considered in the model.

A. Fundamental Factors

1) Related Learning outcomes

The learning outcomes related to fundamental factors are (after playing the game):

- Students should be able to choose proper communication tools.
- Students should appreciate that cultural differences may affect the productivity of global software development teams.

2) Communication and coordination problems

The following two methods of communications can be considered: synchronous and asynchronous methods. Synchronous methods include video conferencing and chatting, while asynchronous methods include email and document sharing.

It has been argued that informal communication is important in enhancing distributed software development [17]. Distance may hinder informal communication. This may result in longer development time [17]. Coordination is affected by distance and time-zone differences as well [17].

A combination of both methods (synchronous and asynchronous) should be investigated in the game. Clear meeting agendas and minutes have to be written and disseminated early enough to give people with high UAI chance to read and prepare for meetings. Local meetings will provide an opportunity for low IDV teams to prepare and discuss in a more relaxed way before the actual formal meetings. A superior moderator for the meetings will be needed to accommodate teams with high PDI (Kuwait), while the moderator role could rotate in groups with low PDI (USA).

3) Cultural Differences

We conducted preliminary research adopting cultural measures in global software engineering [2]. The following table includes the three proposed cultural dimensions for the three proposed sites [4].

TABLE-1 CULTURAL DIMENSIONS IN KUWAIT, POLAND AND USA

	PDI	IDV	UAI
Kuwait	90	25	80
Poland	68	60	93
USA	40	91	46

It can be noticed from Table-1 that:

- Kuwait has the highest PDI, followed by Poland then USA.
- Poland has the highest UAI, followed by Kuwait then USA.
- USA had the highest IDV, followed by Poland then Kuwait.

A. PDI

- Kuwait has the highest PDI (90) which means that people accept an extreme hierarchical order which needs no further justification. Hierarchy in an organization is seen as reflecting inherent inequalities, centralization is popular, subordinates expect to be told what to do and the ideal boss is a generous autocrat.
- Poland (PDI 68) is a hierarchical society. This means that people accept a hierarchical order which needs minor justification.
- The United States score low on PDI (40) which is evidenced by the focus on equal rights in all aspects of American society and government. Within

American organizations, hierarchy is established for convenience, superiors are always accessible and managers rely on individual employees and teams for their expertise [4].

B. IDV

- USA has the highest IDV which means that it is a very highly individualistic culture. This translates into a loosely-knit society in which the expectation is that people look after themselves and their immediate families. There is also a high degree of geographical mobility in the United States and most Americans are accustomed to doing business with, or interacting, with strangers. Consequently, Americans are not shy about approaching their prospective counterparts in order to obtain or seek information. In the business world, employees are expected to be self-reliant and display initiative. Also, within the exchange-based world of work, hiring and promotion decisions are based on merit or evidence of what one has done or can do.
- Poland, with a score of IDV 60 is an Individualistic society. This means there is a high preference for a loosely-knit social framework in which individuals are expected to take care of themselves and their immediate families only.
- Kuwait, with a score of 25 in IDV is considered a collectivistic society. This results in a close long-term commitment to the 'group', be that a family, extended family, or extended relationships. Loyalty to the group in a collectivist culture is essential [4].

C. UAI

- Poland and Kuwait have high UAI thus they have a very high preference for avoiding uncertainty. Countries exhibiting high uncertainty avoidance maintain rigid codes of belief and behavior and are intolerant of unorthodox behavior and ideas. In these cultures, there is an emotional need for rules (even if the rules never seem to work). Time is money, people have an inner urge to be busy and work hard. Precision and punctuality are the norm, innovation may be resisted. Security is an important element in individual motivation.
- USA scores 46 on this dimension and therefore, the American society is what one would describe as "uncertainty accepting." Consequently, there is a larger degree of acceptance for new ideas, innovative products and a willingness to try something new or different, whether it pertains to technology or business practices [4].

4) Language Differences

Non-native English speakers tend to prefer asynchronous communication methods to have more time to understand and plan their answers [17]. However, using asynchronous communication methods may lead to delays due to difference in calendars and working hours.

5) Time-Zone Difference

Difference in time zones is a factor that will affect communication methods. Kuwait is UTC+3:00, Poland is UTC+01:00 (one hour behind Kuwait during daylight saving, two hours otherwise) while the American site follows EST (7 hours behind Kuwait during daylight saving, 8 hours otherwise). It is also worth mentioning that both Poland and USA follow daylight saving while Kuwait does not.

B. Strategic Factors

1) Related learning outcomes

The learning outcomes related to strategic factors are (after playing the game):

- Students should be able to choose proper development strategy taking into consideration distribution overheads and differences in infrastructure.

2) Development Site

Different development sites may have different infrastructures which affect communication. Employees in different regions may have different levels of education which may affect productivity [17].

3) Development Strategy

Development strategy will affect the operations since it affects working hours in participating sites. The three proposed strategies by [17] are: module-based, phase-based and follow-the-sun strategies. Follow-the-Sun (FTS) approach means handing-off work daily from one site to the next time zone site to optimize productivity [18]. In our case, the sequence will be: Kuwait-Poland-USA. FTS approach has many challenges when it comes to coordination, especially in the context of global software development [18].

4) Distribution overhead and effort loss

It has been found that distributed work will take around two and half longer time to complete that identical projects there the project activities are located at the same place [17].

C. Organizational Factors

1) Related Learning Outcomes

The learning outcomes related to organizational factors are (after playing the game):

- Students should properly assign tasks to virtual teams to optimize performance.
- Students should experiment with different team structures and to evaluate the productivity and quality of the outcome in the different cases
- Students should identify the best techniques to manage and avoid risks in the context of global software engineering
- Students should identify techniques to build trust among team members.

2) Team formulation and Structure

Building trust among team members that never met face to face is challenging. It has been argued that face to face kick off meetings improve productivity [14] [17]. It is essential that trust is established as early as possible. Without proper

personal interaction and synchronous communication, the level of trust may decrease over time [17].

Research has shown that team homogeneity is positively correlated with high performance, satisfaction, and better communication. However, overtime, an organization which manages to create a common identity or organizational culture among its diverse team can benefit from a wider pool of talents, backgrounds, and skills. Depending on the context in which they are introduced, training programs could help bridge communication gaps between culturally diverse groups. Hybrid team cultures infuse a sense of common identity that aids team interactions and performance. Earley & Mosakowski's [19] study is particularly important because it captures interactions among transnational and globally distributed work teams, a practice that has been recently growing especially in fields like software development. Although this type of studies involves cost, time, and difficulty in isolating factors, it still holds a lot of research opportunities that are worth investing in [20].

Three different settings for the teams can be investigated using the game and the outcomes can be compared [2]:

- Option-1 a typical team structure with team leader in each participating academic site. Each team has three different types of roles: analyst, designer and developer. In this setup, each team will implement a subsystem of the project then integration will take place.
- Option-2: each site is specialized in a certain activity (requirements, design and development) that better suits the culture and nature of participants in that site. Culture dimensions can be used as guidelines to assign roles. However, timing and coordination will be a challenge.
- Option-3: In this model, each team leader leads a team of a mix of cultures. In this setting, the members of each team are distributed. The role of each member is based on his/her qualifications. Leaders have to be aware of different cultures, otherwise delays and misunderstandings are probable.

3) Learning New Technologies

From the cultural interpretation, cultures with low UAI have larger degree of acceptance for new ideas, innovations and willingness to try something different. Depending on the team structure and culture mix, students will investigate which teams are faster in grasping and learning new technologies in such setting.

4) Documentation and Risk Management

Various risks related to GSD were reported in literature. Lack of understanding of requirements, selecting a wrong project, product quality and poor documentation are among the anticipated risks [21] [22]. Risks in academic environment may vary from the ones related to industry.

Using UAI as a guiding measure, it can be predicted that teams/members with high UAI can be more suitable for carrying out risk analysis and taking care of documentation along the way.

5) Gender and Trust Issues

Percentage of females studying computer science and engineering in Kuwait (around 50%) is high compared to USA and most of Europe [23]. In reality, teams will definitely have unbalanced gender distribution. While gender-segregation is a dimension of culture in Kuwait [23], it is not applicable in the other two sites. In previous research in Kuwait, it was found that gender-segregated students perform better than mixed-gender students [23].

IV. PROPOSED MODEL, IMPLEMENTATION AND VALIDATION

The proposed model is illustrated in figure 2. It includes the main classes of the simulation according to Navarro [6]. The main purpose of the simulation is to fully implement a virtual project within time and budget using the available resources (employees and tools) in the most efficient way. The score is calculated accordingly. The initial model supports a typical waterfall model. The following are the main components of the simulation model. The proposed model is implemented using SimSE model builder. The tool also provides a facility to generate a graphical representation for the developed model. The model builder provides a framework to implement models with the following components:

- Employees: team members with their attributes. Attributes can be added according to proposed model.
- Actions: possible actions to be taken by team members.
- Triggers will cause actions to begin in the simulation.
- Rules will connect actions to triggers.
- Tools: to be bought by team members to help developing the project. Tools should increase productivity.
- Artifacts are the proposed submissions by the teams.

Fig. 2. Class diagram for the model components.

A. Employee

Employees are mainly team members that can be used in the simulation. Each employee can work in one or more activities at the same time. Figure 3 shows a snapshot of the model builder while adding the attributes of employees. The following are the attributes of the employees:

- Language of communication: important to help discussions and communication. Team members who can communicate in more than one language have an advantage over others with limited capabilities.
- Gender
- Location: indicates where the team member is located.
- PDI, UAI and IDV based on Hofstede cultural measures.
- Skills in requirements
- Skills in Design
- Skills in implementation
- Skills in testing
- Leadership skills and knowledge of other cultures.
- Hourly pay rate
- Energy level/productivity

B. Actions

The actions in a SimSE model represent the set of activities in which the objects in the simulation can participate in [6]. The following are samples of the possible actions participants can do:

- Learn about other cultures: can be done at any time, preferably done before the simulation begins to improve communication.
- Create team: only done once at the beginning of simulation.
- Buy tools: can be done at any time of the simulation.
- Change team leader: can be done at any time during the project.
- Change communication method: either use synchronous or asynchronous communication methods.
- Change development strategy: users can either follow-the-sun or phase-based strategies
- Call for a meeting
- Give bonus or salary increase
- Fire
- Build requirements
- Build design
- Implement code
- Implement test plan
- Integrate code
- Submit final product

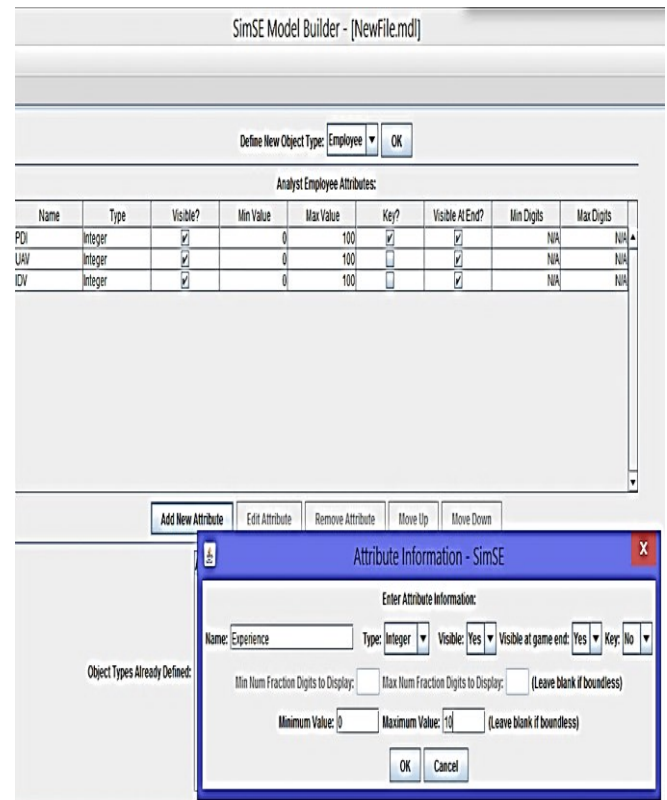

Fig. 3. Model Builder with Employee creation.

C. Triggers

Triggers are what cause the action to begin to occur in the simulation. Three distinct classes of triggers exist: autonomous, user-initiated, and random [6]. Autonomous triggers specify a set of conditions (based on the attributes of the participants in the action) that cause the action to automatically begin, with no user intervention. For instance, an Employee may automatically take a break when his or her energy level drops below a certain threshold. User-initiated triggers also specify a set of conditions, but include a menu item text string, which will appear on the right-click menu for an Employee when these conditions are met [6]. Random triggers introduce some chance into the model, specifying both a set of conditions and a frequency that indicates the likelihood of the action occurring whenever the specified conditions are met [6]. The following are some of the triggers:

- Communication lost
- New Requirements by customer
- Requirements is finished
- Design is finished
- Test plan is finished
- Risk analysis is finished
- Implementation is done
- Integration is done

D. Rules

After all of the action types have been defined, the next task in building a SimSE model is to attach rules to each action

type. A rule defines an effect of an action (if the simulation is affected when that action is active [6])

- Difference in time zone
- Language difference
- Difference in PDI
- Difference in UAI
- Difference in IDV

E. Artifacts

The initial model includes the following components that have to be developed by the virtual teams:

- Requirements document
- Design document
- Test plan
- Risk analysis document
- Final integrated product

F. Tools

Players can buy the following tools to help developing the project:

- Communication tools: Synchronous tools include video conferencing and chatting, while asynchronous tools include email and document sharing.
- Social media to communicate with other team members informally
- Requirements and design tools
- Implementation tools

G. Graphics and Map

Graphical representation for each component is included in the simulation game. The following components have icons: employees, tools, artifacts and project. In addition, each site is represented by a separate room.

H. Validation of the model

Previous research proposed to have two validation models. One of the models shows that distributed software development will reduce the time and cost of software development. In this scenario, it was argued that there are no problems associated to cultural and communication barriers. It was also argued that follow the sun approach increased productivity [17]. The other real life validation model includes the overheads distributed work introduce like language, culture and time differences. Follow the sun approach took 37% longer than single site development [17]. Our developed model and game are validated by the results of the study of Setamnit [17]. Our developed model will be tested by control groups to further validate the results of the game.

V. EXERCISE

The main learning outcomes of playing the simulation game are emphasized in the following exercise. Students have to be familiar with software process models. Process models are mainly introduced in the prerequisite course (Software Engineering). Students are given a set of handouts about cultural dimensions and their interpretations. In

addition, the Global Software Engineering course will include other topics like: risk management and effort estimation in distributed development setting. After that they play the game and answer the following questions:

A. Describe in detail the process

The students should list the steps they followed from the beginning of the game till they submitted the virtual project.

B. What is the effect of having people from diverse cultures work in the same team?

Successful diversity management and training will lead to more productivity. Earley & Mosakowski [19] suggest that successful diversity management training could help diverse teams create a hybrid team culture, “an emergent and simplified set of rules, norms, expectations, and roles that team members share and enact”.

C. What is the effect of having multiple sites developing projects?

Multi-site development will take two and half longer time [17]. Players can try to develop the same project once with one site, and then experiment with two and three sites to appreciate the overheads resulted from distributed development.

D. What are the best communication tools?

The diversity of cultures may affect the choice of the communication tools. Asynchronous tools will be the most appropriate if there is language differences. Synchronous tools would improve the communication and trust if the participants can overcome time-zone differences.

E. How is the outcome of the game affected if you change the team leader in the middle of the project?

Changing the team leader will lead to delays in the development of the project. The attributes of the new leader will affect the overall process. If he has prior knowledge about other participating cultures, this will make up for the delays.

F. Does it pay off to learn about other team members' culture?

Yes, the productivity level will improve if the participants take time at the beginning to know more about other teams' culture. Also, the productivity will be better if participants' use social media to improve informal communication.

G. What is the effect of adopting follow-the-sun approach?

It has been reported that using follow-the-sun development strategy in ideal cases may reduce development time by as much as 50% [20]. On the other hand, if not properly supported with coordination, it may result in delays of approximate 37% [17]. If the player chooses this approach, he has to follow with coordination to avoid delays.

In addition to the game, students are asked to fill a survey after the end of the semester about the experience of playing the game and how it contributed to solving some of the

problems they faced in the real global software development. The outcome is used to improve and fine-tune the model.

VI. CONCLUSION

There is a thirst among scholars and students for practice-oriented studies charting cross-cultural interactions. There have been some attempts in the US and Europe to discuss workforce diversity and its associated challenges. However, very limited research has been conducted outside of these two regions. In addition, the majority of existing literature address the topic from a management perspective, and very few deal with the social, psychological, or anthropological perspectives [24].

In this paper, we presented a model for a simulation game to be used in teaching global software engineering. The model is implemented using SimSE tool. We showed the main elements of the model and how it can include cultural factors and other challenges that affect software development in a distributed environment. The game can be used in global software engineering courses. Control groups from different cultures and backgrounds will be used to test the game. We introduced the simulation using team members from three different cultures. The model can be extended for other cultures. The model can also be extended to include other cultural dimensions. The uniqueness of this paper is in applying using simulation games in global software engineering education.

In addition to helping students to grasp the expected challenges in global software development, the proposed game can be used to explore the following ideas:

- Success factors for global software development projects.
- The benefits of distributing software development vs the overheads.
- The benefits of dividing work between development sites in an efficient way.

On Combining Gamification Theory and ABET Criteria for Teaching and Learning Engineering

Ivan Cabezas, *Member, IEEE*

Laboratorio de Investigación para el Desarrollo de la Ingeniería de Software - LIDIS
Universidad de San Buenaventura
Cali, Colombia
imcabezas@usbcali.edu.co

Abstract— The main contribution of this paper is the introduction of a continuous improvement cycle for devising teaching scenarios and conducting learning experiences in engineering. The proposed cycle consists of seven steps on which gamification theory and ABET criteria are combined. It arose from the adaptation of a gamification design framework, commonly used in industry, into the specific context of high quality education in engineering. It is formulated at high level. Consequently, it should be useful for practitioners having different requirements and expectations. A developed practice, following the proposed cycle, is presented, discussed and evaluated. In particular, the proposal is applied and exemplified, in a scenario for teaching introductory concepts of computer programming in a first-year course. A digital game was used within a gamified learning experience, as a teaching tool. However, the learning process does not rely solely on the use of the game by itself. Moreover, the devised scenario has a purpose beyond edutainment: contributing to achievement of student outcomes, under a continuous improvement approach, according to ABET. A quantitative and qualitative evaluation of the developed practice was performed. A positive impact on students' emotional engagement and behavior was observed as a result of the evaluation process.

Keywords—gamification; ABET criteria; teaching; learning; continuous improvement; student outcomes.

I. INTRODUCTION

Improving the quality on engineering education by incorporating international standards and criteria, such as those considered by ABET, implies not only advantages but also challenges, for both students and faculty members. In particular, an increasing expectation about student outcomes may lead to a complex learning experience. In this paper, a first attempt for combining ABET criteria and gamification theory is discussed. These concepts are briefly introduced as follows.

A. Gamification

The term gamification was coined in 2004 to propose that electronic devices can be profitably turned into games [1]. Nevertheless, the term and its practice took off by a software based approach. It is defined in [2] as the use of game design elements in non-game contexts. Gamification can be understood as an implementation and use of game elements (i.e. design, mechanics, and thinking, among others) in a

process or service, in order to improve user experience, engagement and productivity beyond a pure entertainment area [3]. It has been widely adopted in industry as an engagement strategy for business [4] [5], [6]. Moreover, it is expected that industry will demand a significant number of well trained and highly educated specialist on gamification from professional areas such as business management, design and engineering [7]. In [1], gamification is defined within a learning context, as simple game play to support productive interaction for expected types of learners and instructors. In fact, the use of gamification for educational purposes is on the rise [8], [9], [10]. It is motivated by its potential to engage students in learning activities [8]. Such engagement is positively correlated to the achievement of student outcomes [11], [12].

B. ABET Criteria

ABET is the acronym for Accreditation Board for Engineering and Technology [13]. ABET origins dates back to 1932, when the Engineer's Council for Professional Development (ECPD) was founded by seven engineering societies. The ECPD was conceived as a professional body dedicated to the education, accreditation, regulation and professional development of the engineering professionals and students in the United States. It was renamed to ABET, in 1980, in order to accurately describe its emphasis on accreditation. ABET is a nonprofit organization that accredits college and university programs in the disciplines of applied science, computing, engineering, and engineering technology. Currently, ABET accredits over three thousand engineering programs worldwide [13]. ABET accreditation is voluntarily submitted, and attained by a peer review process. It aims to provide assurance that a college or university program meets the quality standards of the profession for which that program prepares graduates. ABET considers a set of general criteria, as well as program criteria for accreditation purposes [14]. Among the general criteria, student outcomes and continuous improvement are fundamental and inherently related [15]. Student outcomes describe what students are expected to know and be able to do by the time of graduation. The extent on which such student outcomes are being attained should be assessed and evaluated in order to systematically be used as input for the continuous improvement of the program. However, specifying ways or approaches on which assessment and continuous improvement processes should be conducted, is

beyond the spirit of ABET. Consequently, each program has to devise and conduct strategies, not only for accomplish the fulfillment of such goals, but also on generating evidence in this regard [16].

II. PROBLEM STATEMENT & PROPOSAL SUMMARY

There are some proposals on gamification frameworks to be applied on education [17], [18]. However, how to properly and successfully apply gamification mechanisms into education remains as an open question. Moreover, most of previous works reporting a successful use of gamification for educational purposes may exhibit some, or a combination, of the following weaknesses:

- Ignore high quality education international standards.
- Lack of a continuous improvement approach.
- Ignore the inherently cyclical nature of learning, on which an advanced knowledge or a highly developed skill (e.g. analyze, evaluate, create) is constructed upon, or requires, more basic skills (e.g. remember, understand, apply) [19].
- Be mainly focused on applying gamification mechanisms such as badges, bonus points, and gaming elements, among others.
- Require the use of a complex or a specifically tailored gamification platform.

In this paper, a teaching and learning cycle composed of seven steps is introduced. The proposed cycle adapts the Werbach's gamification design framework [4] into the specific context of high quality engineering education. It contextualizes the first four ABET criteria (i.e. students, program educational objectives, student outcomes, and continuous improvement) within a gamified teaching-learning experience. In this way, the former four weaknesses mentioned above are explicitly tackled by the proposal, whilst the latter should be considered by practitioners following the proposal. Additionally, a concise model for estimating students' emotional engagement during the experience is proposed. The model allows obtaining feedback on the way the teaching-learning unit was gamified and conducted.

The remainder of the paper is organized as follows. Required background and related works are briefly discussed in section III. The introduced cycle and the proposed emotional model are presented in section IV. An application of the proposed cycle is exemplified and evaluated in section V. Final remarks are stated in section VI.

III. BACKGROUND & RELATED WORKS

A. Student Engagement

Engagement is defined in [20] as student's psychological investment in and effort directed toward learning, understanding, or mastering the knowledge, skills, or crafts that academic work is intended to promote. It is defined in [21] as a meta-construct including behavioral, emotional and cognitive engagement.

- Behavioral engagement: a positive conduct, absence of disruptive behavior, participation and involvement on learning-related activities, expressed by effort, persistence and attention.
- Emotional engagement: student's willingness to do work, interest in learning activities, enjoyment, and positive attitudes about learning.
- Cognitive engagement: student's investment on learning to achieve deep understanding and expertise.

Engagement is commonly measured by self-report surveys, on which students identify those aspects that best describe them [21]. Among these constructs, behavioral and cognitive engagements are discussed most frequently on literature [22]. Nevertheless, the emotional engagement should not be overlooked, since there is an interplay between emotions and learning, and consequently, a range of emotions occur inherently in a learning process [23], [24]. A model relating phases of learning to emotions is presented in [23]. Such model considers three axes: Learning, Emotional and Knowledge. Additionally, an emotion set for learning, (i.e. associated to the Learning axis), is proposed.

B. Gamification Elements

According to [18], gamification elements are classified into self-elements or social-elements. On the one hand, self-elements engage students for competing against themselves toward recognition of self-achievement. Elements such as points, levels, badges and quests are considered as self-elements.

- Points: a player obtains a reward in the form of a point on the achievement of a certain behavior or the completion of a task.
- Levels: a player has a level that increases as he/she reaches a certain number of points.
- Badges: represent certain achievements of a player.
- Quests: represent tasks that a player has to complete.

On the other hand, social-elements engage students for an interactive competition or cooperation with others towards a public recognition, or a collaborative achievement. Ranking and voting are two commonly used social-elements.

- Ranking: a leader board is presented to all players to increase competitiveness.
- Voting: players can vote on another player's behavior.

C. Gamification in Education

The gamification of a software engineering curriculum is proposed in [7]. This proposal is based on several strategies such as an implementation of gamification-related-topics into traditional courses, an active use of gamification mechanisms in course activities, and an active involvement of students into research projects on gamification and serious games on industry, among others. Nevertheless, presented discussion is focused on incorporating gamification concepts and theory into course syllabus, whilst insights in how to successfully achieve

and implement others aspects of the proposal are not addressed. Moreover, some of the final recommendations, such as including experienced software designers and programmers into project teams, could be difficult to accomplish in a daily basis.

A five step process for applying gamification in education is proposed in [18]. In particular, the process is aimed to gamify an entire learning program. The involved steps are outlined below.

1) *Understanding the target audience and the context:* A good understanding of who the student is, as well as of the context on which the program is being delivered, are required in order to designing a program that empowers the student to achieve the expected objectives.

2) *Defining learning objectives:* Every instructor should state an objective or objectives to be achieved by the students at the end of the learning program.

3) *Structuring the experience:* The program has to be broken down into stages or milestones. Instructors should quantify what the students need to learn and achieve by the end of each stage or milestone.

4) *Identifying resources:* Once the stages or the milestones have been identified, the instructor can more easily judge which stages, if any, can be gamified and how.

5) *Applying gamification elements:* Select and apply game mechanics within the learning process.

Although some of the steps identified in [18] are indeed fundamental for applying gamification in education, this proposal ignores high quality standards and lacks of a continuous improvement approach.

An exploration of the impact of applying gamification mechanisms on students' cognitive engagement and learning about the C-programming language is presented in [8]. To this end, a gamified learning platform was designed and deployed, following the user-centered theoretical framework for meaningful gamification proposed in [17]. They concluded on the positive effects on cognitive engagement by the gamified learning activity employed. Such cognitive engagement was expressed as a desire to go beyond requirements and measured by performing work after having accomplished learning goals. Besides of interesting and encouraging conclusions in [8], this work exemplifies the weakness of requiring a tailored platform for applying gamification in education.

D. Werbach's Gamification Design Framework

The gamification design framework proposed by Werbach [4] is commonly used in industry. It comprises six steps which are outlined below. The purpose of each step is exemplified by questions [25].

1) *Define business objectives:* Why the gamification process is taking place? What are the specific results that will be generated into the organization by the gamification process?

2) *Deliniate target behaviors:* What are the behaviors that will lead to the fulfilment of stated objectives? What metrics will be used to measure them?

3) *Describe your players:* Who are the participants in the gamified activity? What are they like?

4) *Devise your activity loops:* What kind of feedback the system will offer to the players in order to encourage further action? How such feedback will work to motivate players?

5) *Don't forget the fun:* How the gamified system would function without any extrinsic rewards? It is fun?

6) *Deploy the appropriate tools:* How the system would look like? How it is going to be experienced?

E. Engineering Accreditation Commission Criteria

Among the several commissions of ABET, the discussion presented in this document does emphasis on the criteria stipulated by the Engineering Accreditation Commission (EAC). Such commission accredits engineering programs of bachelor's or master's degree levels [15]. A program seeking accreditation from the EAC must demonstrate that it satisfies all the following criteria: students, program educational objectives, student outcomes, continuous improvement, curriculum, faculty, facilities, and institutional support. Among these, closely related criteria to the presented proposal are summarized below.

1) *Students:* Student performance must be evaluated. Student progress must be monitored to foster success in attaining student outcomes, thereby enabling graduates to attain program educational objectives.

2) *Program educational objectives:* The program must have published program educational objectives that are consistent with the mission of the institution, the needs of the program's various constituents, and ABET criteria.

3) *Student outcomes:* The program must have documented student outcomes that prepare graduates to attain the program educational objectives. Student outcomes are outcomes (a) through (k), plus any additional outcome articulated by the program.

a) An ability to apply knowledge of mathematics, science and engineering.

b) An ability to design and conduct experiments, as well as to analyze and interpret data

c) An ability to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability.

d) An ability to function on multidisciplinary teams.

e) An ability to identify, formulate and solve engineering problems.

f) An understanding of professional and ethical responsibility.

g) An ability to communicate effectively.

h) The broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context.

i) A recognition of the need for, and an ability to engage life-long learning.

j) A knowledge of contemporary issues.

k) An ability to use the techniques, skills, and modern engineering tools necessary for engineering practice.

4) *Continuous improvement*: The program must regularly use appropriate, documented processes for assessing and evaluating the extent to which the student outcomes are being attained. The results of these evaluations must be systematically utilized as input for the continuous improvement of the program.

F. Assessment and Evaluation

The EAC makes a distinction between assessment and evaluation [15]. On the one hand, assessment is defined as one or more processes that identify, collect and prepare data to evaluate the attainment of student outcomes. On the other hand, evaluation is defined as one or more processes for interpreting the data and evidence accumulated through assessment process, in order to determine the extent to which student outcomes are being attained.

In a classic approach [26], there are two types of assessment: formative and summative. The formative assessment takes place during the instructional process, while learning is occurring. It refers to an interactive monitoring and feedback of student progress in order to properly understand and identify learning needs, as well as to adjust teaching. Typically, it is not graded. In this way, a primary focus of the formative assessment is to identify areas that may need improvement,—regarding the both roles—, by gauging student learning progress and determining teaching effectiveness. The summative assessment is used to promote students, by measuring what they have learnt. It allows ensuring students has met required standards on the way to earning certification for studying completion [19].

IV. PROPOSAL FOR AN INNOVATIVE PRACTICE

A cycle aimed to teaching and learning engineering, under a continuous improvement approach, is introduced in this section. The goal of the proposed cycle is to serve as a basis for devise high quality teaching scenarios, in order to provide engaging teaching-learning experiences. Additionally, a concise emotional model is presented. It allows estimating the emotional engagement by students during the teaching-learning experience.

A. A Continuous Improvement Cycle for Teaching and Learning Engineering

The proposed cycle is illustrated in Fig 1. It is composed by seven steps: (1) define educational goals, (2) document impacted student outcomes, (3) characterize target students, (4) select tools and gamification mechanisms, (5) plan assessment and evaluation processes, (6) develop the teaching-learning scenario and gather data, (7) analyze data and provide feedback.

scenario and gather data, and (7) analyze data and provide feedback.

Each one of these steps is discussed below.

1) *Define educational goals*: What is expected from the students to learn? Which are the subjects on which the learning unit will be focused on? Which are the subjects that students may require in order to successfully approach and take benefit of the learning activity? Why an specific subject should be gamified? This step considers the specific knowledge or skills that it is expected students will acquire or attain. In this regard, well known curricula recommendations [27] and bodies of knowledge [28] should be taken into account. As a guideline, a *keep it simple* approach may be convenient (i.e. although it is indeed possible to teach elaborate and complex engineering concepts, probably it is not adequate try to teach more than once at the same time).

2) *Document impacted student outcomes*: Which are the student outcomes that students will develop or enhance during the teaching-learning experience? What are the abilities that will take benefit from the learning activity? What is the justification for the specific selection? This step articulates the educational goals, with the impacted students outcomes by the teaching-learning experience. In this step, student outcomes can be selected among a list of previously considered outcomes for the specific course according to the program educational objectives, or in concordance with the defined educational goals in the previous step. As a guideline, it may be convenient to select only a few student outcomes to be considered, and even just a single or a pair of them.

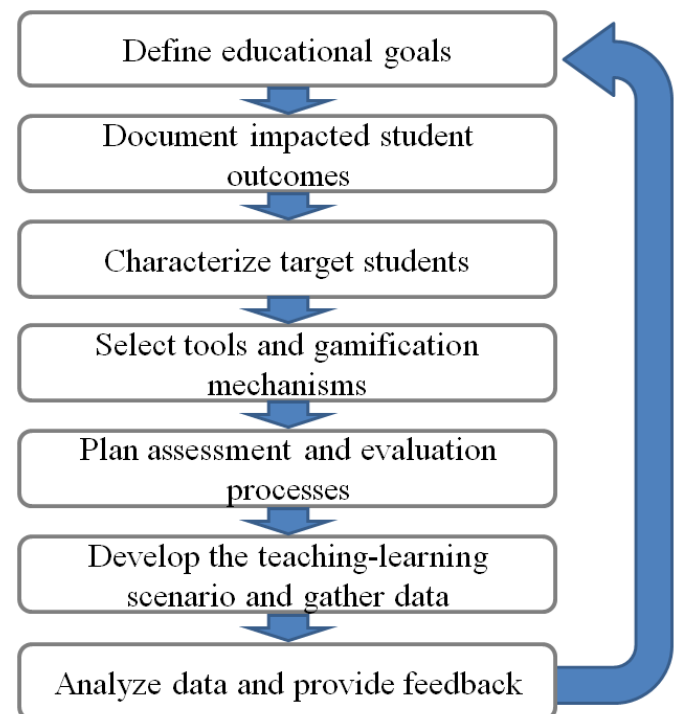

Fig. 1. Proposed teaching-learning cycle.

3) *Characterize target students*: Who are the target students? How are they (e.g. demographically, psychologically)? What strengths or weaknesses, regarding the previous steps, may they already have? Can they be considered as homogenous or what kind of disparities among them should be taken into account? This step highlights the relevance of being aware of the nature of the students in order to properly teach them. As a suggestion, as one of the first activities in a course, some demographic data about the students may be gathered by anonymous self reports. Moreover, an exercise on which students introduce themselves and explicit their expectations on the course could contribute to the development of the student outcome (g), as well as to allow the teacher (and faculty members in general) to get an idea about who they are.

4) *Select tools and gamification mechanisms*: Which are the gamification elements that can be incorporated into the teaching-learning experience? Why the experience may take benefit of such elements? Among the already available tools (e.g. digital games, non-electronic ludic activities, role playing games, among others) [29] which ones incorporate the desired gamification elements? Are such tools adequate to the target students? Why the selected tool it is suited to be used according to all the previous steps? The main guideline in this step is to reuse or adapt available resources.

5) *Plan assessment and evaluation processes*: In the first place, performance indicators should be devised according to the previously considered student outcomes. In this regard, a rubric should be designed or selected accordingly [30],[31]. Moreover, multiple *specific and single point in time* rubrics can be used in conjunction with a single *general and developmental over time* rubric. For each designed rubric, the way on which it will be gathered should be documented. In the second place, ways on how the designed indicators are going to be analyzed and interpreted should be delineated. Such interpretation can be considered as an stop criterion over the proposed cycle. In the third place, an evaluation of how the teaching-learning experience was perceived by the students should be conducted. As a guideline, a formative assessment should be firstly conducted, whilst a summative assessment could take place as a second iteration. Besides, a summative assessment can be approached by some of the gamification mechanisms (i.e. social-elements) considered in the previous step. Additionally it is also important to consider or evaluate, not only the final product the learning unit may have, but also the process followed by students during its development [32].

6) *Develop the teaching-learning scenario and gather data*: When and where the teaching-learning unit will take place? It is the place suited? How data about the students emotional engagement will be gathered, without strong interferences? What to do if any inconvenience arises? What activities should perform the teacher, before, during and after the teaching-learning unit? What are the rules and the constraints for the interaction among participants? As a guideline, the teacher should construct a bitacora about the

development of the teaching-learning unit, and share it with other faculty members.

7) *Analyze data and provide feedback*: Students should be informed by the teacher about how well they performed. Additionally, the teacher must bring a clear indication of what they need to accomplish in the future in order to improve their performance. Moreover, the teacher also requires feedback on his/her own performance. Such feedback process is based on performance rubric, as well as on the emotional engagement estimation by the students' self-report survey. Taking this information into account, an informed decision about the requirements and expectations of the next iteration of the cycle, can be addressed in an proper way.

B. An Emotional Engagement Model for Gamified Teaching-Learning Experiences

The author holds that emotional engagement is not trivial at all to be measured, since such attempt itself may impact on students' emotions. However, in the context of the proposed cycle, the goal is to obtain a fast and reliable feedback about how was perceived the teaching learning experience (instead of obtain an emotional profile of the students). This is quite relevant due to the gamified nature of the proposed cycle. During the innovative practice presented in this paper, an intuitive tool for estimating the emotional engagement was developed. To this end, a variation of the model presented in [23] was conceived. The proposed model, illustrated in Fig 2, is focused on emotions, and consequently involves only two axes, since other dimensions of a teaching-learning experience are considered by rubrics. Such two axes generate the following quadrants: self-engaging, self-pushing, self-reward, and self-punishment. These quadrants are associated to emotional states. In the proposed model, the student navigates through the quadrants during the teaching-learning experience. Thus, in a successfully gamified learning experience, the emotional state of a student may begin in the self-engaging quadrant, and moves around self-pushing and self-reward quadrants. In contrast to, in an unsuccessfully gamified experience, the emotional state of the student may end in the self-punishment quadrant, and consequently the learning process will cease.

Fig. 2. Proposed emotional model for estimating students' emotional engagement during a gamified teaching-learning experience.

Such cases could be associated to gamified activities, too difficult, or too easy, or even to activities perceived as irrelevant by the learner. Additionally, since in practice the emotional state of the student is commonly estimated by a survey, a very basic set of emotions is required. In contrast to the emotion set proposed in [23], the emotional axis presented in Fig. 3 includes just nine elements: four positive, four negative and one of neutral character. Moreover, the presence of a neutral element is a distinctive characteristic. Although, it contains two more elements than the emotions set considered in [24], it is properly balanced. In particular, the set presented in [24] contains four negative elements and three positive elements. Thus, there is a bias on the probability of selecting a negative element.

In order to implement the model in a survey, the elements of the emotional axis may be presented in disorder to the learner, who should select the subset which describes best his/her own perceived state. Additionally, control questions aiming to determine the coherence in answers could be introduced into the survey.

V. DEVELOPED PRACTICE AND EVALUATION

An innovative practice was developed following the proposed cycle. It is presented in this section, and motivated by answering some of the stated questions.

1) *Define educational goals:* The Software Development Fundamentals knowledge area of the Computer Science Curricula 2013 –CS2013 [28]– generalizes introductory programming to focus on more of the software development process, identifying concepts and skills that should be mastered in the first year of a computer-science program, and similarly named engineering programs. It includes Algorithms and Design as a knowledge unit. This unit considers the role of algorithms in the problem-solving process as a topic. Consequently, a first year student belonging to such engineering programs should be able to create algorithms for solving simple problems. It was the educational goal defined for the conducted teaching-learning unit. Apply algorithms on problem solving was considered as suited for gamification, due to its inherent abstraction, since in practice, a problem may be splitted into subproblems in order to be properly tackled.

2) *Document impacted student outcomes:* The (d) and (e) student outcomes were selected for the conducted learning-unit experience. Such selection makes tottally sense, since, by the time of graduation students should be able to perform an algorithmic approach for problem solving, whithin a multidisciplinary workteam.

Fig. 3. Proposed emotional learning axis.

3) *Characterize target students:* Target students were enrolled in two groups of the Introduction to Programming first-year course, during the second semester of the 2014. A total of 45 students composed these two groups. The morning classes group had a population of 21 students (90.5% male) with an average age of 18.8 years (std: 1.9), whilst the afternoon classes group had a population of 24 students (83.3% male) with an average age of 19.3 years (std: 2.1). Most of them were not yet properly familiarized with ABET student outcomes (neither related terminology), but they were aware of concepts related to a competence based educational system. They belong to the following programs: Systems Engineering, Electronical Engineering, and Multimedia Engineering, at the Engineering Faculty of the Universidad de San Buenaventura, in Cali, Colombia. These programs are not certified by ABET.

4) *Select tools and gamification mechanisms:* Lightbot™ is a programming puzzle game associated to the Hour of Code initiative [33], [34]. Such initiative is dedicated to inspiring K-12 students to take interest in computer science. Lightbot™ was developed by D. Yaroslavski, and a free web-based version is available at [35]. This version is composed by three levels –Basics, Procedures and Loops–, for a total of twenty different scenarios. The goal of the game is to guide a robot to light up all the blue tiles in each scenario, by a set of instructions introduced by the user. This puzzle game was selected as the gamification tool. The teacher played the game in order to determine if it was suitable to be used within the teaching-learning experience. He concludes that the difficulty of the three game levels was appropriate. Additionally, the following gamification elements were identified:

- **Quests:** each different scenario implies a new task.
- **Badges:** a certificate of completion is granted to the user when he/she fishes the three game levels. The website allows sharing it on social networks.

Other factors such as having a gender neutral game character, and absence of a puerile context were also taken into account. Finally he introduced an additional gamification element:

- **Points:** a player who completes all the scenarios will obtain a reward.

5) *Plan assessment and evaluation processes:* Two holistic rubrics, with a single dimension each, were developed in order to allow an individual formative assessment. The rubric related to student outcome (d) it is shown in Table 1, whilst the rubric related to student outcome (e) it is shown in Table 2. The latter rubric was used for calculating rewarding points, following the previously introduced gamification mechanism. Points were added later to another grade.

6) *Develop the teaching-learning scenario and gather data:* The Introduction to Programming course has two weekly sessions of two hours each. The devised teaching-learning unit was conducted on the second week of the semester. The concepts of programming, algorithms,

computational problems and subproblems were briefly introduced, intuitively defined, and motivated by examples on the two previous sessions. The web based version of Lightbot™ was presented in class, just before the end of the previous session. Its first level was cooperatively played by the entire class, not only in order to familiarize students with the interface and game goals, but also for allowing the teacher to graphically illustrate and reinforce the previously introduced concepts. The session on which the teaching-learning unit was conducted was divided into three segments. The first segment was used for explaining the activity, its goals and deliverable. The template for reporting developed solutions was posted on the Moodle platform of the University, and used to illustrate the procedure concept in Lightbot™, required to solving levels two and three. This first segment was about fifteen-minutes long. The middle segment was about one hour and half long. It was used by the students in order to accomplish the activity goals, construct the report, and uploaded it in to the Moodle platform. During this segment, the teacher provided some guidance, when required, but only in aspects related to the work report. He gathered data related to the teamwork dimension considered in the rubric, in a non intrusive way, by a passive observation approach. To this end, each team was observed multiple times, considering factors such as who was on the keyboard at a single time, if the team were using more than one computer, the interaction between the team members, and the strategy adopted by the team, among others. Additionally, he wrote some notes about how the students did use the provided template, or regarding the experience as a whole. The last segment was devoted to individually and anonymously answering the survey on the activity and its affective perception. Nevertheless, participating in the survey was optional. The paper survey was filled out in the morning classes group by the 86% of the students, and by the 84% in the afternoon classes group.

TABLE I. TEAMWORK RUBRIC

	Teamwork			
	Exemplary	Satisfactory	Developing	Unsatisfactory
Attitude & Participation	Shows willingness to cooperate by expressing own ideas, and paying attention to others	Exhibits positive attitude and leadership	Exhibits a passive attitude	There is not evidence of willingness for work team

TABLE II. PROBLEM SOLVING RUBRIC

	Problem Solving		
	5	3	0
Task Achievement & Technical Report	All problems were solved, and solutions were properly reported	There are unsolved problems or reported solutions are inadequate	No attempt

7) *Analyze data and provide feedback*: Gathered data by rubrics, were processed and summarized. Each student was informed about his/her own performance. Classroom data were published through the Moodle platform. Further teaching directions were guided based on such summarized data. The obtained teamwork assessment, summarized by classrooms, is shown in Fig. 4.

Additionally, surveys were analyzed in order to obtain an estimation of the emotional engagement perceived by students. The students were asked about to identify on the survey up to three emotions associated to their own experience. The most frequently reported emotions were, in its order: amusement, interest, curiosity, anxiety, happiness, and anger. The emotions of sadness, boredom, and indifference, were not reported at all (or filtered out by the control questions on the survey). The emotional profile of the teaching-learning experience, associated to the proposed emotional model is shown in Fig. 5. It can be observed that there is a trend to the positive side of the axis. Consequently, the emotional engagement of target students during the developed practice can be described as positive.

Moreover, the survey also allowed measuring the combinations types of emotions occurring during the learning process. In this sort of ideas, Fig. 6 illustrates the percentage of students that reported only positive emotions (Totally Positive, 54.8%), more positive than negative emotions (Predominantly Positive, 35.5%), just indifferent or a single positive in conjunction with a single negative emotion (Indifferent, 6.5%), more negative than positive emotions (Predominantly Negative, 3.2), and only negative emotions (Totally Negative, 0%). Thus, a change in the emotional state of students among the quadrants of the proposed model can be observed from data. This observation is congruent with the range of emotions that according to [23] arose naturally during a learning process. In the context of this paper, such observation can be understood as a successful gamification process of the teaching-learning experience. Thus, the teacher has now information about students as learners, regarding their emotional engagement during the conducted activity. Such information, combined with the results obtained by devised rubrics will allow him/her to define which should be the educational goals on the next iteration of the teaching-learning cycle.

Fig. 4. Teamwork performance assessment on the gamified the activity.

Fig. 5. Emotional profile of the conducted teaching-learning experience.

Fig. 6. Percentages of combined emotions reported by students regarding the teaching-learning experience.

An analysis on the variation of the teamwork behavior was possible based on gathered data later on the class's final project. The teamwork performance assessment on the class's final project, according to the rubric shown in Table 1, is illustrated in Fig. 7. Although such project was not gamified, the aspect to highlight is how the data gathering, considered by the proposed cycle, allows analyzing students' behavior on different time moments.

Fig. 7. Teamwork performance assessment on the class's final project.

As can be seen in Fig. 7, there is an increase on the percentage of students with an unsatisfactory teamwork performance. This is due mainly to a high dropout ratio on the course. Simultaneously, there is no evidence of students assessed with a *Developing* teamwork performance. This can be associated to an improvement on this regard by remaining students on the course.

VI. FINAL REMARKS

A plenty of universities and educational institutions in the United States, and many others in well developed countries around the globe, have a long tradition in ABET accreditation process. In contrast, universities in underdeveloped regions are struggling in order to properly incorporate such high quality standards and documented processes in a daily basis. Moreover, such universities are facing another challenges related to a low number of applicants for engineering programs, as well as a high dropout. In the context of such endeavor, the engineering faculty of the Universidad San Buenaventura in Cali, has already started to explore alternatives to fulfill with the guidelines of the EAC. A success in this effort will require a large investment as well as an considerable learning curve by faculty members, and students. The proposed cycle arose motivated for tackling the challenges above mentioned. The main contribution of the proposed cycle is to combine elements from gamification theory with the first four ABET criteria, aiming to make possible a continuous improvement process. Moreover, it considers the most relevant weaknesses commonly found in approaches for applying gamification in education. A detailed description of the proposal was provided in order to facilitate its application by a wide audience of practitioners looking for a concise way to incorporate ABET criteria in the teaching exercise, and also gamification elements into learning activities. In fact, the proposed cycle can be used not only by faculty members starting in an ABET accreditation process, but also by faculty members expecting to promote students emotional engagement. In this sort of ideas, the proposed cycle is a useful tool in order to devising and conduct gamified teaching-learning experiences, under the ABET criteria.

ACKNOWLEDGMENT

The author wishes to express his gratitude to his colleagues at the Universidad de San Buenaventura – Cali, and at the Laboratorio de Investigación para el Desarrollo de la Ingeniería de Software – LIDIS, for their collaboration and many thoughtful discussions. Particular thanks are due to Rocio Segovia, Martha Peñaloza, Beatriz Grass, José Jurado and Luis Merchán, for their advice and support.

Is there a gender difference in Maths competencies achievement between Aerospace Engineering students in Spain?

S. Moll, J.-A. Morano, M.-D. Roselló, L.M. Sánchez Ruiz

Universitat Politècnica de València

Valencia, Spain

[<sanmollp,jomofer.drosello,lmsr@mat.upv.es>](mailto:sanmollp,jomofer.drosello,lmsr@mat.upv.es)

Abstract—The NSF has recently issued the report on “Women, Minorities, and Persons with Disabilities in Science and Engineering” which provides statistical information about the participation of these three groups in science, engineering education and employment. The percentages in Spain, and particularly in the Technical University of Valencia where almost all degrees are technologically related, are not very different even though there is a general feeling in Spanish society to consider engineering studies to be appealing and with high employability possibilities. In this paper we analyze how they perform inside the university in a highly technological degree as Aerospace Engineering. We present their results corresponding to competencies achievement in each gender group and each topic of these Mathematics subjects.

Keywords—*Mathematics in Engineering Education; Assessment and Evaluation Strategies/Approaches Laboratory Experiences; Teaching & Learning Experiences in Engineering Education; First and Second Year Program*

I. INTRODUCTION

Gender inequity in academic Science, Technology, Engineering, and Mathematics (STEM) has been a topic of growing interest and intense debates [1,2]. In many countries, including those belonging to the European Union and in the United States, women are still underrepresented in STEM [3]. For decades this low rate of women has been a concern in the U.S., and more recently in Europe. In the late twentieth century many national committees and professional organizations initiated a number of programs with the aim of increasing female presence in science and engineering (e.g., American Council on Education 1988; National Research Council 1991 [4]). These programs were created to promote the talent pool and mainly worked at school education level changing the attitudes of female students. Despite that the long term interventions led to a progressively increasing number of women in some STEM disciplines, a proportional increase of women faculty members did not take place as expected.

According to a recent NSF report [5] roughly above 20 percent of Engineering students are female, percentage that becomes multiplied by 2 when it comes to Mathematics, thus

making clear the difference appeal in gender towards STEM. This same proportion is also found in Spain [6]. Despite the fact that engineering studies in Spain are considered and accepted as attractive by their employability [7], same gender ratio is maintained in the different engineering schools in the Technical University of Valencia (UPV). The fact is that traditionally there are more female students in careers related to Health Sciences, Social, Law, Humanities and Arts (Nursing, Medicine, Psychology, Teaching, Fine Arts...) [8,9,10]. Many people have attempted to give reasons of the relatively low numbers of women in STEM fields, leading to the rise of a number of biological, structural, and social-psychological explanations [11,12,13]. In fact, Bachelor's Degree in Aerospace Engineering, delivered at the UPV, is one of the degrees in which the enrollment of female students is lower than male students, roughly above 20 percent as in the US and in their first year they have to perform the following compulsory subjects: Business Studies, Chemistry, Computer Science, Materials Science, Mathematics I, Physics and Technical Drawing. In this paper we analyze gender performance of Mathematics I in each of the different blocks: Algebra, Calculus and laboratory practice during 2013-14 and also of Mathematics II of Second Year during 2014-15. We present their competencies achievement results in each gender group and topic of these Mathematics subjects.

II. THE LOCAL SETTING

BEng Aerospace Engineering is a 4 year degree whose strongly motivated students have achieved the highest scores in their pre-university studies. As in most engineering careers, there is a greater male demand (circa 80%).

The first and second course of BEng Aerospace Engineering comprise basic subjects from different areas including Mathematics I and Mathematics II, on which we will focus in this paper.

Mathematics I has 120 contact hours (12 ECTS), 75% of them correspond to Theory/Problems (TP) sessions and the remaining 25% to Lab practice (LP) sessions and covers as topics Calculus of one and several variables and Linear Algebra. Mathematics II with 60 contact hours (6 ECTS) is

Supported by Ayuda Proyectos de Innovación Docente, PID-DMA-2014, Applied Mathematics Department (Technical University of Valencia, UPV) 2014; and Projects for Innovation and Educational Improvement PIME B024, Vicerectorate for Studies, Quality and Accreditation (VECA), UPV 2014.

devoted to ODEs, Analytic Solutions of ODEs, Laplace transforms and PDEs. In both of these subjects all students should achieve basic competencies and skills. In these two subjects of Mathematics we use methodologies that encourage our students to an active learning in line of [14]. Now, we describe briefly the methodology used in TP and LP sessions.

TP sessions are standard and at the end of each topic, the instructors propose students a collection of problems to be solved. If the student has some difficulty on how to solve them, he should meet the instructor during office hours. Students have to perform three exams along the academic year related to Calculus topics and one related to Algebra in Mathematics I. In Mathematics II there are also three exams: the first one, DE1, concerning ODEs; the second one, DE2, to Analytic Solutions and Laplace Transforms; and the last one, DE3, to PDEs. In addition, before each exam the student must perform an assignment.

LP methodology used is based in flipped classroom [15]. The process can be divided into 3 stages: pre-class, in-class and post-class:

- Pre-class: Instructors provide a guide in PoliformaT, an educational platform developed by UPV based upon the Sakai project [16], with topics and exercises that student work autonomously prior the Lab session.
- In-class: In the first part students discuss about the difficulties encountered. Next, they are evaluated by solving a set of exercises by means of PoliformaT.
- Post-class: Students can check their answers and scoring through PoliformaT. In addition, instructors will provide the correct answers.

Instructors assist students in all stages of this process. With this methodology, students follow the subject and do not just prepare it for TP exams.

III. GENDER PERFORMANCE

A. Gender performance at mathematics first year

In this section we present the results performed during the academic year 2013/2014. In that academic year Mathematics I got 126 students enrolled with 102 males and 24 females. We will focus in the following aspects of the subject: Weekly Lab sessions, Lab exam, Calculus, Algebra

The ratings presented in this paper have been divided according to the Spanish system. If x denotes the mark in a 0-10 scale, the grade is considered to be Excellent (if $9 \leq x \leq 10$), Very Good (if $7 \leq x < 9$), Good/Pass (if $5 \leq x < 7$), Fail ((if $x < 5$) or Not taken (if the student has dropped this topic).

Fig. 1 represents the grades obtained by male and female students in the weekly Lab sessions. We can observe that female students obtained grades slightly better, most of them with a grade of Excellent or Very Good and without dropouts. A 90% of female students and a 70% of male students obtained Excellent. In general marks obtained in Lab sessions are significantly good, because students are encouraged to prepare

Fig. 1. Lab sessions grades from Mathematics I. Academic course 2013-14.

Fig. 2. Lab exam grades from Mathematics I. Academic course 2013-14.

the lab sessions in advance and they are able to solve doubts asking the instructor or a partner during the in-class evaluation.

The grades concerning LP exams are represented in Fig. 2. The contents covered in these LP exams are Calculus, Algebra with the CAS Mathematica. Males obtained more disperse marks than females. About a 10% of the males have obtained the Excellent grade whereas no girl has attained such grade. However, all the females obtained a mark greater or equal to 5, while approximately a 12% of the males fail to pass.

The grades obtained in the exams involving Calculus topics are gathered in Fig. 3. We observe that the percentage of male and female students obtaining a mark greater than 5 is similar. However, female students obtained better marks than males since 71% of females obtained a score greater or equal to 7, while only 52% of males obtained these values.

Fig. 3. Calculus grades from Mathematics I. Academic course 2013-14.

Fig. 4. Grades from Mathematics I. Academic course 2013-14.

The proportion of males and females not passing the exam is comparable, being the females the ones with a lower rate of about 12%). Also, the percentages of students achieving Excellent grades are significantly similar, with the females having the higher rate (almost 18%).

Fig. 4 represents the grades obtained by male and female students in the Algebra exam. We can observe that male students failed this exam in a significant higher percentage than female students. In general, females obtained better marks in this exam, achieving a bell-shaped distribution with the weight to the left.

It is noteworthy to mention that 3 male students dropped Mathematics I out. None of the females dropped out.

B. Gender performance at mathematics second year

In this section we describe the students' performance at Mathematics II. Fig. 5 shows the grades obtained by students in the weekly Lab sessions. It can be observed that females still performed better, most of them with a grade of Excellent. An 80% of females and a 62% of males obtained Excellent.

Fig. 6 represents the grades of LP exams. ODEs, Analytic Solutions of ODEs, Laplace transforms with the CAS Mathematica are the contents covered in these LP exams. As seen in the figure, males have obtained a more rectangular-shape distribution than females, with a higher rate of Excellent grades (about 9%). It is noteworthy that the males have obtained a similar rate for Fail, Pass and Very Good grades, meanwhile females show a more bell-shaped distribution with more weight on the right side. The most significant difference occurs in the interval from 5 to 7, in which we find almost 60% of females versus the 28% of the males.

Fig. 5. Lab sessions grades from Mathematics II. Academic course 2014-15.

Fig. 6. Lab exam grades from Mathematics II. Academic course 2014-15.

Fig. 7 contains the grades in the first exam covering ordinary differential equations. It can be observed that, despite the fact that 37% of females fail the exam, the marks are still better for female students, except in the number of students obtaining Excellent grades.

Concerning the second exam, which covers Laplace Transforms and its applications and analytical solutions of ordinary differential equations, Fig. 8 shows that fewer students fail the exam, and that there is a significant increase in the Very Good marks for females (from 32% in the first exam to 42% in the second) and Excellent marks for both genders.

Next, Fig. 9 includes the marks attained by the students in the third exam, covering Partial Differential Equations. Here female students reduce the number of Very Good marks, increasing the number of females passing the exam. The number of females not passing the exam keeps decreasing, as opposed to what happens with the males.

Fig. 7. ODE exam (DE1) grades in Maths II. Academic course 2014-15.

Fig. 8. Laplace Transforms and analytical solutions of ODEs (DE2) exam grades in Maths II. Academic course 2014-15.

Fig. 9. PDEs (DE3) exam grades in Maths II. Academic course 2014-15.

Fig. 10. Comparative study of the averages and standard deviations in Mathematics I. Similar results can be obtained from Mathematics II.

IV. SUMMARY

Underrepresentation of STEM female students in Spain is similar to other western countries. The interest of studying this participation lies in the fact that its increase would likely enhance diversity and innovation and having a positive impact on future generations.

We have focused our study on Aerospace Engineering at UPV where around 20% of students are female analyzing their performance compared to male students. In general results are good as Aerospace Engineering students are highly motivated. The only slight variations observed are that, for very a small difference, in a 0-10 scale, female students get better results in the range 7-10, showing a more stable behavior in the middle zone.

When it comes to the average grades, females perform better than males in all cases and with a significantly lower standard deviation (Fig. 10). Dropout rates are rare in both cases, being more common between male students. On the other hand, male students obtained better marks in LP exams which were done by using Mathematica as CAS.

Further analysis with wider perspective might be needed but from this analysis it seems that there is no significant difference between the performance of both groups of students, male and female when we consider the global numbers and the distribution of grades.

CodePlus – Designing an After School Computing Programme for Girls

K. Sullivan, J. R. Byrne, N. Bresnihan, K. O’Sullivan, B. Tangney

Centre for Research in IT in Education

School of Education and School of Computer Science & Statistics, Trinity College Dublin

Dublin, IRELAND

kevin@bridge21.ie

Abstract—Women are underrepresented in the field of Computer Science. This project aims to help Secondary School girls develop an insight into the role computers play in society and to learn some of the key skills in computing including computer programming. Exposure to Computer Science, in home or school environments, and encouragement from family and peers are leading factors that influence girls’ decisions to pursue careers in Computer Science. Other factors include the girls’ perception of their own problem solving ability, an understanding of the diverse applications of Computer Science and related career paths and the potential for positive social impact. This paper describes the design of an after school computing programme, CodePlus, which uses a novel 21st Century learning model. Pre and post questionnaire are being used to explore girls intentions to study CS, their confidence to study CS, perception of CS as a career, gender perception of CS and IT profession and self-efficacy following participation in the CodePlus programme. Preliminary results comparing pre questionnaire results with a male control group highlight differences in how girls see themselves in terms of CS capabilities and their future potential. Initial post questionnaire findings show a significant increase in the participants’ perceived programming ability.

Keywords— *Computing; 21C Learning; Programming; Scratch; Computational thinking; Collaborative learning*

I. INTRODUCTION

Women are traditionally underrepresented in the field of Computer Science. The aim of this project was to help Secondary School girls develop an appreciation of the role computers play in society and to learn some of the key skills in computing with particular emphasis on computer programming. Existing research points to several factors which influence an adolescent girls’ decision to pursue a career in, or to study, Computer Science. Exposure to Computer Science, in home or school environments, and encouragement from family and peers are leading factors. Other factors include the girls perception of their own problem solving ability, an understanding of the diverse applications of Computer Science and related career paths and the potential for positive social impact.

A distinctive feature of the education system in Ireland is the number of girls only secondary schools which offer an interesting context in which to address some of the issues outlined in the previous paragraph.

Bridge21 is a model of 21C teaching & learning developed in Trinity College Dublin which has been used to deliver a variety of curriculum topics including mathematics [1] and computer programming [2].

This study examines CodePlus, a programming club based on the Bridge21 model, which was set up in three female-only schools. In two schools, a self-selecting sample (~70 girls, age 12 to 17) took part in weekly, two hour workshops. In the third school, one class (~17 girls, age 15-16), took part in a 4 day programme during school time. The Bridge21 learning model was used throughout the workshops and there was a two to one ratio of students to computers. Students worked together on activities including computational thinking, computers in society and programming using Scratch. Pre and post questionnaires were designed to measure the students’ prior exposure to Computer Science and their attitudes to Computer Science in terms of future study and career choices.

The findings will explore the students’ attitudes towards Computer Science via a pre - post workshop questionnaire instrument, and their technical competence based on the work they completed during the workshop and their self-reporting via the questionnaires. This research helps informs whether the Bridge21 approach to Computer Science can both encourage Computer Science career aspirations and develop comprehension of basic programming concepts.

II. LITERATURE

A. Girls in CS: Problems and Solutions

The under-representation of women in computer science is well-documented. Much work has been done both in an attempt to uncover the reasons for this lack of participation and to look for strategies to rectify the situation but, despite this, the discrepancy between the numbers of women and men studying and working in computing continues to exist. In 2012 the US women received just 18% of Computer and Information Sciences undergraduate degrees down from 37% in 1984 [3]. In Ireland only 15 per cent of new-entry students into 3rd level Computer Science courses in 2013 were female [4].

Research suggests a range of explanatory factors that contribute to this inequality. Ceci et al. [5] looked at both possible biological as well as social factors in their review of over 400 articles exploring the causes of women’s

underrepresentation in STEM fields. They found that the research on gender differences in brain structure and hormones is inconclusive. The evidence instead points to sociocultural factors, particularly the power of culturally prescribed gender roles, to explain the gender gap. Spertus [6] suggests that these "factors include the different ways in which boys and girls are raised, the stereotypes of female engineers, subtle biases that females face, problems resulting from working in predominantly male environments, and sexual biases in language."

These sociocultural factors seem to have a particularly strong negative impact on women's self-confidence. Numerous studies have found that women have lower levels of self-efficacy than boys when it comes to stereotypical male dominated subjects such as mathematics, engineering and computers [7, 8], and that it is this lack of self-confidence, not ability, that is the most significant difference between male and female science students [9].

Whatever the causes, and clearly they are manifold and complex, one common finding is that girls are just not that interested in pursuing a career in computing. This manifests itself at a young age and increases through 2nd and 3rd level education with the result that, from early adolescence, girls express less interest in STEM careers than boys do [10, 11]. Consequently it is crucial to introduce computer science to girls before the negative stereotypes have set in [12].

If multiple factors contribute to the underrepresentation of women and girls in STEM, multiple solutions are needed to correct the imbalance. Notable successful interventions include that of Carnegie Mellon University where they increased the percentage of female students enrolled in Computer Science from 7% to 42% between 1995 and 2000 [9]. Factors behind this success included widening the admissions policy and making the culture of the department more female-friendly by implementing policies designed to change stereotypical attitudes and behaviours. These included the addition of greater social context to entry-level computer science courses in response to women being more likely than men to prefer work with a clear social purpose [13-16].

Such work done in the areas of recruitment and retention at 3rd level has clearly shown that attempts to remedy the imbalance can be effective. However, the research clearly points to the importance of earlier interventions. A lot of work in this area has tended to focus on providing early exposure in a more welcoming environment for girls. The establishment of all-girl coding clubs (Girls Who Code, Black Girls Code, CoderDojoGirls) and attempts to provide positive female computer science role-models (e.g. Google's madewithcode.com mentors) fall into this category. Others have tried to making computing less abstract by integrating it into activities and communities that girls and women are already engaged in, such as storytelling [17] or e-textiles [18]. There has been less work done into the effect of pedagogy or *how* we teach computer science as opposed to *who* we teach or *what* we teach. However, research into how pair programming can help female computer science students shows the potential

of collaborative learning to break down the negative stereotype of the solitary nature of computer science [19].

B. 21st Century Learning

Both industry leaders and policy-makers concur that the social and economic trends of the 21st century, promoted by advances in information and communications technology (ICT), have altered the global economy and work practices, from one of material goods and services, to one of information and knowledge [20-22]. These changes require the 21st century workforce to have a higher level of learning capacities and cognitive skills [23]. Despite these shifts in required skills, many argue that the education systems have been slow to adapt to this changing environment and still promote information transfer over the skills development. They also suggest that, pedagogy, curricula, school organisation and assessment remain largely the same as they were in the industrial era of the 20th century [21, 24].

Contemporary pedagogical approaches suggest moving away from developing the simple ability to reproduce received information in subject-specific classes towards learning that focuses more on meta-cognitive skills, problem-solving and the development of the whole person [25]. Rather viewing learners as 'Knowers' who absorb and reproduce received information the aim is to develop 'Learners' with positive transferable learning dispositions [20]. In order to move from the old 20th century industrial paradigm to the new, 21st century information society and economy, requires fresh pedagogical approaches. Voogt and Pelgrum [24] suggest a view that learning should be activities determined by the learners themselves working in small groups, rather than prescribed in a didactic fashion by the teacher during whole class instruction. In order to develop creativity, we need to move away from situations where students apply known solutions to known problems and promote a more productive learning, where students are encouraged to develop new solutions to new problems [24].

III. BRIDGE21

A. The Bridge21 Model of 21st Century Learning

Bridge21 is a practical, pedagogical model of 21st century teaching and learning, that focuses on team-based, project orientated and technology-mediated activities [26]. The essential elements of the Bridge21 learning model are: (1) project based activities, (2) technology-mediated learning, (3) structured team-based pedagogy, (4) recognition of the social context of learning and (5) facilitation, guiding and mentoring, with teachers orchestrating these activities [27].

The Bridge21 Activity Model outlines how Bridge21 activities are designed and consists of seven consecutive steps which form the basis of each lesson. Sessions typically start with an optional (1) 'set up phase' in which introductions are made and teams are formed. This is followed by a (2) 'warm up' activity designed to encourage divergent thinking and get the teams thinking creatively and working together. Next is the (3) 'investigation' stage which promotes convergent thinking and sets the context of the workshop. Teams define a problem and research the context in preparation for planning and

creating some digital artefact. The (4) 'planning phase' has teams discuss and assign tasks and roles and agree a schedule for the delivery of work to be completed. The creation phase is a cyclical process in which teams (5) 'implement' and iterate on their design. Finally teams are invited to (6) 'present' their work to their peers and share what they have learned. A final (7) 'reflection' phase is used to consolidate the learning.

B. Bridge21 CodePlus Programme

The Bridge21 CodePlus workshops were designed to explore a number of issues. These include early exposure to programming; delivery in the distinctive environment of girl only secondary schools and focus on a structured 21C pedagogy. Four instances of the programme were run, following one of two formats. With 3 groups, the programme involved weekly two-hour sessions over a 10 week period. This was a voluntary after-school programme with students aged between 12 and 17 years of age. For the fourth group, the programme took place over a 4 day block, during school time. All students in the class were required to participate. In both cases, the students spent up to 20 hours working on, and learning from, various computing projects.

The programme was based on a set of existing tried and tested CS activities [2] which was extended in a number of ways in light of the literature on girls and programming discussed above. The CodePlus programme covered three broad areas.

1) Computers in Society

In the early sessions, the students, working in teams of four, looked at how they use technology in their daily lives and did online research about how technology is currently used in areas such as medicine, fashion, education and entertainment. They also came up with ideas for new pieces of technology that could solve problems in the same areas. The aim here was to help the students understand the influence technology has on our lives and to see the broad range of potential career paths that computing might involve.

2) Computational Thinking

Throughout the sessions, the students worked on several small problems designed to introduce them to procedural thinking or "thinking like a computer". These included online games such as Blockly, pen and paper activities including several from CS-Unplugged [28] and other games and activities where the students must write instructions or algorithms which their peers will follow to achieve different tasks, such as, walk to a particular location in the building or to draw some simple pictures. These activities often served as warm-up activities at the start of the sessions.

3) Computer Programming

The students used the Scratch programming language to create their first computer programmes. Working in pairs, they created simple animations and then moved on to creating interactive computer games. Through this process, they were introduced to concepts such as initialisation, looping, variables, conditional statements, events and concurrency. Some of the students also used Kinect2Scratch and AppInventor to create more advanced games and simple smart-phone apps. The

students presented their work to their peers at several points during the workshops.

IV. RESEARCH METHODOLOGY

A. Participants

The pre survey was conducted in the first Bridge21 CodePlus workshop with each group. A group of comparison mixed-gender control participants were recruited from a transition year program run in the Bridge21 learning centre. (a programme known as CS-TY) [2] The total sample was 164 students, 110 girls, aged 12 – 17 years old ($M = 15.23$, $SD = 1.18$) 70 on the CodePlus programme, 40 on the CS-TY, and 54 boys from the CS-TY programmes aged 12-17 years old ($M = 15.25$, $SD = 1.54$). At the time of publication the post survey was still on-going, the analysis of pre and post results was undertaken on the smaller sample which had completed both pre and post surveys. This was 38 girls on the CodePlus programme.

B. Instrument

The questionnaire consisted of 6 groups of questions.

1. **Demographic.** Consisted of biographical information, including age, school grades and general access to technology.

2. **Studying CS.** This section examined students understanding of, and confidence and motivation to study CS at third level. It asked students how likely it is that they will attend university to study CS, answers were a 5-point scale (very likely to very unlikely) and how confident that they would be to study CS in university, on a 5-point scale (very confident to not confident at all). They were asked to identify which university subjects they were considering through a closed ended question with 3 responses (yes, no and not sure at this time).

3. **Perceptions of CS & IT.** Questions that explored students' perceptions of CS and the IT profession were adapted from work by Papastergiou [29]. These presented 10 specific areas of CS¹ to the students and asked them to rate on a 5-point scale (1: not at all, 5: to a very large degree) the extent to which they believed that CS involved the specific area. It also asked them to rate on the same 5-point scale the extent to which they believed that the IT profession involved each of 8 aspects².

¹ 'computer architecture', 'human-computer interaction', 'study of algorithms and information', 'use of algorithms and information for everyday life problem resolution', 'telecommunications systems design', 'artificial intelligence', 'business computing', 'development of applications for social benefit', 'computer programming', 'computer systems security'

² 'is creative', 'is competitive', 'is interesting', 'is difficult', 'is well-paid', 'is prestigious', 'offers one the opportunity to engage in a variety of fields', 'demands that one engages in computer programming'

4. **Self-efficacy with CS.** This is a modified version of Papastergiou's self-efficacy scale. Participants were asked to state their level of agreement on a 5-point scale (from "strongly disagree" to "strongly agree") with the 10 statements.

5. **Mathematics.** Students were asked about their current or expected performance in mathematics³ in the Junior Certificate (the state examination taken at the end of the junior cycle of secondary education, age ~15) and about their intentions and ambitions with regard to taking mathematics the Leaving Certificate (the state examination at the end of secondary education, age ~18).

6. **Gender perceptions.** Students were asked to express their perceptions regarding the suitability of CS and the IT profession for men and women, through indicating their level of agreement with statements on a 5-point (strongly disagree to strongly agree).

V. FINDINGS

A. Pre Questionnaires

Analysis of baseline gender comparisons revealed some interesting trends in terms of girl/boy differences in demographics, self-efficacy and likelihood of and confidence to study CS at university. The most pertinent results were as follows. Independent sample t-tests revealed

- No gender difference in expected and actual math grades for both junior and leaving certificate.
- Boys played computer games for significantly more time than girls (on average 1-5 hours per week) $t(159) = 5.59, p < .001$
- Girls spend more time using computers for homework purposes ($t(159) = -3.207, p = .002$), while boys spend more time using computers for general information seeking not related to school ($t(159) = 2.206, p = .044$)
- Interestingly, boys demonstrated significantly higher levels of self-efficacy with CS than girls, $t(159) = 2.85, p = .005$
- Boys were also more likely to study CS at university than girls ($t(159) = 2.53, p = .012$) and they were more confident to get accepted into a CS degree ($t(159) = 2.83, p = .005$)

Baseline comparisons demonstrate clear differences in how girls see themselves in terms of capability with CS and future potential.

B. Post Questionnaires

1) Computer Programming

A paired-sample t-test was conducted to examine changes to the CodePlus student's perceived ability to program a computer following participation in the CodePlus programme. This revealed a significant increase; $t(34) = 2.03, p = .049$, whereby the students perceived their ability to have improved

from time 1 ($M = 2.6, SD = 1.1$) to time 2 ($M = 3.0, SD = 1.2$). See figure 1

Figure 1: Demonstrates an increase in student's perceived ability to program computers following participation in CodePlus

A paired sample t-test also revealed significant increase in computer self-efficacy from time 1 ($M = 2.8, SD = .32$) to time 2 ($M = 3.4, SD = .20$); $t(37) = -9.8, p = .001$.

2) Studying Computer Science

There was no effect on student's perceived likelihood to study computer science or their confidence to study computer science following participation in the programme. This may be due to the fact that it was a self-selecting group with an existing interest in computer science.

However, students were more informed about career options. Paired sample t-tests revealed they were more aware from time 1 ($M = 1.38, SD = .54$) to time 2 ($M = 1.63, SD = .59$) that a CS career involved learning programming language from; $t(35) = -2.65, p = .012$, and that from time 1 ($M = 1.52, SD = .60$) to time 2 ($M = 1.88, SD = .94$) a CS career involves team work; $t(35) = -2.25, p = .030$

There was also a change in how they perceived a CS degree following participation. They were less likely to agree at time 2 ($M = 1.88, SD = 1.07$) than time 1 ($M = 2.22, SD = 1.30$) that Computer Science was a degree for geeks; $t(34) = 2.24, p = .032$

These findings represent positive outcomes which address some of the key factors which affect girls' decisions to pursue careers in CS. Further research will be undertaken as the CodePlus programme continues.

ACKNOWLEDGMENT

The authors would like to thank all the students and teachers involved in this research who generously gave their consent to include written contributions which appear in this paper. The authors would like to thank all the staff at Bridge21, Trinity College Dublin, and Centre for Research into IT in Education (CRITE) for their continued support and guidance, and to ICS Skills, for funding this initiative.

³ Mathematical ability as this is a fundamental for entry to engineering and computer science degrees in many third-level institutions in Ireland and the U.K.

Insights from a First-Year Learning Community to Achieve Gender Balance

William Oakes^{1,2}, Ming-Chien Hsu² and Carla Zoltowski¹

¹EPICS Program, ²Engineering Education
Purdue University
West Lafayette, IN, USA

Abstract—Engineering remains challenged with regard to underrepresentation by gender and ethnicity. Lack of gender parity in engineering has been a problem since the very start of engineering but conversations about and efforts to address the lack of women in engineering has grown in momentum over the past 30 years. The problem is not only that gender disparity exists, but also an inability to make significant progress in closing the gap over time on a national level. This lack of change suggests that new approaches to understanding the complex problem of underrepresentation of women are needed. Research has advanced our understanding of what can attract women to engineering and retain them within the field. This paper presents data from a service-learning program that aligns pedagogically with the literature on gender and diversity more broadly. Specifically a first-year learning community of 120 students that was 54% female is examined to provide the student perspective. 77% percent of the women cited gaining experience in engineering as a motivation for selecting the learning community. 55% of the women cited the opportunity to impact others with 42% combining the two. Sample comments and quotes from the male and female students are presented and discussed.

Keywords—Service-learning, first-year, diversity, gender

I. INTRODUCTION

For more than two decades, engineering has sought to address the issues of underrepresentation of women and students of color within engineering. This past year ASEE made diversity an area of emphasis with its “Year of Action on Diversity”. There has been a great deal of research on the issues of diversity and underrepresentation in engineering science and computing[1-8]. One of the leaders in the area of women in science and engineering is Dr. Sue Rosser who was the distinguished ERM lecturer at the 2002 ASEE Annual Conference. After her lecture, ERM hosted a follow-on session with Dr. Rosser where she was asked about service-learning as it aligns with her work and the other literature on gender in science, engineering and computing. She said that service-learning embodied the characteristics of a gender-friendly curriculum. She discussed this alignment in her address at the National Academy of Engineering at a Symposium on Engineering and Computing Service-Learning in 2004. Dr. Elaine Seymour, another distinguished researcher in this area, visited the campus of Purdue University in 2013 and shared similar views on the pedagogy of service-learning as it aligns with her research and that of others.

Research on service-learning approaches, also called Learning to Serve (LTS) has shown benefits including improved retention [9,10] and increase in attracting and retaining a greater diversity of students in engineering [4,11,12]. EWB-USA currently has more than 12,400 members, of which more than 7,000 are students and forty percent (40%) are female.

The EPICS Program founded at Purdue University (www.purdue.edu/epics) is an example of an engineering and computing-centered service-learning approach. In EPICS, teams of undergraduates earn academic credit by partnering with local or global not-for-profit community organizations to define, design, build, test, deploy, and support engineering-centered projects that significantly improve their ability to serve the community[13]. With its focus on engineering and computing in a context of addressing human and community needs, EPICS has proven to be a very effective vehicle for encouraging women and under-represented groups in engineering. EPICS has grown at Purdue to over 400 students each semester. In the spring of 2014, 29.9% of the participants were female, while 46.7% of the participants were non-Caucasian. Over a 20 semester period, female participation from Electrical and Computer Engineering in EPICS was on average 77% higher than the overall school enrollment [4].

In the fall of 2014, 120 first-year students participated in EPICS through the EPICS Learning Community. This cohort was 54% female compared to the overall college enrollment of 23% female for that year. This class offers an opportunity to examine why such a high percentage of women chose the EPICS Learning Community option and potentially explore the findings for applications to other programs across engineering and computing.

II. EPICS PROGRAM

EPICS is an engineering and computing-centered, multidisciplinary, service-learning design program where students earn academic credit for partnering with not-for-profit organizations to develop and deliver designs to meet community needs. The program began at Purdue University in 1995 with 40 students and has substantially grown since its inception. In 2014-15, over 800 students were engaged in over 90 projects distributed across 33 sections. The program is explicitly multidisciplinary with over 70 majors participating, and it encompasses students from their first-year to senior year. The curricular structure is designed to allow students to participate over multiple semesters and supports long-term,

reciprocal community partnerships. The long-term student participation allows projects to be developed over multiple semesters or years and allows projects to address complex and compelling needs. The project timelines are completely decoupled from the semester schedule allowing projects to span multiple semesters or even years allowing projects of significant scope to be developed. Once a project is delivered, a new project is then identified by students under the guidance of their faculty mentor(s) and community partner(s). The students and teams are mentored by advisors (faculty, professional staff and local industry). EPICS teams, or course sections, consist of 8-24 students and are student led with a faculty or industry mentor (called an advisor), and a graduate teaching assistant (TA). Each team comprises multiple sub-teams, each one of which supports a single design project.

EPICS has been recognized for its curricular innovation by the NAE with the Bernard M. Gordon Prize for Innovation in Engineering and Technology Education (2004), as an NSF exemplar of programs "Infusing Real World Experiences into Engineering Education (2012), by NSF's Corporate Foundation Alliance as an Exemplar Program (2002), by the Chester Carlson Award for Innovation in Engineering Education (ASEE) (1997 and 2012), and as a signature program by the IEEE Foundation (2013).

III. LEARNING COMMUNITY STRUCTURE AND OVERVIEW

The EPICS courses can be used to count as an alternative for many different courses within the engineering curricula and vary by discipline. It is most commonly used as a technical elective. Seniors can count their EPICS courses as capstone with departmental approval in Electrical, Computer, Environmental and Ecological and Multidisciplinary Engineering. EPICS can also fulfill university requirements as part of the University's core curriculum as a Science, Technology and Society requirement as well as part of the Entrepreneurship certificate.

Purdue University has a common first-year engineering program. Students enter the First-Year Engineering Program and complete a common set of courses that includes two required engineering courses before being admitted to their engineering major. The EPICS courses were approved as an alternate path through the first year as part of the university's learning community initiative.

Assessment data from earlier inclusion of first-year students showed that students who were involved in EPICS early in their academic careers reported an increase motivation to remain in engineering. The challenge of engaging students as early as their first year is that students can become intimidated on a team with older students. While the experience can be very positive, when students are adjusting to college life and course loads, the additional variable of an experiential learning environment can be foreign and sometimes overwhelming. In addition, while the vertical integration allows mentoring of younger students, older students do not always embrace the mentoring roles. The results have been bimodal with first-year students in the program having either very positive or negative experiences. To increase the number of first-year students and to insure a

more consistently positive experience, scaffolding and support are needed through their experience.

The learning community structure provides this kind of support and offers the opportunity to impact the recruitment and retention of students from groups traditionally underrepresented in engineering and computing [14]. The EPICS Learning Community structure includes placement into three linked courses. Students were all placed into one introduction to engineering course (ENGR 133) that covered required material including MATLAB computing and an introduction to the engineering majors required of all first-year engineering students. This course brought the entire cohort together for common instruction, community building and peer support.

The second course was the EPICS courses. Students were placed into EPICS teams along with sophomores, juniors and seniors. EPICS students learn design, which is also a required topic for all first-year engineering students. EPICS project teams are typically 4-5 students and the individual divisions are 8-24 students. The small class sizes provided opportunities for mentoring by the faculty or industry advisors and upper division students.

The third course was either an introduction to composition (English) or speech (Communication) in sizes of 20 or 28 respectively. These courses provided another smaller community with only first-year students from the learning community.

Students were given the option to live on the same floor with others in the learning community. Approximately 70% chose to live on the floors. The female floors are the same floors where a residential women in engineering program is housed so that female students did not have to choose between the EPICS Learning Community and the Women In Engineering residential experience. They could participate in both.

Learning community applications and placements are made through a central university office. A holistic placement process is used to place students into the learning communities. The process takes many factors into account to provide as equitable placement as possible. In the first two years of the EPICS Learning Community over 300 students applied for the 120 seats. In both early years, the percent of women was about 30%. The learning community office seeks to have similar demographic profiles across all of the learning communities. For the class entering Purdue in the fall of 2014, a high percentage of the female applicants only selected the EPICS Learning Community as a curricular option. As a result, the central office could not distribute them to a second or third choice as they has in the earlier years. The results was a class that was 54% female (65/120). Of those enrolled, 95% had selected EPICS as their only curricular learning community option. The following sections summarize the results of assessment data from this cohort. The data includes a survey distributed through Qualtrix that probed student motivation for electing to the in the learning community and their expectations, an end of semester survey asking students to reflect on their experience and the end of semester reflections that were assigned across the EPICS course. The beginning of

the semester data included a question on gender but the end of semester data did not include gender. The final reflections were an assignment with names included and could therefore be identified by gender for analysis.

IV. ASSESSMENT RESULTS

At the beginning of the semester, students were asked why they selected the EPICS Learning Community. Figure 1 shows the responses by gender. The open ended responses were analyzed by gender and five codes emerged. They were “Experience (in engineering, hands-on, design), “Community” (making a difference, community engagement, etc.); a blended category “Experience and Community” when they described making a difference while gaining engineering experience; “Learning Community” when they described the benefits of the learning community; and “Particular Learning Community (LC)” when they described wanting EPICS to specifically avoid the traditional first-year sequence. The last code was only explicitly present in the male responses although three women alluded to avoiding the traditional courses as part of their answer but added additional information that aligned with another code.

The results show that the majority of both male and female students were seeking experience in engineering. The women described the connection to the community or helping others while they gained that experience at a higher rate. 77% of the female students cited gaining engineering experience either by itself or connected to the community.

Fig. 1. Why students Chose the EPICS Learning Community

Among the comments for the female students who cited experience as the primary reason for choosing EPICS were the following:

I wanted real world engineering experience and to learn by solving real world problems.

I wanted to work on a project that I was interested in involving characteristics of the discipline of engineering I'd like to study along with wanting hands-on experience, to work with a project partner, work with others, and take on roles for success as a team.

1. Real world experience: unlike most other alternatives for EPICS, I will be able to execute the entire design process; 2. Team work: While working to meet the stakeholder's requirements and needs, I will gain the experience of working in a team with people with different ideas and viewpoints.

These data consistent with prior research on women participating in EPICS [15] where women reported enrolling in EPICS to seek engineering experience. In that study, the women described EPICS as working with the community, implying that this was also a factor. For the Learning Community students, the community and helping others clearly played a role. A majority of the female students (55%) mentioned the community or helping others as part of their reason for enrolling. 42% combined gaining experience and impacting the community, world or the environment. Sample comments of this combination included:

I want to be an engineer so that I can use what I learn to give back to my community and EPICS allows me to start with that before I even get a degree

Community service was an important part of my life in high school, and EPICS was the perfect way to help continue that while learning Engineering skills at the same time

I chose to enroll in the EPICS learning community because I can actually experience and learn how engineers work in real problem-solving situation and also participate in a community work at the same time.

I thought it would be fun to design and build devices for community use, and it will be good experience for when I need to find a job or internship.

Real world experience-getting the chance to create something that could be potentially beneficial to at least one person or a community. Team practice-having the ability to function on a team and learning to cope with any problem that can pop up.

Comments that cited just the opportunity to impact the community as a reason included:

I enrolled in EPICS because I love volunteering to help the community!

I really love the idea of helping out others, and the ability to combine my passion and future career with service is such an incredible opportunity. I also love being connected with people with similar passions and ambitions as me.

During a visit to Purdue for a Women in Engineering event I heard about an EPICS project that worked with Riley Hospital for Children, which is a very important organization to me as I have been a patient there almost my entire life. I wanted to be a part of a program that helped many organizations improving lives like Riley's patients'.

most importantly I wanted a chance to make a difference.

The male students responded more heavily to gaining experience with a rate nearly 40%. It is interesting to note that a similar percentage cited the community involvement as a motivation for selecting the EPICS Learning Community by itself or in combination with the experience. The distributions by gender are similar for the males and females.

As part of the same survey, students were asked “what they hoped to do with their engineering degree?” The female responses were coded and 40% responded that they wanted to help others or make the world or environment a better place. Example quotes include:

I hope to not only make a difference in this world by helping in technological advancements but I also want to inspire others especially women that anything is possible and attainable as long as one works hard.

I hope to make a difference in the world. I want to be able to do something in my life as an engineer that will impact someone else's life for the better

Create things, and make things which will be able to help people.

41% stated that they hoped to obtain a job, either in general or in a specific field such as aerospace, medicine and companies such as Disney.

Summative evaluations were collected at the end of the semester but they did not include gender identifiers. However, the data on the student experience was overwhelmingly positive with all students agreeing or strongly agreeing to recommend the EPICS Learning Community to other students as shown in Figure 2. This is consistent with the earlier two years. In those three years of data, three students have been neutral but none have disagreed with the statement, male or female.

Fig. 2. Responses to “I would recommend the EPICS Learning Community to other students”

The summative evaluations also asked what impact their participation had on their motivation to pursue engineering. One student reported a decrease in motivation. 70% indicated a positive impact on their motivation as seen in Figure 3.

Fig. 3. Responses to “What impact did the EPICS Learning Community have on your interst in Engineering?”

Students were asked if the EPICS Learning Community met their expectations? Figure 4 shows the strong positive response. Students we asked to explain why and their answers were coded positive, negative and neutral. About a fifth of the students used terms that explicitly stated that the experience exceeded their expectations and the “exceeded” code as added as shown below.

Figure 4. Did the EPICS Learning Community Meet Your Expectations?

Positive comments that were coded as “Yes” included

The EPICS learning community met my expectations. It helped me to learn about a specific concept within engineering. It was also helpful for me to learn more about the ethics of working as an engineering team, a concept that can only be learned from being in a team environment.

Yes because I expected to be working on a real world project and learning the process of engineering and EPICS fulfilled my expectations and more.

The EPICS learning community met my expectations and more. When I joined this learning community, I did not know exactly what to expect. I knew I would be living with girls who were also in engineering, and that we could do our homework together, but I had no clue how much fun I would have.

I expected a more diverse group of people and I am very happy with how the learning community worked out. Most of my friends are from the learning community and it had greatly helped me academically. One of the best things that had helped me in college was being able to ask for help from the people on my floor. I am very pleased with how EPICS turned out and I have made my best friends through the learning community.

Comments that were coded as “Exceeded” included:

Yes it did, in fact it exceeded them. I wasn't expecting everything to be so professional, but it was, and I am glad I am a part of EPICS.

It was completely different than what I expected. It was far more involved, and taught me much more than I expected. I didn't think I would be doing much real engineering, and EPICS provided an opportunity to try what I would actually do in our field.

The EPICS Learning Community has exceeded my expectations. I learned a lot in both the classroom and the lab. In the classroom, I learned a lot about Excel and Matlab. I also gained a better understanding of what EPICS is through the group project. In the lab, I was able to become a more vocal teammate, who is able to express his opinions and ideas. I was also able to look at problems from different points of view because of the influence that my teammates have had on me.

Comments that were coded as “Neutral” included

I didn't really know what to expect from the LC, just some vague idea that it would be something like Key Club from high school. However, I found that the learning community was much more than that. It actually allows us to use our engineering for real-life problems and create a solution.

I had no expectations for the EPICS learning community when I applied to be a part of it. I didn't really know what I was signing up for, just that the projects in the community seemed like a good program.

Open ended comments were solicited in the summative evaluations. While the data was collected without gender identifiers, there were comments where the gender could be deduced. These comments were almost exclusively from

female students who commented on the environment being mostly female. These included:

The EPICS learning community met my expectations and more. When I joined this learning community, I did not know exactly what to expect. I knew I would be living with girls who were also in engineering, and that we could do our homework together, but I had no clue how much fun I would have.

As a girl the diversity has caused me to not really see the gender gap so this has definitely made me more comfortable in my studies this first semester. I think this will cause me to be more surprised regarding the gender gap in the future.

I was always told it was a rarity to be a girl in engineering. EPICS isn't like this. Everyone is either a different culture or gender and no one judges each other based on their background.

As a girl, I really liked it. I was surrounded by other girls, something that I wasn't expecting in engineering. I think that I would have done well in a less diverse class too, but I did appreciate how diverse ENGR133 was.

Being a girl in engineering, I felt normal and equal to any and everyone else. I can't necessarily attest to another engineering setting though because I didn't have that experience. Because I felt equal, I had no problem sharing my ideas and putting myself out there.

This impacted me because I got to work with a lot of different types of people and it was especially different because I went to an all-girls school before so I had never had to work with boys on school projects. I think this is a lot different from my high school because it seems like boys and girls have a different type of work ethic.

I have developed a friend and peer group that is so crazy and different but I wouldn't have it any other way. I have really enjoyed having the opportunity to get to know a smaller group really well rather than being just a number among many, many students. I also really enjoy having some a large group of girls in engineering because I feel like the ratio would be much different in the other group. I feel like I understand more points of view than others do. I have had a more rewarding first-year so far because of all the diversity in ENGR 133.

I think I benefited from it because I know that engineering is usually mostly males, but our class was actually more females, and we had people from several other countries. It all added up to an interesting dynamic between the groups because everyone had a different viewpoint and I think it promoted learning. I definitely thought I learned very well and worked with others a lot in this class.

EPICS allows me to meet many new people, and as a women in engineering, I am, for once, in a class that has a greater amount of females than males.

One of the evaluation comments could be identified as coming from a male student who said *“Working with women in my engineering group was a good experience. We had a slightly different perspective on our projects, and they changed the dynamics of how and when work was done, as they motivated us away from procrastination.”*

End of Semester Reflections

All students in EPICS write regular reflections. At the end of the semester, they write a summative reflection where they are given a list of question prompts to choose from. The reflections were examined from the female learning community students and two themes emerged when commenting about their experience. The first was

All students in EPICS write regular reflections during each semester as part of the coursework. At the end of the semester, they write a longer summative reflection where they choose from a list of question prompts. The final reflections were examined for the female learning community students who wrote about their overall experience. Two major themes emerged. The first was about gaining experience. Clearly the student valued the engineering experience they gained. Example comments from these reflections included the following.

EPICS has taught me how much I value the hands on side of working. Writing papers and doing homework while sitting at a desk is not something that I could do as a job (or for the rest of my school career). It is neat to me to be able to do things for myself – solving problems and making things better. I like getting to see how things work first-hand, and, being able to design and build it myself, adds to how fun it is. I definitely have a strength for design. I can visualize things in my head well and love trying to communicate ideas to other team member. Specifically, designing what the solar rig would look like was really neat. We got to draw out and explain concepts for designs on the white board in the lab, and I found that debating which idea would work the best was really fun.

I have learned how to work in ethnically diverse teams as that was not an experience I have had before. It wasn't difficult as it was simply interesting. Other than a language barrier, different viewpoints are brought up because everyone develops different understandings of the situation and different ideas for how a problem could and should be solved. This sort of thinking is important because not all problems only have one answer. It is critical that students are taught to think outside of the box and cover all aspects of a problem. I have learned that problems with multiple issues that need to be addressed are most interesting to me. This mirrors real-world engineering as not everything can be solved all the time, and sometimes the best solution is the simplest one that will leave things out while other times all of the needs absolutely have to be met. I can definitely use

this sort of problem solving in future engineering endeavors.

A second theme emerged where the women talked about learning about themselves and gaining confidence. These included comments that discussed learning to take more initiative and having the confidence to speak up in design groups now and in the future in internships and eventually in permanent jobs. They described examples of where their experience nurtured their ability and their success gave them confidence that they will carry forward into their career. Comments included the following:

From participating in EPICS, I've not only developed many useful lifelong skills that I'll incorporate in the workforce but I also got to learn more about who I am. From all the workload, big projects, and responsibilities, and EPICS deadlines thrown at me this semester, it was crucial for me to get adjusted to this new college life, and there was no other better way to learn more about myself. From struggling and trying new things until getting to the point of my satisfaction taught that I am more persistent and diligent than I already know. I think that is my main strength that puts me far apart from others professionally. Once I set the goal, I'll do or give up anything to achieve that goal.

Taking part of the Camp Riley team and EPICS as a whole has taught me a lot, especially about my individual self. It also helped me decide in a clearer light who I want to be and what I need to change and keep the same to become that person. During this semester I learned a lot about my strengths and weaknesses that I was not aware of before. I learned that I may not know a lot about details about a certain topic, like this semester drainage solutions, but if I try to my fullest potential to understand the situation as a whole that I can contribute a lot to my group.

Being in EPICS, I was taught many things about myself, and who I was becoming as an engineer. I found my strengths, weaknesses, and how to work with others by being in EPICS. By working in teams, I was shown how to work with a group: the pros, the cons, and the in between. I found that working with groups builds self-awareness of what is going on, and teaches you how to do things when it turns out to not go along as planned. Working in groups allows for different input, and in turn a better product to come out of all the hard work. As for myself, I learned that I work best when working together with others. I originally was always a person who enjoyed working independently; however, when we started the project for the West Lafayette Jr./Sr. High School, I realized how much more difficult everything would be if working alone. Teamwork showed me a new sense of leadership, which I had never had before, and working with others also brought out a more outspoken side of me. When working with others I noticed I wasn't afraid to put in my two senses and speak up about ideas that could improve our project.

Through this experience in the beginning of the semester, I realized one of my greatest weaknesses is speaking up. In the beginning of any teaming situation, I tend to remain quiet as I become comfortable with the new team. This is an area I can continue to work on improving in, especially as I look ahead to professional careers. As in EPICS, I will partake in various (design) groups in future jobs. In these teaming situations, in order to be an active participant, I need to be able to voice my ideas and opinions. Otherwise, I may appear as an incompetent co-worker.

Based on the work I accomplished this semester, I determined one of my greatest strengths is helping people to divide up work so it's accomplished in a timely manner. For example, when our team was trying to decide what type of garden plots to implement (community, individual, guerilla), I had the idea to compile all of our research into a shared Google document. Also, when creating the final design of our garden, I recommended we each come to the final design meeting with a general sketch of our ideas. This way, our team could figure how to best incorporate the different aspects of our designs and the survey feedback into the final design. I know in my professional career I will want to remain well organized since it is a valuable skill to employers, and it will help me to be successful in my job.

This semester I learned not to make assumptions about team members' skill levels and let your assumptions about their skill level affect your confidence in your ideas. At the beginning of the semester I felt like I took a little bit of a step back from fighting for some of my ideas for the project because I felt like, as a freshman, I didn't really have the technical knowledge to form fully comprehensive ideas. However, this didn't prove to be the case, and some of my team members made comments about it in my peer evaluations. They encouraged me to fight for my ideas and the direction that I wanted to see the project go, rather than worry about not having as much experience. In reality, no one on the team really had experience with our specific project and specifications, so anyone's input, no matter their background, was equally valid. It's important in any team, especially when brainstorming, to be as open as possible when it comes to coming up with ideas. Everyone should provide input, no matter their perceived knowledge, to try and generate as many ideas as possible. If proper brainstorming is done using strategies like 'piling on', etc, then the range of ideas will be greater and a better solution to a problem may be reached. It is important for freshman, or really anyone working with other people they are not familiar with, to never undervalue their perspective. What I learned this semester is something that I will carry with me into my first internship this summer. Even though I may be working with professionals in their field, it is still very important that I speak up and voice my ideas. Even though they may have more experience or knowledge than me, I

still have a different perspective unique to myself that could introduce something that they've never thought of.

V. DISCUSSION

Decades of research on underrepresentation and gender point to the need to link engineering and computing with people, communities and/or the environment as a relevant context. Humanizing the image of engineering is one of the characteristics of the National Academy of Engineering's report on *Changing the Conversation* [16]. The pedagogy of service-learning aligns with these goals and the EPICS Learning Community was evidence of the impact. A majority female first-year engineering course is unprecedented in the core first-year engineering program at Purdue. The high percentage of women in the EPICS Learning Community was a result in the high demand among women and their choice of only one learning community. The attraction of a higher percentage of women is consistent with the history of EPICS [4] but the 2014 class was significantly higher. It is not clear why a sudden increase occurred. One possible reason is that the EPICS Learning Community operated under temporary experimental course numbers in prior years with 2014 being the first year with permanent course numbers. This may have made it more visible or to feel safer for students to select. Another possibility is that in its third year, former participants in the program have been integrated into the student recruitment volunteer pool and have become advocates for the learning community. Many students reported hearing about the EPICS Learning Community on campus from other students.

While it is not clear why the increase occurred, it is clear why the female students selected the EPICS Learning Community. They seek relevant work experience that will prepare them as engineers and are attracted to gaining that experience within a context that is relevant. They are not just seeking to do service, they want real engineering experience. Being able gain such experience within in the community context became very appealing. They do not want to simply "help people" but to develop as professionals. The male students also responded in a similar way. While more males only listed gaining experience, several also listed the community context as a compelling reason to join.

The female students reported that being in the majority in the Learning Community class was a benefit. Their descriptions of the benefits including the building of community, friendships and support systems. They also reflected on future courses and noted that they expected to be in the minority. Their first-year experience provided a base to build upon to handle what they saw ahead. Their reflections on their first semester included descriptions about gaining experience and self confidence that would carry into the workplace through internships and eventual permanent employment. A strong majority indicated that the experience reinforced their desire to complete an engineering degree.

The data suggests that students, especially the female students seek experience within a context. Such experiences can be as part of a more traditional courses in the form of

content or projects. The nature of the community-based projects provided this naturally. These attributes can be integrated into more traditional courses to impact the image of engineering and computing. There are many ways to put decades of research into practice within the engineering and computing curricula to address the issues of underrepresentation.

ACKNOWLEDGMENT

The authors thank the Purdue University Learning Community Staff for their support and dedication coordinating the learning community efforts. The EPICS staff and faculty make the program work.

Abstract—Computational thinking ability is important in computer science education. It emphasizes abstraction and automation. For automation, programming has become a key ability in digital society recently. As a result, the increase in the importance of coding education in many countries has brought various educational methods to improve teenagers' programming abilities. Among programming abilities, reading ability is important especially to programming novices. This paper focuses on the effects of gender and abstract thinking abilities of adolescents on understanding computer programs. Also, we examine if there is any difference in teaching between adolescents and college students. In order to achieve our research goals, we surveyed on the abstract thinking level, and then measured program understanding ability for 300 academic high school students who had learned C language. From this research, we found that the abstract thinking affects more complex program understanding positively. Also, we found that the language experience before learning brought the difference in program understanding. However, we could not find statistical differences in program understanding between two genders. From this research, we can provide a new point of view to improve adolescents' programming ability with abstract thinking and gender factors.

Keywords—computer science education; computer programming understanding; abstract thinking; gender difference; software metric;

I. INTRODUCTION

Traditionally, programming behavior was classified into 5 activities: composition (writing a program), comprehension (understanding a given program), debugging (finding errors in a given program), modification (altering a given program), and learning (acquiring a new skill) [1]. However, during the programming class in secondary schools, after students learn about how to use a set of keywords and grammar, they key in a few programs their teacher prepared. And then, due to the programming typos, they spend a lot of time on correcting their typos. So far, many researchers continue to find an appropriate way for computer programming learning. Among various programming abilities, this paper focuses on programming understanding ability. This ability is essential to programming novices because they do not have knowledge so much. Thus, before they learn how to write and debug programs, they should have a change to read and to understand

other people's programs. In fact, many of adolescents are programming novices at this moment. Shneiderman and Richard mentioned that programming novices focused more on specific code than the structure of a given program [1]. It seems that the novices tried to understand a program at a low abstract thinking level. In addition, they mentioned that using mnemonic names, comments, and modularity helped to understand a given computer program [1].

Besides, many research works examined the relationships between cognitive personal factors and learning ability of computer programming [2][3][4]. According to the previous literature, motivation and skill are the keys to success in computer programming [2][3]. Self-efficacy is also an important mean of measuring people's performance and it affects computer programming ability[4]. On the other hand, Kramer described his teaching experience for about 30 years that abstract thinking ability helps students' academic achievement in his paper [5].

Recently, due to the advent of the concept of computational thinking ability, abstraction and automation became keys in computer science education [6]. However, the previous literature rarely analyzed how the abstraction or the abstract thinking worked with program understanding. In particular, the researchers did not pay attention to how the adolescents felt and what the problems were when they read computer programming component such as if-statement, while statement, and functions. Also, there rarely exists a measurement to assess the students' abstract thinking ability from the programming point of view.

Thus, in this research, we firstly show how adolescents' abstraction thinking level affects their computer program understanding based on their programming language experience. Next, we examine if there exists gender difference in program understanding ability. In addition, we examined if the traditional metric for measuring software complexity is consistent with the difficulty level the adolescents feel when they solve program understanding problems.

In order to achieve our research, we adopt the Behavioral Identification Form (BIF) [7] as our measure for abstract thinking. According to action identification theory, the identities for an action can be classified into two groups hierarchically. One is low in level and the other is high in level.

Jung Suk Hyun is the corresponding author of this paper.

The low level identity usually concerns about *how* an action is performed, whereas the high level identify usually concerns about *why* the act is performed. Vallacher and Wegner developed 25 items to measure action identification, which have two alternatives; one is abstract and the other is concrete [7][8]. Many researchers have referred the behavioral identification form, and Trope et al. adopted the BIF in their construal level theory [9]. In the theory, the low-level action identification is related to concrete thinking, *how*, whereas the high-level action identification is related to abstract thinking, *why* [9].

Next, we adopted the program examples from the research [10], which are the basic structure, the selection structure (if-else), and the iteration structure (do-while). All the problems were covered in the class of the high school we chose. We assumed that the basic structured programs are lower level in abstraction, whereas the selection and the iteration structured programs are higher level in abstraction. However, we did not know the exact difference in abstraction level among the programs.

The rest of our paper is organized as follows. In section 2, we review the previous literature related to the Behavioral Identification Form and software metric that is a quantitative measure of a degree to which software possesses a set of properties [11]. In section 3, we firstly describe the problems we chose for this study. And then, we describe the experimental process and methods for this research. In section 4, we perform a t-test and ANOVA to examine if there exists any difference due to gender and abstract thinking level. And then, we analyze the relationships among abstract thinking ability, language experience, and program understanding ability in order to see if there exists a moderating effect among the factors. Finally, we conclude our paper in section 5.

II. EASE OF USE

A. The Behavioral Identification Form for Abstract Thinking

The action identification theory insists that any action done by a person can be identified from the person's thinking styles [7]. The thinking style can be divided into two: thinking globally (abstract) or locally (concrete) [7]. Sometimes it can affect adolescents' academic achievement. There are many methods to measure thinking level. One of them is the Behavioral Identification Form (BIF) [7][8]. Vallacher and Wegner developed items to measure the action identification, which have two alternatives; one is abstract and the other is concrete [10]. In the theory, we can calculate an abstraction thinking value by giving 0 score for concrete alternative and giving 1 score for abstract alternative. The BIF is linked with measuring people's spatial distance and mental construal of social events [9]. The BIF is also linked with the Time Perspective theory [11] to figure out the concept of time. In fact, time is abstract concept in many literatures. We can get the abstract thinking level with the sum of the scores of the items. Table I shows the sample questions for measuring the abstract thinking value [7][8].

TABLE I. SAMPLE QUESTIONS FOR MEASURING THE BIF[7]

Questions	Alternative 1	Alternative 2
Making a list	a. Getting organized*	b. Writing things down
Reading	a. Following lines of print	b. Gaining knowledge*
Joining the Army	a. Helping the Nation's defense	b. Signing up
Washing clothes	a. Removing odors from clothes	b. Putting clothes into the machine
Picking an apple	a. Getting something to eat*	b. Pulling an apple off a branch
Chopping down a tree	a. Wielding an axe	b. Getting firewood*

*Higher level alternative. Total score is the sum of higher level alternative choices.

B. Software Metric

Software metric is an objective measurement of software complexity [12]. Software metric is necessary when software engineers establish their schedule and budget planning, cost estimation, and so on [13]. We can find a lot of software metric from the previous literature. In 2008, [14] compared the software metric tools including object-oriented programming. As new components appeared in new programming languages, software metric should be enhanced in order to measure the complexity of some software objectively.

Among the metrics, cyclomatic complexity has widely been used even though there was critique about the theory [12]. Let us get the cyclomatic numbers of the program P2 and the program P3 in Table II. The number for P2 is 3 and the number for P3 is 2. Thus, according to the rules for getting the cyclomatic number, the program P2 is more complex than the program P3. However, in this research, our students felt that P3 was much more difficult than P2. In Section IV, we present the reason for this phenomenon. In fact, there are various levels of programmers in the world. In the past, we did not expect that our kids have a change to learn computer programming at the school curriculum. So far, computer education has mainly focused on ICT literacy and cyber ethics. Thus, researchers such as software engineers have rarely paid their attention not to educate young kids but to develop software.

III. EXPERIMENTAL PROCESS AND TEST PROGRAMS

In this Section, we describe our experimental process and the test programs chosen by this paper. One of the authors of this paper works for J general high school, who majored in Computer Education. She taught C programming language at the high school. In the city where the high school is located, there are 17 general high schools. According to a report comparing the average test grade among the schools, the J high school was placed 9th in 2013 [15]. The author firstly taught 151 male students during 17 weeks of spring semester in 2014. And then, she taught 149 female students during 17 weeks of the following fall semester in 2014. Both of them were 10th grade students. She taught the concepts of variables and expressions, and then taught control structures such as

blocks, if-else statements, and do-while statements. She taught the same content to two different groups divided by gender with the same instructional method.

TABLE II. PROGRAM UNDERSTANDING PROBLEMS

Component	Questions
P1. Simple statements (2 points)	<pre>main() { int i, j=3; i = j+5; j = i*2; printf("i=%d, j=%d", i, j); }</pre>
	<pre>main() { int total; int apple=2, banana=3; total= apple * 2; total = total + (banana * 3); printf("total = %d", total); }</pre>
P2. Conditional statement (if-else) (2 points)	<pre>main() { int no, in=3; if (in + 2 > 5) no = in * 10; else if (in + 3 > 5) no = in * 20; else no = in * 30; printf("no=%d", no); }</pre>
P3. Iterative statement (while) (2 points)	<pre>main() { int x, y, z, noloop=1; x=1; y= 1; z= 0; while (noloop < 5) { z = z + x + y; x = y; y = z; noloop++; } printf("z=%d", z); }</pre>

We selected the same problems described in the research [10]. After 17-week learning was done, we asked the problems with the BIF questions and 4 mathematical problems such as the Perkins problem and the Krantz problem [16][17] for comparing the students in terms of gender and abstract thinking ability. We also asked if the students had any language experience before they learned C language in 2014.

The problems mentioned in Table II were not the final test but the survey questions for this research. Since this research is interested in the program understanding ability when they learn a programming language, we did not offer coding problems. In fact, there have been a lot of previous research about programming aptitude test and programming ability test [18][19]. However, the previous research mostly had the psychological perspective instead of the pedagogy of programming perspective [19][20]. This is a difference between this research and the previous ones.

IV. EXPERIMENTAL RESULTS

In this section, we firstly compare the characteristics of the students participated in our survey from the gender point of view. And then, we compare the program understanding ability from the abstract thinking point of view. Next, we examine the interaction effect among gender, abstract thinking, and language experience. Finally, we describe the difference in program complexity between software engineering field and computer education field. In fact, for the whole students, their program understanding scores were positively correlated with their mathematical problem solving scores ($r = 0.136$, $p = 0.019$).

A. Gender Difference

We examined the gender difference in the BIF, 3 types of program understanding problems, and the mathematical problem solving, and the language experience before the students entered the high school. Table III showed the mean differences between male (M) and female (F). The number of male students is 151 and the number of female students is 149.

TABLE III. GENDER DIFFERENCE

Factors	Gender	Mean	SD	<i>t</i>	<i>P</i>
The BIF	M	14.46	4.65	3.40	0.001
	F	12.68	4.42		
The program P1	M	1.25	0.84	-2.54	0.012
	F	1.47	0.69		
The program P2	M	0.95	0.50	-1.39	0.166
	F	1.11	0.50		
The program P3	M	0.17	0.28	-0.62	0.534
	F	0.21	0.31		
Mathematical problems	M	4.63	1.78	5.58	0.000
	F	3.50	1.72		
Language experience	M	1.19	0.48	2.84	0.005
	F	1.05	0.30		

As shown in Table III, the male students had a higher abstract thinking level than the female students ($t=3.40$, $p=0.001$). In addition, the male students had a higher mean of programming experience than the female students. For the language experience, we measured it as the number of programming languages the students knew. However, there was no significant differences in program understanding score except the problems that contained simple statements. In the simple statement programs, the female students had a higher score than the male students. The female students had lower levels of abstract thinking ability than the male students.

In summary, for gender, the female students solved the simple structured program better than the male students regardless of their language experience and the BIF. On the other hand, the male students did better in the mathematical problem solving. For the higher level language problem, there was no difference between two genders. In the following section, we divided the students into two groups with respect to the abstract thinking ability in order to examine if there is any difference in program understanding ability between a higher level in abstract thinking and a lower level in abstract thinking. In some cases, differences can be cancelled due to

considering the whole sample. If we divide the sample into a few groups with a meaningful measure, then we can get some meaningful results.

B. The Mean Differences between Two Abstract Thinking Levels

We firstly got the mean values of the abstract thinking for two genders. In fact, the abstract thinking ability is statistically different between two genders. Thus, when we divided into two groups for the abstract thinking, we use two different mean values of the abstract thinking. For the male students, the mean value was 14.46, whereas the mean value as 12.68 for the female students. Thus, for the female students, the scores between 1 and 12 were included into the lower level, where as the scores between 13 and 25 were included into the higher level. On the other hand, for the male students, the scores between 1 and 14 were included into the lower level, where as the scores between 15 and 25 were included into the higher level.

Table IV shows the differences in the 3 program types between the two abstract thinking levels. We divided the results into male (M) and female (F).

TABLE IV. DIFFERENCES IN PROGRAM UNDERSTANDING BETWEEN THE TWO ABSTRACT THINKING LEVELS

Program type	Gender	<i>t</i>	df	<i>P</i>	Mean Difference
The program P1	M	-0.56	149	0.58	-0.08
	F	-0.67	147	0.51	-0.08
	Total	-0.86	298	0.39	-0.08
The program P2	M	-0.57	149	0.57	-0.09
	F	1.10	147	0.27	0.18
	Total	0.35	298	0.72	0.04
The program P3	M	-2.64	105.44	0.01*	-0.24
	F	0.09	147	0.93	0.01
	Total	-1.69	281.4	0.09	-0.12

As shown in Table IV, there was no difference between two abstract thinking levels except the program P3 for the male students. In order to find out the reason, we analyzed the previous literature and found familiarity factor played an important role in computer program understanding [10]. Thus, we concluded that since the female students had lower abstract thinking levels than the male students and the female students also had lower language experience than the male students, there was no mean difference in understanding the P3 for the female students. In addition, when comparing the mean values of 3 types of programs, the understanding values of the P3 had the lowest score among the 3 programs. This result is consistent with the theory of Shneiderman et al. mentioned [1]. They proposed that programming novices focused more on specific code than the structure of a given program [1].

C. The Moderating Effect among Gender, Abstract Thinking, and Language Experience

We firstly examined if there was any moderating effect between abstract thinking ability and gender on program understanding in this subsection. And then, we also examined if there was any moderating effect between language

experience and abstract thinking ability on program understanding. A moderating effect means that it may reduce or enhance the direction of the relationship between an independent (predictor) variable and a dependent variable [21]. Or, when the relationship between the two variables changes the direction (positively or negatively), we can define there exists a moderating effect between them [21].

When we performed the analyses to see if there existed any moderating effects, we could not get the effects for the program P1 and P2. Only P3 had the moderating effect. Thus, we only present the program P3 (the iterative structure). Table V shows the result of the moderating effect. The number of the low abstract thinking level male was 75 and the number of the high level was 76, whereas the number of the low abstract thinking level female was 73 and the number of the high level was 76. For the male students, the mean gap between the two levels was significant. However, due to the female students, $F(1,296)$ value is 2.80 and $p=0.095$. There was no difference between the two genders ($F(1,296)=0.41$, $p=0.523$). Finally, the moderating effect between the abstract thinking level and gender was marginally significant ($F(1,296)=3.24$, $p=0.073$).

TABLE V. MODERATING EFFECT BETWEEN ABSTRACT THINKING LEVEL AND GENDER ON P3

Source	Sum of square	df	Mean square	<i>F</i>	<i>P</i>
Abstract thinking level (A)	0.24	1	0.24	2.80	0.095
Gender (B)	0.04	1	0.04	0.41	0.523
A * B	0.28	1	0.28	3.24	0.073
Error	25.64	296	0.09		
Total	29.00	300			

($R^2 = 0.011$, the dependent variable: P3)

Fig. 1 shows the graph that represented the meaning of the data in Table V. It represents that there is a difference in understanding P3 (a more complex program) between the two abstract thinking levels for the male students. Thus, the abstract thinking ability played a role in understanding more complex programs. However, we could not find any difference for the female students. We explained the result in the next subsection.

Fig. 1. The mean values of the point for P3 with two abstract thinking level and gender

Next, we examined if there was any moderating effect between abstract thinking ability and language experience on program understanding. For the abstract thinking level, the number of the high level students was 152 and the number of the low level students was 152. The number of the novice was 271 and the rest of them were experiencing another programming languages. Table VI shows the result of the moderating effect between the abstract thinking ability and language experience. Table VI showed that there existed a moderating effect between the abstract thinking and the language experience ($F(1,296)=20.55, p<0.001$). Also, for each factors, two groups were significantly different (A: $F(1,296)=22.61, p<0.001$, B: $F(1,296)=20.38, p<0.001$).

TABLE VI. MODERATING EFFECT BETWEEN ABSTRACT THINKING LEVEL AND LANGUAGE EXPERIENCE ON P3

Source	Sum of Squares	df	Mean Square	F	P
Abstract thinking level (A)	6.989	1	6.99	22.61	.000
Experienced (B)	6.301	1	6.30	20.38	.000
A*B	6.353	1	6.35	20.55	.000
Error	91.504	296	.31		
Total	116.000	300			

($R^2=0.118$, the dependent variable: P3)

Fig. 2 shows the graph that represented the meaning of the data in Table VI. As we expected, when the abstract thinking level became higher, the moderating effect occurred. In Fig. 2, the two lines were not parallel. It means that when the students' abstract thinking level was low, the difference gap between the novice and the experience students was not big. However, when the students' abstract thinking level was high, the difference gap between the novice and the experience students was very big. Thus, the abstract thinking ability enhanced the program understanding ability based on the language experience of the students. The result coincided with Kramer's work.

Fig. 2. The mean values of the point for P3 with two abstract thinking level and language experience

Finally, we examined if there was any moderating effect between gender and language experience on program understanding. Table VII shows the mean values for the 4 groups made with 2 genders and 2 language experience levels. In this case, the difference between the two genders was

significant ($F(1,296)=4.10, p=0.044$) and the difference between two levels of language experience was also significant ($F(1,296)=20.44, p<0.001$). However, there was no moderating effect between the two factors. The gap between the two language experience level for the female students was bigger than that for male students. Thus, we cannot expect a synergy between gender and language experience factors.

TABLE VII. MODERATING EFFECT BETWEEN GENDER AND LANGUAGE EXPERIENCE ON P3

Experienced	Gender	Mean	Std. Deviation	N
Novice	M	0.11	0.46	128
	F	0.18	0.58	143
	Total	0.15	0.52	271
Experienced	M	0.52	0.90	23
	F	1.00	1.10	6
	Total	0.62	0.94	29
Total	M	0.17	0.56	151
	F	0.21	0.62	149
	Total	0.19	0.59	300

D. Gender Problems and Difficulty Levels in Program Understanding

In this research, we authors wanted to examine if gender factor and abstract thinking factor influence program understanding for high school students, and then show how male high school students and female high school students are different. Also, we would like to show how language experience also affects the high school students' program learning. From the previous results of this research, the mean value of the female students' abstract thinking was lower than that of the male students. In Table III, the female students solved the program P1 better than the male students significantly. It is related to the fact that the female students think more concrete than the male students. In addition, Table V and Fig. 1 showed the difference in understanding P3 between two genders and two abstract thinking levels. Unlike the analysis with the whole sample, the male students at the high level in abstract thinking solved the complex program (P3) better than the female students at the high level in abstract thinking.

On the other hand, the mean values for P1, P2, and P3 are decreasing as shown in Table II. This means that our students felt different difficulties when they understood the 3 programs. According to the scores, we ranked the program P3 as the most complex program. In addition, the abstract thinking ability played an important role when the students understood more complex program. Thus, having a high level of abstract thinking is important while understanding programs.

Next, [22] described three types of software metrics such as McCabe, Halstead, and Program Knots [23]. And, [24] compared McCabe and Halstead for measuring psychological complexity. According to [24], software complexity metrics were related to the difficulty programmers experienced in understanding. However, from our experiment, we saw the difference between the existing software metric and the

difficulty level our students felt even though our programs were simple. For example, we calculated the cyclomatic number for P2 and P3 in Section 2. The number for P2 is 3 and the number for P3 is 2. Thus, according to the rule for the cyclomatic number, the program P2 is more complex than the program P3. However, in this research, our students felt that P3 was much more difficult than P2. This phenomenon tells us that for ordinary computer programmer and for the beginners who learn a computer programming language for the first time, different measurement will be needed. Also, educators should be more careful when they teach novice programmers because the difficulty levels are different with each other.

V. CONCLUSIONS

In this paper, we examined how gender and abstract thinking level affected program understanding ability when we gave a few programs having different complexities. In order to achieve the research goal, we proposed three different types of programs. By using these programs, how the students' abstract thinking ability affected the students' problem solving ability.

In summary, the male students were better in the abstract thinking, mathematical problem solving, and language experience than the female students. On the other hand, the female students did better in understanding the 3 programs in total than the male students. However, in the programs P2 and P3, there was no difference significantly. Only the program P1 (lower complex program) has the statistically significant difference. This phenomenon is related to the female students' lower abstract thinking level. Thus, they think more concretely than the male students do. It means that when the students solve less complex programs, concrete thinking is more important than the language experience and abstract thinking.

However, for the male students, the abstract thinking ability affected to solve the program P3 (containing while statement). When comparing the mean scores for understanding the 3 programs, we can find that the program P3 was the most difficult. Thus, if a student's abstract thinking level was higher, then the student could understand a difficult program better. It means that when an easy programming problem is given, the abstract thinking ability does not play an important role in the students' program understanding ability. However, when a difficult programming problem is given, the high level of abstract thinking ability plays an important role in understanding the problem.

Next, we found a common factor between the male students and the female students. It was the language experience before learning. Even though the number of students who had learned another language before they learned C in 2014 was too small, there existed statistical difference between the novices and the students who had language experience. In this case, the abstract thinking ability enhanced the students' program understanding ability. In other words, for the novices, the abstract thinking ability has no discrimination for measuring the students' program understanding ability. However, for the students who had language experience, the high level of abstract thinking ability plays an important role in understanding the problem.

Finally, from this research we found that the program experts' software complexity and the adolescents' software complexity were different. In other words, the same difficulty level programs for the professionals can be different for the adolescents. This is an important educational aspect when teachers teach programming languages to their students. Thus, more sophisticated measurement is needed in the near future.

Stories of Black Women in Engineering Industry – Why they leave

Monique Ross, Allison Godwin
School of Engineering Education
Purdue University
West Lafayette, USA
ross118@purdue.edu, godwina@purdue.edu

Abstract—The U.S. government has called for more STEM professionals in order to remain competitive as a nation. Increased participation of women and minorities in these fields will capture the rich diversity of their lived experiences and contributions. Many studies examine these issues for women or minorities, but less frequently consider the intersection of gender and race. There have been quantitative studies conducted in recent years that attempt to capture why women leave engineering. However, they lack the rich description at the intersection of race and gender necessary to understand the impetus to leave engineering industry.

Identity theory is the theoretical framework utilized for understanding how engineering industry culture fits with how these women see themselves and feel like they belong or do not belong in engineering. Identity theory can illustrate the meanings that Black women attribute to themselves as engineers and how they negotiate their perceived membership in engineering based on interpretations of status differences, legitimacy and stability of those status differences. This paper presents insight in to methods of data collection, analysis process, and preliminary research results.

Keywords—Black women, engineering industry, identity theory, intersectionality, phenomenology

I. INTRODUCTION

U.S. demographics are changing and currently women outpace men in engineering degree attainment in every ethnic category except white. For these reasons, there have been numerous studies and initiatives in place to broaden participation in engineering. Despite these interventions, more diverse populations are not being retained in engineering after earning a bachelor's degree [7]. These women do not just leave a sector of industry, but they leave engineering entirely [7]. Demographics on the progress of women and minorities in engineering, although staggering on their own, only convey a fraction of the narrative. Disaggregating the data down to the intersections, unveils even more disturbing information; Black women comprise 6.4% of the U.S. Population, 1.2% of the engineering undergraduate enrollment, 0.77% of the engineering graduates, and only 0.6% of the engineering industrial workforce [1,2,3]. In a report by Nelson and Brammer on African American or Black female engineering

faculty, they stated that, “[...] numbers this small would not survive the statistical treatment, which would be necessary if they were samples” [4]. An assertion, such as this one, pushes the experiences of Black women to the margins, and their stories are silenced. Nonetheless, their stories are important, as they contribute to a rich diversity of perspective and thoughts needed in engineering.

Consistently low diversity numbers have spawned \$700 million in U.S. government investment in STEM initiatives and roughly \$8 billion annually on diversity and inclusion strategies in the private sector [5,6]. Based on these numbers, the U.S. is invested in the broadening of participation in engineering. Despite this investment, women are leaving engineering at alarming rates. Fouad and Singh found that 9% of women never made it to industry after completing an undergraduate degree and 20% left industry after just 5 years of participating in the workplace [7]. Meanwhile, Lach reported on a survey taken by 1700 professional women of color that reported that nearly 73% of them intended to leave their company [8].

With the wealth of capital being invested in attracting and retaining women and people of color, why are numbers so low and in some cases declining in STEM fields? Why are they leaving? One plausible argument is that engineering, as a discipline, aims to solve a diversity problem in engineering without adequately understanding the true breadth, and depth of the problem. From prior literature, we are aware that there are factors that contribute to attrition (e.g. culture, environment, etc.) [7]; however, we have drawn these conclusions from a relatively broad categorization. Therefore, we miss the nuances associated with more fine scoped views. Historically, research has been shaped around gender-only (i.e. women in engineering) or race-only (i.e. minorities in engineering) lenses, leaving those that are situated at the intersection of race and gender without a presence in the current body of literature. In recent years, there has been some attempt at looking at the intersection of race and gender (i.e. women of color); however, this implies that all women of color experience bias in the same ways. Such assumptions leave the engineering community with misinformation and an incomplete description of the “diversity problem” in engineering. This work in progress study explores the

experiences of Black women in engineering industry in an attempt to shed light on the reasons for high attrition. This study would fill an evident void in literature on Black women in engineering industry.

II. THEORETICAL FRAMEWORK

The theoretical frameworks utilized while framing this study, in an attempt to shed light on the reasons for high attrition, are: social identity theory and intersectionality theory. Social identity theory provides insight into the identities of the women, the existence of competing identities, the effects of this competition on their engineering identities, and the effects of the interplay on their decision to stay or leave engineering. Intersectionality illuminates the experiences of a demographic at the juncture of race and gender.

A. Social Identity Theory

Social identity theory provides an established theoretical framework that has been utilized effectively in science education research [9]. Borrowing the effective operationalization of science identity for research in engineering could provide an easy transition from one discipline to another, while also contributing to the engineering education body of knowledge. Some science educators have measured identity in their participants through the ways in which they talked about science, how they acted/participated in class, how they described being in the science world (classroom) [10], how they described themselves [11], or how they related to others in the community [10]. They determined that new identities were developed when one began to take on new roles in the learning community, gained more knowledge, and had access to the discourse, tools, and more central aspects of participation in the science learning community [12]. These attributes were measured through the analysis of interviews with the participants, their parents and teachers, observations, and journals. They were able to identify the language used by the participants that reflected a low or high science identity salience. This same approach is used in this work when talking to Black women about their engineering identity. Interview questions were constructed to elicit participants' definition of an engineer and whether they consider their identity in congruence with their definition.

B. Intersectionality of Race and Gender

Intersectionality reminds us that oppression cannot be reduced to one fundamental type; in fact, multiple oppressions work together in producing heightened injustice [13]. Because the intersectional experience is greater than the sum of racism and sexism, analysis that does not take an intersectionality approach is deficient in addressing the particular manner in which Black women are subordinated [14].

Historically, some groups have been systematically underrepresented in research because they exist in small numbers. Under these circumstances, research has been conducted on (for example) minorities or women; this approach has rendered the women that are situated on the

intersection of these two groups (e.g., Black women or Native Women) invisible. Studies that focus on minorities are traditionally male-oriented, and the studies that focus on women are traditionally white-oriented. This results in subcategories (i.e., white women) that only partially represent a larger category (i.e., women); however, they have often been taken as representative of the whole category (e.g., white women, Black women, Hispanic women, Asian women, Native American women, etc.). Intersectionality was developed to describe an analytic approach that considers the meaning and consequences of multiple categories of identity [15]. An intersectional approach to understanding race/ethnicity and gender is one in which consideration is given to the unique positions that exist for people on the basis of the combination of their race/ethnicity and gender; it recognizes that gender and race/ethnicity can only be experienced simultaneously within an individual [16].

Giving attention to those that have traditionally been excluded obstructs the tendency to view a category in essentialist terms. An intersectional approach enables the diverse experiences contained within categories defined by multiple identities to be examined [15]. Failure to recognize that social categories depend on one another for meaning renders knowledge of any one category incomplete and biased [15]. Intersectionality makes it clear that gender, race, class, and sexuality simultaneously affect perceptions, experiences, and opportunities of individuals that live in a society stratified along these identities. Incorporation of previously ignored and/or excluded populations into knowledge construction in order to broaden our knowledge base could facilitate more adequate solutions to traditional questions posed by our discipline [17]. Intersectionality provides a means for answering contemporary questions that increasingly demonstrate the flaws of a race-only or gender-only approach [17].

III. METHODS

The research question for this study is: What effect does engineering industry culture have on engineering identity of Black women engineers? To examine this question, we are conducting an ongoing phenomenological study on the experiences of Black women across sectors of engineering industry. We are interested in stories of why some women stay in engineering while a large fraction leave. The methodology, sampling, research methods, preliminary analysis methods and preliminary results are described below.

A. Phenomenology

Phenomenological research describes the common meaning for several individuals of their lived experiences of a concept or a phenomenon [18]. We, as researchers, focused on describing what all participants have in common as they experience a phenomenon. Our intent is to reduce individual experiences with a phenomenon to a description of the universal essence [18]. The "essence" of a phenomenon from the perspectives of those who have experienced it, is the defining characteristic of phenomenological research [19]. Phenomenology involves the gathering of "deep" information

and perceptions through inductive, qualitative methods such as interviews, discussions and participant observations, and represents it from the perspective of the individual [20]. A phenomenological study attempts to understand an individual's perceptions, perspectives, and understandings of a particular phenomenon. Researchers conducting phenomenological research typically have had personal experience related to the phenomenon and seek a more in depth understanding of the experiences of others [21]. Examining multiple perspectives of the phenomenon, the researcher is better equipped to make generalizations of the experiences from an insider's perspective [22].

Interpretive phenomenology, also known as hermeneutics, was the approach selected for this study. Hermeneutics extends beyond mere description of core concepts and essences to look for meaning embedded in common life practices [23]. Hermeneutic inquiry is focused on what individuals experience rather than what they consciously know. Interpretive phenomenology embraces presuppositions or expert knowledge, on the part of the researcher, as a valuable guide to inquiry. The focus is on describing the meanings of the individuals' existence in the world and how these meanings influence choices. This involves analysis of the historical, social, and political forces that shape and organize experiences [23].

B. Sampling

Purposive sampling was the original method of sampling selected for the research study. Purposive sampling, as the name suggests, selects participants based on specific factors (e.g. race and gender as the topics of this work) [25]. At the Women of Color in STEM conference in October 2014 we gathered contact information for initial participants for the study; however, despite the women's eagerness to share their stories, when the conference concluded, the communication with most of these women ended as well. The few women that responded to requests to interviews were asked to identify other women to participate in this study in a snowball sampling method. This method is useful for sampling populations that are difficult to access, including minorities, marginalized or stigmatized groups [25]. These groups are often referred to as "hidden populations" [24]. Given Black women's small numbers in engineering industry, a snowball sampling was most appropriate to gather an appropriate number of participants

The snowball sampling for this study began with a close friend that, in turn, referred a friend that was unknown to the researchers. That woman in turn referred a friend. The study, to date, has conducted interviews with two women that are currently in engineering industry positions. Celia is a systems engineer with 14 years of experience, currently employed by a government contractor in Alabama, while Jessica is a manufacturing engineer with 9 years of experience with a government contractor in South Carolina. While this sampling, thus far, has been limited to government contractors in the southern United States, it is anticipated that through the use of organizations such as National Society of Black Engineers (NSBE), Society of Women Engineers (SWE), and use of the Women of Color in STEM conference again in 2015, that the

study will include more women from a variety of industry sectors and geographic locations for a target sample of 15-20 participants. We also hope that a snowball sampling approach will allow us to identify alternative cases of women that have chosen to leave engineering to compare their experiences and reasons for leaving with the experiences of women who are still working in engineering.

C. Data Collection and Analysis

Data collection has been achieved through a single, one hour in-depth interview that explored the areas of: background, work environment, identity in engineering, and social identities (e.g. race, class, gender, etc.). The interviews were conducted over the phone and were recorded and transcribed verbatim. The questions coded via a constant comparative method [26] to better understand each woman's journey into engineering industry, including their career selection process, educational background, career path to-date and future career. We also probed the nature of their work environment by asking questions about participants' perceptions of the culture/climate as well as work relationships (e.g. mentoring, social, and hierarchical). Use of the social identity theoretical framework prompted the inclusion of questions on defining an engineer, reflecting on personal engineering identity, as well as social identity (e.g. woman, Black, mother, etc.). These questions provide insight into these women's sense of belonging in the engineering workplace and how these women navigate their multiple identities in a white, masculine culture.

The interview protocol has undergone three iterations, thus far, ensuring ease of transition between categories, to add clarity to the questions, and to provide insight into the purpose of the study. The participants have been incredibly insightful, honest and gracious at the conclusion of the interview on the process of the interview and possible ways to improve the experience for future participants. Immediately, after each interview fieldnotes were drafted to capture a summary of the interview, immediate thoughts, notes about responses that elicited more questions, and potential follow-up questions. This immersion in the data, along with open and axial coding of the emerging themes highlighted by participants has allowed for valuable preliminary data on these two women's experiences. Follow-up interviews are planned, to expand upon topics that have emerged while reviewing the transcripts. To ensure respondent validation, the transcripts have been redacted, formatted, and sent to the participants for member checking. However, no final conclusions have been drawn and certainly, no overarching essence has been achieved.

IV. PRELIMINARY RESULTS

Results currently consist of a few emergent themes in the first two participants in this study. Although both women spoke of satisfaction with their jobs, they also spoke about power struggles at work, the perception of being treated differently due to gender, and the tendency of women to leave due to familial demands. Celia spoke about engineering identity as consisting of anti-social behaviors, power seeking, and territorial. She felt as if she fit right into these categorizations and therefore, has no concerns about belonging. She had taken on the cultural identities within engineering that

she identified in her interview, thus becoming a part of the engineering work culture in which she was immersed. Celia speculated that women left the engineering environment to be homemakers, which was not her desire or interest. She reflected on office pools at work when women went on maternity leave, betting against the woman's return.

[...] when someone goes on maternity leave we start taking bets, like are they coming back [...] we have one on maternity leave now [...] we get all these picture texts from her everyday with her baby [...] I'm like I might want to add a little bit more money to the "not coming back" fund. [...] the women that I've come encounter with, once they leave and have a baby they do not come back like, that's the only thing I've seen that is dwindling of women where I work.

Alternatively, Jessica spoke of not being respected in her role as a woman and mentioned that she was considering leaving work to stay at home with her children. She felt the opposite tensions that Celia described as a part of the inside crowd within engineering. As a woman and a mother, two salient identities, social and role, respectively, Jessica felt that she did not have the same insider status as others. When asked if she would consider leaving if she felt more satisfied in her career, she responded with a simple, "no." She expanded her answer by stating:

If I had more of a supportive leadership team. If I felt as if people were actually rooting for my success, then yes, I think I would feel more comfortable [staying in the workforce] and the pull [to leave work and be a stay-at-home-mom] would not be so strong.

During the one-hour interview she had divulged that she was in fact not satisfied with her career and this was a major contributor to her consideration to leave to be a homemaker.

These preliminary findings highlight interesting and different ends of power dynamics within engineering work culture. Both women in government sectors described environments where being a mother placed the burden of caretaker and worker on a woman's time and carried with it a stigma that inevitably a new mother would simply leave. The underlying assumptions of these cultures that began to emerge in data analysis emphasized a masculine norm consistent with prior literature that women who are mothers must perform both a role as a full-time engineer as well as a full-time parent – an assumption that was not described for men working in these engineering industry environments [27]. Even with two interviews at the beginning of this study, specific examples of microaggressions and structures within the workplace that disadvantage women emerged. By finding essential essences of how Black women's identities may be supported or eroded through practices in engineering culture, we can begin to highlight ways to improve engineering for these groups. These improvements may positively impact everyone. These changes may have the potential to begin to stem the tide of talented, Black women leaving engineering.

V. FUTURE WORK

The future consists of continued identification of potential participants, additional interviews, and conducting a thorough analysis of both individual interviews and the participants interviews collectively through a phenomenological lens and the theoretical frameworks of interest. The study is underway and has already provided some unique insight into Black women's experience in engineering industry; however, there is still much to learn. This study will expand the existing literature on women of color in science to engineering, providing more insight into solutions for solving the diversity problem in engineering.

ACKNOWLEDGMENT

We would like to thank the brave women that have participated in the study thus far, as well as future participants.

The Effect of Using Online Tutors on the Self-Efficacy of Learners

Amruth N. Kumar

Ramapo College of New Jersey
Mahwah, NJ 07430, USA
amruth@ramapo.edu

Abstract— We conducted a study to evaluate the effect of using software tutors on the self-efficacy of students – in particular, whether the type of activity covered by the software tutor correlated with any improvement in self-efficacy after using the tutor along the levels of Bloom’s taxonomy; and whether any differential effects could be observed in the improvement of self-efficacy among the sexes and racial groups. The study was conducted over four semesters using two different software tutors. The collected data was analyzed using paired sample t-test and 2 X 2 ANOVA for three different sets of students – those who used the tutor, those who needed to use the tutor and those who learned one or more concepts by using the tutor. We found that if a significant difference was found among taxonomic levels of self-efficacy after using a software tutor, the improvement was statistically significantly greater on the taxonomic level directly relevant to the topic/activity of the tutor than any other level on Bloom’s taxonomy except comprehension. Such a difference was found at least among those who actually learned one or more concepts using the tutor, if not everyone who used the tutor. In most cases, the improvement in self-efficacy resulting from the use of the software tutor was indistinguishable across sexes and racial groups. (*Abstract*)

Keywords—Online tutors; self-efficacy; evaluation

I. INTRODUCTION

Self-efficacy is one’s belief in one’s abilities [1]. Abilities, in particular as related to computer programming, can be categorized according to the various levels of Bloom’s taxonomy [2], as follows:

- Comprehension – ability to identify and recall data types, data forms, control statements, etc.
- Application – ability to predict the behavior/output of a given program
- Analysis – ability to debug a given program
- Synthesis – ability to write a program for a given problem statement
- Evaluation – ability to critique, refactor and rewrite a given program to meet one or more objectives such as readability, efficiency, etc.

How does using software tutors on programming affect the self-efficacy of students along these taxonomic levels?

How does the activity covered by the software tutor correlate with their post-tutor assessment of self-efficacy along the levels of Bloom’s taxonomy? Is there any difference in post-tutor assessment of self-efficacy among demographic groups – sex (male versus female), or race (traditionally represented versus under-represented groups) [3]?

In order to answer these questions, we conducted a study over multiple semesters using problem-solving software tutors for computer programming, called problets (problets.org). After using each problet, students were asked to fill out a Likert-scale survey on self-efficacy. They were also asked to optionally fill out their demographic information.

The results of this study will be discussed in this paper. The results will be of interest to developers of software tutors as well as their users. Since self-efficacy affects retention in the major, the results will also inform the ongoing discussion on broadening participation in Computer Science.

II. PROTOCOL

Problets (problets.org) are problem-solving software tutors delivered over the web. Students typically use them after class as assignments. Problets cover all the topics typically covered in an introductory programming course, including expressions, selection, loops, functions, arrays and classes. They are available for C/C++, Java and C#, and have been continually used by third-party Computer Science educators since fall 2004.

When a student uses a problet on a given topic, the student is presented problems on specific concepts in the topic, the student is asked to solve the problem and submit an answer, and the tutor grades the student’s solution and provides feedback designed to help the student learn about the concept.

For this study, two problets/tutors were used, both dealing with the concept of functions:

- A tutor on **code tracing** – students were asked to identify the output of programs involving one or more functions. The tutor covered 10 concepts, including parameter passing, calling functions in expressions, multiple calls to a function, and variables with the same name in multiple functions (See Fig. 1).

- A tutor on **debugging** – students were asked to identify bugs in programs involving one or more functions. The tutor covered 8-9 concepts (depending on the language – C++/Java/C#), including mismatch in the number and type of actual and formal parameters, missing return statement in a function, incorrectly calling a function that returns void versus non-void, and re-declaring a formal parameter as a local variable in a function (See Fig. 2).

Both these tutors are on advanced concepts that students in introductory programming courses find to be difficult.

Each tutor was configured to administer the following protocol:

- **Pre-test** – During the pre-test, the tutor presented one problem per concept. If a student solved a problem correctly, the student was given credit for the corresponding concept. No feedback was provided to the student, and no more problems on the concept were presented to the student. On the other hand, if the student solved a problem incorrectly, feedback was presented to the student immediately after the student had submitted his/her solution to the problem. Additional problems were presented on the concept during the subsequent stages described below.
- **Adaptive practice** – During this stage, additional problems were presented to the student on only the concepts on which the student had made mistakes when solving problems during the pre-test. For each such concept, the student was presented multiple problems until the student mastered the concept, i.e., solved at least 60% of the problems correctly. On each problem, the student received feedback including step-by-step explanation of the correct answer, which has been shown to improve learning [4].
- **Post-test** - During this stage, the student was presented test problems on the concepts that the student had mastered during adaptive practice.
- **Self-Efficacy Survey** – Students were asked to respond on a 5-point Likert scale to eight statements related to their self-efficacy with the topic of the tutor.
- **Demographics** - Students were provided the option to identify their demographic information, including sex and race. Demographic information was solicited after the pre-test-practice-post-test protocol to avoid the effects of stereotype threat [5].

The entire protocol was administered online, back-to-back, with no break in between, all by the software tutor [6]. The pre-test-practice-post-test protocol was limited to 30 minutes.

During the self-efficacy survey, students were asked to respond to the following eight statements related to their self-efficacy with the topic of functions:

After using the tutor, I can do the following *better*:

1. Understand the grammar rules of defining and calling functions
2. Understand the meaning of function definitions and calls
3. Read function definitions and calls
4. Predict the output of programs with functions
5. Debug programs with functions
6. Write programs with functions
7. Design programs with functions
8. Critique programs with functions

The 5-point Likert scale used for the responses ranged from Strongly Agree (coded as 1) to Strongly Disagree (coded as 5).

Note that the eight statements on the survey correspond to levels of Bloom's taxonomy as follows:

- Statements 1-3: Comprehension, i.e., constructing meaning.
- Statement 4: Application, i.e., using learned material in new situations.
- Statement 5: Analysis, i.e., breaking down material into its components to diagnose it.
- Statements 6 and 7: Synthesis, i.e., putting parts together to form a new whole.
- Statement 8: Evaluation, i.e., critiquing the value of material for a given purpose.

The statement directly relevant to the topic of code-tracing tutor was statement 4 on application. Similarly, the statement directly relevant to the topic of debugging tutor was statement 5 on analysis. Both the tutors could also be argued to improve comprehension, as stated on statements 1-3. Neither tutor was designed or expected to affect synthesis, covered by statements 6 and 7.

If using the tutors affected the self-efficacy of students, we could expect to see the following behavior:

- Students would respond most positively on statement 4 after using code-tracing tutor, and on statement 5 after using debugging tutor;
- Statistically significant difference could be observed between the student responses to statements 4 and 5 after both tutors (code-tracing tutor did not cover debugging and vice versa).
- Statistically significant difference could be observed between the student responses to the directly relevant statement (4 for code-tracing, 5 for debugging) and statements 6-7, since neither tutor was designed to help students write functions.

III. DATA COLLECTION AND ANALYSIS

Data was collected over four semesters: fall 2012, spring 2013, fall 2013 and spring 2014. In each of these semesters,

students from multiple institutions used the tutors over the web.

The tutors had been used for a controlled study of the effect of using expressive writing on the test performance of students [7]. For the current study, the control and test groups of this prior study were analyzed separately.

The pre-test contained 10 problems in code-tracing tutor and 9 problems in debugging tutor. On each tutor, only those students who had solved at least 6 pre-test problems were considered for this study – this eliminated tentative and incomplete uses of the tutors from the study. Similarly, students who did not respond to the self-efficacy survey were also eliminated from the study.

After combining data from all four semesters, the numbers of students who participated in the study using the two tutors and under the two conditions were as provided in Table 1.

TABLE I. NUMBER OF STUDENTS IN THE STUDY

N	Control	Test
Code-Tracing	105	539
Debugging	348	119

For each of the four cases in Table 1, we considered three sets of students:

1. **Set A:** All those who had used the tutor – the numbers are as shown in Table 1;
2. **Subset N:** All those who *needed* to use the tutor – these were the students whose normalized pre-test score per problem was less than 1.0. In other words, these students solved at least one pre-test problem incorrectly, and could benefit from the subsequent adaptive practice session. These were a proper subset of all those who used the tutor (Set A) – this group excluded the students who solved all the pre-test problems correctly and never solved any practice problems.
3. **Subset L:** All those who *learned* one or more concepts by using the tutor – these were the students who solved pre-test, practice and post-test problems on at least one concept and demonstrated pre-post improvement in score on the concept [6]. These were a proper subset of the students who needed the tutor (Subset N) – this group excluded students who could not solve practice and/or post-test problems on any concept because they ran out of time, the tutoring session having been limited to 30 minutes.

For each of the above three subsets, in each of the four cases shown in Table 1, we conducted a five-way paired sample t-test of the responses on self-efficacy survey, with the pairings as shown in Table II.

TABLE II. PAIRED SAMPLE T-TEST VARIABLES

Variable 1	Variable 2
------------	------------

	Variable 1	Variable 2
A	Comprehension (1-3)	Application (4)
B	Comprehension (1-3)	Analysis (5)
C	Application (4)	Analysis (5)
D	Application (4)	Synthesis (6-7)
E	Analysis (5)	Synthesis (6-7)

As mentioned earlier, we expected to observe significant differences in pairings C, D and E.

In addition, we conducted 2 X 2 ANOVA analysis, with sex and race as fixed factors, of the following three self-efficacy variables:

1. Average response on all 8 statements;
2. Response on statement 4 – the one most relevant to code-tracing tutor;
3. Response on statement 5 – the one most relevant to debugging tutor.

For this analysis, we considered two groups for race: traditionally represented, i.e., Caucasians and Asians [8], and the rest, i.e., Black/African American, Hispanic/Latino, Native American, Native Hawaiian/Pacific Islander and Other. In the study, we asked students to (optionally) identify their sex (biological notion of male/female) rather than their gender (social/cultural notion of man/woman) [9].

A. Code Tracing Tutor – Control Group

Table III lists the sample size N, mean and standard deviation of the responses to self-efficacy statements on comprehension, application, analysis and synthesis levels of Bloom's taxonomy. The data is for all those who had used the tutor (Set A). The score on comprehension is the average of the responses to the first 3 statements and the score on synthesis is the average response to statements 6 and 7.

TABLE III. CODE-TRACING TUTOR – CONTROL RESPONSES

Group	N	Mean	Std. Dev
Comprehension (1-3)	126	2.056	.906
Application (4)	126	1.94	.879
Analysis (5)	127	2.23	.986
Synthesis (6-7)	126	2.266	.997

Table IV lists the pairwise correlation (all correlations were significant at $p < 0.001$), the mean of the difference in pair-wise responses, the corresponding t-value and its 2-tailed significance for the 6 pair-wise comparisons.

TABLE IV. CODE-TRACING TUTOR – CONTROL RESPONSES

Pair	Corr.	Mean	t-value	Sig.
Compr. – Appln.	.911	.111	3.312	.001

Pair	Corr.	Mean	t-value	Sig.
Compr. - Analysis	.816	-.173	-3.371	.001
Appln. - Analysis	.705	-.286	-4.423	.000
Appln. - Synthesis	.724	-.321	-5.113	.000
Analysis - Synthesis	.842	-.035	-.717	.475
Comp. - Synthesis	.850	-.209	-4.457	.000

From Tables III and IV, it is clear that the student response was the most positive on statement 4 (application), which is the statement directly relevant to the topic of code-tracing tutor. Their response on this statement was statistically different from those on other levels of Bloom's taxonomy, e.g., significance of the pairwise comparison of Application (4) versus Analysis (5) is given by $t(125) = -4.423$, $p < 0.001$. In this instance, *the self-reported improvement in self-efficacy after using the software tutor was statistically significantly greater on the taxonomic level directly relevant to the topic of the tutor than any other level.*

The results of repeating the pair-wise analysis for the other subsets - those who needed the tutor (Subset N) and those who learned from the tutor (Subset L) – did not yield any different results.

The 2 X 2 ANOVA analysis of self-efficacy responses with sex and race as fixed factors did not yield any significant difference between the responses of the sexes or the racial groups, i.e., *improvement in self-efficacy resulting from the use of the software tutor was indistinguishable across sexes and racial groups.*

B. Code Tracing Tutor – Test Group

Table V lists the responses to self-efficacy statements for all those who had used the tutor (Set A) in the test group of code-tracing tutor.

TABLE V. CODE-TRACING TUTOR – TEST RESPONSES

Group	N	Mean	Std. Dev
Comprehension (1-3)	593	1.920	.943
Application (4)	593	1.87	.978
Analysis (5)	598	2.06	1.015
Synthesis (6-7)	593	2.127	1.028

Table VI lists the results of the 6 pair-wise comparisons of the responses to the self-efficacy statements along Bloom's taxonomic levels.

TABLE VI. CODE-TRACING TUTOR – TEST RESPONSES

Pair	Corr.	Mean	t-value	Sig.
Compr. – Appln.	.922	.051	3.300	.001
Compr. - Analysis	.875	-.143	-7.087	.000
Appln. - Analysis	.811	-.193	-7.645	.000
Appln. - Synthesis	.765	-.259	-9.149	.000

Pair	Corr.	Mean	t-value	Sig.
Analysis - Synthesis	.890	-.069	-3.485	.001
Comp. - Synthesis	.840	-.210	-9.098	.000

Tables V and VI confirm the results obtained earlier for the control group - student response was the most positive on statement 4 (application), the statement directly relevant to the topic of code-tracing tutor, and it was statistically different from those on other levels of Bloom's taxonomy. Again, *the self-reported improvement in self-efficacy after using the software tutor was statistically significantly greater on the taxonomic level directly relevant to the topic of the tutor than any other level.* The same results were also obtained for the students who needed the tutor (Subset N) and those who learned from using the tutor (Subset L).

Finally, the 2 X 2 ANOVA analysis of self-efficacy responses with sex and race as fixed factors did not yield any significant difference between the responses of the sexes or the racial groups.

C. Debugging Tutor – Control Group

Table VII lists the responses to self-efficacy statements for all those who had **learned** using the tutor (Subset L) in the control group of debugging tutor.

TABLE VII. DEBUGGING TUTOR – CONTROL RESPONSES

Group	N	Mean	Std. Dev
Comprehension (1-3)	285	2.172	1.025
Application (4)	285	2.22	1.071
Analysis (5)	288	2.17	1.049
Synthesis (6-7)	285	2.284	1.103

Table VIII lists results of the 6 pair-wise comparisons of the responses to the self-efficacy statements along Bloom's taxonomic levels for all those who had learned using the tutor (Subset L).

TABLE VIII. DEBUGGING TUTOR – CONTROL RESPONSES

Pair	Corr.	Mean	t-value	Sig.
Compr. – Appln.	.932	-.053	-2.289	.023
Compr. – Analysis	.920	.008	.329	.742
Appln. – Analysis	.901	.063	2.266	.024
Appln. – Synthesis	.902	-.06	-2.089	.038
Analysis – Synthesis	.856	-.109	-3.196	.002
Comp. – Synthesis	.877	-.101	-3.229	.001

From Tables VII and VIII, it is clear that the student response was the most positive on statement 5 (analysis) and statements 1-3 (comprehension). Statement 5 (analysis) is the statement directly relevant to the topic of debugging tutor. Their response on this statement was statistically different from those on all other levels of Bloom's taxonomy except

comprehension. So, *the self-reported improvement in self-efficacy after using the software tutor was statistically significantly greater on the taxonomic level directly relevant to the topic of the tutor than all other levels except comprehension.*

However, these results were obtained for students who learned from using the tutor (Subset L). Among all those who used the tutor (Set A) or those who needed to use the tutor (Subset N), no significant difference was observed between analysis (5) and application (4). So, we qualify the above results as *applying at least to those who actually learned using the tutor* (Subset L), which is a proper subset of those who used the tutor (Set A) and those who needed to use the tutor (Subset N).

The 2 X 2 ANOVA analysis of self-efficacy responses with sex and race as fixed factors did not yield any significant difference between the responses of the sexes or the racial groups for any of the sets (A, L or N).

D. Debugging Tutor – Test Group

Table IX lists the responses to self-efficacy statements for all those who had **learned** using the tutor (Subset L) in the test group of debugging tutor.

TABLE IX. DEBUGGING TUTOR – TEST RESPONSES

Group	N	Mean	Std. Dev
Comprehension (1-3)	97	2.179	.978
Application (4)	97	2.18	1.00
Analysis (5)	97	2.19	1.014
Synthesis (6-7)	97	2.273	1.00

Table X lists results of the 6 pair-wise comparisons of the responses to the self-efficacy statements along Bloom's taxonomic levels for all those who had learned using the tutor (Subset L).

TABLE X. DEBUGGING TUTOR – TEST RESPONSES

Pair	Corr.	Mean	t-value	Sig.
Compr. - Appln.	.948	.004	.107	.915
Compr. - Analysis	.898	-.007	-.148	.882
Appln. - Analysis	.892	-.01	-.217	.829
Appln. - Synthesis	.884	-.098	-2.00	.048
Analysis - Synthesis	.884	-.088	-1.782	.078
Comp. - Synthesis	.908	-.094	-2.195	.031

No significant difference was found among comprehension, application and analysis statements in Tables IX and X, although analysis (5) was the taxonomic level directly relevant to the topic of the tutor. Even the difference observed between synthesis and the other levels in Table X for those who learned using the tutor (Subset L) was not observed for those who used the tutor (Set A) or those who

needed to use the tutor (Subset N). In light of these results, we qualify the earlier results as *observable provided a significant difference is found among taxonomic levels of self-efficacy.*

On the 2 X 2 ANOVA analysis of the responses for statement 5 for the students who learned from using the tutor (Subset L), we found:

- Significant main effect for race [$F(1,81) = 4.931$, $p = .029$]: Caucasians and Asians agreed with the statement ($2.00 \pm .278$, $N=58$) more than students from underrepresented groups ($2.559 \pm .416$, $N=24$)
- Marginally significant main effect for sex [$F(1,81) = 3.073$, $p = .084$]: male students agreed with the statement ($2.059 \pm .266$, $N=60$) more than female students ($2.50 \pm .425$, $N=22$)
- Marginally significant interaction between sex and race [$F(1,81) = 3.073$, $p = .084$]: whereas Caucasians and Asians agreed with the statement the same whether male ($2.00 \pm .283$, $N=43$) or female ($2.00 \pm .479$, $N=15$), underrepresented male students agreed with it ($2.118 \pm .45$, $N=17$) more than underrepresented female students ($3.00 \pm .701$, $N=7$).

The above differences in self-efficacy were found even though no significant differences were found on:

- Prior preparation, i.e., average score per problem on the pre-test between the sexes [$F(1,82) = 1.22$, $p = .273$] or the racial groups [$F(1,82) = .188$, $p = .666$]
- Concepts learned, between the sexes [$F(1,82) = .012$, $p = .911$] or the racial groups [$F(1,82) = .00$, $p = .999$]

However, the differences between the sexes and racial groups on self-efficacy were not found for the other two sets – those who used the tutor (Set A) and those who needed the tutor (Subset N). They were not observed in any of the other conditions either: control group of debugging tutor, or control or test group of code-tracing tutor. So, *while there may be differences in the improvement of self-efficacy of sexes and racial groups resulting from the use of software tutors*, additional data collection and analysis is needed to confirm or refute it, and if confirmed, identify the conditions under which such differences manifest.

IV. DISCUSSION

We found that the improvement in self-efficacy after using the software tutor was statistically significantly greater on the taxonomic level directly relevant to the topic of the tutor than all other levels of Bloom's taxonomy except comprehension. That we found this result in three out of four cases adds credence to the result. However, we found that the correlation between the number of concepts learned and the response to the self-efficacy statement directly relevant to the taxonomic level of the software tutor was minimal in all four cases (e.g., .06). In other words, those who learned more concepts did not necessarily agree more with the statement about improved self-efficacy. This lack of correlation is to be expected, since, testimonials can mislead [10].

In three out of the four cases, the improvement in self-efficacy resulting from the use of the software tutor was indistinguishable across sexes and racial groups. Higher level of self-efficacy has been shown to result in higher performance accomplishments [11]. Given the significant underrepresentation of female and minority students in Computer Science, using software tutors to improve their self-efficacy has the potential to broaden their participation.

In the current study, students had to fill out the self-efficacy survey after having spent 30 minutes solving problems with the software tutor. Filling out the survey was optional, and contained eight statements. Cynicism would dictate that students would skip the self-efficacy survey altogether or fill it out perfunctorily, with the same score on all eight statements. The results of this study are all the more remarkable given these adverse conditions.

Whereas self-efficacy instruments have been created and validated on computing [12], programming [13], introductory courses [14], etc., the focus of this study was a small subset of programming, viz., functions. So, a self-efficacy survey was custom-created for the study, as recommended in literature [15]. Many of the principles for creation and administration of self-efficacy surveys listed in literature [15] were followed: survey items were phrased in terms of “can do” rather than “will do”; the survey was multi-faceted – the items were based on analysis of the programming domain along Blooms’ levels of taxonomy; students were instructed to judge their capabilities *after using the tutor*, and not their potential or future capabilities; and a nondescript title of “Feedback” was used for the survey rather than “Self-Efficacy”. However, the 5-point Likert scale used in this study is considered less sensitive and reliable – scales with 10 intervals or even 100 possible responses are recommended [16]. That statistically significant results were found even with the less sensitive 5-point scale makes the results all the more significant. However, the survey instrument has not been empirically validated, which is a confounding factor of this study.

We plan to repeat the study using data collected with some of the other tutors, including those on expression evaluation and advanced loop concepts, to see if we can replicate the results.

Abstract—The complex and multidisciplinary nature of today's engineering problems demands that new graduates excel in not only technical knowledge but also teamwork skills. In fact, the lack of effective teamwork has been identified among the most important factors contributing to the high failure rate of complex engineering projects. In this paper, we focus on engineering students' attitudes toward teamwork, their self-efficacy and interest in teamwork knowledge, skills, and abilities. Self-efficacy in a domain is an important construct that can predict whether or not someone is willing to undertake a challenge in that domain. Research suggests that the sufficient level of self-efficacy can encourage personal growth and skill development. The relevant research also points out that interest is a construct that can predict students' professional development in a domain. For example, as someone becomes an expert in a domain, his/her interest in the domain becomes individual, which means there is a long-term personal connection resulting in further exploration of the domain. In this paper, we postulate that the development of students in teamwork knowledge, skills and abilities can be tracked by the progress in their teamwork interest. In addition, we argue that interest development should be measured as a part of the assessment efforts to evaluate the professional skills development of students. We have developed and validated an instrument to measure teamwork efficacy and interest. The instrument was used to collect data in a geographically distributed university. The collected data were analyzed to identify the factors affecting students' attitudes toward interest and self-efficacy in teamwork as well as their relationships. The preliminary results indicated that students had a high level of self-efficacy and a low level of interest, which makes it challenging to improve students' teamwork skills.

I. INTRODUCTION

Today's engineering challenges require a large variety of knowledge and skills from multiple disciplines, including non-engineering ones. Therefore, having effective teamwork skills in engineering contexts is important. Multi-disciplinary teams bring together a pool of talents, experiences, and knowledge base, which cannot be embodied in an individual. However, the multi-disciplinary nature of a team does not guarantee successful team performance. The research shows that the success of a team depends on how effectively team members are able to share information, assign tasks based on the strengths of team members, coordinate tasks, and provide feedback to one another [1]. It is essential that engineering graduates have teamwork Knowledge, Skills, and Abilities (KSA) to function effectively in teams. Engineering programs

have responded to this need by incorporating teamwork into all levels of academic curricula. However, the absence of robust assessment frameworks constrains the effectiveness of such efforts.

Previously, we have proposed an assessment framework based on the Model of Domain Learning (MDL) [2] for the assessment of professional skills [3], [4]. In this framework, student development is measured in three dimensions- knowledge, strategic processing, and interest. Within the MDL, three experience-based stages occur (i.e., acclimation, competency and proficiency), which are progressive and incremental. In this paper, our primary objective is to evaluate the feasibility and reliability of using interest as an additional construct to track student development in teamwork KSA. We introduce several questionnaire items to measure students' interest in teamwork. These questionnaire items can also be used in a broader instrument for assessing teamwork KSA.

The MDL considers two types of interest: individual and situational. Situational interest is the temporary interest that arises spontaneously due to external factors such as a new topic or an engaging text. On the other hand, individual interest is the long lasting interest that motivates students to gain deeper knowledge in a domain. Individual interest is an indicator of how much students are willing to immerse themselves into a domain. According to the MDL, an increased individual interest in a domain is a result of higher knowledge and strategic processing abilities in that domain. As one moves from the Acclimation to Proficiency stage in a domain, his/her interest changes as described in Table I. Individual interest is also a precursor for sustaining long-term learning [5]. Therefore, evaluating students' individual interest is especially critical for professional skills assessment, where sustainable, long-term learning is paramount.

II. AN EMPIRICAL STUDY

A. Data Collection Instrument

An online survey was designed to measure students' self-reported teamwork self-efficacy, attitudes, and interest. The survey was emailed to engineering students at a university with multiple campuses in the Northeast United States. It should be noted that the survey did not emphasize a specific engineering course or a class level, and it was available for any engineering student to take, regardless of their class standing

TABLE I. PROGRESS OF INTEREST FROM ACCLIMATION TO PROFECIENCY

Acclimation	Competency	Proficiency
Situational interest: Spontaneous, transitory, and environmentally activated interest	Increased individual interest due to increased engagement in a domain	Individual interest: long-term, deepening, personal connection to a domain, which in turn inspires further exploration of the domain

or the course content. Therefore, the survey measured only students' self-reported perceptions about their teamwork self-efficacy, attitudes, and interest.

To measure students' interest levels in developing their teamwork KSA, students were asked to rate their interest in performing several professional activities. After a preliminary analysis, the average rating of the following three questions (Cronbach's $\alpha = 0.738$) were used to measure interest:

- IQ1-Attending a free workshop on teamwork.
- IQ2-Reading literature about effective teamwork.
- IQ3-While you are browsing a news web site, you have spotted an article called "How to be Effective in Teamwork." Rate your likelihood of reading this article?

In addition, the following two questions were used to measure individual level interest since they demand more personal commitment than the previous questions.

- IQ4-Rate your level of willingness to take an elective course in order to improve your teamwork skills?
- IQ5-In your institution, a renowned teamwork guru will give a workshop on teamwork skills. If you have to pay \$10 for this workshop, rate your level of interest in attending this workshop.

The interest questions were operationalized using a four-point Likert scale ranging from (1)-Very Uninterested to (4)-Very Interested.

Twenty-five teamwork self-efficacy questions were developed based on the KSA areas described by Stevens and Campion [6]. The questions were grouped as follows (the number of questions in each KSA area is provided in parenthesis): Goal Setting (2), Performance Evaluation (3), Team Forming (5), Team Coordination (1), Communication (7), Conflict Resolution (4), and Problem Solving (3). These questions were operationalized with a four-point Likert scale, ranging from (1)-Very Unconfident to (4)-Very Confident. These questions are available upon request.

Attitudes toward teamwork can be defined as how agreeable a person is to work in any team [7]. To measure the overall attitude toward teamwork, the following four questions given in [8] were used (Cronbach's $\alpha = 0.73$):

- I usually have a negative experience with teamwork (reverse coded)
- I would rather work on team projects than on my own

- I like to participate in teamwork
- I am usually motivated to participate in teamwork

The attitude questions were also operationalized with a four-point Likert scale, ranging from (1)-Strongly Disagree to (4)-Strongly Agree.

B. Analysis of the Results

We coded student responses to the background questions into the binary independent variables as given in Table II to investigate the effect of student background and experiences on interest, self-efficacy, and attitude.

TABLE II. CODING OF STUDENT BACKGROUND AND EXPERIENCES INTO THE INDEPENDENT VARIABLES (NUMBER OF SAMPLES)

Independent Variable	Value	
	0	1
Class Standing	Year 1 and 2 (317)	Year 3 and 4 (242)
GPA	<3.5 (319)	\geq (236)
Teamwork Training or Course	None or single (416)	Two or more times (123)
Gender	Male (391)	Female (169)
Work Experience	No (127)	Yes (433)

We calculated Cohen's d values to measure the effect size of the independent variables on the dependent variables. In addition, we performed *t*-tests to evaluate whether the means of the dependent variables were different or not across the two levels of the independent variables. Table III presents the calculated effect sizes. In the table, statistically significant mean differences are indicated by * for *p*-value < 0.05 and ** for *p*-value < 0.01.

We did not observe any positive effect of class standing on the self-efficacy independent variables. Surprisingly, the first and second year students rated their self-efficacy as high as the third and fourth year students did. The negative effects of the GPA group on self-efficacy and teamwork attitude were unexpected. The GPA did not also have any positive effect on interest. The previous teamwork training had a small positive effect on self-efficacy and a small-to-medium positive effect on interest. In order words, students who have already gone through some types of teamwork training were more willing to invest further time and resources for advancing their teamwork KSA than the students who have not.

The dependent variables previous work experience, teamwork training, and class standing had a positive and statistically significant effect on the teamwork attitude dependent variable. In particular, the previous work experience variable had the highest effect size. This observation may imply when students are engaged in a large scope project, that draws skills and knowledge from multiple disciplines, they start appreciating the value of teamwork. At the university setting where the data were collected, the first year engineering curriculum features engineering design learning facilitated through a series of team-based projects supplemented by brief guidance on teamwork. However, these experiences do not represent the rigors of real-life engineering projects yet. Upon declaring the major at the end of the second year, as part of their studies in the third and fourth year of their curricula, students are frequently put in teamwork situations in an effort to prepare them for the actual work settings. Students are also expected

TABLE III. CALCULATED EFFECT SIZES

Dependent Variable	Effect Size (Cohen's d)				
	Class Standing	GPA	Training	Gender	Work Experience
Goal Setting	0.04	-0.06	0.23*	0.14	0.38**
Performance Evaluation	0.09	-0.04	0.17	0.05	0.26**
Team Forming	-0.07	-0.17*	0.13	0.24	0.26*
Team Coordination	-0.09	-0.03	0.07	0.15	0.32**
Communication	0.07	-0.30**	0.25*	0.06	0.32**
Conflict Resolution	-0.11	-0.22*	0.17	-0.08	0.29**
Problem Solving	-0.02	-0.13	0.19	-0.05	0.38**
Attitude	0.30**	-0.52**	0.23*	-0.12	0.37**
Interest (IQ1, IQ2, IQ3)	0.25**	0.10	0.43**	0.23	0.14
IQ4	0.02	-0.01	0.25*	0.16*	0.01
IQ5	0.04	-0.13	0.31**	0.25	0.07

to complete an internship where most of students are involved in teamwork in the context of real-life engineering projects for the first time. Specifically, capstone design experience in their last year is meant to simulate the complexity of the work setting in the rigor level of the project as well as the timeline and professionalism expected in terms of results and conduct. Frequently, students work towards a working prototype or research result sponsored by an industrial company and in doing so they hold regular meetings with company liaisons.

The most significant factor for the self-efficacy dependent variable was the previous work experience that involved teamwork. In summary, the relationships between the other independent variables and self-efficacy were not as anticipated. One of the reasons for this result is that students rated their self-efficacy very close to the level of very confident. Although the first and second year students rated their self-efficacy very high, they had relatively low teamwork attitude. This contradiction also casts a doubt on the validity of using self-reported efficacy as a construct to measure teamwork KSA. Therefore, we postulate that self-efficacy may not be a reliable construct to assess students' development in teamwork KSA based on the results observed in this research.

On the contrary, the relationships between the independent variables and the interest dependent variables conformed to the MDL. As per the MDL, an increased learning in a domain should lead to higher levels of interest in the domain. The class standing and teamwork training had a significant positive effect on interest. This result is particularly important for the feasibility of using the MDL as an assessment framework for professional skills because it shows that the changes in interest can be tracked during students' educational journey. In this paper, we did not observe a high level of individual interest development in the third and fourth year students. This observation is similar to our previous findings [4].

III. CONCLUSIONS

Teamwork self-efficacy was not found to be impacted by any of the academic background variables considered in this research. In terms of interest, we observed a growth from situational to individual interest throughout the engineering students' educational journey, which supported the MDL. In this research, interest was shown to have a stronger relationship with previous teamwork training and class standing than self-efficacy had with those variables. Therefore, we recommend interest as an additional construct to assess students' teamwork

KSA. In future work, we will survey the literature further about student reported self-efficacies and gauge other fields in the STEM disciplines, according to teamwork self-efficacy, interest, and attitudes. In addition, the collected data will be analyzed in multiple dimensions to verify the primary findings in this paper. To apply our findings from our team survey in engineering courses, professors could institute more relatable, intriguing group assignments and emphasize the importance of teamwork in the engineering discipline, so students will make an effort to be more interested and have a positive attitude toward teamwork.

Engineering Self-Efficacy, Interactions with Faculty, and Other Forms of Capital for Underrepresented Engineering Students

Sandra L. Dika, Miguel A. Pando, Brett Q. Tempest, Krystal A. Foxx, & Monica E. Allen

Departments of Educational Leadership and Civil & Environmental Engineering

University of North Carolina at Charlotte

Charlotte, USA

sdika@uncc.edu

Abstract— To address the chronic issues of underrepresentation in engineering education, a small but growing body of research has examined social and cultural explanations for engineering persistence among women, racial/ethnic minorities, first-generation college students, and other underrepresented groups. In this exploratory study, we examine the extent to which relationships with engineering faculty and other forms of engineering-related capital (e.g., aspirational, navigational) are related to engineering self-efficacy among underrepresented engineering students. The findings of the study have implications for future research and practice to increase access to engineering education and persistence of underrepresented students in engineering.

Keywords—underrepresented students; student-faculty interaction; self-efficacy; engineering education

I. INTRODUCTION

The participation of women and underrepresented minorities in engineering has been “disturbingly slow” [1]. To address the chronic issues of underrepresentation in engineering education, a small but growing body of research has attempted to move away from a deficit perspective and has examined social and cultural explanations for engineering persistence among women, racial/ethnic minorities, first-generation college students, and other underrepresented groups. Frameworks emphasizing social and cultural capital; as well as the unique forms of capital possessed by students from marginalized groups (e.g., cultural wealth); offer alternate perspectives to focus on how underrepresented students navigate and persist in engineering.

As part of a federally funded project on the role of student-faculty interaction for the persistence of underrepresented racial/ethnic minority (URM) students in engineering, we have gathered qualitative and quantitative data from undergraduate engineering students. For the study reported herein, we focus specifically on an analysis of questionnaire data from junior and senior engineering students from underrepresented groups to understand how perceived relationships with faculty and other forms of capital are related to engineering self-efficacy.

This study was conducted as part of National Science Foundation Grant 1240299 from the Research Initiation Grant in Engineering Education (RIGEE) Program. The opinions presented herein are those of the authors and not the funding agency.

II. PARTICIPATION AND PERSISTENCE IN ENGINEERING FOR UNDERREPRESENTED STUDENTS

Differing participation and persistence in engineering has been investigated using theoretical frameworks from higher education [2,3], sociology [4,5,6], and psychology [7]. The importance of interactions, resources, and supports is prominent across these theories, as precursors to beliefs about one’s abilities and identity that support academic effort, performance, and career persistence. Research and theory on interactions with faculty, other sources of capital (i.e., cultural wealth), and self-efficacy, particularly for underrepresented students in engineering, frames this study.

A. Interactions with Faculty

Predominant frameworks of participation and persistence in higher education emphasize the role of student interaction with faculty [2,3]. Social capital frameworks offer another way to understand how and why interaction with faculty is important for persistence of students in STEM, through defining ties to institutional agents (faculty, staff, administrators) as links to important information needed to navigate and succeed in the college environment [8-12]. Student-faculty interactions (SFI) are vital to the success of all engineering students, but especially underrepresented racial/ethnic minority groups (URM). Research over the past 15 years has evidenced the relationship of SFI with academic performance, persistence, and academic and personal growth for URM students in STEM disciplines, including engineering.

1) *Academic performance*: Underrepresented students of color (i.e., Black, Latino, Native American) in STEM disciplines benefit greatly from faculty-student interactions. Frequent interactions with faculty and support from contact with faculty are linked with higher grades [13,14]. Additionally, faculty mentorship may lead to higher academic performance even if students had low testing performance prior to college [15]. The nature of interaction with faculty may also be important. While interactions related to course materials may not relate to higher GPA [14], conducting research with faculty members is associated with improvements in academic performance [16,17]. Faculty-student interactions are generally beneficial to URM students

especially when conducting research with faculty or receiving mentorship from faculty, however some literature suggests that receiving criticism from faculty or interacting with faculty to discuss course materials did not suggest that students would increase their GPAs.

2) *Persistence*: The academic persistence of engineering students is higher than students in other majors [18] yet research unfailingly reveals that Black and Latino engineering students are underrepresented and have lower persistence rates than their White peers. Additionally, the literature has found that Black and Latino students may resist initiating contact with predominantly White faculty out of fear of being stereotyped or negatively perceived by faculty and prefer same-race faculty mentors [19,20,21]. Conversely, one study found that interactions with faculty and peers outside of one's ethnicity were beneficial and increased underrepresented students' confidence [22]. Overall, engineering students' interactions with faculty are vital for retention and persistence [24,25,26] and are especially critical for Black and Latino students in ensuring their academic success [8,14,26,27].

3) *Intellectual & Personal Growth*: There are several benefits of faculty-student interactions for URM students in engineering including increased development in intellectual and personal growth while at higher education institutions. Students' interactions with faculty can provide high levels of satisfaction in intellectual ability, problem solving, career development, and scientific reasoning [28,29]. However, problem solving and intellectual growth are especially increased for students of color [28]. More frequent contact with faculty has also been linked to self-efficacy among engineering students [23,25].

URM engineering students' interactions with faculty members are important for developing intellectual thinking and growth because more exposure to knowledge and resources build students' abilities to perform tasks in and out of the classroom. Personal and intellectual growth for Black and Latino students in engineering increases when interacting with faculty because students are able to critically think when engaged with various research and engineering-related projects (as assigned by faculty) and gain more exposure and knowledge than they previously had. However, research shows that URM engineering and STEM students may have frequent interactions with faculty, but feel less satisfied with those interactions since they are less meaningful and are less likely to engage in undergraduate research with faculty members [21,26,30].

B. Cultural Wealth as Capital for Engineering

Traditional social and cultural capital theories [4,5] emphasize how the values and practices of dominant groups are rewarded in education. The notion of community cultural wealth (CCW) [31] was developed to show how communities of color and other non-dominant groups create wealth that is valuable for persisting in education. Six forms of CCW are proposed as part of this framework:

1) *Aspirational capital*: The ability to maintain hopes and dreams for the future, considering real and perceived barriers.

2) *Linguistic capital*: The ability to switch communication styles or languages based on environment (e.g., academic and nonacademic).

3) *Familial capital*: Knowledge gained from, and maintenance of a connection to the home community and culture.

4) *Social capital*: Networks of people and resources that provide instrumental and emotional support to navigate through institutions.

5) *Navigational capital*: Skills of navigating through social institutions that are designed for dominant social and cultural groups.

6) *Resistant capital*: Knowledge and skills developed through oppositional behavior that challenges inequality.

The notion of CCW as an alternative framework to understand the success of URM and other underrepresented groups (e.g., first-generation and students from low-income families) in engineering has yet to be explored in-depth. A recent dissertation study demonstrates this promise and reveals how Black and Latino engineering students are empowered by different forms of capital related to their background, culture, and experiences [32].

C. Engineering Self-Efficacy

Previous research on the role of self-efficacy beliefs in engineering support the notion that they are strong predictors of academic achievement and engineering interest [33,34]. Self-efficacy figures prominently in Social-Cognitive Career Theory (SCCT) [7] to explain achievement and career-related choices. The authors of the theory suggest that contextual factors are particularly influential for underrepresented groups, and have successfully employed the theory to understand engineering interest and goals [35,36,37], adjustment [38], satisfaction [39], and persistence [40] among college engineering students. Other researchers have employed the framework to understand persistence of ethnic minority women in engineering [41,42].

Marra and colleagues [43] developed the Longitudinal Assessment of Engineering Self-Efficacy (LAESE) to measure self-efficacy, feelings of inclusion, and outcome expectations of women studying engineering. This instrument was further revised by Concannon and Barrow [44] to include four subscales—engineering self-efficacy I and II (ESE I and II), coping self-efficacy (CSE), and engineering career outcome expectations (ECOE). In subsequent research, these authors found effects of gender for CSE (women lower than men) and ECOE (women higher than men) [45]. While researchers considered ethnicity and transfer status in this previous work, relationships with engineering faculty and other forms of capital that influence self-efficacy and outcome expectations were not explored.

III. METHODOLOGY

A. Design

This exploratory correlational study examines the relationship of interactions with faculty and other forms of capital with engineering self-efficacy among underrepresented engineering persisters (junior and senior class level) using data obtained from an online questionnaire administered at an urban research institution in the Southeastern United States. The study reported is part of a larger, mixed-methods project on the role of student-faculty interaction in the persistence of underrepresented students in engineering.

B. Instrumentation

The first 4 authors developed an online questionnaire as part of the larger project including support and interactions prior to enrolling in engineering (7 items), frequency of out-of-class interactions with faculty (4 items), assessment of quality of relationships with faculty, students, and staff (6 items), barriers experienced during studies (7 items), engineering self-efficacy (18 items), and cultural wealth (9 items). The focus in this study is on perceived quality of interactions with faculty, cultural wealth, and engineering self-efficacy.

1) *Perceived quality of interactions with faculty:* Students indicated extent of agreement with the statement “I have a positive and supportive relationship with College of Engineering faculty” on a 5-point scale from 1=strongly disagree to 5=strongly agree ($M=4.24$, $SD=0.82$).

2) *Cultural wealth:* While research to study the concept of cultural wealth has generally utilized qualitative methods, we developed nine items for our questionnaire to explore whether and how the different forms of capital could be assessed quantitatively. Social capital was divided into 4 items to assess different networks and resources (peers, faculty/staff, campus organizations, off-campus organizations). The wording of the statements was developed using the descriptions in reference [31], and students indicated a level of agreement with each statement from 1=strongly disagree to 5=strongly agree. The wording of each item, along with descriptive statistics, is shown in the findings in Table 2. Participants expressed high agreement with ability to maintain hopes and dreams for the future ($M=4.41$, $SD=0.73$) and having the ability to switch communication styles or language ($M=4.38$, $SD=0.83$), and least agreement with drawing on connections with off-campus community organizations to be successful ($M=3.37$, $SD=1.13$).

3) *Engineering self-efficacy:* Seventeen items related to engineering self-efficacy [44,45] were included on the questionnaire used for this study (see Table I). Items were rated on a 7-point scale from 1=strongly disagree to 7=strongly agree, as in the original instrument. Three items related to course taking were not included on our questionnaire because they do not apply to students in junior or senior year of studies. Exploratory factor analysis to identify factors among these 17 items supported a three-factor model – engineering self-efficacy (ESE, 5 items), engineering career outcome expectation (ECOE, 7 items), and coping self-efficacy (CSE, 5 items). While previous studies differentiated

between two engineering self-efficacy subscales (four subscales total), the factor analysis did not support separation of these items given the exclusion of the three coursetaking items. The internal consistency estimates are similar to those reported in previous studies, however CSE is lower.

C. Participants

“Underrepresented student” for this study was defined as a student who identified as a student of color (African American, Hispanic/Latino, Asian American) or a first-generation college student (neither parent completed a four-year degree). Of 90 total participants in the online questionnaire, 50 met this definition of underrepresented student. Nearly a third of the students in the underrepresented sample (30%) identified as both student of color and first-generation college student. Among the students of color (50%), the majority identified as Asian-American (30%), while African-American and Hispanic/Latino students each made up 10% of the sample. The majority of this sample (80%) indicated that neither parent had earned a four-year degree. The participants were roughly split between junior (46%) and senior (54%) class level, while the majority indicated they had transferred to the institution (62%). Women were highly overrepresented in this sample (34%) based on their proportion in the undergraduate engineering student population at the institution (9%).

TABLE I. ENGINEERING SELF-EFFICACY SUBSCALES

Scale	Item	Mean (SD)
ESE $\alpha=0.77$	I can succeed in an engineering curriculum.	6.26 (0.90)
	I can succeed in an engineering curriculum while not having to give up participation in outside interests.	4.90 (1.88)
	I can excel in an engineering major during the current academic year.	5.96 (1.32)
	I can complete any engineering degree at this institution.	5.54 (1.42)
	I can succeed (earn an A or B) in an advanced engineering course.	5.50 (1.49)
ECOE $\alpha=0.82$	Someone like me can succeed in an engineering career.	6.32 (0.94)
	A degree in engineering will allow me to obtain a well-paying job.	6.48 (0.68)
	I expect to be treated fairly on the job; that is, I expect to be given the same opportunities for pay raises and promotions as my fellow workers if I enter engineering.	6.40 (0.76)
	A degree in engineering will give me the kind of lifestyle I want.	6.24 (0.85)
	I expect to feel "part of the group" on my job if I enter engineering.	6.08 (1.12)
	A degree in engineering will allow me to obtain a job that I like.	6.27 (0.76)
	A degree in engineering will allow me to get a job where I can use my talents and creativity.	6.29 (0.74)
CSE $\alpha=0.55$	I can cope with not doing well on a test.	4.70 (1.85)
	I can make friends with people from different backgrounds and/or values.	6.46 (0.68)
	I can cope with friends' disapproval of chosen major.	6.16 (1.04)
	I can approach a faculty or staff member to get assistance.	5.88 (1.19)
	I can adjust to a new campus environment.	6.16 (0.91)

D. Analysis

Data collection is ongoing for the larger project at the time of submission, thus, we utilize bivariate correlation in the study reported here to investigate relationships between the variables of interest and prepare for further analysis once data collection is complete. We utilize only the data collected in Spring 2014, and will utilize the data collected in Spring 2015 (ongoing) for future analyses.

IV. FINDINGS

To examine the relationships between sources of capital for students (quality of interactions with faculty, cultural wealth) with engineering self-efficacy, we calculated bivariate correlations, which are reported in Table II. All of the sources of capital were positively related with engineering self-efficacy variables, and all but four correlations were statistically significant at the $\alpha=.05$ level.

A. Relationship of Capital to Engineering Self-Efficacy

Quality of interactions with faculty and most of the cultural wealth variables were significantly related to ESE. Only social capital associated with off-campus organizations and resistant capital did not reach statistical significance. Aspirational capital (maintaining hopes and dreams; $r=.563$), familial capital (maintaining connections to home culture, $r=.559$), social capital associated with faculty and staff ($r=.474$), and navigational capital ($r=.461$) showed the strongest associations with general engineering self-efficacy.

B. Relationship of Capital to Engineering Career Outcome Expectations

Quality of interactions with faculty and social capital associated with off-campus connections were not significantly related to ECOE. The strongest relationships were between ECOE and aspirational capital ($r=.631$), social capital associated with faculty/staff ($r=.529$), familial capital ($r=.522$), and social capital associated with peers ($r=.512$).

C. Relationship of Capital to Coping Self-Efficacy

All of the capital variables were significantly related to CSE. Social capital related to faculty/staff showed the strongest relationship ($r=.600$), followed by aspirational capital ($r=.462$), navigational capital ($r=.461$), social capital associated with peers ($r=.416$), and linguistic capital ($r=.415$).

V. DISCUSSION AND IMPLICATIONS

The descriptive results of this exploratory study suggest that beliefs about engineering ability and career outcome expectations are positively related to perceived sources of capital among underrepresented engineering students. Perceived positive and supportive relationships with faculty were positively related to engineering self-efficacy, but not as strongly as certain forms of cultural wealth.

TABLE II. CORRELATIONS OF FORMS OF CAPITAL WITH ENGINEERING SELF-EFFICACY

Forms of Capital	Mean (SD)	ESE	ECOE	CSE
Relationships with faculty: Positive and supportive relationship with College of Engineering faculty	4.24 (0.82)	.401**	.278	.371*
Aspirational capital: I can maintain my hopes and dreams for the future, even when confronted with barriers.	4.41 (0.73)	.563**	.631**	.462**
Linguistic capital: I have the ability to switch communication styles or languages based on environment (academic and non-academic).	4.38 (0.83)	.292*	.406**	.415**
Familial capital: I maintain a connection to my home community and culture.	4.06 (1.18)	.559**	.522**	.404**
Social capital – peers: I draw on connections with peers to be successful in college. (social-peers)	4.18 (1.02)	.399**	.512**	.416**
Social capital – faculty/staff: I draw on connections with individual faculty and staff members to be successful in college.	3.94 (1.10)	.474**	.529**	.600**
Social capital – on-campus: I draw on connections with campus organizations or offices to be successful in college.	3.64 (1.17)	.303*	.352*	.337*
Social capital – off-campus: I draw on connections with off-campus community organizations or agencies to be successful in college.	3.37 (1.13)	.223	.192	.352*
Navigational capital: I have developed strategies to navigate difficult people and situations at the university.	4.10 (0.86)	.461**	.333*	.461**
Resistant capital: I challenge university practices that seem inequitable.	3.66 (1.04)	.215	.343*	.318*

* $p<.05$, ** $p<.01$

Three forms of cultural wealth stand out in our analysis, and may be particularly important for students who are the first in their families to complete a college degree, or who come from marginalized communities of color. Students who maintain their hopes and dreams for the future despite real and perceived barriers (aspirational), remain connected to home culture and community (familial), and draw on connections with faculty and staff to succeed in college (social) enjoy more

positive beliefs about ability in engineering, expectations about career outcomes, and ability to cope in engineering studies. While previous research has considered first-generation college status as a negative factor for persistence in college [46], and has noted how URM students are less likely to persist in engineering [1], our findings in this study offer an alternative to a deficit perspective on underrepresented students. Further, these findings suggest that beliefs about engineering ability and future career success are linked to the use of connections with faculty and staff to succeed in engineering.

While the nature of the sample and design used in this study limit the generalizability of the findings, they suggest that our continued research should consider the role of cultural wealth in explaining engineering self-efficacy and persistence among underrepresented students.

ACKNOWLEDGMENT

The authors thank Dr. Patty Tolley for advice and feedback on survey design and assistance with recruitment of student participants.

Abstract—In order to perform well, an engineer has not only to solve a task but also cope with the environment. This is very important in military operations, where underperforming might have fatal consequences. As a military academy, we have developed ten coping strategies that we use to increase students' ability to perform in military situations. These strategies have been introduced in the education, but not yet scientifically evaluated. This year, inspired by Peter Shull's FIE Workshop 2014 [1], we focused on the strategies also in engineering subjects. The usage of the strategies in different situations was evaluated by short questionnaires. The results show that all strategies are actively used in military context, and that they are also applicable in engineering subjects, having a positive effect on performance. However, the substance of the strategies in an academic perspective was not as clear as it was in military. In order to benefit from the strategies in engineering subjects the substance of the strategies needs to be discussed with the students. We also found that, the "ability to control", alone had high influence to performance through military and engineering events indicating that this strategy might be the dominant strategy to achieve good performance.

I. INTRODUCTION

In the FIE Workshop 2014 Peter Shull asked how a teacher can influence students self-determination. He identified significant correlation between performance and self-determination through the practice of implementing a victim/engineer awareness-decision model [1]. We saw this model as a light version of a series of coping strategies that we introduced into a two-week long military exercise at the Norwegian Defence Cyber Academy (NDCA); designed to support second year students' ability to perform. The ten coping strategies are introduced in Section III.

The NDCA offers a four-year cyber officer education where students gain both an engineering Bachelors' degree in Information and Communications Technology (ICT) and officer training. The core of the cyber officer study, as defined in the NDCA study handbook [2], is a combination of technical training, leadership development, military skills and physical training. Military exercises are an integrated part of the educational platform at the NDCA. The exercises are designed to develop all these skill sets and empower students' learning and self-determination through the use of coping strategies.

Inspired by Peter Shull's victim/engineer awareness - decision model [3], we introduced the military based coping strategies to our second year students four months earlier

than in previous years. In addition to the military context, we focussed on their usage also in engineering context, such as mathematics, electronics, and programming. The purpose of transferring coping strategies was to connect engineering subjects more closely to military subjects and vice versa. This gave us an opportunity to identify which of the ten coping strategies are actually applied in military contexts and which in pure engineering contexts, if any, and how the usage of coping strategies influences students' performance. We were also interested to know if students used any other strategies. The usage of the strategies was evaluated by short questionnaires where students evaluated their own performance in specific military and engineering situations and selected the strategies they had actively used.

In this paper, we summarise the background information used when the ten coping strategies of NDCA were developed, and link them to the learning process in Section II. After that the coping strategies of NDCA are introduced in Section III. Section IV explains the empirical experiment, and results and discussions are shown in Section V. The conclusion of the paper is given in Section VI. Section VII briefly explains the next steps for ongoing study of the coping strategies in engineering education.

II. STATE OF ART

Acknowledged stressors such as workload, task management, context switching, time pressure, heat, cold, noise and fatigue are all present to us in our modern world [4]. A student, an employee, a leader, an officer or a soldier all experience different levels of physical and mental stress related to their work environment. There are large bodies of literature focusing directly on each of these variables individually, and describing their effects on performance [4]. Lazarus [5] [6] argued that stress consists of three processes. Primary appraisal is the process of perceiving a threat to oneself, secondary appraisal is the process of bringing to mind a potential response to the threat, and coping is the process of executing that response.

Research has been conducted regarding the use of coping strategies in military operations as well as how we face difficulties in normal working life; for example [5] [6] [7] [8] [9] [10]. Sørensen [7] describes the word "coping" as referring to the tricks that we think work at the given moment to maintain balance. Coping strategies can be understood as skills and abilities used to handle physical and mental stress. They

are often referred to as different techniques like visualization, meditation, breathing, self-hypnosis etc. [11]. The more overall general idea of coping strategies is *to believe in yourself and your ability to perform*.

Coping strategies can be viewed as a form of active components used to face threats or demanding situations that may increase the likelihood of mastery. Eid and Johnsen [12] describe three main directions of coping strategies: task-oriented coping, emotional-oriented coping and avoidant coping. The task-oriented coping style is characterized as an individual trying to grasp the problem and then to solve it. The emotional-oriented style will emphasize discussion and analysis of own feelings, without necessarily grasping the problem. The avoidant coping style will attempt to withdraw and avoid dealing with the problem [12]. However, individuals with avoidant coping styles are more prone to both chronic [8] [9] and traumatic stress disorders [12]. On the other hand, individuals who have an active attitude towards coping are less burned-out than others [13].

Research has shown that preferable responses to stress can be learned [11], and that the capability of coping and performing under higher stress levels can be trained [12]. Awareness, reflection, emotions, self-regulating, and social support play an important part in learning to cope with stress [10] [11]. To learn from experience and develop preferable and conscious automaticity of coping strategies, the understanding of the connection between your emotions, actions and the perceived consequences are crucial to capture [14]. Systematic reflection is an important tool to gain this insight and understand these connections in order to develop individual higher order cognitive skills [15] [16]. In addition, the learning can be strengthened by repetitive positive feedback, which in turn can raise individual self-efficacy [11].

Both coping and not coping create emotions that influence self-perception [11]. Baumgardner and Crothers [17] say that: "Many of our feelings about the past are related to our success or lack of success in accomplishing personally important goals" [17]. Which, in turn, has an impact on future actions and performance. They further point toward strong correlation between self-perception and processing of information, regulation of emotion and motivation. In addition, achieving important personal goals is associated with increased self-esteem [17].

Looking at the educational research, we find that self-efficacy - *an individual's belief about his capabilities to complete a task with certain performance levels* - is the most central concept in contemporary psychology research [18]. According to Bandura [19] mastery experiences, vicarious experiences and social persuasion contribute to self-efficacy. Self-efficacy contributes to learning as a higher level of self-efficacy raises the probability of using and combining knowledge in new ways [19] [20]. However, as highlighted by Judge et. al [18] high self-efficacy does not equal high performance levels due to strong individual differences. Regardless, self-efficacy contributes to performance, and performance prediction based on self-efficacy is more accurate in task-related situations. Self-efficacy is an important part of learning, but one needs to be realistic about own capabilities and behavior in order to perform well and achieve good grades in an academic sense. Studies [3] [21] [22] have pointed out a need to make students understand

connections between their own expectations, capabilities and behavior regarding learning process and performance. As well as teaching students how to perform better through changing behavior and improving their own capabilities. As it can be seen, belief in ones capabilities is not only an important part of coping, but also in learning. Therefore, the task and solution-oriented coping strategies (introduced in Section III) can be considered to be usable in an academic learning process as well.

III. TEN COPING STRATEGIES OF NDCA

The ten coping strategies came to life in the late winter of 2011, and were the result of a comprehensive and experienced-based discussion and planning process. By reflecting on personal experiences from different military operative contexts, the research and education section of the academy were able to identify factors that were decisive in supporting mastering the mental and physical stress presented by the external environment. Intuitively three decisive strategies for coping were identified. It was agreed - despite different operative experiences - that *accepting the situation* is crucial to release a persons potential to perform. Let us say that there is a 50% attack probability during the next patrol. In order to move on and cope with this situation, a soldier needs to accept this fact. By accepting the attack probability, the focus can then be placed on *being proactive* and preparing and building confidence by applying the *skills and knowledge* acquired through training. These three steps of coping evolved further into the following ten coping strategies, which are explained within a context of a patrol operation.

Situational Understanding: With situational understanding we mean a person's *ability to observe* (to gain a comprehensive overview and to see current problems) and *ability to consider* (to understand the task and possible further problems that might occur). A person should actively strive to provide an overview of the situation, to begin a mental process of managing change: plan, prioritize resources, consider time and evaluate external and internal factors that can shape performance [23]. Contemporary military patrol operations incorporate a complex network of various types of human capabilities integrated with multiple levels of technical sensors, giving measurable details from the "current picture". However, these details are not the only factors that should contribute to decision making. Factors such as social, historical, cultural, legal and geo-political aspects are required to be included.

Accept the situation: By situation acceptance we mean a person's *ability to accept the facts* (the operational environment and the available resources) and then mentally prepare to work purposefully within these conditions to achieve a goal. Schunk [24] states that interpretation - based on historical and current facts - and self-regulation based on the ability to modify and transfer knowledge, makes individuals more likely to accept situations that include risk and uncertainty. As in the case of military patrol operations.

Use of knowledge and tools: This is the *ability to keep track of own and others' resources and make use of them*. To use logical common sense, to make it easy, to not over analyze tasks, to use experience and to apply theoretical and practical knowledge. At all levels of a patrol operation, the

individuals are using their cognitive capacities to support accurate decision-making. They are applying knowledge and skills gained in training and from experience, implementing knowledge acquired from understanding the situation, and learning to modify their skills to master the complex evolving operating environment.

Ability to be proactive: To be proactive means *to be forewarned and be prepared for changes in the situation*, to look forward and constantly revise, and to trust intuition. In a dynamic military operation, none of the participants can sit back and expect learning and knowledge to come to them. The urgency to maintain control of the situation demands every individual is proactive and seeking knowledge concerning the environment, the enemy, their own level of exposure and the risk.

Finding alternatives and solutions: By this we mean a persons ability *to be open to others' inputs, intuitive, creative thinking and logical thinking, and common sense*. In a military patrol operation it is important to find what assets can be used to perform best in a constantly evolving situation. Finding these assets requires rapid analysis, continuous awareness and the capacity to see alternative solutions.

Ability to prioritize: Prioritizing relates to *setting priorities among assignments, personnel, material and intellectual resources, and ability to make difficult decisions*. A team carrying out a patrol operation need to decide how to best use assets to capture relevant and important information, whilst at the same time minimising exposure. This prioritization must consider the type of mission and the level of risk that is acceptable to personell operating in enemy terrain. Prioritizing capabilities increases sustainability and enhances situational understanding that leads to better self-regulation and self-determination amongst all personnel involved. At all levels the interplay between human and technical resources contribute to performance abilities and getting the most out of the assets available.

Ability to control: Having the ability to gain control of a situation or a task means that a person has *a manageable level of oversight concerning available resources, areas of responsibility, risk, and own capacities and capabilities (emotional and practical) in the given context to effect change*. The ability to control also requires the person to be aware of the relative power and agency of those around them (both internal and external). Within a patrol context, controlling oneself and control of the overall situation demands a high level of interaction between human and technical resources as observations transfer from the physical domain, through the information domain and into the cognitive domain.

Ability to influence: By this we mean an individual's *ability to cut through complexity and tension to find suitable and effective means of affecting positive outcomes*. To be able to organize and motivate oneself and others in such a way that supports self-determination without losing sight of the purpose. To influence means the ability to implement and manage technical resources in such that their effects support operational outcomes; rather than adding to the complexity and clouding judgements. In a military context it is not only and always the designated leader who should have the means to influence the situation. The other members of the team

can also influence performance and outcomes through similar means. For example; by behaving correctly, keeping calm, keeping others calm, encouraging and motivating others and contributing with constructive ideas. It should be noted that, as a team leader, too much focus on control and influence or your own people could contribute to negative outcomes [25].

Self-confidence and belief in oneself: Self-confidence is *a feeling of trust in one's abilities, skills, knowledge, and judgement*. Self-confidence and trust amongst the team has an empowering effect. When all participants execute their tasks to the best of their ability, an acceptable level of performance is achieved [26]. The will to perform should be equal under all circumstances whether routine or critical.

Ability to handle uncertainty: This is the ability to *focus on ones own reactions and take steps to actively manage uncertainty*. The key element here is to experience what one can and what one cannot influence and then playing deliberately on the matters one can influence [27]. By using double loop learning [28] [29], the state of conscious action can be achieved. Double loop learning requires one to look back at the event or situation to see how one responded to uncertainty, complexity and risk, to study the outcomes and learn from them. Mosse [30] has a similar perceptive to handling uncertainty in development when he talks about opening the "implementation box". Instead of just boxing experiences, one should actively reflect on events and evaluate how behaviour, actions and decisions affected the outcome. A deeper understanding can then be gained by carrying out the same task again with all knowledge learned from the evaluation. This is a way to change one's behavior to handle uncertainty [30].

IV. EXPERIMENT SETUP AND METHOD

The ten coping strategies were presented to second year Bachelor engineering students in the beginning of January 2015. During the presentation each strategy was explored briefly, along with the intent of gaining individual experiences by using coping strategies and capturing learning through a process of reflection. The possible relationships between strategies were not discussed, the strategies were handled as equals. The idea behind presenting the strategies was to make the students more aware of how they think, how they react and how they mentally deal with stress in order to perform. We clearly stated for our students that the ten coping strategies were examples and not a definite recipe. They were encouraged to use other strategies that they felt appropriate. The coping strategies were also referred to when appropriate in military leadership courses during the spring semester of 2015. However, none of the specific situations where usage of coping strategies was evaluated were mentioned or discussed.

Students' continuous focus on coping strategies was gained by making students reflect over both military and engineering related situations. The students completed short questionnaires self-evaluating their own performance on a scale from 1 to 6 (6 being the best performance rate), selecting the strategies they had actively used in a situation, and informing if they used any other strategies. In addition, the questionnaire included an open question, where students could write their reflections over the situation and any specifics regarding the usage of the coping strategies.

The students self-evaluated 14 military and engineering events. The engineering situations contained four different electronic laboratory exercises (El 1, El 2, El 3, and El 4), four online status tests in a statistic and discrete mathematic course (Ma 1, Ma 2, Ma 3, and Ma 4), and three lectures: one in Computer Network Operations (CNO) and two in Python programming language (Py 1 and Py 2). The military situations were delivered through operational training scenarios: battle procedure phase (BP: battle preparation regarding all equipment and oneself), emergency shelter (ES: making a snow shelter and sleeping in it), and a night military patrol (NP). The military events took place during our winter exercise in February 2015 and the engineering events in February-April 2015.

V. RESULTS AND DISCUSSION

In total, we had 38 second year students. The total amount of participants answering questionnaires varied from 33 to 37 students depending on how many of them actually participated in a specific event. Not all students answered the questionnaire - even though they had taken part in the event - leading to the answering percent varying from 89% to 100%.

We computed the average self-evaluated performance level and the average usage percent for each coping strategy for each of the 14 events. In addition, the correlation between the average performance levels and the average usage percents in the cases of the military events, the electronic laboratories, the online mathematic test and the lectures was computed even though we intuitively suspect that there are dependencies between the strategies. We used Equation 1 to determine the correlation coefficients [31], where r is the correlation coefficient, x_i is the average usage percent of each strategy and y_i the average performance rate of the specific event.

$$r = \frac{\sum x_i y_i - (\sum x_i)(\sum y_i)/n}{\sqrt{[\sum x_i^2 - (\sum x_i)^2/n][\sum y_i^2 - (\sum y_i)^2/n]}} \quad (1)$$

Due to possible dependencies, the correlation coefficient might be slightly biased. However, in our opinion, strong positive correlation ($r > 0,7$) is a valuable indicator for a strategy having a positive influence on performance. The average performance rate, average usage percent of each strategy, and the correlation coefficient between the average performance rate and the average usage percent of a strategy for each 14 events are shown in Tables I, II, III, and IV.

TABLE I. AVERAGE PERFORMANCE RATE, AVERAGE USAGE PERCENT OF STRATEGIES, AND CORRELATION BETWEEN AVERAGE PERFORMANCE RATE AND AVERAGE USAGE PERCENT OF STRATEGIES IN BATTLE PREPARATIONS, NIGHT PATROL AND EMERGENCY SHELTER EVENTS.

	BP	NP	ES	corr.
Average of performance	4,79	4,09	5,09

Ability to handle uncertainty	36,1	31,3	39,3	-0,69
Some other strategy	2,8	0	0	

As can be seen from Tables I, II, III, and IV the percentages of alternative strategies were very low. The alternative strategies mentioned by the students were "co-operation within a group" in the battle preparation phase (BP), "stop thinking" and "group support" in night patrol event (NP), "creativity" in the first electronic laboratory (EL I), "educated guessing" in the first mathematic test (MA I), and "wish to learn" in the CNO lecture. However, after a formative evaluation, we concluded that these additional strategies provided additional substance to the original strategies. "Group support, co-operation and creativity" are included in *finding alternatives and solutions* strategy. "Educated guessing" falls into *use of knowledge and tools* strategy. "Stop thinking" is a part of the *ability to handle uncertainty* strategy. "Wish to learn" is a motivation factor which includes the *ability to influence*

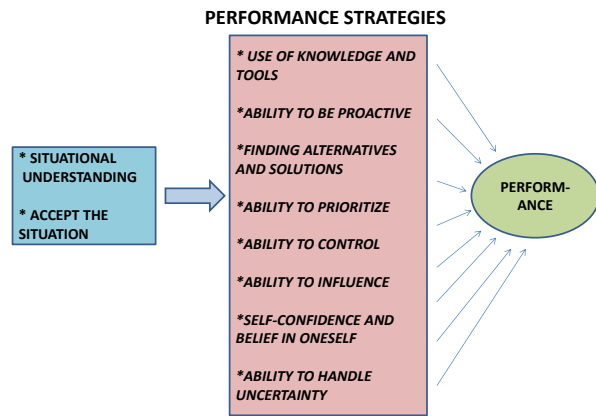

Fig. 1. Division to strategies into two sets of strategies.

strategy. The percentages of these have not been added to the original usage percentages of strategies, as the students had not fully understood the full substance of each strategy.

A. Situational understanding and accept the situation vs. the rest of the strategies

Tables I, II, III, and IV show that: *situational understanding* and *accept the situation* strategies, along with: *use of knowledge and tools* strategy, have the highest active usage percentages (more than 82% on average) among all strategies through the cases of military events, mathematic tests, electronic laboratories and lectures. However, neither *situational understanding* or *accept the situation* had strong positive correlation to performance. However, the rest of the strategies had stronger positive correlations to performance.

In our understanding, as mentioned in see Section III, one needs to understand and accept the situation before one can respond to a situation, a task or a difficulty. This suggests that the *situational understanding* and *accept the situation* strategies are applied when coping with an actual situation, and the remaining strategies are used to support better performance through empowered learning. In more complex situations and especially in dynamic situations, the relationship between the two first strategies and the remaining strategies are synergistic. However, in any context the first step is to understand and accept the situation, separating the rest of the strategies to "performance strategies" that actually have direct impact to performance. The relationship of the strategies in a simple case is shown in Figure 1.

Figure 2 then displays general usage of the performance strategies among military events, electronic laboratories, on-line mathematics test and lectures. Figure 2 also includes markings of correlations if the correlation coefficients between average usage of the strategy and performance is strong and positive (SPCP) or moderate and positive correlations (PCP), ($r > 0,5$). Neither weak or negative correlations are marked.

B. Performance strategies in extended military training

Table I shows gathered data in extended military training during the winter exercise in February 2015. As it can be

seen from Table I more than 50% of the students had actively used all strategies in the battle procedure phase (BP) and the night patrol (NP) phase. All strategies except *ability to handle uncertainty* were also used by more than 50% of the students in the emergency shelter activity (ES). Students commented that there was no need for *ability to handle uncertainty* strategy under the emergency shelter activity as the weather turned out to be a mild winter night. It was cosy to sleep under an open sky for a change instead in a tent. The fact was, there was nothing to be afraid of or concerned with, compared to the two other military activities.

Table I and Figure 2 show that in the military cases in general, the students performance was strongly and positively affected, ($r > 0,7$), by *finding alternatives and solutions*, *ability to prioritize*, and *ability to control* strategies. *Ability to be proactive* strategy also had positive effect, ($r > 0,5$).

C. Performance strategies in engineering subjects

In the spring semester of 2015, the students have studied and engaged in electronics, mathematics and military subjects. The mathematic course consists of both statistics and discrete mathematics. Both courses have had special events: laboratory days in electronics and online status tests in mathematics. In addition, they have been given a number of specific lectures focusing on specific needs concerning a two-week long military exercise in May. These engineering lectures included CNO (3 hrs) and two sessions of Python (total 8hrs).

The usage of the strategies in general was lesser in engineering subjects than in military subjects. The average usage of the strategies in four electronic laboratories was 72%. This was the closest to the average usage of the strategies in three military events (BP, NP, ES) that was 77%. The biggest differences were found among two strategies; less than 50% of the students used *ability to influence* and *ability to handle insecurity* in electronic laboratories (see Table II). Military events and electronic laboratories are both events where students have several things to do simultaneously and where good performance has a direct impact on their final grade. *Ability to handle uncertainty* strategy was understandably low in electronic laboratories due to the fact that the laboratory

	BP, NP, and ES	ELECTRO LABS	MATH TESTS	LECTURES
USE OF KNOWLEDGE AND TOOLS		SPCP	SPCP	
ABILITY TO BE PROACTIVE	PCP	SPCP		
FINDING ALTERNATIVES AND SOLUTIONS	SPCP	SPCP	PCP	
ABILITY TO PRIORITIZE	SPCP	PCP		
ABILITY TO CONTROL	SPCP	SPCP	SPCP	PCP

SELF-CONFIDENCE AND BELIEF IN ONESELF			SPCP	SPCP
ABILITY TO HANDLE UNCERTAINTY		PCP		

Strategy used by more than 50 % and
 used by less than 50% students.

SPCP: strong positive correlation ($r > 0,7$) and PCP: positive correlation to performance ($r > 0,5$).

Fig. 2. The usage of strategies and their correlation to performance.

environment - the teacher and the procedures - were known to the students. In the laboratory, the students felt that they had limited influence on affecting the situation. However, they only considered the actual pre-determined tasks they had to carry out. They did not consider their surroundings or their own welfare. These have an impact on the execution of the actual tasks. Looking at the correlation coefficients (see Figure 2) most of the performance strategies had a strong positive effect to performance in the electronic laboratory ($r > 0,7$). *Ability to prioritize* and *ability to handle uncertainty* had positive effect ($r > 0,5$). *Self-confidence and belief in oneself* had weak positive effect ($r = 0,43$). The findings show that the use of military based performance strategies are transferable into electronic laboratory tasks.

The active use of the strategies was greatly reduced in the four mathematic status tests and in three lectures. They showed 54% and 57% respectively. Within these cases (see Table III and Table IV) less than 50% of the students had used *ability to be proactive*, *ability to prioritize*, *ability to influence* and *ability to handle uncertainty* strategies. Also, the correlation between all these four strategies and performance was either non-existent or negative (see Figure 2).

With *ability to handle uncertainty* and *ability to influence* strategies, the similar explanation as given in electronic laboratory tasks applies. The mathematic tests and lectures are both well-known situations. However, it is our understanding that the students have too narrow a perception of coping strategy substance. This limits their possibilities to identify and influence the factors that can have a positive effect on the situation and outcomes.

The usage of *ability to be proactive* strategy was low in the status tests and lectures. This came as no surprise. The status tests in mathematics were only check points confirming knowledge and skill level at that specific time. The results of the tests were not used when the final grade was given. This meant that the students did not study any more than normal for the tests, leading to low proactivity levels. In the lecture cases, the CNO lecture came as a surprise to the students. They were not able to be proactive in a formal, pre-studying sense. However, the programming lectures were known beforehand, but only a couple of students were motivated to study the programming language in advance of the lecture.

The students answered that there was little use for *ability to prioritize* strategy in the status test and the lectures. However, analysis of reflections in the questionnaire indicate that not all of students necessarily understood what the whole concept of *prioritizing* actually meant. When something is *prioritized up*, something else will automatically be *prioritized down*. In our cases, the students had higher prioritizing for the electronic laboratories than for the status tests and the normal lectures, as they do not have direct impact on final grades. Their answers were based on *what they prioritize* not *prioritizing in general*. We admit that in this case, answering the questionnaire was ambiguous, and the results might be slightly biased.

The strategies that had strong positive correlations to performance in the mathematic status test were *use of knowledge and tools*, *ability to control* and *self-confidence and belief in oneself* ($r > 0,7$). *Finding alternatives and solutions* had positive effect to performance ($r > 0,5$). In the case of the

normal lectures, *self-confidence and belief in oneself* had the strongest correlation to performance. Also *ability to control* strategy had a positive correlation ($r > 0,5$).

The results can be interpreted as follows: the more concrete the task is and the more impact it has to a final grade, the more actively the performance strategies are used in engineering tasks. In these cases, the effect of the strategies in performance is also high. The challenge for a student is to see the usage areas of the strategies in a task or a situation that generates low-motivation. In order to perform well when motivation is low, one needs to increase self-determination. In our study, the students who used *ability to influence* in electro laboratories or *ability to control* in mathematics performed well, even though these strategies were generally found to be non beneficial due to the situations generating low-motivation (see Figure 2).

In the end, Figure 2 reveals an interesting fact. Even though the strategies were originally presented to the students as equals, the results support the intuitive thinking that in reality there are dependencies between strategies. The results show that the *ability to control* strategy has strong or moderate positive correlation to performance throughout all the cases. A reason for this might be due to the dependencies between the strategies. Better control is achieved through the application of knowledge, being proactive, finding alternatives and solutions, being able to influence and steer positive outcomes. The control strategy gives meaning to the iterative nature of coping strategies. The product of better control supports increased situational awareness and improved acceptance of stressful or complex situations. Figure 3 shows a model of the possible relation between *ability to control* and the other performance strategies.

All in all, this indicates that the military performance strategies have a positive effect on performance in engineering subjects. However, the full substance of the strategies in an engineering context is not as easily understood as it is in a military context. The strategies, their substance and link to self-determination needs to be discussed with the students.

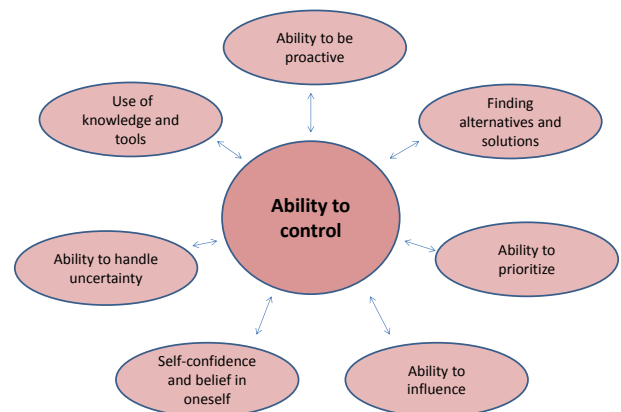

Fig. 3. Relationship between ability to control and other performance strategies.

D. Guidance of performance strategies in engineering subjects

As mentioned, the usage of coping strategies was not understood intuitively in a pure educational context. It is our understanding that this is based on two factors. The first being a mismatch with the phrase "coping strategies". We discovered that they should be called "performance strategies." The second reason was shown to be the narrower understanding of the strategies in an academic context compared to a military context. To address these factors going forward, we have decided to call the strategies "performance strategies", and introduce better guidance for using strategies within engineering subjects. An example is shown in the following paragraphs.

There are two main levels in *situational understanding* and *accept the situation* in engineering education. The first level is understand the bigger picture: what kind of education a student is entering, what does it take for a student to get through this education and what does a student gain by finishing this education. The second level is to understand and accept each smaller situation occurring during the education, e.g. lectures, individual studies, group works, home works, deliveries, laboratories, tests, and exams. In addition, other factors affecting education such as economical situation, family situation, and health situation should also be discussed. The educators can empower students earlier to understand their education in its wider context and help students to adopt a mind-set that the expectation on them at school is no less than that placed on a team of professionals engaged in a real time operation.

Use of knowledge and tools, finding alternatives and solutions, and the *ability to prioritize* are easily understood in an academic setting. However, it should be discussed that these are not introduced as methods to be used inside a classroom or a laboratory, when a specific engineering task is to be solved. Where Shull [3] encouraged reflection at the moment his students faced a problem, we encourage *reflection occurring in advance*. By supporting students to reflect early over situations, their own actions, behavior and performance, they might, for example, identify a potential problem in advance and avoid it. This we call a *proactive* response and it applies also to the *ability to handle uncertainty*. If a student is prepared to *reflect on uncertainty*, and see it as an opportunity and not a barrier to learning, then they might become more open to criticism and be more receptive to the idea of thinking differently. Encouragement can come from teachers, however it is best sourced from fellow students as this avoids any feeling of top-down pressure.

In our study, the students felt that there is no real need for the *ability to control* and the *ability to influence* in classroom teaching or in a test situation. One cannot control or influence the questions asked in the test, but one can control and influence environment. Things like alertness, nutrition and hydration level, and other personal physical needs can be controlled and influenced as well as the noise and light levels in the classroom. One also has control of the situation when the procedures in the test situation are known. For example, interactive discussion initiated by the students, can empower learning. It can be the case that there exists several students with the same problem but are too shy to say anything. This brings us to self-confidence. *Self-confidence and belief in oneself* increases by mastering the tasks. Therefore, it is important to start at a level that guarantees each individual the

feeling of mastery. Then increase the difficulty level of the task which simultaneously increases the students' self-confidence.

These "performance strategies" are not independent. They are integrated and fragmented, and complement each other. Their agility and transferability must be understood. To cope better is the sum of many parts. Applied in isolation, a coping strategy may support learning, however, it is unlikely to lead to deeper learning, change in behaviour and better outcomes. Learning to draw the best out of yourself, your team and the environment is a skill that requires capacity building in hard and soft skills.

VI. CONCLUSION

In this paper, we showed how the ten coping strategies of the Norwegian Defence Cyber Academy (NDCA) were developed. We showed how the strategies were originally used and how they are currently being used. The original use was limited to military contexts. However, inspired by Peter Shull's FIE Workshop 2014 [1], we have now introduced our coping strategies (*situational understanding, accept the situation, use of knowledge and tools, ability to be proactive, finding alternatives and solutions, ability to prioritize, ability to control, ability to influence, self-confidence and belief in oneself, and ability to handle uncertainty*) into engineering subjects.

In this paper we have identified which of these ten coping strategies were really applied in military contexts and which in pure engineering contexts. We have also studied if the usage of coping strategies influences the performance of the students. The usage of the strategies was evaluated by using short questionnaires. Students evaluated their own performance in specific military and engineering situations and ticked the strategies that they actively used.

We found that the strategies *situational understanding* and *accept the situation* are used first, before the other strategies can be applied. When a person has understood the situation and accepted it, he/she can start to act and by act we mean to perform. The rest of the strategies are then performing strategies, having positive correlations to performance. The *situational understanding* and *accept the situation* strategies are applied when coping with an actual situation, and the rest are used to support better performance through empowered learning. We also found that the *ability to control*, alone had high influence to performance through military and engineering events indicating that this strategy might be the dominant strategy to gain good performance. This experiment could not measure the role of the *ability to handle uncertainty* strategy due to the very secure events we used.

Furthermore, we found that the original name "coping strategies" should be changed to "performance strategies" as it would give more intuitive understanding of the usage areas of the strategies. The results showed that all strategies are applied in military context and that they are also applicable in engineering subjects, especially in electronic laboratories. They are also usable in other subjects. However, in order to get their full benefit, the strategies and their substance needs to be discussed with the students.

VII. FUTURE WORK

The research of performance strategies (earlier: coping strategies) continues to the end of the year 2015. We will be looking at relationships between performance strategies more deeply in cases where the level of complexity and uncertainty within every task is raised and the shifts in context are more rapid. This is achieved by simulating a high intensity operational environment where the applications of the educational skills are required to perform.

ACKNOWLEDGMENT

The authors would like to thank the students of the NDCA for taking part in the research project.

Abstract—It is very challenging to provide a learning experience which is meaningful, motivated and at the same time enjoyable in nature. This often affects the students who cannot learn or do not want to learn due to lack of engagement and guidance. The same scenario is also true for working professionals in industries. Cognitive flow, defined as the mental state in which a subject is fully concentrating with a feeling of full involvement and enjoyment, is reported to play a key role in this. There are different questionnaire based indirect methods for measuring ones' flow state. However, in our present work we attempt to measure the flow state more directly using Electroencephalogram and multi-modal physiological signals including heart rate variability and galvanic skin response. Twenty right-handed engineers from our research lab played a video game to induce conditions of boredom and flow. A modified colour based Tetris (similar to Stroop test) game is used for the said purpose. A comparative study is done between the offline questionnaire based and the physiological signal based flow measurements. From the results it is clear that flow/boredom state can be derived from brain signals, which is modeled using Markov chain, as well as from other physiological signals. Hence can be used as an important feedback in various applications for maintaining a steady flow state for a longer period. Finally, the flow-boredom model generated from brain signals has been used in Web Based Learning to automatically measure the learning experience.

Keywords—Flow state, Boredom, Anxiety, EEG, learning experience

I. INTRODUCTION

Teaching professionals have observed that children have limitless curiosity for knowledge before they enter school. Several years later those same children lack attention, motivation and suffer from boredom. Finally they disengage themselves from learning and have a negative feeling towards knowledge and learning. This is true for working professionals as well as they need to go through various training programs for new knowledge/skill development. The main purpose of the work is to provide a better learning experience by maintaining student's engagement as well as enjoyment with the help of positive psychology. In psychology, cognitive flow

[1] is defined as the mental state in which a person performing an activity is fully concentrating with a feeling of full involvement and enjoyment. A person's skill and the challenge of a task together result in different cognitive and emotional states. When skill is too low and the task too challenging, people become anxious. Alternatively, if the task is too easy and skill is comparatively higher, people become bored [2]. However, when skill and challenge are roughly proportional, people enter *Flow state* i.e. a state of focused concentration and enjoyment as shown in Fig. 1(a). Individual's performance measurement, emotional state assessment are some of the applications of flow while subjects perform different tasks. Application of flow in education will aid enormously in performance analysis, characterizing student's skill level against the given educational content, automatic adaptation/ suggestion of study materials etc. A modified Tetris game as shown in Fig. 1(b) is designed for the modeling and measurement of boredom and flow state of an individual. The details of the game is described later.

Fig. 1. (a) Flow state for skill and challenge, (b) Snapshot of the game

So far very few attempts for direct measurement of flow state have been seen. Most of current approaches use indirect methods for measuring flow [3], [4], [5]. In this paper we have used Electro-encephalogram (EEG) signals recorded by commercially available, low cost, single lead Neurosky¹ device. There are several approaches to study brain activations like functional Magnetic Resonance Imaging (fMRI) [6], functional Near Infra-Red (fNIR) [7] etc. We have used EEG as it is non-invasive, relatively low cost, and easy to use. Apart from the brain signals we have used two more

¹ <http://neurosky.com>

physiological sensing namely, heart rate variability (HRV) and Galvanic Skin Response (GSR) for measuring the level of stress for boredom and flow conditions.

In this paper, the approach involve two phases – (i) a game design for creation of a boredom-flow model, (ii) analysis of subjects' performance on a web based learning (WBL) material using the above model. The game design is motivated by the Tetris game [7] where the falling objects are replaced by Stroop color-texts and the bottom platform is replaced by seven color containers as shown in Fig. 1(b). The color of the texts are chosen to be different from the text itself. Subjects are asked to move the texts and place them in the container such that the color of the both matches. The speed of the falling texts is increased programmatically at certain intervals where a subject is expected to move from boredom state (at low speed) to flow state (at higher speed). This is validated through questionnaire based *Game Flow Inventory* (GFI) [8] [9]. A two state first order Markov chain is used for creation of the boredom-flow model. The states of the Markov chain are estimated as a Gaussian Mixture Model (GMM) using Maximum Likelihood Estimate (MLE). Finally, the model is used to estimate the performance of a subject against a given web based learning video material. The performance is derived with respect to the transitions between boredom, flow and vice-versa.

The paper is organized as follows. The Section I of the paper dealt with a brief introduction to the flow state of brain and its associated implications. Section II reviews the existing approaches to assess the flow state. The methodology used for the proposed implementation is discussed in Section III followed by the experimental setup in Section IV. Results and discussions of our findings are given in Section V. Finally the paper concludes in Section VI along with the future avenues of research.

II. RELATED WORK

As reported by Csikszentmihalyi [10] [11], flow state is experienced by workers who like their jobs, by teenagers who love studying, by drivers who enjoy driving [11]. Thus, “*flow*” can be attributed to the state of the brain in utmost involvement in a task of interest, thereby avoiding the distractions and other aspects not concerned with the task..

Flow has also been compared against the concept of ‘presence’. These two aspects share many things in common but at the same time, they are distinguishable from each other. Flow describes a state of immersion into a particular activity whilst ‘presence’ pertains to the immersion into a given environment (virtual in case of gaming). Fontane [12] described ‘presence’ state of consciousness to be most apt for performance in unfamiliar ecologies whereas the flow could be better attributed with familiar ones. Thus, ‘presence’ is relatively more focused on technological characteristics pertaining to a medium while flow stresses on task related characteristics [13].

It has been observed that at times, people spend most of their time in activities that do not lure them much. This could be attributed to the fact that every flow inducing activity expects a preliminary investment of attention. Very often, due to lack of discipline to overcome the hindrances, tiredness, anxiety or negligence; enables in avoiding a person to switch

to a flow inducing task. It then results into settling for any alternative, which seems more accessible, perhaps less enjoyable [10]. This factor is a serious issue that comes in the way of success of e-learning domains, thereby hindering their widespread usage. When it comes to games or social networking, the initial investment of attention is comparatively less challenging. Thus training programs must devise low initial attention demanding schemes in order to enjoy mass-acceptance.

There are different approaches for measuring flow state [3] [4] [5] namely, (i) semi-structured interviews – gives a qualitative measure, (ii) questionnaires – flow state questionnaires/scales used to describe user experience and performance, (iii) experience sampling method – objective is to measure flow and other states of consciousness occurring in activities encountered in everyday life. Jackson and Marsh had devised a feedback-questionnaire based method to evaluate flow, popularly known as the flow state-scale [14]. These feedback or indirect questionnaire based approaches seem to be feasible and less complex, but they are not reliable enough. Recent works show that brain signal analysis seems to be the most promising approach, due to its excellent data rendering, portability and cost effectiveness [15]. Based on the brain and physiological signals obtained, Maurizio Mauri et al, have found that *Facebook* usage induces a high positive valence and high arousal (Core Flow State) that can be attributed to its mass acceptance and increased usage [16].

In terms of educational perspective, flow state of mind is crucial for the involvement in the study process for the grasping of concepts. Flow measurement in case of piano playing [17], video-game playing [18, 19], online games [20], athletes subjects [21], using social networking sites [16] etc. have been extensively researched. Also, the advantages of flow are effectively used to foster e-commerce business [22]. Yoshida et al, have detected the increase in oxygenated Hemoglobin content in the right and the left Ventrolateral Prefrontal Cortex (VLPFC) during flow state using fNRI [7]. John Pearce, classified flow to be ‘task’ and ‘artefact’ oriented, for the students subjected to e-learning paradigm [23], wherein the multimedia aspects of e-learning sites culminated into the arousal of ‘artefact flow’ in the subjects. In case of collaborative learning in immersive virtual environments, flow was measured using Guo and Poole’s inventory model [24].

Recent attempts have been made to use low cost EEG devices for different applications like measuring cognitive load [25], user interface evaluation [26] etc. EEG is extensively being used in educational tasks through the advent of Brain Computer Interface (BCI) technology [27]. The analysis of cognitive load for different learning objectives is presented in [28] using low cost EEG device. In [18], greater left temporal alpha activity was noticed when compared to that of right temporal lobe affecting the performance associated with flow. In conjunction to this, the mid beta activity and theta activity also have an effect on performance whereas there was no significant results with respect to delta waveforms. In [16], higher alpha activity coupled with lower beta activity is found to be characterized for flow state.

Given the landscape of the work done on experiments with flow state for a given task, it can be seen that there have been

very less work done on web based learning materials. Moreover, there is no work that provides a formal way of measuring the performance of a subject in terms of boredom-flow models for web based learning.

III. METHODOLOGY

A. Game design

We have developed a game which is a modified version of the Stroop test and the standard Tetris game. The game is developed using Pygame. Here the names of the colours used in the Stroop test descend from the top of the screen. The falling words were pseudo randomized. The playing field is 24 cells high and 14 cells wide. The task is specially designed into 2 versions to induce flow and boredom conditions with variations in speed of the falling words. Seven different colored containers are placed at the bottom of the screen with a fixed distance between each of them. The screen shot of the game is shown in Fig. 1(b). The users are supposed to drop the falling texts into the appropriate containers so that the font color of the falling text matches with the color of the container. The subjects have the provisions to control only the left and the right movements of the falling texts and not the down movement. These movements are implemented using left and right arrow keys of the standard QWERTY keyboard. For boredom experience, the texts descend down at the rate of 1200 milliseconds per block. In case of flow state inducing condition, the texts initially descend at the rate of 1000 milliseconds per cell and then decreases by 200 milliseconds

at every 30 seconds per two cells. On each correct match, the score is incremented by one. Both the sessions have been designed to run for 2 minutes each. At the end of the game the final score is displayed on the screen.

B. Dimensions of flow experience

According to the flow theory, learning and practicing are essential to remain or re-experience the flow. Csikszentmihalyi [15] initially identified four flow components like control, attention, curiosity and intrinsic motivation. These are essential for experiencing the flow. Later Csikszentmihalyi modified these dimensions further and established that there are basically nine dimensions which are indicative of flow experience, namely, challenge vs. skill balance, concentration and focusing, direct and unambiguous feedback, loss of self-consciousness, clear goals, sense of control, time transformation, autotelic experience, and action-awareness merging. In this paper we have tried to measure flow based on these dimensions. For first three dimensions we have used direct measurement approach as shown in Fig. 2. We are using EEG signals for estimating skill-challenge balance and GSR signals for measuring concentration / focus during the task. Unambiguous feedback mainly can be of two types: internal feedback (like body movements, heart rate, etc) and external feedbacks (like performance score etc.). In this paper, we have used pulse rate as the internal feedback and the results of keystroke analysis as the external feedback. For remaining six dimensions, we have adopted a survey based approach.

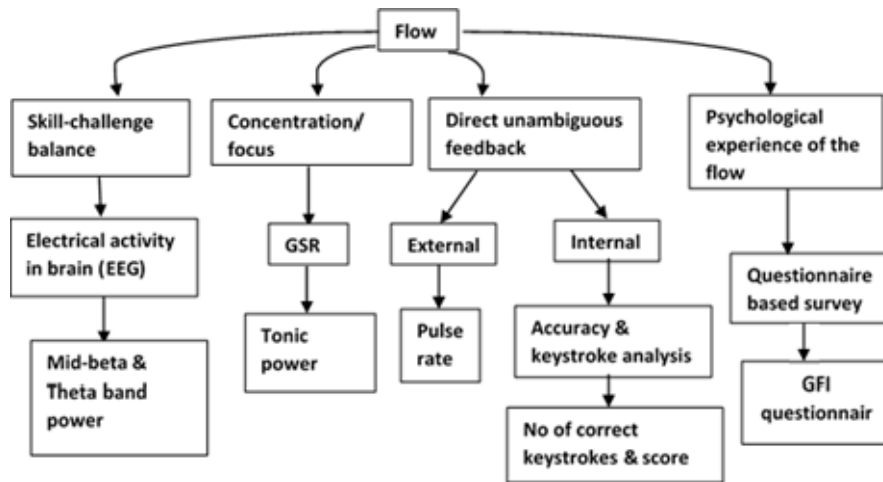

Fig. 2. Dimensions of flow experience and corresponding measurement approaches

1) EEG based skill-challenge analysis

For measuring the skill-challenge balance, we have measured direct electrical activities originated in brain. For this we have used a single lead EEG device from Neurosky. Participants are asked to play the modified Stroop game while wearing the device. The EEG signals along with certain metadata are recorded using an in-house Python based setup at a sampling rate of 512 Hz. The metadata includes the time stamps related to the presentation of various texts (Stroop color) on the screen along with the state of the game. The state

of the game is related to the speed in which the texts move and is detailed in the previous Section III.A.

In order to analyze the EEG signals, initially a window of length W is created with 50% overlap. Considering the short term stationarity, in our experiment, the window length is taken as 1 second. This also allows us to detect the windows containing eye blink and filter the same using algorithm proposed by Berka et. al. [29]. It is to be noted that, usually the duration of eye blink varies between 300 msec to 800 msec. In the present work, we have experimented with

frequency band energies [30], [31] and time domain Hjorth parameters [32], [33] as features as shown in (1).

$$F = \{E^\delta, E^\theta, E^\alpha, E^{l\beta}, E^{m\beta}, H^a, H^m, H^c\} \quad (1)$$

where the first five features are the energies in various frequency bands namely, delta (E^δ as 0.5 - 4 Hz), theta (E^θ as 4 - 7.5 Hz), alpha (E^α as 7.5 - 12.5 Hz), low-beta ($E^{l\beta}$ as 12.5 - 16 Hz) and mid-beta ($E^{m\beta}$ as 16 - 20 Hz) respectively. The energies in each band is extracted using Welch's power spectral density estimation [35]. The last three features in (1) are the Hjorth parameters namely Activity (H^a), Mobility (H^m) and Complexity (H^c) respectively as given by (2).

$$H^a = \text{var}(x(t)) \quad H^m = \sqrt{\frac{H^a \left(\frac{dx(t)}{dt} \right)}{H^a(x(t))}} \quad H^c = \frac{H^m \left(\frac{dx(t)}{dt} \right)}{H^m(x(t))} \quad (2)$$

where $x(t)$ indicates the time domain signal in a window and $\frac{d(x(t))}{dt}$ is the first order derivative of the signal.

The skill-challenge analysis is performed using a first order Markov chain where we have considered two states, $S = \{S_{bo}, S_{fl}\}$ corresponding to boredom (S_{bo}) and flow (S_{fl}) as shown in Fig. 3. The state transition probability p_{ij} is defined as the probability in which the chain moves from state S_i to state S_j , $i, j \in \{bo, fl\}$. In case of first order Markov chain, the transition probability depends only on the present state and is independent of any previous states. It is possible to use more number of states, including a neutral state, anxiety state etc. However, in order to understand the feasibility of the proposed approach, in this paper, we have intentionally used a simple model with minimum possible states.

Fig. 3. Markov Chain with two states namely boredom and flow state along with the state transition probabilities

In the current work, the states (S) of the Markov chain are characterized by the Gaussian probability density functions (PDF). An unsupervised approach is used to generate a Gaussian Mixture Model (GMM) [35] of individual features (f) as given in (3). Maximum Likelihood Estimation (MLE) [36] is used to derive the Gaussian parameters ($N_j(\mu_j, \sigma_j)$, $j \in \{1, 2\}$) comprising of two mixtures. These two Gaussians correspond to the two states in Markov chain. Once the GMM is estimated, the probability of a feature belonging to a Gaussian is given by (4). Finally the detected state S^d for a given feature in a window of EEG signal is given by (5) and (6).

$$p(f) = \sum_{j=1}^2 P(j) p(f|j) = \sum_{j=1}^2 P(j) \frac{1}{\sqrt{2\pi\sigma_j^2}} \exp\left(-\frac{(f - \mu_j)^2}{2\sigma_j^2}\right) \quad (3)$$

$$P(j|f) = \frac{p(f|j)P(j)}{p(f)} \quad \forall j \in \{1, 2\} \quad (4)$$

$$S^d = S_b, \quad \text{if } P(1|f) > P(2|f) \quad (5)$$

$$S^d = S_f, \quad \text{if } P(2|f) \geq P(1|f) \quad (6)$$

The above model is generated using each features derived from the modified Tetris game. The intention behind performing the GMM on individual features is to find the most important feature which is able to generate a model that maximizes the state detection accuracy (A). The accuracy is derived by comparing the detected state S^d derived from the feature of each EEG window against the state $S^g = \{S_{bo}^g, S_{fl}^g\}$ of the game. The boredom and flow state of the game are denoted by S_{bo}^g and S_{fl}^g respectively. For a given feature, the accuracy for the boredom state (A_{bo}^f) and flow state (A_{fl}^f) are given by (7), where the function M is the number of EEG windows for which the detected state (S_{bo}^d, S_{fl}^d) and the game state (S_{bo}^g, S_{fl}^g) are same for a given feature $f \in F$. The total number of EEG windows for the boredom state and flow state for the game are W_{bo} and W_{fl} respectively.

$$A_{bo}^f = \frac{M(S_{bo}^d = S_{bo}^g | f)}{W_{bo}} \quad A_{fl}^f = \frac{M(S_{fl}^d = S_{fl}^g | f)}{W_{fl}} \quad (7)$$

The most important feature f_{imp} is derived as the feature that provides the maximum accuracy for both boredom and flow state as given in (8). The important feature thus derived is used for analyzing flow state of a subject for a given educational content as part of web based learning.

$$f_{imp} = \underset{f \in F}{\text{Arg max}} (A_{bo}^f + A_{fl}^f) \quad (8)$$

Finally, the parameters (λ) those are stored for the evaluation of the performance (in terms of boredom-flow) of a subject against a learning material are given in (9). This includes the two Gaussian distributions (N_1, N_2) and the state transition probabilities $p_{ij}^{g,bo}, p_{ij}^{g,fl}$ derived during the two types of games namely boredom and flow respectively. It is to be noted that the parameters can be stored for each subject for subject dependent analysis or can be derived as a global parameter while considering all the subjects. In this paper we have performed subject specific analysis.

$$\lambda = (N_1, N_2, p_{ij}^{g,bo}, p_{ij}^{g,fl}), i, j \in \{bo, fl\} \quad (9)$$

2) GSR based concentration measurement

The galvanic skin response (GSR) is an electro-dermal response where the skin conductance changes with the state of the sweat glands in presence of stressful, likeable events. Therefore GSR can be a good predictor of concentration, mental workload etc. in flow study. During flow experience, subjects should experience a higher concentration and complete focus on the task. Galvanic skin response can be successfully used to measure the level of concentration [37].

The GSR applies a constant voltage to the skin through two electrodes. The voltage is so small that it cannot be felt or perceived by the individual. However, the current that flows

through the skin, as the voltage is applied, can be detected. The GSR signal is characterized by two components: a fast component called ‘phasic’ and a slow component called ‘tonic’. Both tonic and phasic components contain information associated with specific physiological aspects of brain states. Here the tonic component is calculated only taking the inverse transform of first few Fourier coefficients as in (10), whereas the phasic component is calculated by inverting the higher coefficient of Fourier coefficients as given in (11).

$$\text{tonic component} = \text{IFFT}\left(\sum_{n=0}^{N-1} x(n) \cdot e^{-j\left(\frac{2\pi}{N}\right)nk}\right), k=0,1,2,3 \quad (10)$$

$$\text{phasic component} = \text{IFFT}\left(\sum_{n=0}^{N-1} x(n) \cdot e^{-j\left(\frac{2\pi}{N}\right)nk}\right), k=4,5,\dots,N-1 \quad (11)$$

3) Direct/unambiguous feedback

Individuals in flow state must receive direct unambiguous feedback on how well the task is being performed. There are two different ways of evaluating the subject performance: i) external feedback and ii) internal feedback [38]. Internal feedback refers to the feedback provided by bodily movements and external feedback is provided by the sources outside the body. In the present work, we have used heart rate as the internal feedback approach. We have also analyzed the keystrokes [39] as these gives the direct measure of the user performance.

a) Internal feedback - Heart rate analysis

Heart rate variability is an effective indicator of one’s present stress level [40]. Hence it can be used as a feedback for validating Csikszentmihalyi’s concept of moving from anxiety through Flow to boredom model. When the challenge of the undertaking task is low compared to the subject’s skill level, then the heart rate variability (HRV) is high compared to the flow state where the skill matches with the challenge level required. There are quite a few medically accepted HRV parameters. McDuff et al. [35] extracted the PPG from the face video, we have used the SPO2 device wearable on the index finger for sensing the Photoplethysmogram (PPG) signal. The HRV is computed in the similar manner as detailed in [35]. We have calculated three time domain HRV parameters namely 1) RMSSD (Root mean square of successive differences between adjacent NN intervals), 2) SDSD (Standard deviation of successive differences between adjacent NN intervals), 3) SDNN (Successive difference between NN Intervals).

b) External feedback - keystroke analysis

In this paper the external feedback is provided based on keystroke analysis and overall score of the game. The data capture tool was designed to log all the keystrokes (both left keystroke and right keystrokes) while playing the game (the task). The score was initially set to zero and was incremented by one, each time the user successfully placed the falling texts in the corresponding containers. At the end of the game timer (2 min), the total score is displayed on the screen.

For each falling text, total number of left keystrokes N_{KL} and total number of right keystrokes N_{KR} were extracted from the data file generated by the capture tool. For each text to be collected in the correct container, the user need to press either left key or the right key. Hence majority key-presses actually

represents the correct number of keystrokes for that particular object. If $N_{KL} \gg N_{KR}$ then number of correct keys N_{KC} is given by (12). Similarly if $N_{KL} \ll N_{KR}$ then the number of correct keys is given by (13). The total number of keystrokes for a particular falling text is given by (14).

$$N_{KC} = N_{KL} - N_{KR} \quad (12)$$

$$N_{KC} = N_{KR} - N_{KL} \quad (13)$$

$$N_K = N_{KL} + N_{KR} \quad (14)$$

Next a correctness measure was calculated by dividing the correct number of keystrokes by total keystrokes using (15).

$$C = \frac{N_{KC}}{N_K} \quad (15)$$

For boredom condition C is close to 1 as all the keystrokes are expected to be the correct ones. As the speed of the falling object increases, subjects tend to press some wrong keys and the value of correctness measure decreases. In the anxiety condition, the number of wrong keystroke is expected to be maximum and hence value of C is minimum.

4) Psychological experience of the flow

Apart from the first three dimensions of flow, remaining six dimensions are evaluated by a questionnaire based survey as they are mainly related to human perception. After finishing the game, the users are asked to fill up a questionnaire to obtain an indication of their perception during flow and boredom experience. For this purpose we used a 7 point rating scale called Game Flow Inventory (GFI). GFI has been derived from original 13 point flow rating scale and is specifically applicable for gaming environments [8] [9]. GFI measures level of engagement, enjoyment or happiness and intrinsic motivation.

C. Application of flow model in Web Based Learning (WBL)

The models created based on the EEG, GSR and physiological sensing is used for analyzing the behavior of a subject for an unknown educational content. In order to perform this experiment, subjects were shown two types of learning materials from web where one is in the interest area of the subject and other is in an unrelated area. The goal is to derive certain attributes for the subject for a given learning material. This is done using different types of sensing. Using the EEG analysis, the state transition probabilities (p_{ij}^t where $i, j \in \{bo, fl\}$) for the learning session are derived using a two state Markov chain whose states were earlier modeled with the help of the modified Tetris game. A distance metric D^k , $k \in \{bo, fl\}$ is computed to analyze the closeness of the Markov chain for the learning material with the previously generated boredom and flow Markov chains using the modified Tetris game. The distance metric D^k gives an estimate on the overall experience of the subject related boredom and flow.

$$D^{bo} = abs\left(\sum_{i \in \{bo, fl\}} \sum_{j \in \{bo, fl\}, j \neq i} (p_{ij}^{g,bo} - p_{ij}^t)\right) \quad (14)$$

$$D^{fl} = abs\left(\sum_{i \in \{bo, fl\}} \sum_{j \in \{bo, fl\}, j \neq i} (p_{ij}^{g,fl} - p_{ij}^t)\right) \quad (15)$$

The physiological signals are used to measure the heart rate variability (HRV) and then derive metrics on minimum, maximum and average HRV along with the duration of the same in percentage of the complete tutorial session. Longer duration in low HRV indicates that a subject is in flow state. This is derived from the HRV observation and the user study during the game analysis. The GSR analysis is also used to derive the maximum, minimum and average tonic feature along with the duration of the same in percentage for the given training material. Longer duration in high tonic feature indicates that the subject is in flow state.

IV. EXPERIMENTAL SETUP

A. Participants

We have selected a group of 20 subjects, 10 male and 10 female, from our research lab. They were all right handed engineers having normal or corrected to normal 6/6 vision with spectacles. The average age group of the subjects selected was 28-32 years. While selecting the subjects we also ensured that they are from similar cultural and educational background. These factors were taken into account to ensure minimum variance in brain lateralization across the participants.

B. Data collection setup

The physiological data collection has been accomplished using an in house python based data capture tool. The application enables us to show the stimulus in a standard computer screen and at the same time collect the EEG signals. Subjects are asked to play the game while wearing a single lead EEG device from Neurosky. It is a dry sensor with a lead placed in FP1 position and the grounding is done with reference to left earlobe. For recording the variance in skin conductance level, we use a GSR device from eSense. All our participants are right handed and hence we put the GSR sensors on the middle and ring fingers of the left hand. The right hand is kept completely free so that the user can play the game comfortably. The oxygen saturation level and the pulse rate are assessed by the pulse oximeter from Contec (CMS50DL1), through the left index finger. The devices used are shown in Fig. 4. During the gaming session, keystrokes (both left and right), game scores, GSR data, EEG data and SPO2 data were logged in for further analysis.

C. Experimental procedure

1) Creating the boredom-flow model

The experiment has been conducted in a block, in which the experimental task is performed four times: twice during boredom condition and twice under the flow condition. For half of the subjects the order of the conditions are boredom-flow-boredom-flow and for remaining participants the order is flow-boredom-flow-boredom. Each block lasted for 10 minutes and consisted of two tasks: 1) participants performed the experimental task for first 8 minutes (2 minutes for each conditions and 2 sessions per conditions) 2) next they completed the questionnaire based survey using GFI.

Fig. 4. Data collection devices: (a) Neurosky EEG device, (b) Galvanic skin response from eSense (www.mindfield.de/en/biofeedback/products/esense/esense-skin-response), (c) Pulse oximeter from Contec (http://www.contecmed.com/index.php?option=com_virtuemart&Itemid=592)

2) Application in Web-based learning

The experiment with web based learning is performed on a smaller subset of five subjects. These subjects are selected from the 20 subjects participated in the modified Tetris game. The selection criteria is based on the value of $(A_{bo}^{fimp} + A_{fl}^{fimp})$ derived from (7) and (8), where the top four subjects are chosen, whose detection accuracy of the boredom and flow state are maximum for the game task. These subjects were shown two types of videos namely one which is of their interest area and the other which is not. Each of these videos are of duration 5 minutes. The sequence of the two types of videos are distributed among four subjects in a balanced manner.

V. RESULTS AND DISCUSSIONS

This section provides the results for game based experiment and the web based learning. Initially, for the game, the following analysis are performed. Later the application of the boredom-flow model is demonstrated as part of the web based learning where the subjects flow state is measured.

A. Subject feedback as part of questionnaire

The subject feedback taken using GFI has been used to assess if a particular subject experienced boredom and flow experiences during the experiments. For doing this, the overall scores for both flow and boredom questionnaires are calculated assuming 1= strongly disagree, 2= disagree, 3 = undecided, 4 = agree and 5 = strongly agree. Next we performed t-test on the scores obtained to find out the differences between two conditions: flow and boredom. Next we observed the differences in mean and variance for both the conditions for each subject. Based on these differences, we finally concluded that 16 out of 20 subjects actually entered in flow state as there is a significance difference between the mean values. For remaining two subjects there are no differences between the mean values and hence are not expected to be in flow state.

B. Keystroke analysis

We analyzed all the left and right keystrokes logged by the capture tool. We calculated the correctness measure for both flow and boredom conditions using (15). Fig. 5 (a) and Fig. 5 (b) shows the correctness measure plots for both the conditions. As expected, for boredom condition most of values of C are close to 1 whereas for flow condition value of C decreases as the speed increases.

Fig. 5. Correctness measure for (a) boredom condition (b) flow condition

C. EEG analysis for boredom-flow model creation

The data analysis can be well understood with the aid of Fig. 6 which shows the 4 quadrants that partition the boredom and flow states against the 2 mixtures framed by GMM. The thick arrow represents the separation. Higher the value, higher is the capability of the HMM to distinguish the two cognitive states. Fig. 7 and Fig. 8 represents this separation achieved using 8 different features as given in (5), for 16 participants in total. It was found that the separation by each feature was not fixed for all subjects. However, it is evident from the graph that the difference value for the feature theta is greater than mid-beta for 12 subjects out of 16 subjects. When the four participants' feedback was assessed, it was found that they were not engrossed in the task, neither were they bored of the task. This state can be attributed to an intermediate state apart from the flow and boredom states.

Fig. 6. Data analysis for based on the separation between Boredom and Flow

D. Results of GSR analysis:

The GSR data file is subdivided into a number of windows of duration 1sec. with 50% overlap between the windows. Next we calculated both tonic power and phasic power using (10) and (11). The phasic power does not show sufficient separation between flow and boredom condition whereas the tonic power gives good separation between those two conditions. Hence we used tonic power as the distinguishing feature for further analysis. Table I shows the maximum tonic power for all 20 subjects for both flow and boredom condition. From the table we see that for 16 subjects the tonic power is higher in flow state compared to that in boredom state. For four subjects reverse trend is observed (marked in red). For these four subjects the t-test results also confirmed that, there are no significant differences between boredom and flow state i.e. according to GSR results and the questionnaire based survey, they did not reach flow state. Fig. 9 (a) and Fig. 9 (b) show the tonic component of GSR for a particular subject during boredom-flow-boredom-flow and flow-boredom-flow-boredom conditions. Thus we see that, in flow state due to increased mental activity the sweat level is more which in turn changes the conductance, making the two tonic component of boredom and flow conditions far apart.

Fig. 7. Separation between boredom and flow state for all the features for boredom-flow-boredom-flow

Fig. 8. Separation between boredom and flow state for all the features for flow-boredom-flow-boredom

TABLE I. MAXIMUM TONIC POWER FOR FLOW AND BOREDOM STATES

Subjects	Maximum Tonic in boredom state	Maximum Tonic in flow state
S1	0.89	0.96
S2	0.72	0.78
S3	0.65	0.58
S4	0.73	0.94
S5	0.28	0.31
S6	1.17	2.34
S7	0.49	0.52
S8	3.44	5.02
S9	0.23	0.27
S10	1.5	1.3
S11	12.9	14.7
S12	3.64	3.54
S13	0.26	0.32
S14	0.20	0.22
S15	4.99	6.77
S16	0.15	0.16
S17	1.43	2.02
S18	13.45	54.96
S19	0	0.184
S20	0.18	0.174

It is to be noted that, when subjects experience boredom condition first, and then move to flow state, there is a huge difference between the corresponding tonic components of the GSR data (Fig. 9).

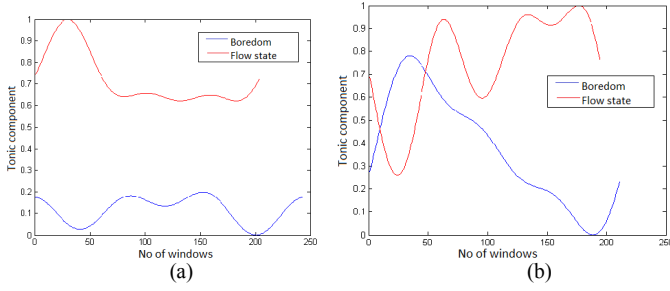

Fig. 9. Tonic component of GSR during (a) boredom-flow-boredom-flow condition and (b) flow-boredom-flow-boredom condition

On the other hand, if they first experience the flow state and then move to boredom state, then initially there is an overlap between the tonic components but finally there is a significant difference between the tonic components. This indicates that, it takes some time to get rid of the effects of the flow state. Similar trend is observed for all the subjects.

E. Results of heart rate variability analysis:

HRV values are calculated as given in [35]. Out of all three parameters, SDNN gives a distinguishable value for flow and boredom condition. SDNN for all the subjects for both the conditions are shown in Fig. 10. Here, it is visible that for 17 subjects, the HRV is more during boredom state and less in the flow state as the user have enjoyed the flow related experiment more and in the flow state they are expected to be in a calm, enjoyable state, leading to less variations in heart rate. For 3 subjects reverse trend is observed. The t-test results also show that for these 3 subjects the differences in mean values for two conditions are also very less.

Fig. 10. HRV (SDNN) during flow and boredom conditions

F. Application of EEG based boredom-flow model in WBL

Two types of learning materials are used to experiment on 5 subjects chosen from the 20 subjects with the criteria as mentioned in section IV.C(2). These two types are one in the area of interest of the subject and the other not in the area of interest. The parameters λ given by (9) are used for each subjects to derive the state transition probabilities as given in Table II. These probabilities indicate how a subject shifts between boredom and flow state and how long the subject remains in the same state. Further the distance metric D^f, D^{bo} as given in (14) and (15) are given in Fig. 11 and Fig. 12. It can be seen from Fig. 11 that for the learning material not in the area of interest, for subjects 2, 3 and 5, the $D^{bo} < D^f$ indicating the Markov chains is closer to boredom Markov chain. From the feedback from the subjects 1 and 4 it is found that they came to know many new things from the learning

material which is not in their area of interest. From Fig. 12, it can be seen that in spite of having the learning material in the area of interest, the subjects 1, 2, and 5 didn't enter the flow state as $D^{bo} < D^f$ for them.

TABLE II. STATE TRANSITION PROBABILITIES FOR TWO TYPES OF LEARNING MATERIALS FOR 5 SUBJECTS (S) USING THETA FEATURE

S	Not in areas of interest				In areas of interest			
	$bo \rightarrow bo$	$fl \rightarrow fl$	$bo \rightarrow fl$	$fl \rightarrow bo$	$bo \rightarrow bo$	$fl \rightarrow fl$	$bo \rightarrow fl$	$fl \rightarrow bo$
1	0.005	0.98	0.007	0.007	0.39	0.25	0.17	0.17
2	0.045	0.93	0.01	0.01	0.005	0.97	0.01	0.01

VI. CONCLUSION & FUTURE SCOPE

In this paper, we have tried to measure flow from brain signals and certain physiological signals like heart rate measurement, galvanic skin response. We have also tried to compare the results obtained from these direct approaches with the results obtained from questionnaire based survey and keystroke analysis. Results show that EEG signals can be successfully used to create a flow-boredom model based on first order Markov chain using a modified Tetris game. Results show that theta and mid-beta frequency band power are the most distinguishable features for flow and boredom experience. The Markov model is then used for deriving the flow-boredom state transitions for a given learning material and also getting insights on whether they enter flow state during the learning process. Future work involves fusion of brain and physiological signal and creation of a composite model with more number of states in Markov chain.

Abstract—The University of Texas – Pan American (UTPA) is a minority serving institution in south Texas. The student population is predominantly made up of students from the local region, which includes two of the poorest counties in Texas. A significant number of high schools in the region offer some form of Calculus course, and in practice we find a number of incoming students with Calculus or Pre-Calculus on their high school transcript but who do not have college credit for these courses, and who are placing into College Algebra via the usual placement mechanisms. These placement mechanisms are largely test based.

The goal of this intervention is explore the possibility of improving these students preparation so that they will be successful in a Calculus 1 class in their first semester at UTPA. We have chosen an emporium model course design for the intervention in an effort to make use of student's previous experience as demonstrated by high school course work. In the first cohort we successfully transitioned 16 students to Calculus 1 for the Fall 2014 semester, and 10 of these were successful in that class. This is not a statistically significant better performance in Calculus 1 over the traditional pre-requisite pathway (College Algebra and Pre-Calculus), and in future cohorts we will continue to adjust the course content and support structure.

I. INTRODUCTION

The University of Texas – Pan American is a minority serving institution in Texas. The student population is predominantly made up of students from the local region, which includes two of the poorest counties in our state. The region has significantly lower levels of educational attainment and median incomes compared with the state as a whole. Most students are first generation college students. The student population is 90% Hispanic, and more than 80% of them are bilingual in Spanish and English. The College of Engineering and Computer Science at the university offers Bachelors degrees in Mechanical Engineering, Manufacturing Engineering, Electrical Engineering, Civil Engineering, Computer Engineering, and Computer Science.

Typically more than half of first-year Engineering and Computer Science students do not place into Calculus for their first semester. A fifth to a quarter of the students are placed into College Algebra. Given prerequisites for foundational courses in engineering such as Physics, this effectively delays the students' time-to-graduation by at least a year. Though they can attempt to catch up in the summer semesters, the abbreviated and intense nature of summer Calculus and Physics courses

can also inhibit the student's mastery of later coursework in their engineering program.

We also see a significant number of first-year students at the university with high school transcript Calculus courses, but without credit for those courses through the AP test or other mechanisms. Many are placing into College Algebra and not Pre-Calculus through the use of standardized placement tests or through not taking a placement test at all. Studies of students in College Algebra courses in Texas indicate that rates of test aversion and anxiety are high for students in these courses [1].

Engineering students who do not take Calculus 1 or 2 in the Fall of their first year are substantially behind the curve because Calculus is the primary gatekeeper to sequences of courses in each of the Engineering and Computer Science degree plans. We aim to improve the overall degree experience for Engineering and Computer Science students who demonstrate two key features: previous course experience in mathematics that is not reflected in their placement, and a level of engagement in their course of study. We have designed a summer bridge intervention that uses an emporium model course design and combines this with mentoring and engineering design challenges. The program targets students who have high school experience in Calculus or successful experience in Pre-Calculus, and who have achieved the Texas College Readiness Standard as defined by the Texas Success Initiative [2], yet whose other placement performance has been insufficient to place into Calculus or Pre-Calculus.

It is worth noting that an alternative approach would be that of the Wright State University model of engineering mathematics, which delays the formal instruction of Calculus until later in the student's academic career and instead focuses entering students on engineering applications of mathematics [3]. Our goal is to address students who have specifically demonstrated some prior work with concepts from Calculus in the relevantly recent past and to make use of that prior experience in our intervention. It would be interesting in the future to study whether allowing a delay in this effort would be as, or more effective, however such a redesign of the curriculum was beyond the scope of our project. We do make use of the engineering design challenges that are an important feature of the Wright State University model. We also note that one goal of our effort was to develop an intervention that if successful could be adapted as an institutional model for any student needing Calculus 1 in their degree plan.

The first cohort saw 17¹ of 22 participating students successfully transition to a Calculus 1 course who would otherwise have started their first semester in Pre-Calculus or College Algebra. This is a significantly higher success rate than has been found in other Pre-Calculus courses, including other courses with an emporium model design. Our hypothesis is that by asking participants to commit to a 6 week summer course before their first official semester at UTPA, we have successfully found a measure of student motivation and engagement in their degree plan. Sixteen of these students enrolled in Calculus 1, and ten of them successfully completed Calculus 1 with an A, B, or C. While this is an improvement in the passing rate over general Calculus 1 students, it is not statistically significant. We have included data on the continuing coursework of this first cohort in the Spring 2015 semester, particularly in the downstream courses of Calculus 2 and Engineering Physics 1. Future versions of the intervention will refine the focus on topics necessary for success in Calculus 1, and will also focus strongly on providing advice in life skills and education engagement for students. For the Summer 2015 cohort we utilized an advertising effort which targets students in the ROTC and Veterans programs at UTPA and our sister school the University of Texas at Brownsville.

Results for the Fall 2014 semester were previously reported in [4], this report contains further data on the performance of the students in subsequent courses in Spring 2015.

A. Alignment with Calculus 1 Courses

If successful in the intervention course, a student will be Calculus ready for the fall semester of their first-year. The intervention is producing students who have higher pass rates in Calculus 1, and higher GPA. However, for the first cohort we did not find that these increases were statistically significant. Still, by accelerating Calculus readiness and providing a learning environment that promotes general college readiness, we should have reduced time-to-graduation and hope to show improved knowledge mastery in later courses, especially those that are Calculus or Mathematics intensive.

Discussions with Calculus 1 instructors have identified two types of deficiencies in students: deficiencies in expected mathematical knowledge, and deficiencies in engagement in the Calculus 1 course. In the first cohort we focused heavily on aligning the topics in the course with the identified content knowledge and mathematical skills deficiencies. The engineering design effort focused some on the engagement aspect, trying to give students exposure to areas in Engineering where mathematical techniques they were studying would be used. Future cohorts will have activities focusing on working with students to develop work and persistency skills such as: time management, team work, stress management, and an overview of support services offered on campus. The course will develop a plan for success in Calculus 1 for participating students that will include using freely available online resources in addition to the class they register for. Combined with the emporium model used in the summer bridge, which emphasizes the importance of practice, participating students will have a significantly improved point of view on what is needed for successful completion of Calculus 1 and other courses.

¹Of these 16 took Calculus I in the fall and one was a concurrent enrollment high school student.

B. Emporium Model

The mathematics course is a specialized course combining material from the College Algebra, Trigonometry, and Pre-Calculus courses. Material is chosen based on feedback from Calculus instructors at the university on specific problems and techniques in which the student population in their courses is deficient. Subsequent interviews with Calculus 1 instructors indicate that student engagement is one of the most important identifying characteristics of successful students.

The course is structured as a partial emporium model class. The emporium model involves students using a computer program such as the Assessment and Learning in Knowledge Spaces (ALEKS) in a computer lab [5]; the students spend class time answering questions in the system and also use the system for their homework assignments. The instructor, along with student mentors, circulates through the lab providing one-on-one assistance for problems students struggle with. These in class helpers are also involved in the mentoring of students in their engineering degree plans and generally in their integration into the campus environment.

The software used is adaptive, and provides each student with an individualized version of the course. The first activity of the students is to take an initial assessment that attempts to identify what prior knowledge they have entered the course with. This is especially important for courses that are an initial step in a chain of mathematics courses, as with traditional mechanisms of placement students are entering the course with a wide variety of experiences. The software effectively rewards students for retaining prior knowledge, which is significantly different from a standard course design [5]–[7].

The emporium model is being used on many campuses for students who place into remedial mathematics courses (courses on content from below College Algebra). It is used at our university in remedial mathematics classes as well as sections of College Algebra and the Elementary Probability and Statistics courses. The emporium model works based on the hypothesis that students who have spent more time on task with the material from the class will have better mastery of the material, and will perform at a higher level in subsequent courses which depend on that material. Emporium model courses have shown large increases in the percentage of students completing their remedial mathematics courses at our university, and increases in students completing their college level mathematics courses. This course design incorporates many of the features of mastery-based courses. Students are not allowed to proceed until they have demonstrated mastery of earlier material. One further reason for the use of an emporium model for the course design is to attempt to address participating students' test aversion through the use of the extreme amount of practice emporium models put to students.

The use of software such as ALEKS in a summer intervention has proven successful as a method of improving student placement and preparation in the mathematics sequence at universities broadly and specifically in engineering programs. It has been shown to give a better predictor of student success than the typically used placement mechanisms of student test score [8], [9].

Our approach differs from other emporium models in that we are targeting the intervention specifically at Engineering

TABLE I. PRE-CALCULUS PASSING RATES

Grades	ABC	%	DFDrW	%	Total
Summer 2014 Traditional	34	29.8 %	80	70.2%	114
Summer Bridge	17	77.3%	5	22.7%	22
Fall 2014 Traditional	55	35.9%	128	64.1%	153
Fall 2014 Emporium	28	31.8%	60	68.2%	88
Fall 2014 Online	15	42.9%	20	57.1%	35

majors. We are including student mentors from their major as the in-class and out of class assistants. Finally the course includes design challenges through a partnership with the Railway Safety Center at our school; design projects were chosen which emphasize applications of algebra and trigonometry in railway engineering, and included a tour of the laboratory spaces used by the center. This aspect of the program will be expanded in future iterations to assist in focusing on improving the engagement of students in their university studies.

II. FIRST COHORT - SUMMER 2014

The first cohort entered the program in Summer 2014. We had 22 students, all had placement into our College Algebra or Pre-Calculus course (a difficulty was finding enough interested students from just the College Algebra placement). All had non-college credit for Pre-Calculus on their high school transcript, and ten had prior experience in a Calculus course from high school, however they had not received college credit for the course. The program was run through the university as a special section of the Pre-Calculus course, and we will compare the success rates with the other sections of Pre-Calculus. In the Fall semester three sections of Pre-Calculus were run as Emporium courses using the ALEKS software; these courses did not include the student mentors or an engineering design project, but otherwise used the same course materials as the summer program. There was also a section of Pre-Calculus run in the Fall semester that was fully online. All other sections of Pre-Calculus were traditional, largely lecture-based courses with students who either placed into the section or had completed College Algebra in a previous semester. Table III gives the results and grade distributions for the various flavors of Pre-Calculus offered in Summer 2014 and Fall 2014.

We observe that the success rate of students in the Summer bridge program differed significantly from that of the other Pre-Calculus sections. Most likely students who elected to participate in this summer bridge were self-selecting as mathematically ahead of their peers in general College Algebra and Pre-Calculus courses. They were declared as Engineering or Computer Science majors; they had some level of College Preparedness; and they elected to take a mathematics course prior to their first official semester as first-year students. Evidence that this population is special is that the effort needed to find 22 interested students for the first cohort was extreme. It is notable that attendance for the course was nearly perfect with no absences and only two tardies. Also note that no students dropped or withdrew from the course (their final grade would affect their GPA and potentially financial aid for AY2015-2016).

Of the 5 students who were not successful in the program, we found that 4 had significant work commitments outside of

TABLE II. PASSING RATES IN FALL 2014 CALCULUS 1

Grades	ABC	%	DFDrW	%	Total
Fall 2014 Calculus 1	205	27.4 %	211	50.7 %	416
Summer Bridge Students in Calculus 1	10	63%	6	37.5%	16

class. In the next iteration we will place a restriction on how much outside commitment students may have.

A. Success in Calculus 1

Of course the real measure of success for the program is how the students do in the subsequent mathematics (and mathematics intensive) courses. All but one of the passing students enrolled in a Calculus 1 course for the Fall 2014 semester. The one exception was a student who took the summer bridge as a concurrent enrollment student; due to him being a minor, and being in a unique situation we have not been able to secure permission to include his current activity in this report. Table II summarizes the grade distribution from the Fall 2014 sections of Calculus 1, and from the students who participated in the summer bridge program. Using a hypergeometric distribution we find that a random sample of 16 students from the Fall 2014 Calculus 1 classes would have a 20.5% chance of having 10 or more students successfully passing the course. So we cannot conclude that the success rate was statistically significant for this population. Likewise the Calculus 1 GPA of students who successfully completed the bridge program was 1.8 on a 4.0 scale, compared with a 1.55 from the general Calculus 1 classes. However the chance that a random sample of 16 students from Calculus 1 had a GPA of 1.8 or higher is 26%, so again we cannot conclude that this change was statistically significant.

In future iterations of the project we hope to show a significant improvement in performance in Calculus 1 over the traditional sequence of courses these students would have been asked to work through. The choice of an emporium model course design here was specifically made to make use of students' previous course work. It is not expected by the authors that this course design would be likely to have as strong an effect on students who lacked previous experience with Calculus 1 and its pre-requisite topics.

The emporium model course design asks students to work many examples. Figure 1 shows the grade in Calculus 1 in Fall 2014 for students who successfully completed the summer bridge program versus the number of topics marked as mastered by the software (obtained through repeated success in software assessments and by answering the question correctly three times without asking for help). It is important to note that throughout the emporium course it is possible for a student to have a topic marked as mastered removed because of a periodic assessment. Here we see a correlation, indicating that we almost certainly need to be including a minimum number of topics as a requirement for completing the program. This table and subjective questionnaires of the Calculus 1 instructors are going to be used to adjust the focus of the topics to better address Calculus readiness.

In table III we have included two more students from the

Fig. 1. This chart gives for those students who went on to Calculus 1 in Fall 2014, the grade they received versus the number of topics that they mastered in the summer bridge program.

TABLE III. COURSE PERFORMANCE BY SPRING 2015 FOR THE 2014 COHORT, ORIGINALLY 21 STUDENTS

Course	Number Completed
Calculus 1	12
Calculus 2	4
Physics for Engineering 1	7
Engineering Materials	2

16 who were successful and have subsequently passed their Calculus 1 course in the Spring semester. Of the five students who were not successful in the summer program: 4 have been unsuccessful in subsequent mathematics courses ranging from remedial to Pre-Calculus, and 1 has successfully completed College Algebra with a B.

B. Success in downstream courses

Currently the number of students in downstream courses is too small to draw broad conclusions. We have 12 students from the initial group of 21 who successfully completed Calculus 1 by the end of the Spring semester (ignoring the concurrent enrollment student).

One issue identified is students who are not registering for Calculus 2 the semester after completing Calculus 1, that is not all of the 10 who passed Calculus 1 in the Fall were enrolled in Calculus 2 in the spring; most likely this is related to the overall GPA of students completing Calculus 1 (5 of this cohort passed the course with a C).

We have discarded from the course topics some items which are included in the traditional Pre-Calculus syllabus because of their relevance in courses downstream from Calculus 1, and it is important that we understand whether the effect has been detrimental to students success.

Based on experience of the author in Calculus 2, students who have gone through the traditional sequence of pre-requisite courses do not typically demonstrate mastery of these topics in any case.

III. ADJUSTMENTS AND CONCLUSION

The program successfully transitioned 16 students to Calculus 1 for the Fall semester of their first-year; of these, 10 successfully completed this Calculus 1 course. A success rate that is comparable for that of students who place into Calculus 1 via other mechanisms. These 10 students took combinations of Calculus 2 and Calculus based Physics 1 in the Spring 2015 semester, overall the number of student persisting in the downstream courses is low, and the sample size is currently too small for broad conclusions. Regardless these students are one or two full semesters ahead of where they would be in their mathematics course sequence for the Engineering and Computer Science major if we had not conducted the intervention and they had registered for Pre-Calculus or College Algebra. One conclusion is that the UTPA may be able to successfully make use of students' high school transcripts for placement decisions and not rely solely on placement test scores.

ACKNOWLEDGMENT

The authors would like to thank the Division of Undergraduate Education at the National Science Foundation for its support through the STEP, "Graduate 10K+," initiative under grant number NSF-DUE 1317661.

Abstract—Providing students with suitably complex exercises is crucial to keeping them motivated and leading them to deeper understanding. Making such problems manually takes mathematics teachers' precious time which can otherwise be used to mentor students. Many software tools and services for automatic generation of math problems are found on the Web, but all of them provide only materials of high-school level or below. In addition, no standardized methods are provided to evaluate and control the computational complexity of generated problems. General concepts of complexity in various forms can be found in standard textbooks. The authors treat a different flavor of complexity, subjective complexity, where complexity is measured by the difficulty that learners feel. The authors proposed a new framework for evaluating computational complexity from learners' view, aiming to apply our framework to automatic generation of college math problems with controlled computational complexity. To prove the effectiveness of the new concept of complexity from learners' perspective, we developed some automatic generation tools based on our framework. In this paper, we will present one of the tools that supports automatic generation of eigenvalue problems. Controlling the complexity of eigenvalue problems involves restricting the number of calculation steps, the heights of the involved rationals, and the algebraic number fields appearing in the model solution of the problem. The small-scale experiments showed the relevance of our framework. Our system makes a path to strict quantitative control on various complexity from the learners' view. Future work includes the application of our methods to other areas such as differential equations, number theory and so on. We also should prove that this system has a positive effect on the engineering education at college level. Therefore, demonstration experiments in classroom will be scheduled in the next step of our research.

I. INTRODUCTION

We propose a framework for evaluating the computational complexity of college-level mathematics problems, with the aim of applying our framework to automatic generation of such problems controlled computational complexity.

Providing students with suitably complex practice problems is crucial for motivating them and facilitating deeper understanding. Manually constructing such problems consumes time, which mathematics teachers can otherwise use to mentor students.

Many software tools and services for automatic generation of mathematics problems are available on the web, but they provide only materials up to high-school level. In addition, no

Fig. 1. GUI for generating eigenvalue problems

standardized methods are provided to evaluate and control the computational complexity of the generated problems. Among the popular web sites and services, we list some examples. Wolfram Problem GeneratorTM [1] and Davitily Math Problem GeneratorTM [2] deal with mathematics problems for high-school students. SuperKids Math Worksheet CreatorTM [3] deals with arithmetic problems for children attending elementary schools. However, our framework is new as it deals with math at the college level and introduces suitable methods for evaluating computational complexity from the learners' perspective.

Eigenvalue problems are usually taught in linear algebra

courses at engineering departments. Since most textbooks do not provide sufficient practice problems, teachers must make additional problems to be used in classes, assignments, and exams. We took this topic as a case study to develop our framework.

Figure 1 shows a GUI for generating eigenvalue problems using MathematicaTM. Here, the user selects parameters such as the algebraic number field used in the calculation, the number of the calculation steps, and the matrix dimension, which determine the outline of the problems. The user then selects the problem category and provides the required parameters that control the computational complexity. To further reduce the burden for busy users, predefined sets of recommended parameters are also stored in the system, which eases the parameter selection process. Problems with the required complexity along with model answers are generated.

In this paper, we present an automatic generation of diagonalization problems for Hermitian matrices to illustrate the relevance of our proposed framework.

This paper is organized as follows. Section 2 describes the method of measuring complexity from learners' perspective. Section 3 and 4 demonstrate automatic generation under given conditions. Section 4 describes our experimental results and discussion. In the final section, we conclude this paper.

II. COMPLEXITY FROM LEARNERS' PERSPECTIVE

General concepts of complexity are available in various forms in standard textbooks such as [5]. We deal with a different variety of complexity, subjective complexity, where complexity is measured by the difficulty from learners' perspective.

Designing practice problems that are sufficiently but not excessively complex is crucial for keeping a learner motivated. We propose a new framework for estimating such computational complexity and demonstrate its relevance by developing a framework for automatic generation of complexity-controlled practice problems. Our framework enables us to

- 1) control the number of the calculation steps,
- 2) limit the height of rational numbers involved in a calculation, and
- 3) deal with algebraic numbers.

The computational complexity of generated problems is mainly determined by the sum of the heights of the rational numbers (the maximum ratio of the absolute values of the denominator and numerator) appearing in its model solution. In the hope of extending our work to other mathematics areas, we incorporated controls over algebraic number fields in our system. The user can select the calculation field from the rational number field and other algebraic fields extended by irrational numbers, especially, quadratic irrational numbers, and fourth-power irrational numbers.

A. Automatic Generation of Linear Equations

This subsection is a summary of our early work on the linear equation problems aiming to control the complexity from the learners' perspective. Solving linear equations is a part of eigenvalue problems. The system generates linear

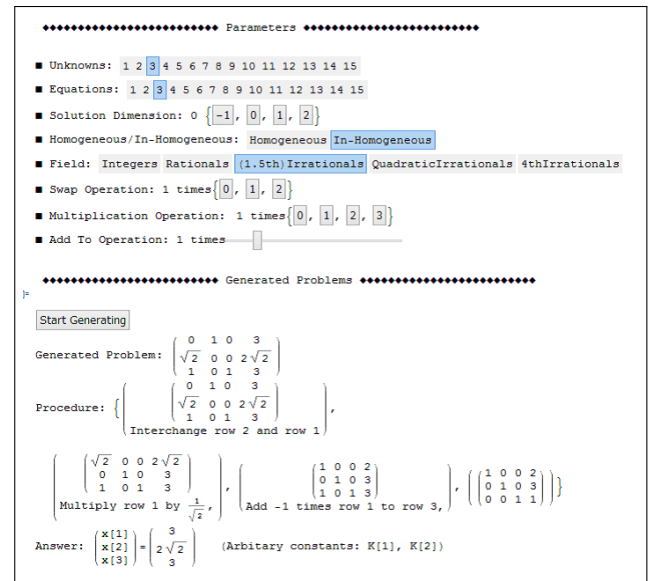

Fig. 2. GUI for generating row-operations problems

equations as the elementary row operations problems and model answers. The row operations are classified as follows.

- 1) Row switching (A row within the matrix can be switched with another row.)
- 2) Row multiplication (Each element in a row can be multiplied by a non-zero constant.)
- 3) Row addition (A row can be replaced by the sum of that row and a multiple of another row.)

It is commonly practiced that the matrix representation of the problem is reversely constructed from the solution space. Teachers do such reverse-row operations by their hands, controlling the level of difficulty at every step of the transformation by their naive concept of complexity. Our system does all these things automatically and controls perfectly the computational complexity as specified by the user. See Fig. 2.

The system controls the number of the calculation steps by limiting the number of the reverse-row operations steps, and limits the heights of rationals in the row multiplication and row addition.

In the following sections, we will show an application of our framework to eigenvalue problems and discuss the computational complexity from learners' perspective.

III. AUTOMATIC GENERATION OF EIGENVALUE PROBLEMS

Eigenvalue problems are usually taught in linear algebra courses at engineering departments. Eigenvalue problems appear in two forms: diagonalization of Hermitian forms and Jordan canonicalization of linear endomorphisms. In this paper, we deal with diagonalization of Hermitian matrices. The process of generating complexity-controlled eigenvalue problems includes

- 1) creating a pool of nice looking matrices,
- 2) generating eigenvalues with specified multiplicities,

- 3) generating a set of candidate Hermitian matrices, and
- 4) filtering out those matrices that are not suitable for exercises with some criteria.

We explain each step in detail. First, we generate nearly the entire set of tractable unitary matrices and classify them by algebraic number fields. We define an utility function that can extract all of the irrational numbers appearing in the entries of a tentatively generated matrix. For example, this function returns the list $[\sqrt{-1}, \sqrt{2}, \sqrt{3}, \sqrt{5}]$, where

$$\begin{pmatrix} \sqrt{-5} & \sqrt{2} \\ \frac{1}{\sqrt{3}} & 7 \end{pmatrix} \quad (1)$$

is entered as a primary material that is later subject to Gram-Schmidt orthonormalization. Diagonalizing a given Hermitian matrix requires

- 1) calculating eigenvalues,
- 2) selecting mutually orthogonal eigenspaces each of which corresponds to an eigenvalues, and
- 3) constructing a unitary matrix using these eigenvectors.

In the requirement 2, selecting an eigenspace is either giving an eigenvector or giving a set of eigenvectors. In the latter case, the eigenvalue has multiplicity greater than 1. Note that the choice of eigenvectors in degenerate cases does not affect the final result. Hence, the number of calculation steps does not vary once all the multiplicities are specified. General Hermitian matrices can be generated from a diagonal matrix D and a unitary matrix U as

$$H = UDU^\dagger \quad (2)$$

where U^\dagger is the conjugate transpose matrix of U . Equation (2) is rewritten as $D = U^\dagger H U$. The most difficult part is generating a unitary matrix with the specified properties. However, the number of matrices suitable for this purpose is relatively small because the entries of those matrices must be obtained from a given algebraic number field, and the heights of the involved rationals must be restricted, furthermore, all of the column vectors must form an orthonormal system. Therefore it is possible to predefine almost entire sets of unitary matrices that can be used to generate Hermitian matrices that can be diagonalized with specified complexity. This stage can be skipped once the pool is created. However, we may recreate another pool with slightly different parameters.

A. Generation of Unitary Matrices

This section describes the generation of 3×3 unitary matrices through examples. The procedure for generating a matrix comprises four major steps:

- 1) generating a unit column vector,
- 2) verifying that all the entries belong to the given number field,
- 3) constructing an orthonormal basis from two other linearly independent column vectors using the Gram-Schmidt procedure, and
- 4) verifying again that all of the entries of those basis vectors belong to the given number field.

```
u1 = Orthogonalize[{{1/10, 1/10, 7/(5*sqrt(2))}, {1, 0, 0}, {0, 1, 0}}]; u1 // MatrixForm
```

$$\begin{pmatrix} \frac{1}{10} & \frac{1}{10} & \frac{7}{5\sqrt{2}} \\ \frac{\sqrt{11}}{10} & -\frac{1}{10\sqrt{11}} & -\frac{7}{15\sqrt{22}} \\ 0 & \frac{7\sqrt{2}}{3} & -\frac{1}{3\sqrt{11}} \end{pmatrix}$$

```
FieldFilterFunction[u1]
{sqrt(2), sqrt(11), sqrt(22)}
```

```
u2 = Orthogonalize[{{1/10, 1/10, 7/(5*sqrt(2))}, {0, 0, 1}, {0, 1, 0}}]; u2 // MatrixForm
```

$$\begin{pmatrix} \frac{1}{10} & \frac{1}{10} & \frac{7}{5\sqrt{2}} \\ -\frac{7}{10} & -\frac{7}{10} & \frac{1}{5\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \end{pmatrix}$$

```
FieldFilterFunction[u2]
{sqrt(2)}
```

Fig. 3. Example of orthogonalization. The upper part shows failure in retaining the number field after orthogonalization in the case in which $(1, 0, 0)^t$ and $(0, 0, 1)^t$ are appended. The other shows success in retaining the field, when $(0, 0, 1)^t$ and $(0, 0, 1)^t$ are appended.

```
u3 = Orthogonalize[{{1/10, 1/10, 7/(5*sqrt(2))}, {0, 0, i}, {0, 1, 0}}]; u3 // MatrixForm
```

$$\begin{pmatrix} \frac{1}{10} & \frac{1}{10} & \frac{7}{5\sqrt{2}} \\ -\frac{7i}{10} & -\frac{7i}{10} & \frac{1}{5\sqrt{2}} \\ -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \end{pmatrix}$$

```
FieldFilterFunction[u3]
{1, sqrt(2)}
```

Fig. 4. Example of expansion of the orthogonalization to imaginary matrices.

In step 1, we generate various unit vectors that are the form in Equation (3).

$$e_1^t = (\pm \frac{i}{j\sqrt{k}}, \pm \frac{l}{m\sqrt{n}}, \pm \sqrt{1 - ((\frac{i}{j\sqrt{k}})^2 + (\frac{l}{m\sqrt{n}})^2)}), \quad (3)$$

where i, j, l , and m are rational integers, and k and n are 2, 3, 5, 7, or 1. In step 2, all of the irrational numbers such as $\sqrt{2}, \sqrt{3}$, and $\sqrt{-1}$ are extracted from the vector and matrix. We select the vectors whose entries belong to the specified number field. In step 3, e_1 and two other vectors are orthogonalized. Only an additional two vectors are required to form a linearly independent triple together with e_1 . Hence, for easy calculations, we can take them from sparse matrices, where only the positions of nonzero entries are important. Figure 3 indicates that the field may possibly be extended after orthogonalization.

We generated three patterns of unitary matrices by changing the position of the non-zero element of each vector. If the user wants a complex number field, then $\sqrt{-1}$ must be added in some entry of an initial vector (see Fig. 4). In step 4, the number field of the components is verified again. This step is necessary because Gram-Schmidt orthogonalization takes square roots which may cause further algebraic extension of fields. We select matrices all of whose entries have rationals of low heights in their subexpressions. These forms the basic

TABLE I. PREDEFINED ORTHOGONAL MATRICES

Field \ Dimension	2 × 2	3 × 3	4 × 4
Q	65	20	4245
$Q(\sqrt{2})$	27	33	2503
$Q(\sqrt{3})$	12	10	930
$Q(\sqrt{5})$	20	25	1714
$Q(\sqrt{7})$	12	3	927

TABLE II. PREDEFINED UNITARY MATRICES

Field \ Dimension	2 × 2	3 × 3	4 × 4
$Q(\sqrt{-1})$	129	20	25066
$Q(\sqrt{2}, \sqrt{-1})$	65	33	8488
$Q(\sqrt{3}, \sqrt{-1})$	30	11	2862
$Q(\sqrt{5}, \sqrt{-1})$	68	26	9068
$Q(\sqrt{7}, \sqrt{-1})$	24	5	2142

set of tractable unitary matrices. Of the 500,000 generated unitary matrices in a preliminary stage, the filter selects 681 matrices according to the criterion described in later sections. The number of predefined matrices are listed in Tables I and II. Though the basic set is relatively small (681), we can generate other tractable matrices by multiplying them among themselves and by taking direct sums as follows: given two matrices of the same dimension

$$U_1 \text{ and } U_2 \in U(n), \quad (4)$$

we obtain

$$U_1 U_2 \in U(n). \quad (5)$$

Given two matrices of possibly different dimensions

$$U_1 \in U(m) \text{ and } U_2 \in U(n), \quad (6)$$

we obtain

$$U_1 \oplus U_2 \in U(m+n). \quad (7)$$

Note that the number field involved is preserved under both multiplication and direct sum operations. For example,

$$\begin{pmatrix} -1 & 1 \\ 1 & 0 \end{pmatrix} \text{ and } \begin{pmatrix} \sqrt{-1} & 0 \\ 0 & 1 \end{pmatrix}. \quad (8)$$

Using such methods, we can obtain sufficient unitary matrices, as presented in Tables I and II.

IV. DEMONSTRATION

We demonstrate the automatic generation of eigenvalue problems for Hermitian matrices and evaluate the complexity of the generated problems. Figure 5 presents the results of ten generated Hermitian matrices. The dimension of each matrix, multiplicity of eigenvalues, algebraic number field, height h of numerical calculation, and number n of problems is 3, 1, $\sqrt{-1}$, 100, and 10, respectively. The system generates n problems on demand. Each matrix

- 1) has a maximum absolute value of involved rationals less than h ,
- 2) has entries that belong to specified number field, and
- 3) differs from already generated matrices.

In this case, generating ten problems took 4.16 seconds. The time measurements for generating problems are listed in

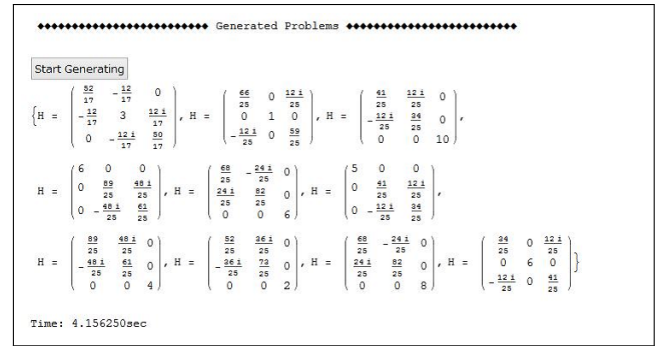

Fig. 5. Samples of generated Hermitian matrix

TABLE III. TIME (SEC) FOR GENERATING PROBLEM 1

	2 × 2	3 × 3	4 × 4
Q	5.33	17.14	1615.72
$Q(\sqrt{2})$	702.81	1185.03	768.2
$Q(\sqrt{3})$	702.00	1324.84	810.72
$Q(\sqrt{5})$	353.91	1677.19	484.39
$Q(\sqrt{7})$	320.05	3154.67	1684.18

Tables III and IV. The machine's specification is as follows. The adopted software is Wolfram Mathematica 9.0 (Windows 8.1, 64 bit, Intel(R) Core i5-4300U CPU 1.9 GHz. The main memory is 8.0 GB.)

Tests were conducted generating 1,000 problems for each number field. Generating one problem takes 1.18 seconds on average. As the tables indicate, generation consumes more time when the number field is complex because the system needs to decompose all of the matrix entries to check the maximum height of the rational numbers.

As a preliminary experiment, we asked 10 CS department students to solve two sets of problems: one set consists of the problems with controlled complexity, the other consists of uncontrolled ones. See Tables V and VI. On average, the former case, students required 2 min to calculate eigenvalues and 6 min to construct a unitary matrix, while for the latter case students required 6 min to calculate eigenvalues and 7 min to form a unitary matrix. In addition, 4 students could not reach the answers of the uncontrolled problems at first. These results demonstrate the validity of our proposed framework. Large-scale verification experiments will be conducted out with the cooperation of university teachers.

TABLE IV. TIME (SEC) FOR GENERATING PROBLEM 2

	2 × 2	3 × 3	4 × 4
$Q(\sqrt{-1})$	110.61	170.72	1712.11
$Q(\sqrt{2}, \sqrt{-1})$	655.34	2175.56	809.42
$Q(\sqrt{3}, \sqrt{-1})$	599.29	4585.61	924.39
$Q(\sqrt{5}, \sqrt{-1})$	691.75	3439.33	500.33
$Q(\sqrt{7}, \sqrt{-1})$	3543.17	22911.11	1821.26

6s	3 students	7s	4 students
7s	6 students	8s	5 students

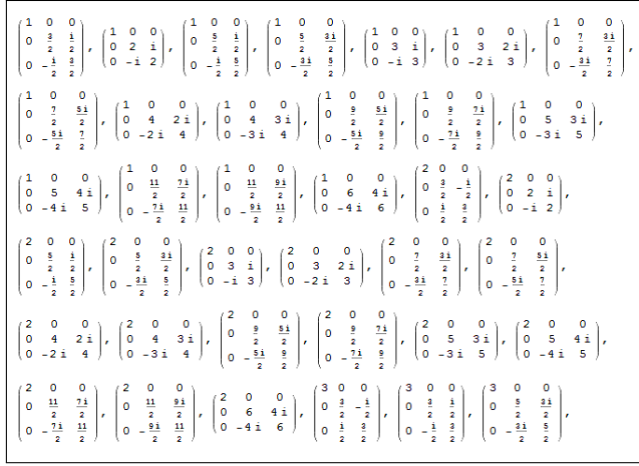

Fig. 6. Generation of Hermitian matrices from one unitary matrix by changing eigenvalues

A. Discussion

In our experiments, some learners felt excessive difficulty in calculating characteristic equations to get eigenvalues. The complexity of calculating eigenvalues can be reduced by restricting unitary matrices to more tractable ones. In other words, some of predefined unitary matrices are not tractable. We knew that the unitary matrices which generate good Hermitian matrices can be use to generate other good Hermitian matrices by rechoosing eigenvalues.

Some teachers criticized that irrational numbers such as $\sqrt{5}$ and $\sqrt{7}$ look ugly as exercise problems. Therefore we chose only matrices which include Q , $Q(\sqrt{2})$ and $Q(\sqrt{3})$. Finally, we got 174 tractable 3-dimensional unitary matrices after changing some parameters. These predefined unitary matrices include other variable number field such as $Q(\sqrt{10})$ and $Q(\sqrt{13})$ because these unitary matrices often generate nice looking unitary matrices regardless of including such irrational numbers.

The number of finally obtained matrices is 174. Although this number seems smaller than what we obtained in our previous work, we can still get virtually infinite Hermitian matrices because of virtually infinite assignments of eigenvalues to eigenspaces. See Fig. 6. These Hermitian matrices are generated by using one unitary matrix by changing a target diagonal matrix.

Learners also felt excessive difficulty because the number fields varied from ones that we specified. The number field varied because of procedure of orthogonalization. Learners should start orthogonalization of vectors in ascending order of the norms. When they refer the generated model answers, they may learn the importance of the procedure of orthogonalization.

TABLE VII. THE NUMBER OF THE STUDENTS BELONG TO EACH TIME (MIN) FOR SOLVING THE GENERATED PROBLEMS.

	Eigenvalues		Eigenvectors
1s	1 student	4s	4 students
2s	5 students	5s	4 students
3s	4 students	6s	2 students

Some parts of the automatic generation system of row-operations problems, our early work, can be reused in the generation of eigenvalue problems. Calculation of eigenvectors involve row-operations.

After this refinement, we conducted a second experiment in which we asked the same CS students to solve the generated problems again. See a Table VII. Students required 2 min to calculate eigenvalues and 5 min to construct a unitary matrix. And also, teachers satisfied the complexity-controlled problems.

V. CONCLUSION

In this paper, we presented a new framework for evaluating and controlling computational complexity from the learners' perspective. In addition, we developed an automatic generation system for eigenvalue problems based on our framework. The automatic generation of complexity-controlled eigenvalue problems is one of the sample implementations that validate our framework. Controlling the complexity of eigenvalue problems involves restricting the number of calculation steps, the heights of the involved rationals, and the algebraic number field appearing in a model solution. In small-scale preliminary experiments, we could decrease the computational complexity and answering time.

Constructing problems with sufficient computational complexity is essential for maintaining learners' motivation. The system can generate virtually infinite exercise problems. Our framework helps teachers prepare learning materials and thereby save time for mentoring students.

We expect our technique to be applicable to other subjects in linear algebra and analysis. Our system paves a path to strict quantitative control on various aspects of complexity from the learners' perspective. Future work include the application of the row-operations system to the evaluating the complexity of a constructing a unitary matrix. And also we will apply our methods to other areas such as differential equations, and number theory. We also would like to show that this system has a positive effect on college-level engineering education. Therefore, demonstration experiments in classroom will be the next step of our research.

Abstract—We have designed and built CalcTutor, an online educational tool for Calculus that employs the Teachers Dilemma methodology. This methodology is centered around a game framework where students take on, and are rewarded for playing well, both the role of learner and teacher. Students create machine-verifiable questions for each other and gain points based on not only correct answers but also asking good questions. This framework has been used and studied in a variety of projects, mostly in the K-12 arena. The CalcTutor tool expands this approach to college level classes, specifically introductory Calculus. In this paper, we are reporting on our experience with a pilot study of CalcTutor, as used in conjunction with a college Calculus class.

The system is designed to support learning in two ways, teachers can build quizzes for their students and the students can pair off and play games with each other. The students are given dynamic feedback about how appropriate their question is for their partner in the game as they develop each problem. During this pilot study, students asked and answered problems of two types: finding the derivative of a function and calculating the tangent line to a function at a point.

The system was simultaneously tested in five introductory Calculus sections which generated a sizeable body of system data as well as survey feedback. Unfortunately, like many new tools, some of the students found getting used to the interface hard and some of our theoretical concepts did not pan out. Nevertheless the technical parts of the system worked well; students and teachers were able to create and answer questions without any issues. Some of the untested ideas that we were trying out met with success. And many students enjoyed some features of the system, particularly the instantaneous feedback.

I. INTRODUCTION

One of the enticing promises of online education is the ability to scale up class size dramatically while maintaining, or at least not significantly lowering, the level of learning. The Teacher's Dilemma offers a way to realize this goal. By creating a framework within which peers are rewarded for being good teachers we can turn the usual limitation of having a large number of students into an asset. The hope is that this might be a viable way to improve larger classes and to improve open online learning.

The purpose of this pilot study was to take the Teacher's Dilemma one step closer to this goal. Previously the concept had only been applied to small isolated problems in the K-12 learning space. For example, figuring out how to make a specified cash amount out of quarters, dimes, nickels and

pennies. We wanted to pick a larger, more complete corpus in the higher education space. We decided that college level introductory calculus would be a sufficiently advanced, rich topic around which to build a system.

For the pilot study we wanted to demonstrate the viability of the system from a technical standpoint as well as make inroads into showing how some of the theoretical aspects might work. We built a new web based system on a foundation that will easily allow scaling up to a large number of users. The system has a custom differentiation engine and mathematical functional equivalence checker that allows question creation to be easy and answer checking to be automated. In particular, students can easily create questions because they don't need to know the correct answer to write the question. We also wanted to begin exploring some of the details that are needed for the theory to work. For example the basic version of the teacher's Dilemma requires a difficulty score for problems. This would ideally be generated by user data, but until that can be obtained we need to have a heuristic to bootstrap the process in a reasonable fashion. In this pilot study, we found that our initial heuristic for the student score correlates with difficulty as measured by number of student attempts to arrive at a correct answer.

II. RELATED WORK

Online support for learning, and more general computer support for learning, has been around almost as long as the internet, or indeed almost as long as computers have existed [1]. These educational efforts have taken a wide variety of forms and as such there are many efforts that are, at least tangentially, related to our work.

Perhaps the most traditional learning support comes in the form of sites which have example problems and solutions [2]. Other sites provide online tutoring from a live person [3]. Indeed, even many organizations that were initially brick and mortar tutoring and testing prep services now have online components [4]. Online learning spaces like Khan Academy [5], and Coursera [6] also routinely feature quizzes designed to target a specific skill. Like CalcTutor, all these systems have the ability to challenge the student with questions, but they either require the student to assess their own skill level and pick the appropriate challenge, or ask a human expert to

do the same. Also the systems that have automated questions have a fixed set of them and, unlike CalcTutor, adding more questions can be difficult and is often only possible by the creator of the system.

Online homework systems represent a sort of next step in customization and automation for these online resources. Systems like WebAssign [7] and WebWork [8] have large libraries of questions that can automatically determine if the student's answer is correct. Several papers have been published showing that these at least do not harm student learning [9] and in some cases can help [10]. These systems can also be effective pedagogical tools [11]. Generally speaking, studies find that students enjoy getting immediate feedback, that they often continue working until they get the right answer even if it takes many tries, and that they spend less time studying for the class for at least similar grades. Finally, the teachers find that it saves a great deal of grading time, which they can then use for other purposes such as office hours or research. The usual pedagogy for these systems is to have a teacher select the homework questions and the students simply do whatever work is assigned to them. It should be noted that, for example, WebWork does allow teachers to create problems but this is an advanced feature that requires coding knowledge. These systems are similar to CalcTutor in that they allow automated answering of questions but their selection is again done by experts and creating new questions is, at best, difficult.

Gamification is a general term used to describe systems that take advantage of the techniques games use to create motivation in non traditional game environments. There have been several strong arguments for using this strategy in education [12]. This motivation can come from competition or more esoteric means like storytelling. These gamified learning environments can take on a wide variety of formats, from adapting simple Board Games structure [13], to MMO based around science material [14]. Some have expressed worries that gamification or at least competitive games might have a negative emotional impact. But at least some cases studies have shown that competition has had little negative impact [15] or that it is possible to redesign games to reduce the negative effect [16]. While the CalcTutor is not heavily gamified we do hope students will become excited and learn better by having game style rewards (more points) for performing better. Additionally while the player interaction is largely framed as supportive we do provide leaderboards for students to check their standing compared to their peers.

Intelligent Tutoring Systems (ITS) are, in some ways, a strong parallel to the Teacher's Dilemma method. Both are centered around attempting to create a system that delivers the right level of content to a student. ITS systems do this by having a model of the student's capabilities and using that to determine what the student should be working on. For example, some do this by supplying the student with questions of the right difficulty to answer [17] [15]. ITS systems have been built for Calculus [18] and have, in some cases, been shown to be more effective than Online Homework Systems [19]. The key difference between our work and the

ITS domain is that we push the work of modeling the student and devising appropriate challenges onto their peer tutor and thus can avoid the difficulty inherent in the need to model the student properly.

Peer tutoring and online study group systems have been built for general education [20] as well as math learning [21]. These systems assist student learning in small group environments where a computer system provides structure, automation and support. They can generally be considered to fall under the Computer Supported Collaborative Learning umbrella (CSCL). There are a wide variety of such systems and the CalcTutor could also be considered a CSCL system. Where CalcTutor differentiates itself is by having an explicit reward system for a peer teacher. This allows us to provide immediate and definitive feedback that, in theory, helps peers become good instructors. For example, the Teacher's Dilemma method provides a student with a measure of the quality of each individual question they asked another student.

The work that the CalcTutor is most strongly related to is Dr. Ari Bader-Natal's 2008 PhD dissertation "The Teachers Dilemma: A game-based approach for motivating appropriate challenge among peers" [22]. We are directly continuing the Teacher's Dilemma concept and expanding it in the scope of domains to which it applies (i.e., Higher Learning, specifically Calculus) as well as expanding on the theory by attempting to keep track of a more advanced notion of "relative" question difficulty and a deeper insight into the error paths people take before getting the correct answer.

III. TEACHER'S DILEMMA

The goal of the Teacher's Dilemma is to have a framework that provides appropriate motivation for peers to become good teachers for each other. The end goal is to reduce or even eliminate what is normally a powerful limitation: a large number of students in a class. This would mean it would then be possible to efficiently scale up class sizes or greatly improve the effectiveness of MOOCs, which in turn could help equalize the education gap, or at least reduce the cost of bringing quality education to those who need it most. It could also be useful in the traditional higher education setting by promoting high quality study groups.

The core idea of the Teacher's Dilemma revolves around how to reward peer teachers. Bader-Natal's thesis covers this in detail but we will give a summary here. We consider the situation of two peers, one playing the role of teacher and the other student. If we simplify things and assume that a teacher's role is to ask questions of various difficulties (say ranging from 0, easiest, to 1, hardest), then the question becomes how hard a question should they ask to maximize learning? And, more to the point, how should we reward them given what question they asked and how well the student did answering it?

The response to this question is based loosely off the Prisoner's Dilemma notion from Game Theory (hence the name Teacher's Dilemma). We think of the universe as a payoff matrix. Did the teacher ask a hard question or an easy one and did the student answer the question correctly or not?

Again a full explanation of what assumptions are required to analyze this are covered in Bader-Natal's thesis but the condensed version is as follows. We reward the teacher a high number of points if they ask a hard question the student gets right or an easy question the student gets wrong. Intuitively the idea is that we want harder and harder questions that the student can figure out to push their limits. On the other hand, we also want to expose holes in the student's knowledge by asking them easy questions they get wrong.

More formally, if we call the question difficulty D , and C indicates if the student got the question correct we award the teacher points in the following manner:

if C is true the teacher receives D points if C is false the teacher receives $1-D$ points

This yields the desired result of rewarding hard questions that are answered correctly and easy question that are answered incorrectly.

One minor note of difference between our work and the original formulation of the Teacher's Dilemma is that we use a notion of relative difficulty when computing the teacher scores in games. What this means is that when we compute the teacher points for a game question we take the D in the teacher points formula to be the difficulty of the question divided by their partner's student points. Thus as their partner improves a user will need to keep asking more difficult questions to get the same number of teacher points. On the other hand, if they pair up with a less experienced partner they will need to adjust the difficulty of the questions they are asking or their partner won't get any correct.

IV. CALCTUTOR

The CalcTutor system is a semi-automated online learning system designed to teach students Calculus by asking them a variety of questions appropriate to their skill level. The system has instant answer checking so students get immediate feedback on whether they got a question right. It can be used by a teacher to easily construct a quiz that students can take or students can pair off and play games with each other. In this latter mode, students create questions for each other and are rewarded for answering questions correctly and asking good questions.

A. Organization

The CalcTutor system is currently designed with the classroom in mind (although it will be easy to adapt to a more open internet model later, and this is one of our goals). The system has a concept of Organizations that serve as umbrellas for Classes. Users can sign up for Classes, either as a teacher or a student. Teachers are allowed to create quizzes that are shared with everyone in the class. Quizzes are simply a list of questions that anyone in the class can attempt to answer. In general, users are allowed to attempt to answer a question as many times as they want. Every attempt is recorded and teachers can see all the attempts a student makes.

Other Player's History

When creating your questions it may help you to know what the other player has done recently. Below is a quick summary of the recent history of what questions they've answered correctly and incorrectly.

Correct

Here are the questions Tim-instructor-3 answered correctly recently:

1. derivative of: $-\sin(x)$
2. derivative of: $\frac{\tan(x)}{\cos(x)}$
3. derivative of: $\sin(x)$
4. derivative of: $5^{e^{3x}}$
5. derivative of: $\frac{\sin(x)}{\cos(e)}$
6. Tan line of: $\sin(x)$ @ 0

Incorrect

Here are the questions Tim-instructor-3 answered incorrectly recently:

1. derivative of: $\frac{\ln(x^2)}{\sin(2 \cdot x^2 - 1)}$
2. Tan line of: $\ln(3 \cdot x^2 - 2x) \left(2 \cdot e^{4 \cdot x^2} \right) - \frac{\ln(x+3)}{2x + e^2}$ @ 1

Fig. 1. Interface for students to see history of other students.

B. Games

Students can also initiate Games with other students in their class. To do this the student picks a partner (from a list of all the other students in the class) and the other student receives a request. The partner can see the request in a sidebar on most pages that indicates the current status of games. The students can also set up their preferences to receive emails notifying them about game updates. Each player then constructs a game quiz (a set of three questions) for the other player.

While the player is building a game quiz they have access to several important pieces of information. They can see a list of questions the other player got correct recently, as well as a list of their most recent incorrect questions (see Figure 1). As students are writing each question, they can see a difficulty rating for the question as well as how many points they will get if the other player gets the question correct or incorrect. (See Figure 2.)

C. Questions and Answers

Regardless of whether the question is being built for a quiz or a game the basic process is the same. The system allows users to create two different types of questions. Either: "what is the derivative of this function?", or "what is the tangent line to this function at this point?". Question creation is quick and easy. Users select the type of question they want to ask and then enter either a function (of x) to differentiate or a

function and a value if they are asking a tangent line question. The functions (and values) are entered as text, "x^2 + 3" for example, in an html input box. As soon as anything can be parsed it is displayed to the right of the input in a nicer format. If the system can't understand the current input a red warning icon is displayed. Most operations and functions used in an introductory calculus class are understood, including +, -, *, /, exponents (which can be written as ^), log, exponential and trigonometric functions like sin, cos, tan, etc. are all valid. When the user is finished they click submit. Figure 2 shows the user interface where the user is about to close the parenthesis on $\sin(x)$. The system shows the nicely formatted part of the expression that it is able to parse and uses the red asterisk to indicate that the expression is not yet a valid formula.

It should be noted that the system is constantly checking what the user enters and it does not allow an invalid function to be submitted. Thus, whatever the user submits will be a valid function and (since we only allow differentiable functions) it will be differentiable. So anything that gets into the system will at least be a mathematically valid problem.

The system computes a difficulty level for a question when it is created, for use with the Teacher's Dilemma framework. We were unable to find a simple method for quickly ranking the difficulty of calculus questions numerically so we created a heuristic that we are using to bootstrap the system. The heuristic works by thinking about Questions in terms of constants, variables and functions. Functions include operations (like +, -, *, etc.) and differentiation rules (like product, quotient and chain rules) as well as functions like sin, cos, log, etc.. Each Question is broken down into a binary tree where terminal nodes are constants or variables and branches are functions. Each constant, variable or function adds a set number of difficulty points, determined beforehand by the authors, based on teaching experience. If one or more of a function's children are again functions the points are added recursively, along with points for applying the chain rule. Thus the difficulty of a Question is defined by starting at the root node, adding its value and then summing the values for all of the children below it, with additional points for embedded functions.

Answering Questions is done in a similar manner to their creation. The user gets an input box (or boxes) and types text versions of mathematical functions and/or numbers. Once the answer is submitted the system has a custom symbolic differentiation engine that allows us to differentiate the function for

Answer	Result
$\frac{2 \sin(2 \cdot x^2 - 1) - \ln(x^2) (4 \cdot (x \cos(2 \cdot x^2 - 1)))}{(\sin(2 \cdot x^2 - 1))^2}$	incorrect
$\frac{2 \cdot \frac{\sin(2 \cdot x^2 - 1)}{x} - \ln(x^2) (4 \cdot (x \cos(2 \cdot x^2 - 1)))}{(\sin(2 \cdot x^2 - 1))^2}$	correct

Fig. 3. Question detail page showing all previously-entered answers

that question. The answer and the differentiated function are then compared on a large number of random points. If they ever disagree the answer is deemed incorrect and if they agree everywhere the answer is correct. For the purposes of the pilot study, students were allowed as many attempts as they wanted until they got the question correct.

It is possible, in certain cases, for the system to be unable to evaluate the function at a given point. This can lead to a case where the system simply cannot tell whether the two functions are equivalent. In this case the system sends that information back to the user and requests that they try again. In practice, because we restrict what functions a user can use and users are either teachers or introductory Calculus students, this eventuality has not occurred in any live tests.

D. User Information

The system has multiple ways it tracks and displays user progress. Users can review Quizzes and Games they've participated in and see both summaries and details.

For Quizzes, there is a Quiz summary page that shows the user which Questions they answered correctly. There is also a Question detail page which shows all of the answers they have ever entered for a specific Question. (See Figure 3.)

For Games, there are summary pages, one for the quiz the user took as a student and one for the quiz the user wrote as a teacher for their partner. In the former, the user can see which Questions they answered correctly and this page also lists their student score for this Game. The student score is simply the percentage of questions they answered correctly. (See Figure 4.) In the latter, the student can see which of their questions were answered correctly by their partner. They can also see their partner's skill level at the time of the Game; the difficulty level of each question they asked; the teacher score they earned for each of those questions; and their overall teacher score for that Game (which is the average of the three teacher scores for the three questions). (See Figure 5.)

We also keep track of an overall student score for each user, which the user can see in the upper right corner of every page. This score is currently set to be the average of the top five highest difficulty levels of questions they have answered correctly.

Student Game Score ?

You played a **game** with Player-63 on 4/1/2015 7:00:01 pm
Your results for each question:

question	correct
derivative of: $\ln(3 \cdot x^2 - 2x) \left(2 \cdot e^{4x^2} \right)$	correct
derivative of: $\frac{\ln(x+3)}{2x+e^x}$	correct
Tan line of: $\ln(3 \cdot x^2 - 2x) \left(2 \cdot e^{4x^2} \right) - \frac{\ln(x+3)}{2x+e^x} @ -1$	incorrect

Your score for this quiz: 67%

Fig. 4. Game summary for the quiz *taken* by the user (as a student)

Teacher Game Score ?

You played a **game** with Player-63 on 4/1/2015 7:00:01 pm
When you played the game Player-63 had a skill level of 41.6 ?

question ?	correct ?	difficulty ?	score ?
derivative of: $\frac{\tan(x)}{x^2+1}$	correct	19	37%
derivative of: $e^{(\sin(x))^2 + (\cos(x))^2}$	correct	59	100%
Tan line of: $x \ln(x) @ 1$	correct	18	35%

Your score for this quiz: 57%

Fig. 5. Game summary for the quiz *written* by the user (as a teacher)

Users can compare their standing to others via a Leader Board that shows the top players in terms of Highest Student Skill Level, Most Games Played, Most Unique People Played, Highest Total Student Score and Highest Total Teacher Score. (See Figure 6.)

E. Technical Details

The system was built in Scala using the Play Framework, a web development platform, it uses Postgres for storage and is designed to be deployed on Heroku. Play itself is a highly scalable platform that could support many users but pairing it with Heroku, a "Cloud Application Platform", means that we can dynamically request virtual hardware as usage demands and scale up dramatically if needed.

V. PILOT STUDY

We ran a pilot study of the CalcTutor tool in April 2015. Our goal was to obtain preliminary data and feedback to determine the effectiveness of the tool as it currently stands and to influence directions and priorities for future development.

The tool was used by students in the differential Calculus course (Math 10a) at Brandeis University. The students were asked to complete a "Pre-quiz", play at least three games with other students, complete a "Post-quiz" and then take a survey. This was assigned as a homework set, in which the students would receive 5 points for completing each of these obligations (regardless of performance). The questions on the post-quiz were essentially the same as the questions on the pre-quiz (with only minor changes, such as different numbers or swapping sine for cosine). The students had several days to complete the tasks.

Leader Board

Highest Student Skill Level

Rank	Player	Skill Level
1	Josh - Instructor-20	93.8
2	Player-49	72
3	Fresh2Death-24	67.8
4	Player-21	64
5	Becci - Instructor-2	62.4
6	Player-56	62.2
7	Player-79	61.8
8	Player-63	57
9	Calc2OP-17	56
10	Player-16	55.8

Most Games Played

Rank	Player	Games
1	Josh - Instructor-20	7
2	Player-32	6
3	Player-22	6
4	The b tiger-41	6

Fig. 6. Leader Board (partial view)

We had 117 students enrolled, split among 5 sections. Out of these 117 students, 96 participated in the study in some capacity. Of the 96 who participated, 94 tried the pre-quiz and 86 tried the post-quiz. We had 74 students who played at least 3 games, 10 students who played 2 games and 8 students who played only 1 game. We had 68 students who completed the survey.

This pilot study was performed after the students had learned the mechanics of taking derivatives and had been tested on their understanding in an exam. The pilot study was then viewed more as a review for the final exam rather than a formative assessment. Nevertheless we expected to see some learning, as not everyone in the class had fully mastered the process of applying all of the differentiation rules.

VI. RESULTS

The main goal of this pilot study was to gather initial data on the use of CalcTutor in all of the Calculus courses at a University. We were looking at several broad measures:

- Scalability. Does CalcTutor scale well to handle hundreds of simultaneous users?
- Learning Outcomes. Does CalcTutor have a positive effect on learning outcomes?
- Student Response. What do the students think about using CalcTutor?

We were also interested in a technical point that would help us fine tune the system for future experiments:

- Question Difficulty. Is there a positive correlation between the heuristic measure of problem difficulty and

an empirical measure - the percentage of students who answered it correctly, possibly weighted by the number of attempts required to find the solution?

A. Scalability

While users experienced some confusion about how to type in answers, there do not seem to have been any errors, delays, or sluggishness on the part of the system. All users were able to get into the system, create and answer questions. The symbolic differentiator and functional equivalence testing seem to have been up to the task of handling the quiz and game questions and answers. We did need to expand the Heroku platform beyond the free offering to the "2 dyno" level.

B. Learning Outcomes

There were 86 students who took both the pre-quiz and post-quiz in our experiment. Each quiz had 8 derivative problems and the questions for the post-quiz were created by making slight modifications of the pre-quiz questions (e.g. changing constants, replacing special functions by similar ones, e.g. sin by cos). We looked at three ways to measure learning outcomes.

- Correct on First Try. This corresponds to the traditional pencil and paper exam where students only get one attempt at answering the question.
- Correct Eventually. This corresponds to the exam where students get immediate feedback (as with CalcTutor) and are allowed to resubmit an unlimited number of times until they get the correct answer or give up.
- Average Number of Attempts per Question. This measures the average number of attempts a student makes on a problem that he or she eventually gets correct. Measuring the average number of attempts for incorrect problems would give a measure of persistence, but not necessarily of learning.

The data in Table I shows that students performed significantly better on the post-quiz than the pre-quiz when measured with "Correct on First Try" ($p = 0.016$) and when measured by the "Average Number of Attempts per Question" ($p < 0.001$), but there was no statistically significant difference when the "Correct Eventually" measure was used.

TABLE I
LEARNING OUTCOMES FOR PILOT STUDY

Test	Correct on First Try	Correct Eventually	Avg Attempts per Question
pre-test	52.75% (sd=26)	75.38% (sd=29.25)	1.52 (sd=0.85)
post-test	61.75% (sd=24)	74.63% (sd=24.00)	1.26 (sd=0.30)
diff	6.12% ($p=0.016$)	-0.75% ($p=0.40$)	-0.26 ($p<0.001$)

C. Student Response

We expected (from prior feedback on WeBWorK) that students would experience difficulty and frustration with entering mathematical functions on the computer. We did indeed see this feedback in our survey. The average response to our

survey question "How hard did you find it to input answers?" was 1.65 out of 5 (where 1 was "hard" and 5 was "easy"). Out of 68 survey respondents, 44 either mentioned (in open-response questions) that they did not like typing in math or suggested improving the input system and 23 of these students recommended having buttons for common mathematical functions and operations (like a calculator). We believe that some of this frustration around input of math would have been alleviated by having more time for students to acclimate to the tool and by having a schedule in which students were really using the tool to learn, rather than review (thereby increasing motivation). Several students recommended either showing answers or giving hints for students who had made multiple attempts without getting to the correct answer. A few students recommended showing which students are currently online in order to improve the experience of finding a partner for a game.

D. Question Difficulty

Ideally we would determine the difficulty of a question from data. But since we need to bootstrap the system we constructed the difficulty for Questions as described above. To verify that this heuristic is reasonable we looked at the results for our quiz questions for the Calculus students who used this system. Specifically we used linear regression to predict the number of students who got a question correct with the question ranking score heuristic as the only explanatory variable.

In terms of Derivative questions, there were a total of twenty two questions and a hundred and two students who were answering the questions. The result was that the ranking score is significant and accounted for a sizeable amount of the variance ($p = 7.88e-05$ with $r^2=0.5271$). So while it will take a great deal more experimentation to actually find a more conclusive difficulty metric, our approximation seems to be a solid starting point.

If we look only at the 16 derivative quiz questions used in the pre and post-quizzes, we can create a scatter plot of the empirical problem difficulty calculated as the percentage of students that answered it incorrectly, versus our heuristic. The scatter plot is shown in Figure 7. It clearly shows that the problems students have more difficulty with tend to also have higher difficulty heuristic values.

VII. PROBLEM SOLVING MARKOV MODELS

The CalcTutor system stores a time-stamped version of every attempt each student makes on every problem they attempt to solve. This allows us to conglomerate the data for all students' attempts on one problem into a Markov Model that represents a probabilistic model of the problem solving strategies of the class. We expected that these models would give us a deeper insight into the kinds of problems that students were encountering while trying to solve the quiz questions. We also suspected that comparing the Problem Solving Markov Models (PSMMs) for the corresponding pre and post-quiz problems would give us a deeper insight into

Fig. 7. X=percentage of students answered problem incorrectly, Y = difficulty heuristic value

Fig. 8. Problem Solving Markov Model for pre-test question: $\frac{d}{dx} e^{3x}$

Fig. 9. Problem Solving Markov Model for post-test question: $\frac{d}{dx} e^{5x}$

the learning outcomes of our students' interaction with the CalcTutor tool.

Figure 8 shows the Problem Solving Markov Model (PSMM) for the problem of finding the derivative of e^{3x} in the pre-quiz. The nodes in this graph correspond to all of the answers that were submitted as possible solutions to the problem. The area of each node is proportional to the number of students that submitted that attempted solution. The edges between nodes are labeled with the number of students that went from one attempted solution to the next in one step. Thus we can see that 50 of the 86 students went from the start state to the solution $3e^{3x}$ in one step. Figure 9 shows the PSMM for the corresponding problem in the post-quiz – finding the derivative of e^{5x} . These two PSMMs provide a qualitative understanding of the effect of using CalcTutor on their pre and post-quiz performance. We can make the following observations:

- In the pre-quiz only 50/86 students went directly to the correct solution in one step. Another 10/86 students made one or more attempts before giving up, and 26 out of 86 students made one or more attempts before getting the correct solution.
- In the pre-quiz PSMM there are many more attempted solutions and several that are shared by multiple students.

Fig. 10. Problem Solving Markov Model for pre-quiz question: $\frac{d}{dx} \cos(x)e^{2x}$

Fig. 11. Problem Solving Markov Model for post-quiz question: $\frac{d}{dx} \sin(x)e^{3x}$

The most common error is a syntax error where the correct answer " $3e^{(3x)}$ " is entered without the requisite parenthesis as " $3e^3x$ " which corresponds to $3e^3x$. The other most common errors are " $3e^x$ " and " $e^{(3x)}$ " which correspond to conceptual errors.

- In the post-quiz PSMM, the only common error is forgetting the parentheses in the correct solution: " $3e^{(3x)}$ " and it is made by many fewer students.

Figures 10 and 11 show a pair of more complex (but structurally similar) problems: to find the derivatives of $\cos(x)e^{2x}$ for the pre-quiz and $e^{3x}\sin(x)$ for the post-quiz, respectively. Again, visual analysis of these two graphs shows that the class problem solving behavior became more direct and effective between the pre and post-quizzes. Indeed, we observe

- In the pre-quiz, 38 students go directly to the correct solution, but the 20 other students that eventually get it correct take 15 different paths from the start state to the correct solution and some of these paths go through five or more attempted solutions.
- In the post-quiz, 50 students go directly to the correct solution, and the 10 remaining students that eventually get the correct solution take 7 different paths from start to the correct solution.
- The two common errors occurred less frequently in the post-quiz than the pre-quiz, and in general there were many fewer steps to get from the start state to the correct solution in the post-quiz.

VIII. CONCLUSIONS AND FUTURE WORK

In this pilot study we were able to show that the Teacher's Dilemma approach can be extended to more complex domains than had previously been tried. The heuristic metric for problem difficulty is well-correlated with the empirical

measure of difficulty and the system can automatically verify the correctness of any univariate function created by the user by combining constants, algebraic operations, and the standard trigonometric and exponential functions.

The study was not extensive enough to provide data on the pedagogical effectiveness of having students play the Teacher's Dilemma game, but it did demonstrate that after playing a few Teacher's Dilemma games students were able to improve their standard quiz scores and were able to get to a correct solution more quickly (i.e., in fewer attempts).

In the future, we plan a larger study where students use CalcTutor for several assignments. This will require us to greatly expand the range of questions that the students can create and which can be automatically graded. The current system only allows two types of questions:

- Find the derivative of the function
- Find the slope and intercept of the function at the point

In the coming months we plan to add many more question types that can be automatically verified by our system. For example, finding the maxima, minima, and inflection points of cubic polynomials, or determining the sign of the slope of a function at a particular point, or calculating simple antiderivatives. We will also need to create a difficulty heuristic for these new problems and to introduce student skill level and teacher skill level metrics that make sense over these larger domains.

We plan to make CalcTutor available to colleagues at colleges and high schools around the world and to more deeply explore the use of the Problem Solving Markov Models as a pedagogical tool for Calculus instructors.

Atlanta, USA

Abstract— The Center for Engineering Pathways to Innovation (Epicenter)'s initiative for faculty development and institutional change – called Pathways to Innovation – is now working with more than 35 schools across the country to embed learning opportunities in innovation and entrepreneurship into the undergraduate engineering curriculum. At each institution, Pathways teams begin their work with a structured process of mapping the assets and identifying gaps at their school to create a "landscape analysis." This process can be useful as a starting point in any institutional change process, particularly when a broad set of stakeholders within engineering or across disciplines need to be considered and engaged. At this special session, participants will have the opportunity to explore the landscape tool using an authentic data set co-created by the group, and provide input into the next version(s) of the tool. Presenters will also provide case studies of how the tool has been used by schools of engineering to drive curricular and co/extra-curricular change at both small and large institutions.

Keywords—institutional change, curricular change, entrepreneurship, innovation, faculty development, evaluation

I. INTRODUCTION

The Pathways to Innovation program (Pathways) is a faculty development and institutional change initiative of the Engineering Pathways to Innovation (Epicenter) project, funded by the National Science Foundation and managed by Stanford University and VentureWell (formerly NCIIA). Epicenter's aim is to equip engineering students with the knowledge, attitudes and skills needed in a world marked by rapid technological transformation. Based on a preliminary literature review of effective strategies for faculty development and change in higher education [1], Pathways uses a team-based guided change process to help faculty and institutions introduce and embed innovation and entrepreneurship (I&E) into curricular and cocurricular educational experiences for undergraduate engineers.[2]

Schools participating in Pathways assemble a team of faculty and administrators (and students in some cases) to explore exemplary models for including I&E in engineering and then implement appropriate strategies on their own campuses. The two-year process is highly context-specific; the program provides teams with a range of possible opportunities and avenues and provides coaching as they select and combine

those most appropriate.

The remainder of this document summarizes the content that will be presented in the special session and describes the interactive components in which attendees will be invited to take part.

Note: a much fuller description of the tool, the basis of its development and use in the literature, and the results of its use, is being submitted in a separate full-length paper and will also be available to special session participants.

II. RATIONALE AND GOALS FOR THE TOOL

The literature review that informed the design of the Pathways program found limited evidence of research-informed transformation efforts in higher education (examples of change were plentiful in other fields, such as business). The literature did, however, identify key themes for staff to incorporate into the program, two of which became the goals for a tool to support teams in their work.

The first theme was the need for a mechanism to provide outcomes-based feedback to Pathways institutions themselves, Pathways program staff, and evaluators. The tool and accompanying process are intended to efficiently, systematically and (where possible) quantifiably document the state of the institution before and after the program intervention. By describing the status of the campus at a point in time, it can also serve as a mechanism to confirm campus awareness of said institutional changes. The tool also evaluates the degree to which Pathways provides effective tools and processes for effecting change on a campus.

The second theme identified emphases on context-specific changes, rather than "imposition" of a single approach. The landscape tool therefore fosters strategic change by providing teams with a clear assessment of their environment and the institutional strengths they might leverage in the service of a range of approaches.

III. TOOL DESCRIPTION

The original landscape tool (developed in 2013) was a spreadsheet comprised of six worksheets, each cataloging different parts of an institution's ecosystem that might foster I&E knowledge, skills, attitudes and experiences. In the "Courses," "Programs" and "co-curricular" sheets, teams document curricular offerings; in the "Spaces" sheet teams list

This work is supported by the National Science Foundation: DUE 1125457.

physical spaces that foster I&E learning; in the “Leadership” worksheet, teams capture initiatives and strategies emerging from either central administration or engineering that could ultimately foster I&E education on campus (e.g., incentives for new course or program development, or faculty professional development); in the “Champions” worksheet, teams identify individuals that might have the enthusiasm, skills, knowledge and time to assist teams in their efforts. In keeping with the assessment goals of a traditional rubric, a “scorecard” column is included on each sheet, along with the number of students served by different programs where appropriate. Given the Pathways focus on the integration of I&E, various concepts deemed critical to this field of study are also incorporated.

In late 2014/early 2015, the tool was revised to address several shortcomings identified by evaluators and through user feedback:

The tool was converted from a standalone Excel document to a cloud-based spreadsheet using Google Sheets. All members of the Pathways team from a school are given access to the document and can work on it, synchronously if desired, from their own computers. This approach also facilitates the process of knowledge sharing[3] across the team. By ensuring the landscape tool can be completed by a broader group, teams are also better able to engage those beyond the core team, including faculty from other disciplines, students on campus and possibly even off-campus partners in this process. By engaging a broader group in the landscape completion process, the team members may develop a more expansive view of their campus ecosystem, an increased understanding of the opportunities available to students and the possibilities for cross-campus strategic collaboration.

A data visualization capability was added. This was deemed critical for two reasons: (1) given the complex nature of the tool, institutions, Pathways program staff and evaluators needed a way to be able to efficiently draw broad conclusions about the data, and (2) staff and evaluators needed a process for capturing and quantifying changes in the landscape over time. The resulting landscape data is now aggregated in a separate file and reviewed for accuracy before being stored in the cloud. Pre-defined queries on this data create data-driven websites with “snapshot” visualizations for each team that illustrate the status of their campus ecosystem on key dimensions using pie charts. The visualizations also compare their institution to the entire group of Pathways schools on these dimensions.

An update capability (and supporting data structure) was introduced. The landscape data is now stored together with the date of any changes made including modification to existing assets and new assets. This allows teams to make changes to their landscape, both in real time if they discover new information, but also at designated times for evaluative purposes. Those changes are presented in updated charts in the dashboard, and are also available to the teams and to program staff and evaluators to measure the impact of the program at individual institutions as well as in the larger cohort of participating schools.

I&E-specific modifications better aligned the tool with the project’s underlying theoretical base and with teams’

information needs. Some data points collected in the original sheets were deemed too granular and removed. Other elements were more fully incorporated into the tool because they were considered important to the work being undertaken. For example, teams now identify where each individual course lies on Duval-Couetil’s “innovation education continuum”[4] and the degree to which each course and program listed integrates active learning. To ensure teams consider change strategies that move beyond changes to curriculum and space, Graham’s[5] characteristics of a balanced and effective entrepreneurial university were incorporated with specific focus on student-driven change, collaboration with the off-campus ecosystem and campus policy and culture.

IV. EXPLORATION OF THE TOOL

The majority of the time allotted to the special session will allow participants to experience use of the tool in a abbreviated, but authentic participatory activity. This segment of the special session will include:

Introduction to the tool. The basic architecture of the tool will be described, with attention to how the categories of items collected are aligned with Graham’s taxonomy of successful university entrepreneurship ecosystems, given the specific context in which this version of the tool is used.

Co-creation of a data set. Participants will collaboratively assemble a set of assets for a fictional school, Midville State University, from what is offered at their own institutions (presenters will also have available a set of assets to supplement the group’s information as needed). Participants will use the tool to categorize the assets assembled in the session.

Data analysis. As is done by Pathways teams, participants in the special session will review the data visualizations of both Midville State’s information as well as the aggregated data. Participants will be invited to reflect on how (and why) Midville State’s profile might be similar or different from the aggregate.

Experiencing the value of the tool for curricular change. Participants will use the Midville State example to identify ways in which that institution could address a strategic objective through “linking and leveraging” one or more of the assets on their landscape.[6]

V. CASE STUDIES

The landscape tool helps teams identify many different kinds of opportunities for intervention on their campus, by:

- highlighting the lack of a particular kind of asset, such as a makerspace;
- revealing specific existing assets that could be targeted for improvement - *ie*, those rated by the team as “needs attention”;
- providing guidance on the degree to which courses were (and were not) being delivered using active learning strategies;
- identifying individuals and organizations (both on- and off-campus) that could be engaged to support the team’s efforts;

- showing areas in which the campus was significantly “out of step” with the larger Pathways community; and

- identifying a lack of strategies that fall outside of the more typical faculty driven intervention like curriculum and space (e.g. students driven efforts and off-campus collaborations).

In the special session, two case studies will be presented from among the 37 institutions now using the tool. The institutions will be chosen to provide contrasting perspectives on the ways in which data was collected and used over the course of the institutional change process. Team leaders or members from the case study institutions will be present to participate in the session.

Across the larger body of schools participating in Pathways, the program’s context-specific, asset-driven approach has resulted in the pursuit of a wide variety of initiatives. The case studies will elaborate on these various strategies, the ways in which the landscape tool led to the choice of these strategies, and the effectiveness of the strategies.

VI. POTENTIAL ENHANCEMENTS AND EXPANSIONS TO THE TOOL

Participants at the special session will be invited to identify ways in which it might be enhanced and/or expanded. The program staff have identified some preliminary options, but the session will provide an important source of “real-life” perspective on these ideas (as well as adding other possibilities for consideration):

Development and design of a data warehouse. The warehouse could incorporate the landscape data along with historical information about other activities the institutions have engaged in; IPEDS data could also be incorporated into the data warehouse. These kinds of technical modifications would enhance the end user experience by providing access to more extensive and customizable data sets. More sophisticated graphical outputs could also be incorporated to enhance the end user experience.

Use as an educational vehicle to campus constituents. To date the landscape tool has been conceived of as something that provides only Pathways teams, program staff and evaluators with information to better understand a campus ecosystem. However, the data collected could also be used to inform other campus constituents about I&E resources and spaces, for example through the design of self-service interactive campus maps that highlight I&E hotspots.

Marrying the tool with a project management interface. Designing a component that helps track and “grade” the outcomes of team’s campus-specific interventions may add additional value. The project’s external evaluators currently gather this data through surveys and interviews with team members, and manually map the teams’ efforts to the assets in their landscapes. Integrating this process into the landscape tool is under consideration.

VII. OPPORTUNITIES FOR RESEARCH

Finally, the special session participants will reflect on the research opportunities that might be available using the data

collected by the tool. Some of these opportunities may be specific to the domain of innovation and entrepreneurship, but others will be applicable across a range of domains. These opportunities may include projects such as the following;

Examination of the growth of campus entrepreneurial ecosystems over time. including the degree to which location, institution size, public or private status, Carnegie classification and an institution’s initial assets impact that trajectory and the kinds of strategies undertaken. As part of this examination, one could, for example, canvas a suite of institutions of a similar Carnegie classification and determine which offerings are most prevalent and use these findings as a springboard for rich qualitative investigations into how and why this might be the case. Such research might also inform best practices for modifying a campus ecosystem: for example, whether a school should undertake a more modest grassroots approach first, such as the launch of an extracurricular project, or a more ambitious project, like the launch of an entrepreneurship center.

Research into how the landscape is used. Some teams adopt a collaborative approach, while others treat it as a solitary task. One team used the tool as a foundation for creating a visual representations of their campus ecosystem. Another institution shared their landscape with high level administrators to realize a goal of strategically combining spaces and creating a new position. Additional research into these and other practices will increase the understanding of best practices for completing and sharing the landscapes.

Additional opportunities contingent on tool enhancements. If the more ambitious enhancements to the tool are undertaken, the research possibilities broaden. For example, through the inclusion of IPEDS data, one might research the extent to which I&E activity impacts retention and graduation rates.

VIII. CONCLUSION

The development and deployment of a landscape tool has proven to be a highly useful strategy in helping faculty teams plan and implement curricular changes in the domain of innovation and entrepreneurship education for engineering students. The data gathered through the tool provides ample opportunities for ongoing research, particularly as the tool is enhanced and expanded in future versions. While some of the data collected through the tool is specific to this domain, the underlying rationale for the tool - to collect a robust array of information that can inform decision-making while also developing the social capital and team behavior that will enable implementation of change - is broadly applicable to many of the challenges in engineering education. Participants in the special session will be able to experience first-hand some of the benefits of the use of such a tool, while also informing the development of its next generation.

Abstract— The purpose of this proposed mini-workshop is to connect our research in conceptual change [Collaborative research: Getting Engineers to Talk Across Disciplines, EEC 1129447] to instructional practice. Our research suggests that one potential indicator of students' conceptual understanding across several engineering disciplines is their use (or misuse) of language. During this mini-workshop participants will be able to read excerpts from interviews we conducted, discuss how to draw inferences about student learning from these interviews, and then brainstorm how they can be more explicit about the use of language in their classrooms.

Keywords—conceptual change, misconceptions, research-to-practice

I. INTRODUCTION

Professors often think their students share their understanding of fundamental terms. But our research findings suggest that this might not be the case. A common theme in our findings across several engineering disciplines is that students misuse (and probably misunderstand) fundamental engineering terms [1, 2]. Students often confuse the specific engineering meaning of a term like "normal force" with the meaning of the term in common usage. We see this mini-workshop as an opportunity to have a discussion about how this tendency to misuse the language of engineering may play out in various disciplines and to brainstorm instructional strategies to mitigate this issue.

More specifically, the mini-workshop will be an opportunity to answer the questions: (1) So what? Why might this misuse of language matter? And (2) what can an instructor do to reverse these misunderstandings?

We will use a community of practice framework as a model for our session. We will form small ad hoc

communities [small groups] around specific domains [related engineering disciplines] and focus on practice [in this case, instructional practice]. Participants will share their pedagogical content knowledge to build a shared understanding of what parts of their field might contain problematic language (terms that are often misunderstood) and what strategies might be used to allow students to better understand these terms.

II. SESSION DESCRIPTION

A. *Intended Audience*

This workshop should have value for any engineering faculty member with instructional duties. Our examples will come from undergraduate engineering classrooms and so the information will be most easily transferred to undergraduate contexts.

B. *Goals*

The goal of this session is to use research on conceptual change to inform instructional practices.

C. *Expected Outcomes*

By the end of this session it is expected that:

1. Participants will be able to identify problematic language in their respective field of instruction.
2. Participants will be able to identify instructional strategies to mitigate the problematic language uncovered in learning objective 1.

III. SESSION AGENDA

Our session will be highly interactive and will allow participants to connect with the research as well as with colleagues in their discipline with whom they may form a

community of practice. The structure of the session is as follows:

- **Overview of the session and introduction of session presenters** (5 minutes)
- **Participants organize themselves into small groups of related disciplines and introduce themselves to each other** (5 minutes)
- **Distribute portions of anonymized transcripts taken from our research that highlight areas where problematic language is used.** These transcripts will contain sections that illustrate students' misunderstanding and misuse of fundamental terms. The examples will come from a variety of disciplines and will be matched as much as possible to the disciplines represented in the small groups. (5 minutes)
- **Small groups discuss the transcripts and predict instances of misuse/misunderstanding they see in their students' language.** (20 minutes) - Full group discussion. (15 minutes)
- **Presenters and participants discuss instructional strategies that may mitigate the issues raised in the previous discussion.** (25 minutes)

- **Individually, participants reflect on and document what they have learned in the session to (1) identify potentially problematic language in their courses and (2) identify instructional strategies to mitigate #1.** (10 minutes)
- **Participants complete session evaluation** (5 minutes)

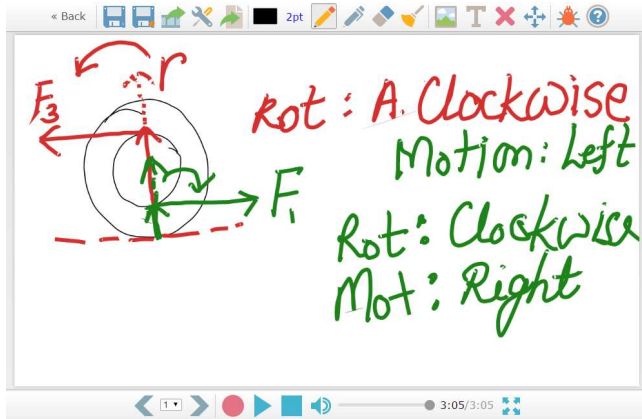

Fig. 1. ShowNTell Editor

Abstract—The use of recording applications for teaching is increasingly popular, with tools such as Ink2Go and ShowMe being available on many platforms and at reasonable cost. However, most recording applications available are typically native applications and do not work within the web browser. In this work, we study the feasibility of implementing a recording solution in the web browser environment.

I. INTRODUCTION & MOTIVATION

ShowNTell is an implementation of a screen recording application that runs within a web browser on a mobile device [1]. The application will provide an interface similar to a virtual whiteboard, and allows the recording and playback of drawings made on the whiteboard (see Figure 1). Audio recordings are supported to facilitate the creating of lessons and tutorials within the application for the purposes of eLearning.

We describe our motivations for this work in the following sections:

A. Web platforms

New browser technologies under the umbrella group of HTML5 technologies have provided new opportunities for new

This work is supported in part by the National University of Singapore Learning Innovation Fund Technology (LIF-T) under the research grants C-252-000-113-001 and C-252-000-117-001. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the granting agency, National University of Singapore.

types of applications to run within the web browser, providing services normally done by native applications. For instance, the introduction of the 2D Canvas API allows images to be generated in real-time within the web browser, instead of being generated on the server [2]. This paves the way for applications such as interactive games and media that requires graphical content to be updated in response to user input.

Improvements in communication technologies such as access to higher and more stable bandwidth as well as faster transfer speeds can allow us to provide real-time services that may require continuous transfer of relatively sizeable amounts of data from the client device. This is crucial for ensuring responsiveness of the application which has data dependencies on content on the server.

As many mobile devices have access to the Internet, we would also perform user experience studies on the use of touch-based interfaces for the use of recording and drawing, which would be one of the primary input interfaces for ShowNTell. Many mobile browsers also support the new APIs that are available on desktop browsers, allowing our application to potentially work on those platforms without the user requiring installation of an application.

As a result of these emerging changes, it is now possible to implement a recording solution that runs on a web browser. Thus this acts as a primary motivation for pursuing this project. Our project would attempt to implement an application with native-like capabilities on the web platform by using APIs available on web browsers, as well as evaluate techniques that can potentially improve its usability or responsiveness in a web browser environment. Additionally, we would attempt to test our implementation on multiple platforms under different conditions, in particular the desktop and mobile browser environments.

B. eLearning

Recording applications are increasingly popular tools for the purposes of education and entertainment. For instance, the webcast system provided by the National University of Singapore (NUS) is able to generate automated recordings of a lecture in modules supporting that feature. Other modules have used other creative means aside from recordings such as gamification to improve the learning experience of the content in the module [3][4]. eLearning serves as an alternative or supplementary means for students to revise on topics that were

covered earlier through traditional mediums. For our project, our main focus would be towards approaches that involve recordings.

Recordings are also used as tools to illustrate ideas that are typically difficult to describe as text or images [5]. This is because with the inclusion of time-based events, animations such as circling or highlighting become more prominent. Additionally, annotation mechanisms such as free-style drawing are easier to use than other traditional inputs for displaying mathematical equations or simple diagrams. This coupled with audio capture can allow for easier conveying of ideas that might be difficult to convey with a static document.

In ShowNTell, we attempt to build a recording tool that works in a web browser, allowing the application to work on a wide variety of platforms without requiring the installation of additional software. Unlike recordings used for lectures, ShowNTell is designed for shorter recordings that typically last for a few minutes, typically sufficient for answering questions or explaining concepts. The tool would act as a complement to the existing eLearning tools available.

II. RELATED WORK

The idea of a whiteboard and video recording application is not a new concept, with many such applications available in the market. In this section we study several different types of applications that support screen recordings, enabling us to adopt similar techniques that allow us to manage data generated in recordings.

A. Desktop Implementations

There are many applications that support recording capabilities available on computers, such as CamStudio, Camtasia, and Open Broadcasting Software [6][7][8]. These applications are typically screen recorders which capture video input from the graphics hardware, usually through system APIs such as bitblt [9]. Screen recorders are applications that poll the screen and stores what is displayed into a file, thus capturing all visual details that are visible to the user. Screen capture applications may also capture audio from the audio input hardware. Other screen recording software may support annotation capabilities that allow adding details to the currently displayed screen, such as Ink2Go [10].

As recording generates cumulative data, different applications have different methods of handling the recording. Typically, a video recorder will continuously write frames to a file rather than retaining them in memory in order to keep memory footprint low. Ideal file formats for this include AVI files [11], as these files support the appending of video data into the file with minimal performance overhead. In other implementations such as Fraps [12], the recording may be distributed into multiple files, moving from one file to the next when a file size reaches a certain threshold. Distributing a recording into multiple files enables longer duration recordings on file systems that have an inherent file size limit, such as the 4GB limit in FAT32 systems [9].

In ShowNTell, we have adapted the file splitting approach which splits recording data into multiple fragments. This enables handling of certain data types such as audio much more easily, as well as allowing for responsive save times by allowing part of the document to be saved in the background while recording is ongoing. This approach is preferred over the single-file method because in a web browser environment, uploading of data to the server takes much more time compared to writing a file to the hard disk. Thus, we can reduce the perceived upload time by simply uploading parts of the earlier recording during the recording process.

B. Mobile Implementations

Mobile applications that support recording capabilities do not typically capture the screen, in contrast to desktop applications. Due to the sandboxed nature of mobile applications, capturing the screen is typically not allowed [13]. However, recording software with annotation capabilities and microphone support are widespread, such as ShowMe and ExplainEverything [14][15]. These fully utilize the touch-screen to provide an input suitable for free-style drawing.

Mobile applications face a larger resource constraint compared to desktop applications; in particular file-system access and computational resources are not a luxury. Thus recordings will typically record the input or the sequence of actions used to render the current scene, instead of recording the entire screen as a video. For example, when the user performs a free-style drawing, instead of capturing the image of the screen, it captures the coordinates needed to reproduce the same effect. This method of replaying events to simulate a recording will greatly reduce the storage, computational, and memory footprint of the recording, since only events will need to be stored instead of image frames. In the event a video output is desired, those events can be replayed to generate the video frames to produce the video.

In ShowNTell, we have attempted to emulate the same feature set provided by these applications, which include slide support, document import, and video export. Similar to ShowMe and ExplainEverything, ShowNTell will not actually record the screen contents, but instead the events to reproduce the visual state of the screen.

C. Web-based Implementations

Due to the resource requirements and limitations of existing browsers, there are not many recording applications available as a web application. There are some implementations such as BigBlueButton that provides recording and collaboration capabilities [16]. However, those implementations require the use of plugins such as Adobe Flash. Such plugins are typically not available on mobile devices due to either deprecation of the existing software packages or prevention of installation of the plugins by the operating system [17][18][19].

While there are web-based applications that provide drawing/annotation capabilities, or even provide the ability to collaborate with others over the internet, there are not many

complete solutions that support the ability to record the annotations and drawings for later playback. However, with newly available HTML5 APIs, it is now possible to implement a drawing and annotation web-based application with recording support.

Because HTML5 is in the emerging state, most browser vendors have only implemented a subset of it [20]. Nonetheless, some browsers such as Google Chrome have implemented most of the required APIs on publicly available versions of the browser, providing feasibility to the implementation and deployment of our application.

III. SYSTEM DESIGN

As ShowNTell is a web-based application, we have chosen to use a client-server model for the application. The client will be designed to run within a web browser, and does not require the installation of additional software aside from the web browser. The server will use a normal LAMP stack to serve web pages and store data, as well as NodeJS for the video rendering and document import systems.

A. Feasibility Analysis

Prior to and during the implementation of the project, we have evaluated whether the project can be implemented using available APIs and tools. Preliminary analysis has given the conclusion that majority of the browsers on desktop environments have support for the features that we require for our application, particularly Canvas 2D and Media Capture APIs [2][21].

On the mobile platform, Google Chrome and Firefox on Android offer the features that we require. Browsers such as Safari on iOS and Internet Explorer on Windows RT do not support the Media Capture API, thus features requiring the use of the microphone would be disabled on these platforms. Nonetheless, because a sizeable fraction of the browser market supports the APIs that we require, we have decided to proceed with the implementation of the project. A comparison between the different browsers as well as their support for key HTML5 API features our application requires is summarized in Table I. We have attached the version number as the feature set

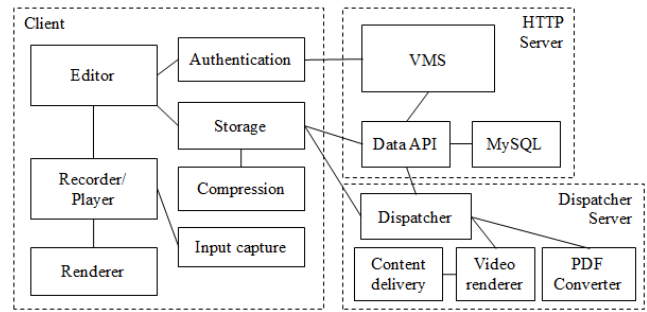

Fig. 2. Components in ShowNTell

available in a browser may change in later revisions of the browser.

B. Program Design

Our application uses a client-server model. Our client is designed to run within a web browser, and does not require the installation of any software aside from the browser itself, which is assumed to already be available on the user's device. The architecture used by ShowNTell is summarized in Figure 2.

The client is the front-end of our system, which is a website which the user can visit in order to use the services offered by our application. Using Canvas, we can implement whiteboard-like functions easily. We have also added other annotation tools such as highlighters and erasers which are tools available in similar software in other platforms. Browsers with Media Capture API support allow us to access the microphone on the user's device, allow us to capture audio for recording purposes. The Web Worker API which is commonly available on most modern browsers allows us to perform computationally expensive operations in the background, thus we usually perform data-related operation such as compression and conversion in workers.

The editor handles run-time drawing of visual data, as well as handles the state that will be displayed to the user. The editor includes the user interface such as the toolbar buttons, as well as the canvas drawing interface. The event recorder handles the capturing and replay of user input such as mouse coordinates. It also provides audio input capture if there is a microphone available. The storage component manages data belonging to the document and automated saving. The renderer renders the current document state to the user such as drawings, images, and textual objects.

On the server-side, we have two major servers, which are the HTTP and Dispatcher servers. The HTTP server hosts the web application for clients to access. The main scripting language used on this server is primarily PHP, which is a server-side language. The HTTP server also exposes external APIs for the uploading and retrieval of document data. The VMS (Video Management System) provides the front-end for users to manage their documents as well as share the documents with other users. Like typical HTTP servers, it uses

Fig. 3. Main timeline structure

normal LAMP stack which includes the Apache web server and MySQL database.

The dispatcher server is used to provide features that require long-running operations that should not be performed by the client due to its resource requirements. This server uses the JavaScript scripting language, and is run via NodeJS. The dispatcher server provides video rendering and PDF conversion capabilities.

IV. IMPLEMENTATION

A. Recording

During recording, audio from the microphone and user actions are captured simultaneously. In ShowNTell, user actions are referred to as events.

Events stored on the main timeline include slide change events and audio playback, which are typically global events that do not belong to any particular slides. Each document will only have one main timeline. During recording, events are added into the data structure representing the main timeline. Because recording involves time, time information has to be attached to each event. Playback requires an efficient means of traversing through events in the correct order.

Timeline data for the main timeline is represented in a 2-dimensional structure. The first dimension is the time, while the second is an ordered set of events occurring at that specific time. A visual representation of the timeline structure is shown in Figure 3.

During playback, we traverse across the time dimension, and process each event individually for each time slot. To reduce the amount of processing needed, each play-through will only go through the entire timeline once. Cumulative states are used to allow pause and resume without incurring significant costs. Fast forwarding of events is also efficiently supported.

B. Audio Recording

Audio capture is performed using the Media Capture API available in browsers such as Google Chrome and Mozilla Firefox. The API offers the ability to access raw audio PCM (Pulse-Code Modulation) data as it is generated [21].

In order to reduce the amount of time needed to save the document, we have chosen to upload audio as it is generated, rather than upload it at the end of the recording. Thus the audio is no longer a single contiguous file but instead distributed over multiple fragments. During recording, audio data is streamed to a buffer until a threshold is met. An interval of five seconds is chosen as the threshold as it offers a balance between the amount and size of fragments generated.

The number of fragments may increase complexity during playback and could also introduce additional overhead as each

fragment is treated as an individual unit. However the size of a fragment should not be too large as it can incur additional computational requirements in processing of each fragment. When the threshold is met the buffer is encoded as a WAV file and uploaded to the server, after which the buffer cleared.

Not all browsers support the Media Capture API, thus we have developed a fallback which will involve the use of the Adobe Flash plugin. However, this fallback may not work on platforms that do not support the plugin, particularly mobile-based platforms. In the event whereby the application is unable to gain access to the microphone due to the software or hardware environment, the audio recording feature in ShowNTell will be disabled.

C. Audio Playback

Because we are pushing data as soon as it is available during recording, the audio recordings are not available as a contiguous audio stream but instead as fragments. In order to play the audio as a contiguous track, we have to perform audio chaining. Audio chaining involves preparing each audio to be played at some point in the future. The process of audio chaining is summarized below

- 1) Obtain list of fragments belonging to an audio collection
- 2) Playback is paused to buffer audio fragments in the collection
- 3) Relevant audio fragments are downloaded
- 4) Once sufficient fragments are downloaded, the fragments are arranged to play at a specific time
 - a) Fragments whose end time precedes the current time marker are skipped.
 - b) Fragments whose start time precede the current time marker, but end time does not will be played partially. These fragments will have their playback time set to the appropriate location, and played immediately.
 - c) Fragments whose start time occurs after the time marker is to be played at a future time are queued at the appropriate time.
- 5) Once audio arrangement is done, playback is resumed

For smooth and seamless playback during audio chaining, each audio fragment should be encoded in a format that allows playback without any “gaps” or distortions. Formats such as MP3 and AAC may insert silence at the beginning of the audio file during the encoding process as compression artifacts [22]. Other formats such as Ogg and WebM do not have gaps as silence introduced as compression artifacts are already accounted for in the format. Lossless formats such as WAV will be gapless because there is no change in information in decoded audio data. We have used avconv which is part of libav [23] to perform audio compression on the server-side. The file sizes of the different formats are summarized in Figure 4.

The measured time (in milliseconds) to complete compression for a five second audio fragment is summarized in Figure 5. WAV is uncompressed data thus can be used as benchmark.

Fig. 4. Audio file sizes (in bytes)

Fig. 5. Time taken (milliseconds) to compress and retrieve audio

Note that these timings do not include network transfer, thus while WAV takes the least processing time, the actual time taken to load a WAV file in the live environment could be slower than that of compressed files simply because compressed data is smaller in size. As compression of fragment can be done quickly, we can simply invoke the compression tool via PHP.

We have used caching to improve the server responsiveness during fetching of the compressed audio. Because audio data do not change, we can reuse data that was already compressed. Audio that have already been compressed are stored into the cache table in a similar manner as regular audio fragments, and retrieved when the relevant audio file is requested. Because the compressed audio fragments are small in size, storing them on the server will not require a large extra storage overhead.

D. Drawings

In order to generate drawings that appear smoother compared to the naive implementation (connecting points with straight lines), we have decided to employ a basic curve-fitting algorithm [24]. The following code snippet shows a portion of the curve drawing code that we have used when drawing a particular point:

```
if (thresholdmet) {
    var midX = (last.x + current.x) / 2;
    var midY = (last.y + current.y) / 2;
    context.quadraticCurveTo(last.x, last.y,
        midX, midY);
    last2.x = last.x; last2.y = last.y;
    last.x = current.x; last.y = current.y;
}
```

The above code generates a curve that passes near to the points, making it an approximation of a curve-fit. As we

Fig. 6. Angle-based heuristic to account for changes in curve trajectory

are using Bezier curves[24], it will have the C-1 continuity property, giving a smooth appearance for the curve. Although the approximation introduces some small errors to the result, it still yields reasonable quality since the errors are usually small enough and not noticeable to the user. We are aware that there are algorithms that can produce curve-fits pass through all points however they will introduce greater complexity to the system [25]. Bezier curves require 3 control points. Hence, if there is only 2 points in the drawing we default to a straight line, and if there is only 1 point we simply render a dot.

Even with Bezier curves, the resulting curve still suffers from a “wavy” effect as a result of having points that deviate from the general path of the curve. These points are usually introduced due to vibrations during motion of the input device or by the user’s hand. We have applied a simple de-noising algorithm to produce even smoother curves by eliminating points that do not contribute to the overall shape of the curve, but are significant enough that they introduce artifacts in the curve.

We have used two factors to determine whether a point should be rejected, these are Euclidean distance and the angle. If a point is very close to the last accepted point, it should be rejected as it is likely to not contribute much to the shape of the curve. An exception would be the case of sudden changes in curve trajectory, whereby we will need to keep the points as they contribute to the shape of the curve even though they are close to each other. We define a sudden change in trajectory as a significant change in the relative angles of the points in the trajectory (see Figure 6).

The last (V_1) and second last (V_2) points are points that have already been accepted in the curve. The candidate point (C) is the one which will be added. We measure the angle θ between the two vectors which can be obtained via dot-product between $\vec{V_2V_1}$ and $\vec{V_1C}$ unit vectors. A larger angle implies significant deviation in trajectory. We still apply a distance condition to prevent points from clustering near each other. The conditions for accepting a point are summarized below:

- First point (0 points): Starting point is always accepted
- Euclidean distance (≥ 1 point): $|\vec{V_1C}| > 4$ pixels.
- Trajectory angle (≥ 2 points): $\cos^{-1} \frac{\vec{V_2V_1} \cdot \vec{V_1C}}{|\vec{V_2V_1}| |\vec{V_1C}|} > 1$ radians, and $|\vec{V_1C}| > 2$ pixels.

Figure 7 illustrates the difference between the scenario where no de-noising is applied, and when de-noising is applied. The overall shape of the curve should be the same, although in the de-noised version there are less “wavy” patterns, particularly at gentler curves. The algorithm used

Fig. 7. Comparison between non-denoised (left) and noise reduction (right)

Fig. 8. Storage mechanism in ShowNTell

gave reasonably good quality drawings, and does not require expensive computation, allowing it to be deployed for the web browser.

E. Storage

Like most typical client-server and web-based solutions, data is stored on the server as the persistency of data on the client is not guaranteed. There are two common mechanisms for storing data for a client-server application, one of which is storing as records in a relational database such as MySQL, and the other is storing as regular files in the file system. As data is associated with a document, we represent this property as a relationship, thus the relational database was initially chosen as the storage mechanism. However, in practice we find that we can yield greater performance by storing larger records in the file system [26], thus we have adopted a hybrid storage mechanism which is shown in Figure 8.

Because we need to preserve relational information of all records in order for other components to perform lookups of document data, all units of data would have an entry in the database, including those that are stored on the file system instead of as a record on the database. If a unit of data exceeds a certain size threshold, it would be stored on the file system, thus we set a flag in the record to determine if the data returned would be from the database value or from the file system.

There will be some overhead when storing data corresponding to a record into a file, since the file must be created or overwritten on top of setting a flag in the database record. We observed that for file sizes less than 100KB, the difference in timings between the file system and database are minor and comparable to each other. The variance in timings is observed to be due to io-bound operations and network latency which affects both mechanisms. Beyond 100KB, we find that the database method will require significantly more time to

Fig. 9. Comparison between file and database storage

perform the put operation, and at sufficiently large sizes, the put operation would fail. We also observed that the get operations for both systems are comparable. The following experimental results were captured from our experiments. In the experiment we simulate a client-server interaction and measure the time taken (in milliseconds) to upload or retrieve fragments of different sizes (in kilobytes) from the browser to the server using both methods. The results are summarized in Figure 9.

For our system, we have set 128KB as a threshold for determining which storage system to use. Small records such as metadata are stored in the database. Records larger than 128KB, which are typically audio fragments, images, and timeline data, are stored into the file system.

F. Other services

There are some services that do not run within the web browser, but instead performed on the server as it requires significant computational resources. These are usually handled by the dispatcher server, which provides video rendering services. Our video renderer is written using JavaScript and runs as a NodeJS application. When a user requests for a document to be rendered, the document ID is passed to the dispatcher service, which spawns the video rendering process. The video rendering process performs the following actions:

- 1) Download the document chunks.
- 2) Render the timeline data into a video frame-by-frame, using avconv (from libav) "pipe2image" feature. Each frame is rendered as a JPEG using node-canvas. The intermediate video (without audio) generated uses the MKV format.
- 3) Combine the audio chunks into a contiguous audio file. We are using SoX to perform the splicing of audio. The intermediate audio file generated uses the WAV format. The audio file may be re-encoded to 44100 sample rate to ensure that all fragments have the same sample rate.
- 4) Combine the generated video and audio into a single video file. The resultant file uses the MP4 (H.264) format. We are using avconv to combine the files.
- 5) Upload the final video file to the CDN (Content Delivery Network).
- 6) Send an email to the owner of the document informing them that the video has been rendered completely.

When rendering the frame, we have chosen JPEG as it provides a smaller sized image while retaining image quality, reducing the amount of time needed to transfer the image from our renderer to avconv. We have used WAV as the audio input since WAV files are generated by our client application. The intermediate video format is MKV as we find that the generated video track is of good quality, and does not suffer from significant compression artifacts when re-encoded to MP4 in the final stage. The resultant video format is MP4 with H.264/AAC encoding as it is supported by most of the modern CDNs and our CDN of school's Integrated Virtual Learning (IVLE) platform [27].

In addition the the video renderer, ShowNTell supports PDF documents which can be imported as slides used by ShowNTell. Document conversion uses the imagemagick tool which has support for PDF to image conversion [28]. The output image chosen is PNG as it offers good image quality.

V. EVALUATION

In this section, we highlight the usability, performance and scalability of ShowNTell system. The evaluations include analysis of user feedback on our system, as well as other evaluations we have drawn from our testing of the system.

A. User Study

We conducted field tests on our application with users. Most of these users came from the Faculty of Computing, although there were others from the Faculty of Science of our University. In this initial study, students and instructors from the following modules tried the system: PC1431 (Physics IE), CG3204L (Computer Networks) and CS3247 (Game Development). Our user study primarily focuses on participants from the CS3247 module.

During the March of 2015, we allowed students from the class of CS3247 to complete their assignments using our implementation of ShowNTell, thus allowing us to gather some information on user behavior, preferences, as well as the readiness of our system in terms of scalability. Altogether there were over 40 participants. The experiment was conducted over a period of one week, thus the load on the system could be confined and evaluated during this period. Prior to the student study, we had also opened up the system to other educators who were interested in our implementation so as to make any adjustments to the system if needed.

During this experiment, participants were to complete a recording to answer two technical questions of the module assignment using ShowNTell tool. The use of slides was required for the assignment, and was limited to 10 slides, thus it was expected that most students would attempt to use the PDF import feature. As the presentation was to be delivered orally, the students must also use the audio recording feature. There was an original requirement to use the video export, but that was lifted due to technical issues experienced towards the end of the experiment. The expected recording duration was at most five minutes. Upon completion of the experiment, the students were asked to fill in a feedback form.

TABLE II
USER STUDY DEMOGRAPHICS

Participants	45 (30 respondents)
Participant type	Students (97%) Academic Staff (3%)
Browser used	Google Chrome (80%) Mozilla Firefox (17%) Safari (7%)
Recording duration	<3 minutes (7%) 3 to 5 minutes (49%) 5 to 10 minutes (42%) >10 minutes (2%)
Input used	Mouse (93%) Touch (40%) Stylus (50%)

Fig. 10. User responses to various aspects

B. Evaluation Results

The survey primarily covered on user demographics as well as their preferred methods of using the system. Other feedback questions were also designed so as to inspire future iterations of our project. The survey results are summarized in table II. Majority of the users used ShowNTell on Google Chrome for Windows. Most of the participants were familiar with other video recording solutions, in particular Camtasia, Camstudio and OBS. The most common recording duration created by users was approximately five minutes long. The most commonly used input device was the mouse, as many students were using ShowNTell on a computer instead of a mobile device.

In general, most participants (76%) find our implementation easy to use and adequate (see Figure 10). The participants have indicated that ShowNTell provided sufficient capabilities to complete the requested assignment, although most have indicated the system could be improved further. Participants have indicated that ShowNTell is usable with the mouse and stylus, although participants who have used touch-based inputs mentioned them to be less comfortable. We hypothesize that touch-based input is harder to draw objects accurately for extended periods of time compared to a stylus or mouse.

Most participants (93%) have indicated that the performance of ShowNTell is adequate. Playback, recording, and saving of documents were perceived to be completed within reasonable time, fulfilling the main objective of our project which is to implement a responsive and usable recording solution in a web browser. Most actions on a recording can be completed within seconds, without the user needing to wait too long before

getting a response.

In terms of features, many participants (43%) find the PDF import function to be the most useful feature. It is observed that most participants (97%) have used the feature to import their slides, allowing them to quickly create the materials for a recording. Users have also found the sharing functions useful and easy-to-use.

It is observed that a number of documents (32%) have no additional drawings/image annotations. As the use of slides coupled with audio overlay is sufficient to complete the assignment, we suppose that these users do not use the annotation functions simply because it is not needed to complete the task.

Among those who have tried adding annotations, there were some who have found it frustrating to use the feature, particularly those using only a mouse-based input, thus only use the annotations in a limited way. For users who have tried a stylus or touch-based input, their rating is split between easy-to-use and challenging-to-use. We find that most users who have prior experience with recording solutions that do not have annotation capabilities (such as Camstudio) are more likely to indicate a negative experience with annotations.

Many users have suggested non-linear editing of the recordings. While we have evaluated the idea of introducing non-linear editing to ShowNTell, we find that it might be too technical challenging to implement it in the remaining time frame, thus we would leave this challenge as a form of future work that others could take up.

C. Evaluation Conclusions

We find that ShowNTell is a reasonably good implementation of a browser-based recording solution. However, we find that most users prefer to use it as a simple recording tool that overlays audio on top of slides. Nonetheless, we find that ShowNTell offers sufficient capabilities to act as an eLearning tool, and thus is capable of satisfying the tasks outlined in the experiment. There are many possible improvements that could be done to improve the usefulness of ShowNTell, such as support for rewriting past recordings.

Most users indicated that ShowNTell is responsive, implying that our performance optimization techniques and management of data is adequate for our solution to deliver a responsive experience within a web browser. Users were able to create recordings up to 10 minutes or longer, showing that ShowNTell is capable of supporting recordings of sizeable duration.

An Individual educator's evaluation statement: "The application is very good for the modules such as physics and mathematics which have lots of equations and drawings. I have used the import pic, free hand drawing and writing using stylus, highlighting, voice over recording and video rendering to answer students query. All these features makes the explanations very clear, with minimum text usage, saves time to input equations and symbols and brings it to a level which is comparable to face to face consultations with the students".

VI. LIMITATION

As some browsers have not implemented the APIs used by ShowNTell, the application is not expected to work on all browsers available in the market. However, as the application uses standards compliant APIs that are in the W3C draft specifications, the application will eventually be supported by browsers in the future that eventually implement those specifications.

At present, ShowNTell works well on Google Chrome and Mozilla Firefox. For browsers that only support a subset of the APIs required by ShowNTell, we may opt to use a fallback mechanism or simply disable the feature that uses the API. Due to performance limitations particularly in the mobile environment, certain techniques such as client-side compression might not be feasible in practice thus we use alternative approaches like server-side compression to obtain a similar result. However, this limitation is expected to ease with better hardware in the future.

ShowNTell is currently supported on most browsers for desktop and notebooks, which includes Internet Explorer, Google Chrome, Mozilla Firefox, and Safari. For Internet Explorer and Safari, we have taken steps to address the lack of support for certain APIs by providing a fallback, such as in the case of audio playback and recording.

On Android, ShowNTell is supported by Google Chrome and Mozilla Firefox. Among these browsers, we find Google Chrome to be more stable in performance compared to Firefox. Other browsers on Android such as the stock browser is not capable of supporting ShowNTell as it lacks many of the required APIs needed by many basic functions in ShowNTell.

On iOS, ShowNTell is partially supported by Safari and Chrome. As there are no browser-based APIs for microphone access in these browsers on iOS, ShowNTell will not be able to record any audio on those platforms. Nonetheless, other features in ShowNTell are still supported, thus users can still watch documents on these devices.

VII. CONCLUSION

We have found that it is feasible to implement a recording solution for the web platform that is supported on most web browsers. We have also presented solutions that can enable a fairly responsive application even when manipulating sizeable amounts of data. User studies have indicated that ShowNTell is comparable to other similar tools in the industry.

Overall ShowNTell works well in providing the features of a standard whiteboard recording system over the browser, and provides sufficient features to accomplish the basic requirements for its purposes in E-Learning. As ShowNTell is supported across multiple platforms and does not require installation of any software, it poses a low barrier to entry for students and instructors to use it, making e-learning more effective. ShowNTell is continuously evolving. Future releases will include complete video editing and real-time collaborative content editing modules to further enrich the learning experience.

Abstract — In the current electronic industry, embedded systems have become essential components in most electronic devices. The fast growth mobile devices have been used in every sector and brought wide applications in many aspects of our society. These devices involve in internet connections, wireless communications and even cloud computing, which increases the necessity of both hardware and software securities. Therefore there is an urgent need of efficient education in EE, CE and CS in embedded systems, especially in hardware and software co-design with the concepts of modern security methods. In this paper, we present a work-in-progress development of an effective learning tool which benefits from active learning concepts and modern mobile technologies. The contributions of this tool on promoting engineering students' learning of embedded system designs and security are also investigated.

Index Terms – Mobile embedded labware, low-cost and portable, modular design, authentic and creative learning.

I. MOTIVATION

In the modern engineering industry, embedded system (a.k.a. microcontroller unit (MCU)) has become an indispensable component with profound influence in many different applications, such as consumer electronics, robot controls, industrial automations, military services, aviation systems, modern architecture, and telecommunications [1]. Combined with embedded technologies, wireless monitoring and remote sensing have shown significant potential to promote better services in healthcare, environmental protection, and national security [2]. These advances fuel the growing requirement of wireless embedded system especially the hardware and software co-design education due to its importance at the nexus of future global competition and strong workforce demands. Much progress has been made to promote and implement underlying courses in various engineering fields of education, such as electrical, mechanical, mechatronics and computer engineering. However, the quality and quantity of the trained engineers with both hardware and software skills still lag behind the demand from all aspects of industry. This challenge would be mainly subject to less students' engagement in computational programming skills, shortage

of practice in real-world relevant questions, and unsustainable learning and training strategy.

Empowered by different types of personalized functions on ubiquitous pattern of people-people communication, the mobile technology has profound changed the mechanism of the information processing, influenced people's life styles, thinking, working and even the strategies to acquiring new knowledge and developing new skills. Mobile learning (m-learning) has become an emerging topic and various researches have been launched to show values of implementing mobile technologies in teaching and learning. In an early pioneer work in m-learning, Madeira et al. reported the development of a mobile learning course for a classic analog electronics [3]. The course was structured in several interactive modules to teach students analog circuit designs and all underlying theories. Sukittanon demonstrated using a quiz-style application (app) to test different electrical engineering subjects including digital logic analysis, discrete signal convolution, and digital filter design [4]. Vate-U-Lan et al. studied the topic of how mobile learning would be suitable to whole university students in different disciplines. Their study revealed that mobile learning could be more extensively used on different subject learning, especially in STEM educations [5].

In regard to the value of m-learning, Batagan et al. reported their analyses of the m-learning impact on the educational process. They concluded the flexibility, collaboration, motivation, accessibility and portability are all main reasons invoked in supporting of m-learning [6]. Bruns et al. in their review of m-learning further addressed that "...mobile technologies are able to support learners' engagement in creative, collaborative, critical, and communicative learning activities." which emphasized the students' engagements in leaning with mobile technologies [7]. The authentic learning, which involves real-world relevant problems or projects solving, was also studied with m-learning. Traxler reported a case study of authentic learning and multiple benefits from m-learning. In his analysis, m-learning enables students engaged in exploration and inquiry around authentic tasks, allows learning tasks on data capture, location awareness and collaborative works from physically remote students [8]. All these studies demonstrated that learning with mobile technologies is motivating for both students and instructors. It also represents an effective pedagogical method as compared to

any other conventional education models. However, employing the same idea using mobile technology to improve students' learning of the modern embedded system design is still dearth. This encourages PIs to develop an innovative learning method combining with the mobile learning technology in this project.

II. METHOD

To overcome the abovementioned difficulties in cultivating professional embedded system engineers and broaden students' technical skills in emerging topics such as embedded security, we present herein a new learning tool to promote the effectiveness of learning mobile embedded system design and significantly enhance students' active and authentic learning. The tool is designed as a labware to engage students' active and hands-on learning in topics of embedded system designs and embedded security. We adopted the method of using smart phone app technology to integrate all lab activities in the tool and cloud computing technology to allow the tool to be used anywhere and anytime. The app was named "embedded systems" which corresponds to the course to be implemented. The app consisted of several function pages, and each page showed clear images and instructions to provide a convenient user experience (Figure 1).

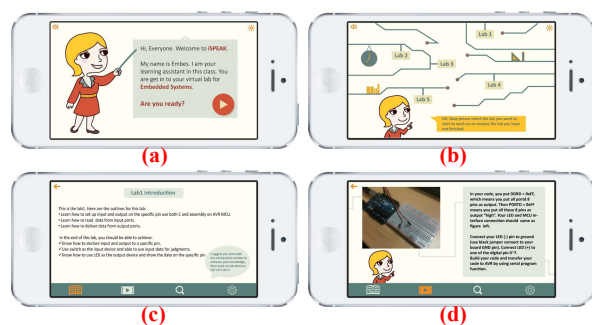

Figure 1. Schematic illustration of the contents of the learning app. (a) the main entry page; (b) the lab selection page; (c) the introduction page of a Lab. (e) a page shown in the "lab exercises" section.

We employed a module lab style in the app for different lab activities. This design creates an easy-to-adopt benefit for tool disseminations and keeps the flexibility to add or remove the contents in a specific curriculum based on the duration of the course, instructor knowledge, difficulty of materials, and budget of lab activities. Each module (lab) focuses on a group of topics or concepts in embedded systems designs, and is constructed as a self-contained lab package with all learning materials associated with the topic. The difficulty level in each lab is mutually the same so students will not be frustrated if they miss or forget the concept in previous topic. In addition, since each module is independent, students can gain self-efficacy by finishing each lab and accumulate their confidence through the whole course.

As shown in figure 1(a), we designed an animated characteristic to lead whole activities in the app. The design has two fold. First, we want to create a relaxing environment to let students work on their lab without any stress and pressure. It is believed that students with good emotional state may easily gain self-efficacy and vice versa [9]. In addition, a growing number of studies have demonstrated teens in this generation prefer informal type of communications through online communities such as google+, Facebook, twitter or YouTube [10-12] to learn information and share information [13-15]. We want to use this design to further promote the *participatory cultures* [16] to students' learning and eliminate their fears in the difficult topics in this engineering discipline. From students' point of view, learning from an animated character is similar to learning from their peers, and therefore, is more attractive and confidence inspiring than a professor-lead lab section. Secondly, this female avatar reinforces efforts to reduce disparity in engineering education. As the matter of fact, enrollment and graduation rate of women is low in most of the engineering fields. The number of female professors or instructors is even scarce. We want to put the effort on advancing women in engineering by using the animation female model to lead the technical teaching in the learning tool. Based on the social cognitive theory, observers can easily engage with vision recognition of a model in behavior they learned. We believe by dissemination of the project, the animation female character will be the role model to inspire more female students' interest in engineering subjects and further encourage them to pursue engineering degree or career.

The app consists of 5 labs which are essential to embedded systems designs (2 labs), wireless communications (1 lab) and embedded security (2 labs). Each lab consists with "concept introduction", "lab exercises", "real-world problem" and "report and discussion", where the "lab exercises" and "real-world problem" are designed to enhance students' hands-on experiences. The students can work on these sessions in sequence or randomly. The "concept introduction" provides a material review on the specific lecture covered techniques to be used in the lab. The "lab exercises" section provides step-by-step video demonstrations on hardware interfacing and software coding techniques with several examples on pre-defined questions (Fig 1d). Students learn these techniques through completion of all exercises. The user can stop, accelerate and replay the video anytime in the process. By completing all exercises and repeatedly reviewing these videos, students are able to gain solid fundamental skills with their mastery experiences and further inspire themselves to continue work on other topics. The real-world relevant problem features a special situation or a problem. The problem is real-world relevant to allows students to work on a question by using their creativity as well as integrating technologies they learned with their working knowledge in different aspects. This problem is designed without a predetermined solution, so students need to

evaluate their knowledge and ability with their creativities to accomplish the task. It will lead to diverse answers based on culture, finance and life experience. Thus, students are able to explore different thinking and problem solving from others, broadening their experiences and knowledge base. In “report and discussion”, students take a video of their working processes and their result demonstration and then post it on social media (i.e. YouTube) and join discussions with others.

We designed a hardware kit accompanying with the learning tool for students’ hands-on experience. The components of the kit include a low-end smart phone, an embedded IC, Bluetooth module and off-the-shelf peripheral devices. We have controlled the budget of the kit to \$100 and the kit is re-useable for students in different terms of the same course. All necessary electronic components are packed in individual bags. Students use the tool kit on all their lab exercises to learn hardware techniques. This portable kit allows students to work on hands-on exercises actively. They can also practice all exercises by constructing components repeatedly and gain experience as well as learn from their failures iteratively until they are proficient in the skills. Scheduling a lab time or not remembering all techniques learned are no longer concerns. Students work individually and are not affected by the deficiency of their prerequisite knowledge to slow down the progress of the group working in a team. The tool also provides a choice to encourage students to try different hardware constructions by themselves after they finish all required exercises. This extra task builds not only on their knowledge in the topic but also on their confidence and self-efficacy gained from all previous tasks. Figure 2 shows some components of the tool kit to employ in preliminary evaluation.

Figure. 2. The tool kit used for students’ hands-on activities. (a) All components used for all lab activities in a big Ziploc bag. (b) Low end android smart phone. (c) Microcontroller unit. (d) ~ (f) Peripheral electronics.

III. PRELIMINARY EVALUATION

The tool has been tested on volunteer students for the preliminary evaluation. All students in the evaluation have working knowledge in C/C++ programming learned from pre-requisite courses. None of them has experience on

embedded designs but all of them are highly interested to learn the skills. For the time being, students only worked on 2 modules (labs) related to embedded systems I/O programming and device communications. Emphasizing the enhancement of the self-efficacy by using the tool, we conducted an entry/exit survey on student participants. The questions are:

- Do you think embedded systems design is a difficult subject?
- Do you worry your software programming skill is not enough to handle all labs in this course?
- Do you prefer to work individually or in groups?
- Do you want to demonstrate your learning outcomes in public? For example, show your ideas and results in a video clip and upload it to YouTube?
- Do you believe you can work on a real-world relevant project on your own?

Figure 3. A screenshot of a YouTube video shows that a student demonstrated his idea and design results after learning embedded design with the tool.

Most feedback from our preliminary evaluation was positive and encouraging. After using the tool in a short period of time (4 weeks), students were confident to show their knowledge in hardware and software embedded co-design and understood the basic MCU communication issues. In addition, they were eager to learn more topics in the embedded systems and techniques to enhance mobile device securities. Students would like to apply the knowledge and skills they learned to other aspects such as their senior design projects. Figure 3 shows a screenshot of a YouTube clip of student demonstrating his idea and the results of his senior design project.

IV. PROJECT IMPLEMENTATION

We will redesign our embedded system curriculum following the model curriculum of 2004 IEEE/ACM [17] to implement the developed tool into the related courses. At this time, the tool can be applied on courses in electrical engineering, computer engineering, and software engineering and we would like to continue our efforts to

make the tool usable for more engineering courses and benefit all underrepresented students in engineering education.

In the redesigned curriculum, the related concepts and skills among the impacted courses will be emphasized by utilizing previous designs as components in subsequent courses. This vertical integration of concepts and skills of mobile embedded system among courses is expected to significantly increase students' proficiency in mobile embedded system design.

Abstract— The advancements made in handheld devices and the widespread use of these devices among users all over the world has opened up new avenues for the use of these devices in education. Many applications have been developed to work on these devices to support the teaching and learning process in all its dimensions. CommEasy is an innovative, interactive communication system for smart handheld devices based on Internet and WiFi technology. This system has been developed mainly to enhance communication and participation in distance-learning classrooms that use video-conferencing technology. It allows students to pose questions for the instructors using their own Apple smart handheld devices, guarantees them complete anonymity and allows the instructors to respond to their students. It also enables instructors to evaluate the learning of their students by posing questions with multiple answers to which students can respond through their devices. This paper concentrates on the role of CommEasy in enhancing teacher-student communication and interaction. The hypothesis to be tested is that CommEasy will increase the level of student participation in the distance-learning classroom. According to the results of the experiment conducted in King Saud University, the null hypothesis is rejected, and the experimental hypothesis mentioned above is accepted.

Keywords—*PRS; communication; participations; distance learning; smart handheld devices.*

I. INTRODUCTION

The nature of the "information age" and communication is changing quickly. Many technologies that previously were considered advanced are becoming commonplace and new ones are being developed. This trend affects many aspects in our lives and changes the way we live. Distance-learning is one of field that has been affected by this revolution. The rapid advancement in computers, mobile technologies and telecommunications capabilities has made a paradigm shift in distance-learning, in all its dimensions. Many institutions worldwide take advantage of these new technologies and offer advanced distance-learning courses as an alternative to traditional education, in order to respond to students' demands to learn.

Distance-learning have been defined as "planned learning that normally occurs in a different place from teaching and as a result requires special techniques of course design, special instructional techniques, special methods of communication by electronic and other technology, as well as special organizational and administrative arrangements" (p.2) [19]. Schlosser and Simonson [25] have defined distance-learning as "institution-based, formal education where the learning group is separated, and where interactive telecommunications systems are used to connect learners, resources, and instructors" (p.1) [25]. Most definitions of distance-learning have emphasised the role of technology in the successful building of distance-learning. These technologies allow learning to be delivered to students and bridge the instructional gap between them and their instructors. Many technologies have been used, ranging from video tapes, printed material and instructional television to the advanced two-way audio and video conferencing technologies used today.

Video conferencing is an advanced technology that allow to deliver real-time, bi-directional interactive communication through using telephones or internet technologies to allow instructors and students in different locations to communicate interactively. Numerous advantages has been reported for using video conferencing technology in distance learning such as encourage collaborative in the classroom, encourage interaction in the classroom, allow immediate feedback to be delivered to students and allow to transfer non-verbal communication such as body gestures and facial expressions that considered an essential part of successful and effective communication [17,23]. In King Saud University (KSU), video conferencing technology has used to allow male instructors to teach female students in distance-learning classrooms. In such communication, female students can hear, watch, ask and answer questions from their male instructors while males instructors can hear females and create discussions without seeing them (Fig. 1).

Fig. 1: One-way Video Conferences in Saudi Arabia

It has been argued that the effectiveness of distance-learning is dependent upon how interactive the process is and how the barriers that are faced by students in this regard are overcome. Lack of motivation, resistance to change and anxiety, lack of technical support and equipment failure, lack of student-teacher interaction, lack of student preparation and training are all examples of the barriers that students faced in distance-learning [7,12]. Among these barriers, this paper will consider overcoming the communication and participation barriers faced by students in distance-learning classrooms and how to encourage students to participate and interact.

Effective ways of communication and interaction in the classroom are the cornerstones of learning and have a basic role in the transfer of knowledge from the instructor to the students [12]. Any barriers that might hinder the communication and interaction process between instructors and their students should be considered and solved [7]. It has been reported that there are many reasons that can prevent students from interacting and participating, including psychological, social and cultural reasons [5,13]. Hesitating and shyness to interact and ask questions, overcrowded classrooms, lack of lecture time, fear of being labelled as incapable by their instructor, are all examples of reasons that might affect interaction in the classroom and prevent students from participating with their instructors [4]. Such problems can be minimised by adopting new methods of teaching as well as adopting new technologies. Adopting different teaching methods that encourage interaction and discussion in the classroom are known to benefit learning. However, some factors, such as the large size of the classroom, make the teaching methods alone insufficient to encourage students to participate and, therefore, some advanced technologies should be used to help instructors in this regard.

II. THEORETICAL FRAMEWORK

The significance of student participation and interaction in the learning process has been confirmed by many educators and researchers worldwide and is supported by strong evidence [20,31]. Cohen stated that participation is a way to bring “students actively into the educational process” and to help in “enhancing our teaching and bringing life to the classroom” (p.699) [6]. Numerous benefits of participation have been reported, including increased attention, improved learning ability, increased motivation to learn, higher grades, ‘higher levels’ of thinking and improved problem-solving, decision-making and communication skills [10,16,18,31]. Enhancing participation and interaction in distance-learning settings is no

less important than in traditional settings and has received much attention recently.

Despite the importance of communication and participation, and although educators encourage questions during lectures, many students still do not participate. Many reasons for this have been reported in the literature, including shyness, overcrowded classrooms and short lecture times [5,13,4]. Such barriers are faced by students and educators in Saudi Arabia and worldwide.

Researchers and educators are making considerable efforts to overcome these barriers and encourage students to participate in the classroom. One solution is to incorporate new technologies into the classroom and use them to encourage students to participate. Mobile-based educational systems have become popular and are used for many educational purposes, including enhancing interaction and participation in classrooms. The spread of these applications has been supported by strong pedagogies as well as the increasing number of higher education students who own and use mobile devices. It has been reported that using mobile technologies in the classroom can enrich students’ learning experiences, improve their level of participation and interaction and overcoming many of the challenges they face [12]. CommEasy, a personal response system that can be used in both traditional and distance-learning classrooms, is one example of an innovative interactive communication system that can be used to enhance communication and participation for distance learning students as will be discussed in this paper.

III. TECHNOLOGIES TO SUPPORT COMMUNICATION AND INTERACTION

Communication and interaction in the classrooms has been affected by the continuous growth of technologies and the tools that are used to support the teaching-learning process in all its dimensions. Many technologies and tools have been developed, mainly to increase interactivity and to support the communication between students and their instructors. These technologies support many platforms, ranging from old desktop computers to laptops, to the latest generation of handheld devices with touch screen capabilities. The huge advancements made in the development of these devices and their widespread use among students all over the world has pushed educators and researchers to use these devices in education to bridge gap between the way students live and the way they learn and to support the teaching-learning process, as well as to solve the problems faced by students. Numerous applications have been developed to work on these devices during the past few years. Interesting results have been reported about the positive impact of these applications in supporting communication and interaction in the classroom, as well as minimising and reducing barriers faced by students [14, 15].

This paper has taken into consideration the advantages of this widespread use of smart handheld devices among higher education students in Saudi Arabia and the positive impact of mobile applications in enhancing communication and participation. It has implemented, from scratch, an innovative interactive communication system that runs on smart handheld devices, CommEasy. CommEasy is a type of Personal Response System (PRS) that allows students to pose questions for the instructors using their own smart phones (iPhone and iPads) and allows the instructors to respond and send answers to their students. It also enables instructors to pose questions for their students in the form of voting and presents the result for instructors in an appropriate format. This system has been used to enhance interaction and participation in the distance-learning classroom that uses video conferencing technology in KSU.

IV. PRS TO SUPPORT COMMUNICATION AND INTERACTION

As stated previously, communication and interaction in the classroom has been affected by the continuous growth of the tools and technologies that have developed to support the teaching-learning process in all its dimensions. Many technologies have been developed during recent years mainly to support and increase interactivity and participation in the classroom and to tackle the communication and participation barriers faced by students. One popular technology that has gained recognition during the past few years is the PRS.

PRS is a technology consisting of a combination of hardware and software that enables students to communicate with the instructors and answer the questions, without the need to speak to the instructors or raise their hands. PRS has been defined as a communications system that allows instructors to collect and analyse large amounts of data about students' learning and consequently investigate whether learning has taken place [22].

PRS consists of a sender device (clickers), which is a small handheld device given to each student to allow them to respond to the instructors' questions; receiver devices, which are usually connected to the instructors' computers and allows instructors to receive a signal sent by students' devices and present the results for the instructors; software is used to allow instructors to create questions and process the information sent by students' devices, as well as to tabulate and display student responses, e.g. in the form of bar charts [1].

In older generations of the PRS, Radio Frequency (RF) technology and Infrared (IR) technology was used to establish communication between clickers and the instructor's computer. In the latest generation of PRS, many personal handheld devices such as PDAs, smartphones, etc. can be used as input devices instead of older clickers and WiFi technology can be used to establish communication between these devices and instructors' computers. This shift in using PRS has enabled the development of numerous applications that work on personal

handheld devices and can be used in both a traditional setting, as well as a distance-learning setting, as it is based on internet and WiFi technology. These applications were used for many purposes, one of which was to increase interaction and participation in the classroom.

Numerous advantages have been recorded for the role of the PRS in supporting the teaching-learning process, such as increasing interaction and participation in the classroom [30], supporting collaborative learning [24], monitoring students' performance [3], encouraging proactivity by shy and deprived students [28], improving student performance in exams and assignments [21] and making the classroom a happier and livelier environment [9]. However, students' anxiety, instructor resistance to change and technical issues are some concerns related to using PRS in the classroom.

This paper has concentrated on the role of PRS in enhancing teacher-student communication and interaction and increasing the level of students' participation in the distance-learning classrooms that use video conferencing technology. Many studies have revealed that the use of PRS in the classroom can support teacher-student interaction and lead to increased student participation in the classrooms [8]. Students are more likely to participate and tend to stay focused on task in the classrooms using PRS, compared with the typical classroom that does not use PRS [27]. Quieter students or students who are shy or easily embarrassed found PRS to be a comfortable and easy way for them to participate with instructors [28,24]. Hall et al. [11] have confirmed that PRS has been used for many years and helps to increase the level of student engagement and participation in the classroom.

The advancements made in the PRS that are based on the latest wireless technologies and handheld mobile devices have allowed it to be applied in the distance-learning setting. The PRS has proved its positive impact in enhancing communication and interaction in distance-learning classrooms [26].

V. COMMEASY, A SYSTEM TO SUPPORT COMMUNICATION AND INTERACTION IN DISTANCE-LEARNING CLASSROOMS

CommEasy is an innovative type of PRS that is based on personal handheld devices (iPhone and iPad) and *WiFi* technology. It has been used to support communication and participation in the distance-learning classrooms that use video conferencing technology in KSU in Saudi Arabia.

The main advantages of the CommEasy system are that: it allows instructors and students to interact instantaneously during lectures; it allows students to pose text-based questions to their instructors, as well as receive answers for their questions once they have been answered by instructors; it enables instructors to evaluate the learning of their students by posing them questions with multiple answers in the form of

voting to which students can respond through their devices, the instructors can browse the results of voting in an appropriate format; it enables instructors to post announcements to their students and the students can browse these announcements. Both the instructor and students are able to use Apple's devices that they already own, so this saves the cost of using other response devices, such as clickers. Finally, CommEasy can be applied to enhance participation in traditional learning, as well as in distance-learning classrooms.

To fulfil all these requirements, CommEasy has been developed to include two applications: the student application and the instructor application. Both applications will run on the individual iPhone / iPad devices of the instructors and students and allows them to communicate interactively with each other. The applications supports iOS version 5.0.1 to iOS 7.0.4.

Both applications allow the instructor and students to create an account using their chosen email address and passwords (Fig. 2).

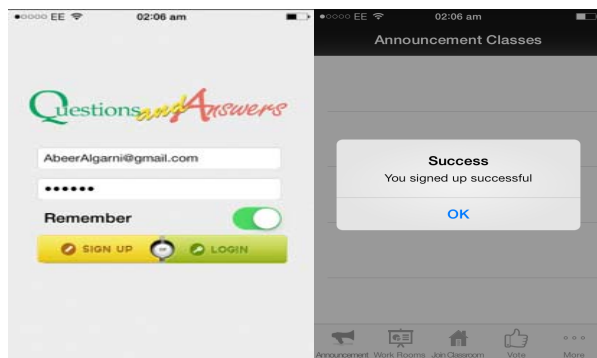

Fig. 2: Main Screen of the Application

The instructor application allows instructors to create a new virtual classroom with venue, date and time. The instructor is provided with a unique access key for each classroom created, to be given to students to allow them to join this classroom and interact with instructors (Fig. 3). The instructor can add a list of topics for each classroom and such topics will be used by students when they want to pose questions to their instructors (Fig. 4).

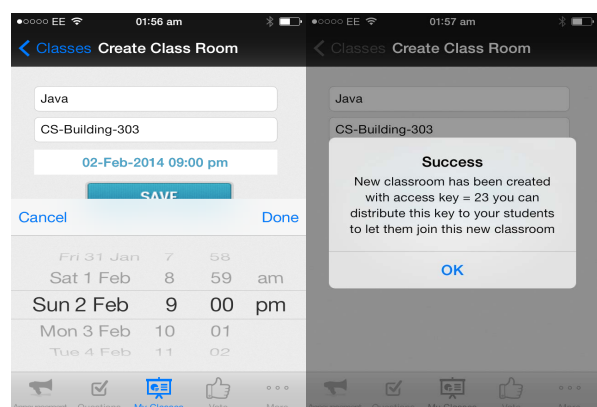

Fig. 3: Create New Classroom

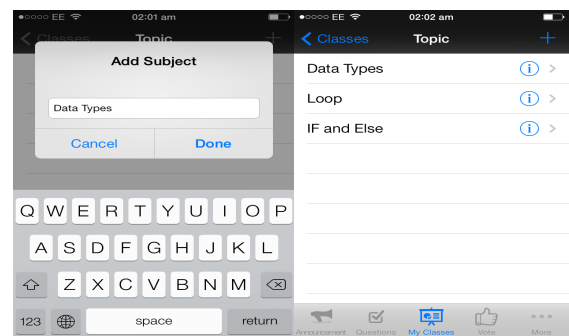

Fig. 4: Add Topics to the Classroom

The student can register to the classroom with the key given to them by their instructors (Fig. 5) and will be able to pose questions for their instructors, as well as chose topics (subjects) for their questions (Fig. 6).

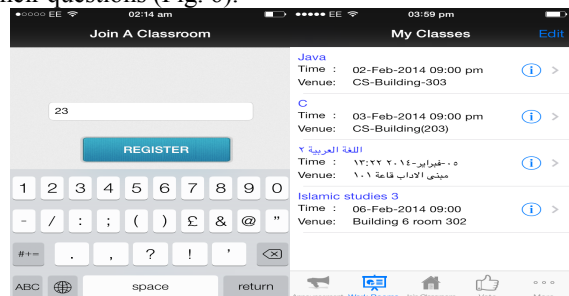

Fig. 5: Registering to the Classroom

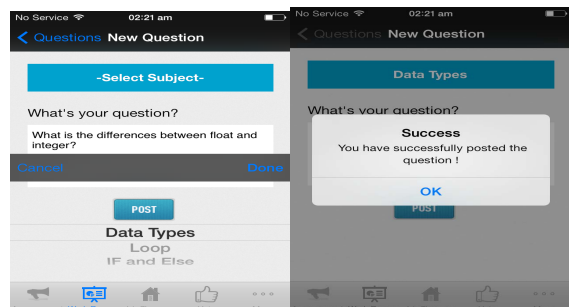

Fig. 6: Pose a Questions for Instructors

The questions will appear on the instructor's application instantaneously and the instructor can post an answer back to the student (Fig. 7). The answers will appear on the student's application once it has been posted by the instructor (Fig. 8). Instructors can also create voting questions with multiple answers (Fig. 9), and students can respond to these questions (Fig. 10). The instructors can browse the results on their own application (Fig. 11).

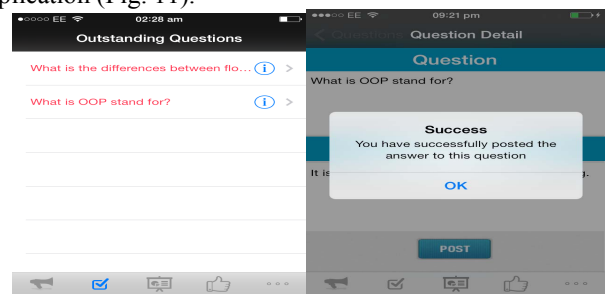

Fig. 7: Sending Answers to the Students

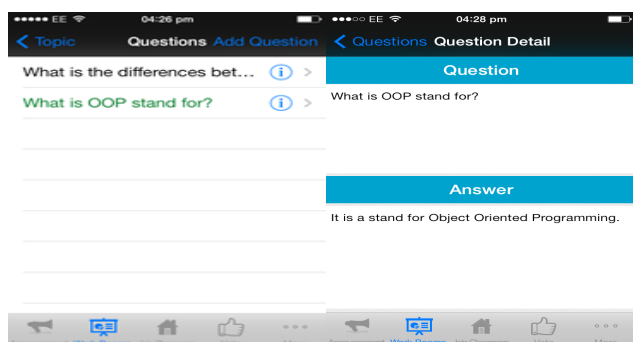

Fig 8: Browsing Answers in Students' Application

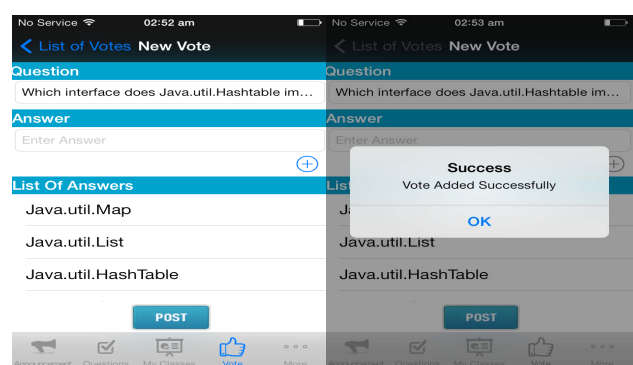

Fig. 9: Create the Question for Vote (Instructor Application)

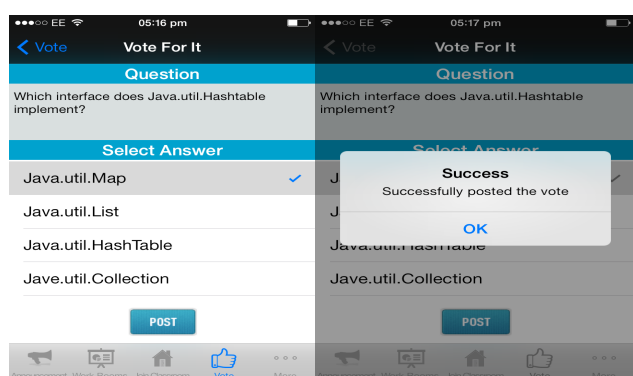

Fig. 10: Answer the Voting (Student Application)

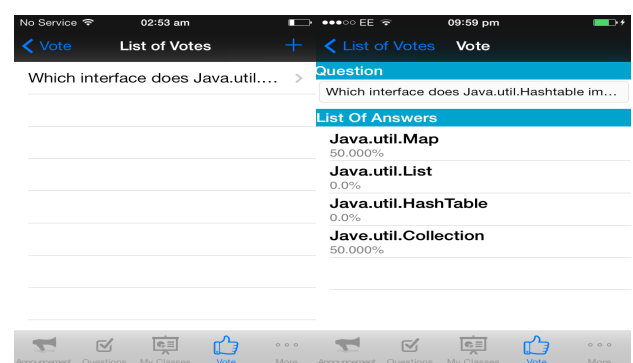

Fig. 11: Browsing the Voting Results

The instructors can also post announcements to their students (Fig. 12) and students can browse these announcements in their application.

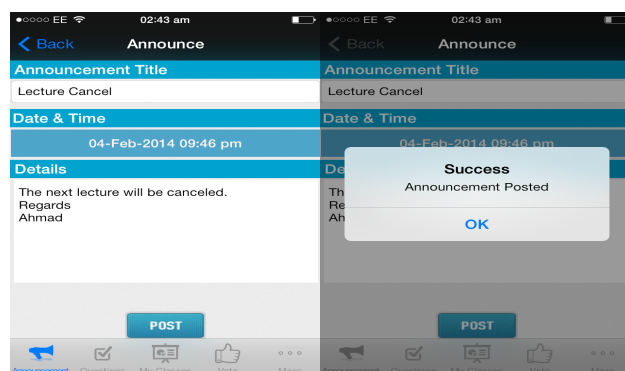

Fig. 12: Create Announcement (Instructor Application)

Both applications also have all the basic functionalities that allow students and instructors to signup, login, remember password, reset password and logout and include all the required help and contact us information.

VI. EVALUATION

A one-month-long quasi-experiment was conducted to evaluate CommEasy. The experiment was carried out in the KSU and involved 30 female students who were enrolled with a male instructor in a distance-learning classroom through video conferencing technology. Before the experiment began the system was introduced to the students, a link to download the system was sent to the participants' devices and a manual of six pages was given to the students. The utility of the system was evaluated using comparative analysis: measuring the students' participation in the classroom with and without use of the system and then conducting a comparative analysis between the two outcomes. Four lectures were observed over a four-week period. In the first two weeks students participated with the instructors traditionally, by leaving their seats and walking to the microphones that were spread along the walls of the classroom where they push a button and speak to the instructor. In the next two weeks the students were allowed to use the CommEasy application downloaded on their own devices and were able to send their questions to the instructors, as well as receive answers on their handheld devices (iPhone and iPad). The number of participations of each student in each lecture was observed and recorded to be used in the analysis. In order to control other variables, as far as possible, between the two conditions (with CommEasy and without), the experiment was conducted in the same classroom, the same module (Islamic Studies), the level of lectures were similar as they were chosen according to advice of the instructor and the lectures were held at the same time every week. Once the participations were recorded for the month, a data analysis was undertaken to evaluate the role of the system in increasing students' participation and to accept or refuse the hypothesis.

Figure 13 gives an overview of students' participation by week by displaying mean and median. It shows the average number of times students participated in class. As shown in the figure, student participation was positively affected when using CommEasy. As the intervention began in week three,

the data shows an expected trend with a steep increase in participations between weeks two and three.

Fig. 13: Mean and Median Average Participations by Week

It can be concluded from this chart that student participation in weeks 1 and 2 differed from that in weeks 3 and 4. However, to formally test the hypothesis, a Paired t-test was carried out. This test looked at the changes in levels of a measurement that occurs at two points in time for the same group. In this case, it looked at how students' participation differed in weeks 1 and 2 in comparison to weeks 3 and 4.

To use the paired t-test, each pair of weeks is combined to create single measurements for 'before' and 'after'. The number of participations of each student were added in weeks 1 and 2 (before) and compared with the number of participations they had in weeks 3 and 4 'after'. Table 1 shows the mean and median values for the combined pairs of weeks, as well as the difference between the weeks. The difference is calculated by subtracting the number of participations in the 'before' weeks from the number of participations in the 'after' weeks. This difference variable will be used in the t-test

Time	n	Mean	Standard Deviation	Median
Before (Weeks 1&2)	30	2.77	2.67	2
After (Weeks 3&4)	30	5.60	3.32	5
Difference (After-Before)	30	2.83	2.41	3

There is an assumption of normality in parametric testing procedures, so it is important that the difference variable is normally distributed. To test this, a normality tests, Shapiro Wilks and Kolmogorov-Smirnov, were used (Table 2). As both tests have a p value >0.05 , the Differences variable follows normal distribution. Therefore, it is safe to use the paired t-test.

Test	Test Statistic	Probability (p)
Shapiro Wilks (W)	0.94	0.1058
Kolmogorov-Smirnov (D)	0.12	0.1500

The result of the paired t-test indicates a very significant difference between Weeks 1-2 (Before) and Weeks 3-4 (After)

($p < .0001$). Therefore, it can be concluded that there was a very significant increase in participation in Weeks 3-4 compared to Weeks 1-2. According to these results, the null hypothesis was rejected and the experimental hypothesis, which states that female students' participation with male instructors in distance-learning classrooms will increase using the CommEasy system, compared with not using CommEasy, is accepted. These results confirmed the ability of CommEasy to enhance communication and interaction between students and their instructors. The system encouraged students to be more active in the classroom and to participate and interact with their instructor, as observed in the classroom. This was also confirmed by the instructor. Students showed great enthusiasm for using the system in the classroom and expressed appreciation for the system's features. Most of the students commented that the anonymity of CommEasy made them feel safer and many female students found it very convenient and easy to use. They also enjoyed the fact that CommEasy provides all students with a chance to participate and interact with the instructor. Furthermore, they appreciated the fact that they could participate without leaving their seats; in the past, they had to walk to a microphone to speak, which was stressful, especially for students who were shy or embarrassed. However, as stated previously, the experiment only lasted one month due to time and administrative restrictions. It is recommended that further experiments be conducted over longer periods of time, as this may lead to more interesting results.

VII. CONCLUSION

The CommEasy system for enhancing communication and participation in the classroom has been presented in this paper. The system allows students to pose questions for the instructors using their own smart handheld devices and allows the instructors to respond and send answers to their students. It also allows instructors to pose questions for their students in the form of voting and obtain the results. The intended goals have been met, according to the results of the experiment, which proved that the CommEasy system increased the level of students' participation in the distance-learning classrooms that use video conferencing technology. This study contributed to previous literature by confirming the positive impact of CommEasy, a mobile-based educational system, on communication and participation in the classroom. It encouraged students to ask questions and overcame all the barriers to participation that students had faced previously, such as shyness, crowded classrooms and lack of lecture time. These problems are faced not only in Saudi Arabia but also worldwide, so this system could help students all over the world. Additionally, the system should be transferable to any traditional or distance-learning educational setting. In the near future, CommEasy will be supported by additional platforms, such as Android, making it accessible to even more students. Further longitudinal experiments are recommended to obtain more interesting results.

Abstract— The educational field has been greatly affected by the current revolution in ICT, especially the advancements made in the use of handheld devices such as smartphones with touch screen capabilities, which have become extremely popular among university students worldwide. Universities and educators have realised that using such devices in education can help to bridge the gap between the way students live and the way they learn as well as enrich the learning experience and tackle the problems students face. This trend has led to developing numerous educational mobile systems to support the teaching-learning process and to tackle the problems that students and instructors face. Hesitation, shyness and crowded classrooms are barriers that can discourage students from participating. This paper presents the perceptions of instructors and students of the interactive communication system CommEasy. This system was developed mainly to tackle a number of communication barriers that female students face in distance-learning classrooms and provide them with a convenient way to pose questions to instructors using their own handheld devices. Results of the evaluation show that students and instructors have a very positive attitude toward the role of CommEasy in supporting communication and participation and removing the barriers they face.

Keywords—Participation; Communication; Handheld devices.

I. INTRODUCTION

There is a considerable part of the literature that emphasizes the importance of interaction and participation in creating an effective learning environment and in enriching the learning experience of students. Effective communication methods through discussion, asking questions, debating, etc., has proved to support active learning, encourage comprehension, encourage collaboration, improve teacher-student relationships and a better atmosphere will be created for both the instructors and students [2]. Such communications methods have influenced how students feel about learning as well as their level of participations and their achievement in the classroom [7].

In distance-learning, effective communication and interaction methods have also been regarded as a pivotal element for

creating a successful distance-learning environment [6,12,13]. These interactions influence many other factors, such as student satisfaction and achievement and the quality and quantity of learning [4,10]. This interaction takes place with the help of technology, including asynchronous and synchronous communication technologies. However, some barriers might hinder the interaction process between students and their instructors in a distance-learning, and such barriers should be considered and solved. Crowded classrooms, lack of time, and shyness and embarrassment when asking questions are examples of communication barriers that discourage students from participating in distance-learning classrooms.

In Saudi Arabia, most universities use video conferencing technology to allow male instructors to teach female students in distance-learning classrooms, as this is the only authorised way for males to teach female students. In such communication, female students can see and hear the male instructor, and can interact in the classroom by asking questions, responding to instructor's questions, etc., while the male instructors can interact with female students without seeing them (Fig. 1).

Fig. 1: Video Conferencing Technology in Saudi Arabia

Female students who enrol in such distance-learning classrooms in King Saud University (KSU) have reported many barriers that hinder their communication and interaction with their male instructors. The most common barriers reported by students include [1]:

- Hesitation and embarrassment in terms of speaking to the male instructor and in asking questions.
- A shortage in the number of microphones available in the classroom, there are only four microphones in a

classroom that accommodates up to 100 students and these microphones mounted on walls on both side of the classroom.

- A crowded classroom makes it difficult for students to move around the classroom and reach the microphones, preventing them from participating. Crowded classrooms also reduce opportunities for student participation and interaction.

The CommEasy system has been designed to tackle all of these barriers and pressures. The CommEasy system has been developed to provide female students with a convenient way to pose questions to their instructors using their own handheld devices (iPhone/iPad), and allows instructors to respond and send answers to their students on their own devices. The system also allows instructors to send questions to their students in the form of quiz and get feedback from their students.

II. PEDAGOGICAL CONSIDERATIONS

The recent revolution in handheld devices such as smartphones, and the falling prices of these devices have driven an increase in the number of students all over the world who use and own such devices. Such a trend has led to the development of many educational mobile systems and applications that are used to support the teaching-learning process in all its dimensions. One of the main purposes that such applications are used for is to facilitate interactivity in the classroom and to encourage students to participate and interact in the classroom. There is evidence that the use of mobile technologies in the classroom can enrich the learning experience of the students, as well as to encourage participation and interaction in the classroom [5,8].

Encouraging students to participate and ask questions in the classroom is a major concern of educators worldwide. Asking questioning during lectures are critical to learning, because it create an active engagement in the learning process. Whilst most instructors welcome questions during class, students mostly hesitate and are embarrassed to ask questions [9]. Educators have reported numerous reasons that can prevent students from asking questions and participating, including psychological, social and cultural factors [3]. Such reasons have been mentioned by female students in KSU, as stated previously. Other reasons can include lack of lecture time, the fear of being labelled as incapable by their instructor, the prospect of embarrassing oneself in front of fellow students, a large number of students in the classroom, etc.

This paper takes into considerations the spread of smart handheld devices among students in higher education in Saudi Arabia and the positive impact of using such devices in supporting and increasing participation and interaction in the classroom. The paper presents the CommEasy system that runs on the individual handheld devices (iPhone and iPad) of students and instructors, and provides them with an easy and

convenient way to communicate and interact. This system has been used to increase communication and participation in the distance-learning classrooms and to tackle the problems reported by students in this regard.

This system provides students who are shy to ask questions, are embarrassed to talk to male instructors, or cannot participate due to overcrowded classrooms or a shortage of microphones in the classroom with an easy, convenient way to pose questions to their instructors and receive answers using their own smartphones. This system also allows instructors to ask questions and receive responses from their students in a form of quiz. This system provides many features: It guarantees students complete anonymity, allows instructors to deliver immediate feedback to students, and enables instructors to evaluate students' learning through posing questions with multiple answers. It can be used in both classroom-based and distance-learning settings as it based on WiFi technology.

III. COMMEASY, SYSTEM DESCRIPTION

CommEasy consists of two applications - the students' application and the instructor application. Both applications work on the personal devices of the students and the instructor (iPhone and iPad) and allows them to interact instantaneously during the lecture. Both applications allow the instructor and the student to create an account with their chosen email and password (Fig. 2).

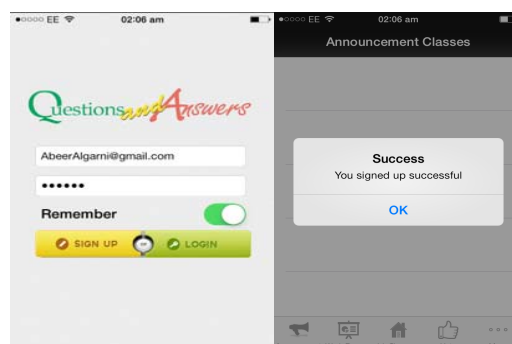

Fig. 2: Main Screen of the Application

The instructor application provides the following features:

- It allows the instructor to create a new virtual classroom with its own details (title of the class, venue, date and time) and the system will provide the instructor with a unique access key (Fig. 3). This access key will be given later to the student to allow students to join the class.
- It allows the instructor to add a list of topics that will be discussed in the classroom. This helps to categorise the questions posed by students under these categories.
- It allows the instructor to answer any questions posed by students and to send an answer to the students;
- It allows the instructor to pose questions to their students in a form of quiz (questions with multiple

answer) and allows the instructor to browse the results of such voting (Fig. 4 and Fig. 5).

- It allows the instructor to post announcements related to the class with the following details (title of announcement, date and time, and details of the announcement).
- The instructor application will also provide the instructor with many basic functionalities such as login, logout, remember my password, change password as well as allowing them to browse the Help, FAQ and Contact Us for technical assistance.

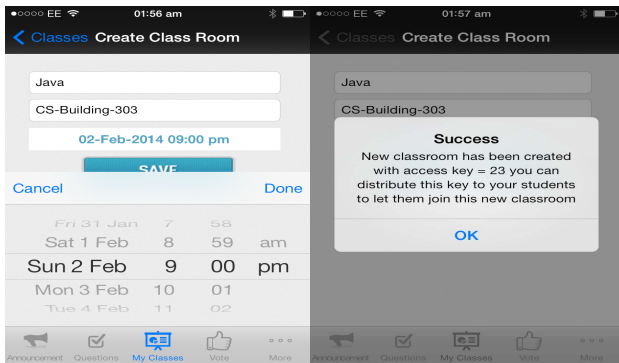

Fig. 3: Create New Classroom (Instructor Application)

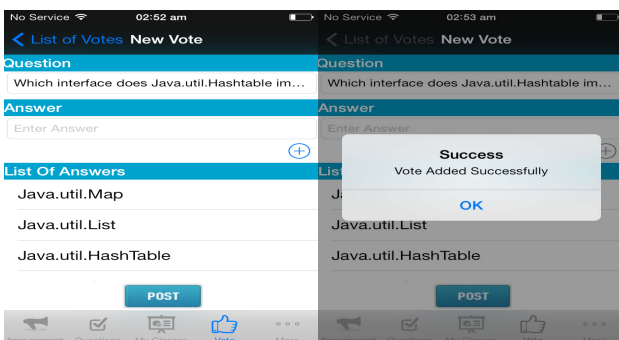

Fig. 4: Create the Question for Voting (Instructor Application).

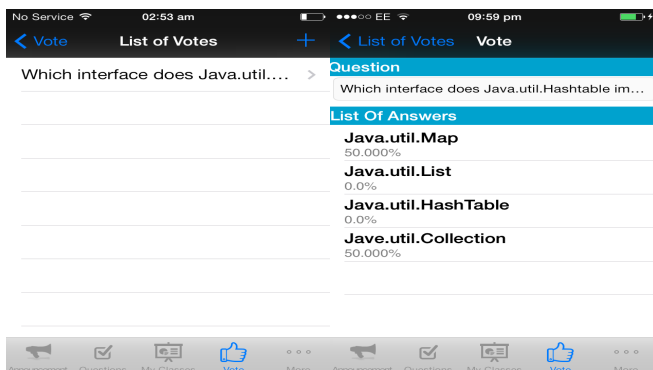

Fig. 5: Browsing the Voting Result

The student application provides the following features:

- It allow students to join the class using the access key given by their instructor (Fig. 6);

- It allow students to pose text-based questions to their instructors as well as to browse the answer sent by the instructor (Fig. 7 and Fig. 8);
- It allows students to browse the questions sent by their peers, along with the answers provided by the instructors to these questions;
- It allows students to answer the questions sent by their instructor and to post the answers to their instructor (Fig. 9);
- It allows students to browse announcements sent by their instructor (Fig. 10).
- The student application also provides students with many basic functionalities such as login, logout, remember my password, change password as well as allowing them to browse the Help, FAQ and Contact Us for technical assistance.

IV. METHODOLOGY

One of the most useful approaches to obtaining information regarding people's characteristics, opinions, attitudes, perceptions, etc., is by using a survey approach [11]. In the survey approach, many different data collection instruments can be used, including questionnaires, interviews, etc. Participants' perceptions and attitudes can be effectively measured using a questionnaire that asks participants to express their level of agreement with the questionnaire items using a five-point Likert scale [14].

In this paper, it has been decided to design two questionnaires - one for measuring students' perceptions with regard to the student application, and the other for measuring instructors' perceptions with regard to the instructor application. Both questionnaires were evaluated with the assistance of a group of five experts who were majoring in Computer Sciences, Software Engineering and Technology Enhanced Learning. The participants included 30 female students from KSU who were chosen randomly from 63 students and were enrolled with a male instructor in a 'Islamic Studies' subject in a distance learning classroom through the use of video conferencing technology. Data collection was carried out in March-April 2014. Both students and their instructor were allowed to use the system for one month. During the first two weeks, students and instructor communicated without the using of CommEasy. In the following two weeks they were able to communicate with

each other with the use of the CommEasy system. At the end of the month, online questionnaire were emailed to both students and instructor in order to identify their attitude towards the system.

The aim of the student questionnaire was to identify the perceptions of the students with regard to the role of the CommEasy system in terms of enhancing communication and participation in the classroom, and in solving the problems students face in this regard. It is also aimed to evaluate the application by using some metrics such as ease of download, ease of use, ease of run, etc. The survey also aimed to identify the advantages/disadvantages of the application from the students' point of view, as well as gathering students' comments and suggestions.

The student questionnaire included two parts: the first part concentrated on evaluating the role of the system in solving the problems that students faced in terms of participation and communication with the male instructor. In this part, students were provided with a list of items and, for each item, they were asked to express their level of agreement using a five-part Likert scale (Strongly Agree, Agree, Neutral, Disagree and Strongly Disagree). The second part of the questionnaire was used to assess the application based on some metrics such as ease of download, ease of run, ease of use, etc. Similarly, students were asked to express their level of the agreement using a five-part Likert scale (Strongly Agree, Agree, Neutral, Disagree and Strongly Disagree). The questionnaire also included an open question to allow students to express their own opinions regarding the advantages and disadvantages of the application, and to offer any comments they might have (See Appendix A).

For the questionnaire aimed at the instructor, it had similar objectives to the student questionnaire. The aim was to explore how instructors perceive the system in terms of facilitating and supporting communication with their students. The instructor questionnaire included similar parts as the one directed towards the students (See Appendix A).

V. RESULTS

Descriptive statistics have been used to analyse the results of the questionnaires. In general, the results of the questionnaires showed that both students and instructor exhibit a very positive attitude towards the role of the system in enhancing communication and participation in the classroom, and solving the problems students were facing in this regard.

The results of the student questionnaire showed that the majority of female students (70% or more) agreed that the system provided them with a convenient way to communicate with the male instructor, to pose question to him and to answer question that he posed (Table1; Table2; Table3).

Table1: Evaluation of CommEasy from students' perspective (1)

Question	The system provides a convenient way to communicate with male instructors in the distance-learning classroom.				
Response	SD	D	N	A	SA
Frequency	2	6	1	11	10
Percentage	7%	20%	3%	37%	33%

Table2: Evaluation of CommEasy from students' perspective (2).

Question	The system provides a convenient way to pose questions for instructors during the lecture.				
Response	SD	D	N	A	SA
Frequency	1	3	0	15	11
Percentage	3%	10%	0%	50%	37%

Table3: Evaluation of CommEasy from students' perspective (3).

Question	The system provides a convenient way to answer the instructor's questions during the lecture.				
Response	SD	D	N	A	SA
Frequency	3	2	2	18	5
Percentage	10%	6%	7%	60%	16%

In terms of the role of the system in solving the barriers that students were faced in communication and participation in the classroom, 67% of the students confirmed that they no longer felt embarrassed with regard to communicating with the male instructor when using the CommEasy system, 73% confirmed that they were able to participate easily even if they were seated far from the microphones, and 87% confirmed that they could participate easily in the crowded classroom using the CommEasy system. However, 53% mentioned that they felt more engaged and interested in the learning environment as a result of using CommEasy, compared with 20% who were neutral and 27% who disagreed with this.

In terms of the impact of the system in terms of increasing and enhancing students' participation in the classroom, 83% confirmed that they participated more when using the CommEasy system in the classroom.

With regard to evaluating the system according to the given metrics, the results show that more than 75% confirmed that the system was easy to download, easy to run, easy to use, the GUI was user-friendly, and the Help feature of the system was informative.

In terms of the aspects that students like/dislike regarding the system, the anonymity provided by the system in posing questions to the instructor and in answering the instructor's questions was the aspects most commonly mentioned by the students. Aspects of the system such as it being reliable, easy to download quickly, and easy to use, were also liked by students. Students did not report any aspect that they disliked with regard to the system.

In terms of further comments provided by the students, they mentioned that they would prefer to improve the system in order to support additional mobile platforms such as Android.

In terms of the instructor questionnaire, the instructor agreed that the system provided him with a convenient way to communicate with female students, to receive questions from students, to answer the students' questions, to evaluate students' learning, and that the system helped to promote students' participation in the classroom.

The instructor also agreed that the system was easy to download, easy to run, easy to use, that the GUI is user-friendly, and that the help feature of the system was informative.

The instructor commented that he found the system to be an excellent endeavour to promote communication and interaction in the distance-learning classroom and appreciated the value of the system in terms of increasing the level of female student participation compared with traditional lectures where the system was not used. He also strongly welcomed using mobile applications in higher education as the majority of university students in Saudi Arabia owned such devices and they had become a part of their everyday lives. However, he mentioned that it would be better if the application could be improved to support additional platforms such as Android.

VI. DISUSSION

From the results presented above, one can conclude that both the female students and their male instructor had a very positive attitude toward the role of the CommEasy system in enhancing communication and participation in the distance-learning classroom. The system encouraged students to be more active in the classroom and to participate and interact with their instructor, as observed in the classroom and as they reported. All students who used CommEasy were enthusiastic about continuing to use the system and reported that it is the best way to participate in the distance-learning classroom as it is very convenient and easy to use. The majority of students (70% or more), as presented in the results, confirmed that CommEasy provide them with a convenient way to communicate with their male instructor and ask questions as well as receive answers. The male instructor also confirmed the importance of the system in supporting interaction in the classroom. He reported that the level of student participation increased when CommEasy was added to the classroom and that the female students became better engaged in the learning environment. Furthermore, the system allowed him to evaluate students' learning through post them quizzes. Therefore, CommEasy proved its value in enhancing students' participation in the classroom, which, as stated previously, is a very importance part of the learning process and has numerous advantages, including leading to better learning and better marks and enhancing students' motivation to learn.

However, as presented in the results (Table 1), a minority of students (27%) did not perceive CommEasy as a convenient way to communicate with male instructors in the classroom. The comments those students provided suggest that this could be due to some psychological reasons. In Saudi Arabia, female students are not used to engaging with male instructors, having spent more than 18 years studying in completely segregated learning environments. Thus, those students mentioned that they preferred not to participate with male instructors, with or without CommEasy. They expressed that they preferred face-to-face classrooms with female instructors instead.

The students and their instructor also demonstrated a very positive attitude toward the role of CommEasy in overcoming the barriers they were facing in distance-learning classrooms. Female students appreciated the value of CommEasy in reducing and removing the barriers they faced in these classrooms. The system allowed female students to participate and interact easily with their instructors without a need to leave their seats, use the microphones or speak to the instructors. As previously mentioned, such elements were pressures or barriers for female students in Saudi Arabia, and CommEasy has effectively solved all these problems. Hesitation to speak to the instructor, hesitation to ask questions and crowding in the classroom are major concerns for educators not only in Saudi Arabia but also worldwide. CommEasy has proven to offer a valuable solution that can help to abolish such barriers and provide students worldwide with a convenient and easy way to pose questions to their instructors, as well as to respond to instructors' questions.

CommEasy includes many features that make it an excellent endeavour that can be used to enhance communication and participation in both traditional settings as well as distance-learning settings. The system guarantees students complete anonymity. This is considered by many educators to be a major feature that encourages students to participate and interact in the classroom. The system allows both students and instructors to use their own smart handheld devices, and this reduces costs compared with other technologies such as clickers. The system proves that is easy to download, run, use, with an effective graphical user interface and effective help and support as reported by the students and instructor considered in this paper.

Therefore, CommEasy supports the current trend and pedagogies that assert that using mobile applications in education can promote student communication and participation in the classroom.

VII. CONCLUSION

This paper presented the perceptions of instructors and students with regard to the role of the CommEasy system in enhancing communication and participation in the classroom and in removing the barriers that students face in this regard. The perceptions of instructors and students have been

identified through the use of two questionnaires: each included a list of items, and the participants were asked to express their level of agreement using a five-point scale (Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree). According to the results of the questionnaires, both students and instructors show a very positive attitude towards the role of the CommEasy system in support of communication and interaction, and in solving the barriers that student faced in this regard. However, support for additional platforms such as Android will be provided in following versions of the system.

APPENDIX A

The perceptions of female students towards the CommEasy system

With regards to the CommEasy system that you have used in the participations with the male instructor during the last two weeks, please respond to ALL of the following items by choosing the response that best matches your opinion (Strongly Agree, Agree, Neutral, Disagree, Strongly Disagree).

- The system provides a convenient way to communicate with male instructors in the distance-learning classroom.
- The system provides a convenient way to pose questions for instructors during the lecture.
- The system provides a convenient way to answer the instructor's questions during the lecture.
- I no longer feel embarrassed to communicate with the male instructor with the CommEasy system.
- I feel more engaged and interested in the learning environment with using CommEasy.
- I participate more with using the CommEasy.
- CommEasy makes communication with male instructors after lecture easy.
- I can participate easily in the crowded classroom using CommEasy system.
- I can participate easily even if I sit far from microphones.
- The system is easy to download (application loads quickly and does not crash).
- The system is easy to run (account can be created easily and quickly).
- The system is easy to use (you can launch and navigate within the app easily).

- The GUI is user-friendly (allowing you to interact with the application in a natural and intuitive way).
- The Help of the system is informative (the system's help page provides useful information).
- What aspect(s) of the CommEasy system did you like/dislike?
- Do you have any suggestions or comments to improve the system?

The perceptions of the male instructors towards the CommEasy system

- The system provides a convenient way to communicate with female students.
- The system provides a convenient way to receive questions from students.
- The system provides a convenient way to answer the students' questions.
- The system helps instructors to evaluate students' learning.
- The system promotes students participation in the classroom.
- The system is easy to download (application loads quickly and does not crash).
- The system is easy to run (account can be created easily and quickly).
- The system is easy to use (you can launch and navigate within the app easily).
- The system is user friendly (the GUI is functional and visually stimulating).
- The Help of the system is informative (the system's help page provides useful information).
- What particular aspect(s) of the CommEasy system did you like/dislike?
- Do you have any suggestions or comments to improve the system?

Online Game-based Programming Learning for High School Students – a Case Study

Abstract—[Context] The inclusion of programming concepts in high school education has been emerging, since applying computing in high school education is a way to motivate and prepare students into the field of technology. [Objective] This work evaluates the teaching programming games for high school students based on different forms of distance education (online video lessons, broadcasted live or recorded, and tutorials in PDF). [Method] A case study was performed in the second half of 2014 with 30 high school students enrolled in an online game programming challenge. The students had access to the different formats of online lessons and they were monitored by tutors in a online learning environment. [Results] Over 75% of the students performed and sent all the activities requested in the study, suggesting that all investigated online formats are effective. However, 85% of students indicated their preference to use recorded video classes to learn programming. Finally, 100% of the students said that they would participate again in such challenge, showing the attractiveness of the game development. [Conclusions] We considered that online formats (specially recorded video) can be used to promote the development of games to introduce programming knowledge in high school education. However, the lessons learned (difficults found and improvement suggestions) should be taken in consideration to implement online solutions in large scale.

Keywords—Game; Programming; Learning.

I. INTRODUCTION

The advance of the information technology industry is demanding more computer professionals than they are provided by the graduation courses. In fact, the search for undergraduate courses related to computing is decreasing, as well as the proportion of students who graduate in these courses [1].

To attract more students to the computing area, a lot of initiatives are teaching programming concepts to students still in K-12 education. Some of these initiatives use games to make the process more playful. Despite the easiness offered by these learning platforms, its uses often require minimal knowledge of programming by the high school teachers, making the scalability of these proposals more difficult. The use of online teaching-learning solutions, on the other hand, might not be so efficient for students who are too young.

In this context, this paper evaluates the online teaching programming, based on video lessons (broadcasted live or recorded) and tutorials (PDF text), that teach high school students how to program games. The videos and additional didactic materials utilized were created in a way that allowed the student himself to perform the proposed activities in their schools or even at home. Each lesson focuses on the development of a game, starting with the game design and going through to its implementation, organized in a sequence of steps followed by students.

Thus, to evaluate this online learning proposal, a case study was performed in the second half of 2014 with 30 students enrolled in high school education. This study aimed to evaluate the implementation of tutorials and video lessons, in order to characterize the effects of this approach on these students, regarding the teaching of introductory programming concepts – variables, data types, selection/decision structures, etc. – using the context of games. Another purpose was to capture useful information to allow the creation of new methods of online teaching-learning programming.

Promising results indicate the viability of online learning of game programming in high school education, their effectiveness and ability to scale, satisfying a considerable number of students (75% of study participants) at reduced costs. In this perspective, we hope that this paper inspires new initiatives in the online programming education, especially based on video lessons. The rest of this article is organized into six more sections. Section II presents a background of related studies. Section III describes the execution of the study. After that, in Section IV, the methodology used; In Section V, the overall results; a discussion in Section VI, and finally, in Section VII, the conclusions and perspective of future work.

II. BACKGROUND

A. Teaching programming in high school

Although computing is present in all sectors of society, there is a lack of knowledge and interest of the population in this area. One of the reasons is the lack of teaching programming in high school.

Studies involving teaching programming with K-12 students, both in distance education and on-site presence, with the gaming theme, have been reported by other researchers [1][2][18][19]. In addition to contributing to the development of problem-solving skills and logical thinking of students, these works eventually disclose the computing area as a possible professional career. The introduction of programming concepts, as a science, in the high school, is of fundamental importance and relevance [3], both to spread this concept in schools, and to possibly attract new talent to the area.

In this context, there are many factors that point to the importance of the insertion of programming education in schools. In [4], two factors are highlighted. The first is that the programming education enables the development of capabilities that contribute to improve the logical thinking of students, and the second is that such proximity can help setting the vision and attitudes of students regarding the use of technologies that they usually handle. On the second factor, Resnick (creator of Scratch software [5]), presents his point of view about the term "Digital Natives" [17]. For him, there is a mistaken view about the ability of digital natives regarding the use of technology. According to Resnick, young people spend most of the time consuming technology, but that does not make them fluent in it. In his perception, they end up developing the ability to be good consumers of information, but they are not able to realize the potential of producing technology.

In this perspective, some countries have implemented a programming curriculum in their schools [3]. Estonia has implemented a program for teaching programming to students from seven years and up [6], Israel has also implemented a coherent computing curriculum for their schools [7] [8]. The United States have been keen to build those skills early on, from the very first levels of education. According to [9], this is because the governments of these countries understand that this will generate impacts on their economies and on the ability that their citizens will have to adapt to changes. Other countries have also placing these concepts in their curricula, such as UK [20] and New Zealand [21].

However, in most countries the learning of programming concepts in general is still reserved for those who choose graduation courses in the area or related courses. In general, the main goal of this study is to investigate the introduction of programming concepts to students in high school through game programming, since these are part of the reality of many students, motivating and working on them the vocational awakening and development of computational thinking.

B. Online learning

New innovative practices in education include the use of video classes. The goal of using video classes is to enrich the process of teaching and learning.

Video lectures for content related to programming learning are easily found. Many teachers have created materials to support student learning and posted on the

Internet, for example, through YouTube or Khan Academy¹. Studies have also highlighted the efficiency of video lectures in the programming learning process [14] [15]. The main differences of video lectures with other teaching methods are the following [16]: (i) Instructive, encourage students to think independently; (ii) Practical emphasis, emphasizing the application capacity; (iii); (iv) Teachers guide students to participate, in the importance of communication; (v) Emphasis on teamwork, developing the collaboration sense of students.

Being an audio/visual feature, a video lecture plays a didactic function, where the transmitted information can be heard and viewed, facilitating the understanding of them, thus contributing to spread the use of video lectures as a way to insert the programming concepts in high school .

III. STUDY CONTEXT

This study was conducted in the context of an online training challenge and competition of gaming programming. This initiative aimed to: (i) encourage creativity and skills related to the design and development of digital games; (ii) encourage the programming in high school ; (iii) work the vocational awakening and attract new talent to the computing area; (iv) train and develop students' skills in the development of digital games through the use of game tools (engines) such as Construct2; (v) promote an online learning environment in order to enable students into the development of digital games in the academic area; and (vi) engage students and teachers in activities that stimulate knowledge about computational thinking and use of digital games in high school .

This challenge was built and made available as an online learning environment (Moodle) with recorded classes, live online classes and tutorials that taught the programming of digital games through the Construct2², a visual programming environment for creating games, that is, no coding is required to create games. The students create games in Construct2 by manipulating graphical elements according to the programming logic to be used (events, conditions, actions, etc.).

Despite being an open challenge to any Brazilian student, its disclosure was more restricted to the state of Rio Grande do Norte. In this challenge, three online Moodle tutors were made available during the morning, afternoon and evening, while the initiative was running. The tutors were scholarship students of a research lab in games and educational platforms. They were students from computing undergraduate courses with knowledge in game development with Construct2.

Although we provided tutors for students, the interaction between them in the carrying out of activities by the students was in the form of "learning by developing," that is, there was no prior training of the students and it was not

¹ <https://www.khanacademy.org/computing/computer-programming>

² <https://www.scirra.com/construct2>

determined prior requirements for the participation of students, for example, having initial knowledge of programming logic or algorithms.

The challenge was divided into three steps: Dissemination, Training and Competition. The disclosure was carried out through social media (Facebook, Twitter and Google+) and visits to some schools in the city of Natal, Brazil.

The training step aimed to enable students into the game development with the Construct2 tool. At this stage, classes were recorded and online classes and tutorials were transmitted. The classes took place between the period from September 1st to 16th, 2014, every Monday, Wednesday and Friday. These classes were available on Moodle, where students could access the lessons and question the tutors. In each class, it was provided a different game that worked various concepts, such as variables, conditional structures and the introduction of the tool's features.

The competition step aimed to evaluate, select and award the best participants of this initiative. At this stage, the participants met in teams of two to five members and submitted one game for competition. Each team had to have a teacher as advisor, and all games developed in this step had to be educational games. At the end of the challenge, the best games were awarded.

IV. CASE STUDY PLANNING

This study aims to evaluate different forms of online teaching in game programming for students of high school, in particular, the recorded video lessons. For the case study design and report, we followed the guidelines proposed in [10] [11].

A. Research Questions

The Research Questions (RQ) addressed by this study are the following:

- **RQ1:** Is the way of teaching used in the study efficient?
- **RQ2:** What is the impact of the lessons transmitted online, recorded and tutorials on the students' views?
- **RQ3:** Is this kind of study attractive?
- **RQ4:** What is the scalability of the study?
- **RQ5:** What difficulties were shown by the students by participating in the study?
- **RQ6:** What difficulties were shown by the tutors for the conduction of the study?

B. Participants

The participants are students who participated in the game programming challenge. Although the challenge was open to students of any educational level, only the results of students enrolled in high school education were considered to answer the research questions of this study.

The challenge had more than a hundred of participants, but only 49 were from middle and high school (target audience of the study). From these 49 students, only 30 of them answered our online questionnaires (22 men and 8 women). The oldest student was 19 years old and the youngest was 14. The average age was 17 years old. Table 1 shows the number of participants by level of education. See that nine students were from technical high school.

TABLE I. AMOUNT OF STUDENTS PER EDUCATIONAL LEVEL.

Level of Education	Quantity
High School	21
Technical high school	9
Total	30

C. Study Object

The objects investigated in this case study were the classes used in the challenge. There were 17 classes in total, with 12 recorded video classes, 3 tutorials described in text and 2 live classes transmitted online. The high number of recorded video classes is due to restrictions by the rules of the challenge, which prioritized the use of recorded video classes. Each lesson was about a different game, displaying the game at first and then, the walkthrough for the implementation of it with Construct2. At the end, students should create extended versions of the game and submit them in the Moodle platform.

The games utilized in each class had approximately the same development complexity. They all exercised the basics of programming (variables, loops, conditional structures, etc.). To respect the rules of the challenge, the 12 recorded video classes were utilized first, 3 per week, on Mondays, Wednesdays and Fridays for 4 weeks. After that, the students had access to other 4 classes, 2 per week, a written tutorial on Wednesdays and a lecture broadcasted live on Saturdays. The choice of transmitting on a Saturday was made so a greater number of students could participate.

D. Analysis Unit

The analysis unit in this study was each student, of high school, that participated in the challenge. In each class, it was monitored if the student had accessed the lessons and sent their task, if he had performed interactions with tutors and participants, etc. They also had their opinions collected through web forms, applied by the end of the challenge.

E. Data Collection

In this case study, the following data were collected from participants: The executable file of the games; Dialogues of students enrolled in discussion groups and chat rooms; Answers to questionnaires applied to students and tutors; Notes on the behavior, questions and difficulties of students in carrying out activities.

The data were collected through forms available in Moodle, where students answered voluntarily.

V. RESULTS

In this section, it will be presented the study results according to the answers to the research questions.

A. [RQ1] - Is the way of teaching used in the study efficient?

One way to encourage students to improve their knowledge in a particular area is the development and engagement in knowledge competitions in specific areas, in our case, the teaching of programming. When entering the study, the participating students were engaged in the mission to prove their knowledge by carrying out the activities, in other words, the proposed challenges (development of games).

The way of teaching in the initiative was inserted to provide the student with a situation that arouse curiosity and love of learning and investigate; ability to solve problems, predict outcomes and choose solving strategies of a particular problem, and with that, we could note that the motivated students tend to be more persistent and show higher levels of performance.

To participate in the study, students had to carry out activities like, watch video classes and tutorials, and at the end of these activities, submit a game with a requested improvement. The whole process was accompanied by tutors. Therefore, in this study, 17 activities were made available, being 12 recorded video classes, 3 written tutorials and 2 lessons transmitted online.

Fig. 1: Percentage of submission of activities by the groups.

To answer the research question 1, we randomly divided the students into 10 groups of 3 students each, to analyze the rate of submission of activities. Figure 1 summarizes these results.

As can be seen in Figure 1, for the 17 activities, most groups have managed to send over 75% of the activities. Analyzing the data individually, 20 of the 30 participants were able to send all activities.

It became clear, then, that studies like this, in which the activities are carried out in a playful way, with the teaching programming linked to game development, may enhance the development of initial concepts of programming. Also, it brings this knowledge to the daily lives of students by showing them how to apply it to solve real problems and that

involving playful activities, using games, is a healthy way to insert teaching programming in schools.

Therefore, by looking at the results obtained, we believe that this teaching method is effective for teaching programming to students who are enrolled in basic level of education, finding that over 75% of the students performed and sent all the activities requested in the study.

B. [RQ2] - What is the impact of the lessons transmitted online, recorded and tutorials on the students' views?

To answer this question, an online form was made available to students with seven questions; six subjectives and one objective. In these questions, students presented the advantages and disadvantages of the three formats used in this case study and by the end, chose the most appropriate way for them. To administer the questionnaires, we adopted Google products, because they are stable tools and known to most students.

Regarding the recorded video classes, a particular student described the following advantage: *"The main advantage of the recorded lesson is to be able to pause and/or return to the video and follow the explanation at your pace, and that in the video we can see the teacher actually making the game work"*; another student added: *"to be able to watch at any time, if you cannot attend the scheduled time because of some unforeseen event"*. As a downside, a particular student presented *"the lack of interaction with the teacher"*.

However, regarding the video classes transmitted online, another student pointed the following advantage: *"watching a live class can be more of a privilege to some people, like you were actually in a classroom with the teacher"*. Another recurring point was the interaction between student and teacher. A downside of online classes was highlighted by a student: *"the impossibility of returning the classes immediately"*. Another point mentioned was that, since the classes had a specific schedule, there was the possibility that some students were not available at a given time.

Ultimately, another available method was the use of tutorials with a walkthrough of the developed games. This aspect was highlighted as essential by the students, because it presented written instructions of steps for the development of games. This method was highlighted as relevant by students in the programming learning process. One student highlighted the following benefit of this method: *"the tutorial format may be the easiest form of access to all and also a format that allows the student to do the proposed activities and to monitor the lessons at his own pace"*. As a downside: *"The reading of the tutorial makes this format a little more tiring and we lose a little more interaction with tutors"*.

The results of our case study showed a higher preference for the use of recorded video classes, 85% of students indicated that they prefer to use this method to learn programming. However, 10% prefer online classes and 5% prefer tutorials.

In this context, we believe that the study had a considerable impact on the participants about teaching and

learning of programming with the use of games. However, we did not have, in practice, the knowledge of what would these impacts be and how they would contribute to the learning of the students. After the study, the following results were observed:

- The students learned the initial concepts of game programming in a short period of time: programming is usually taught as a basic subject in the beginning of a college course. Thus, inserting this concept in high school , we are encouraging new talent to the computing area and working the vocational awakening of these students;
- The challenge was organized based on a constructivist approach to learning [12], in which each student learns at their own pace and steadily builds their own knowledge through the development of games. We believe, as many researchers [1] [13], that this kind of approach can attract new students to computing and also spread this knowledge in the basic level of education, by inserting this subject as a way of solving problems through programming.

C. [RQ3] – Is this kind of study attractive?

We observed in the study that 100% of the students who participated in this first study said that they would participate again in a second version. This analysis was performed using a questionnaire during the execution of the study. For these students, this way of teaching is attractive because it presents the programming concepts through an instrument that is of use and knowledge of them, the games. The volume of applications was large, 300 students signed up, but only 30 answered the questionnaire.

By applying the practices presented in this study, we could see a good feedback from the participants, and this was reflected in the results of the questionnaire that was used during the study, which its results are presented below.

Considering a general assessment of the quality of the study, 84% said it was excellent, while 16% of people thought that was good. It was also questioned, how often students would like to have programming classes of digital games in schools. This response is illustrated in the graph of Figure 2.

Fig. 2: Frequency of digital game programming classes in schools.

As seen in Figure 2, students of this level of education have interest in learning programming in the schools they attend weekly. This factor shows the need for more research that insert this content for students. These data justify the need for this study, to work computational thinking in schools and attract new talent to the computing area.

We believe that the teaching of algorithms related to the activities seen in class motivates students to learn, both the content of the discipline and programming, because they are working concepts involving school subjects content with the programming elements.

In another point, students were asked to evaluate the statements presented in Table 2, and answer between Strongly Agree (SA), Partly Agree (PA), Neutral (N), Partly Disagree (PD) and Strongly Disagree (SD).

TABLE II. EVALUATION OF AFFIRMATIVES.

Affirmatives	SA	PA	N	PD	SD
AF1: The study is meeting my expectations	27	3	0	0	0
AF2: The time of video classes are suitable	12	16	0	2	0
AF3: I managed to perform all activities.	20	10	0	0	0

Regarding affirmative AF1, the 3 students who agreed partially wanted the video classes to present more advanced features of the tool, and to provide more advanced content of programming. But the goal of the challenge was to insert basic programming concepts and that goal was achieved. In future studies, classes will be offered with more advanced content.

Regarding AF2, 2 students said that the duration of the video classes was not appropriate. The video classes had an average of 30 to 45 minutes and for some students this time was excessive. At this point, a questionnaire was given to students with the following question: How long do you think video classes should be? By seeing the answers, we realized that there is no homogeneity of the students regarding appropriate video classes duration. At this point, 8 students thought the ideal duration is 30 minutes, 6 considered that the adequate duration is 40 minutes and 5 reported that the duration should be 35 minutes. To another 5 students, the duration should be 45 minutes, but to other 3, 60 minutes is enough. Finally, 3 students thought 25 minutes is the ideal duration. In the future, we will elaborate classes of up to 15 minutes and resources for specific functions, for example, a lesson to resolve collisions problems, at most 4 minutes.

Regarding AF3, we found that most students were able to send, totally or partly, the activities. In this statement, we could identify two problems in which students were unable to send the activities in its entirety. The first is that the activities had a deadline to send and some participants waited to do the activities near the end of it and, consequently, there was no time. The second point was regarding the activities of the schools, which were on exam period, and some students could not do these activities on time. In such cases, it was given a second chance to students to send the activities.

At the end of the initiative, it was noted that the students had acquired knowledge regarding the common concepts present in most algorithms, such as variables, loops and

control, and that may help them learn a programming language. In this perspective, the intention is that the next edition we will include other technologies, such as HTML5.

These results demonstrate that this study is attractive to students of high school, and that could be analyzed through the performance of the activities, the interaction of students with tutors, either through chats, like the forums, and especially, by the fact that 100% of the students said they would participate in future studies involving programming and games.

D. [QP4] – What is the scalability of the study?

To answer this research question, we used the questions reported in the forums and chats exchanged between students themselves, and between students and tutors. The scalability question is related to how many students we were able to meet in different locations and affordably, and this is related to the volume of generated questions.

The scalability of the proposal was considered high after analyzing the total number of access to forums and chats through logs in Moodle, and also the fact that we should be able to meet students located in different physical locations. The number of students involved is considered great, since these students participated voluntarily and had no initial incentive to participate in the study, like for example, saying that the students who participated in the study would gain a higher score in a given discipline.

To increase the scalability of the proposal, it was decided to perform synchronous and asynchronous activities. We defined that the activities should take place three times a week, regardless of the time that each student was willing to use them, and we considered this part as an asynchronous activity. But to avoid the difference in the learning pace and so we could track the progress of students in the study, we set a deadline for the delivery of activities and online service hours (performed by tutors), and this step was defined as a synchronous activity.

With the results of the study, we considered that the proposal is scalable and can be implemented for teaching programming in primary schools without having to significantly increase the number of tutors, as many of the questions were common and answered in the forums, including by the participants themselves in some cases.

E. [QP5] – What difficulties were shown by the students by participating in the study?

To answer this research question, we used feedback from students in the questionnaire that was applied after the case study. We will deal with the difficulties of students considering their own opinions. We also presented suggestions for improvement, according to reports of the students.

Difficulties related to classes and functions of construct2

The difficulties reported by students were regarding the amount of lessons per week. Since the study was performed within one month, it was made available 3 per week, and

some students thought that was too much because they also had other activities related to schools in which they studied.

Another difficulty was noted regarding the use of specific events in Construct2. As can be observed, the following two questions were in a discussion between a student and a tutor:

Student A: *I can only make the first enemy shoot and the enemy's frame does not change.*

Tutor A: *if the frame does not change in the event 'Every 2 seconds', add an action to the enemy and then 'Stop', he'll stop in the first one you choose.*

Student B: *when an object collides with another, how do I get a different reaction if they collide again? Example: the ball object collides with a block, adding 1 point to the score, but when it collides again, it adds another point to the score. What can I do to make sure that the score does not change at every collision with the same object or anything that's in the collision event?*

Tutor B: *Create a variable, assign 0 to it and make the score, if the variable has value 0. If the ball hits the object, increase the score and the variable changes its value, so it no longer counts the point if the ball hits again.*

As seen in the examples, whenever the students had a doubt about the functionality of the tool or difficulties in the development of the game, tutors answered these questions with possible implementable solutions. It was not given a direct solution, the tutor always helped the student to think by himself to find a solution to the problem, working only as a facilitator in this process.

Suggestions for improvement

The students reported the following suggestions for improvement: Extend the time for delivering the activities; Provide one class per week; Fictitious awards to encourage students, for example, using gaming resources.

F. [QP6] – What difficulties were shown by the tutors for the conduction of the study?

To answer this research question, we used the results from the questionnaire answered by the tutors, which was applied after the case study. The three tutors who participated in the study completed the questionnaire.

In this study, tutors had the responsibility to encourage and answer questions from students when they were in doubt and guide them in solutions of the games, since the course was not compulsory and students participated voluntarily.

Therefore, we presented the answers obtained in this questionnaire in a summary form and arranged in the form of threads, as shown below.

Observed difficulties in students

According to the tutors, the main difficulties encountered were:

- **Contact by chat:** at the beginning of the activities, students did not have the initiative of questioning tutors when in doubt. Because of that, tutors

initiated the interactions encouraging students to question;

- **Time to carry out the activities:** students also questioned about the time given for submission of activities. Since there were 3 lessons per week, they found that it were too many classes in a short period of time.

Suitability of the material provided to students

The tutors consider that the material provided to the students is suited. The suggestion for improvement is to have specific classes for certain functions in Construct2, for example, how to use the behavior platforms, using the Physics behavior, and so forth. This brings benefits, because the student learns more about the tool and the classes would have a shorter duration. These specific classes would help students to solve certain problems during development. For example, if a student is in doubt about how to make a particular character jump, he will attend the particular lesson on this functionality. These specific classes are now being developed for the next editions of the studies.

Encountered difficulties by tutors in conducting the study

When starting the activities, tutors felt difficulty in engaging students in discussion forums and chats about the activities that would have to be sent, as well as guide them to think about the development of activities applied for each class. To keep students active, tutors used the following strategies: Keep students motivated to develop their own solutions to the requested activities; Monitor the activities of the students; Avoid piling up questions.

Suggestions for improvement

Tutors pointed as suggestions for improvement to reduce the number of lessons per week and develop lessons for specific functions of the game.

VI. DISCUSSIONS

Given the difficulties of the study, we sought to establish a close relationship between tutors and students. In the challenge, all the tutors were responsible for all students. Each tutor had three fixed online schedules every week to serve the students and it was the students' responsibility to choose the most appropriate time to get in touch with the tutor. A disadvantage of this point is the lack of proximity between tutor and student, but the upside is in the aspect of scalability because it was possible to help a higher number of students with the amount of available tutors and also in the flexibility of the study for students, for there were always tutors available at the specified times to clarify any doubts.

In addition to using the specified schedules of tutorials, students also used the forums for discussions about usual questions. In the analysis of the forums, a question was answered by an average of 30 minutes. An important point in this regard was the fact that the students themselves were helping solve the problems, maintaining a cooperative learning environment.

Regarding the programming classes (video lectures both recorded and online, and tutorials) it became clear in the evaluation of students that these features facilitate the construction of programming learning. The study identified that the integrated use of video resources, with the use of games in the learning process of basic concepts of programming, attracts attention and the interest of students for this discipline, even if they do not have an initial knowledge of programming, and they also have their participation stimulated in the process, providing an interactive and dynamic programming learning environment.

It should be noted that the objective of the study is not to make the students experts in programming, but to present this science so it can be used cooperatively in the learning process and in solving school activities.

A. Validity Assessment

For the conducted case study, it were evaluated threats to three types of validity: external, internal and construction.

- **External validity:** The results of the study refer to the creation of mini-games (within 2 hours/work) and the use of the Construct2 tool. To evaluate other scenarios, further research is required;
- **Internal validity:** The questionnaires revealed that 30% of students had some previous experience with initial programming concepts. In addition, activities were carried out at distance, without the supervision of the staff. Despite these facts may have influenced the outcome of the study, we did not detect any sign of such influence;
- **Construction validity:** capturing the data of the implementation of this case study was carried out through the application of impersonal questionnaires (without identification of the students). The interpretation of data was conducted by a researcher who avoided errors and tendentious interpretations in the study.

VII. CONCLUDING REMARKS

This case study described the results of the insertion of programming concepts in elementary school with the use of games. The students were very receptive to the proposed activities, comprehending the concept of programming, realizing its application in solving problems and contextualizing them in their daily activities.

These results provide new ways of looking at contents that are able to involve students more efficiently, so the application of these new techniques, such as, the programming education through games, is providing a new way to enrich the teaching-learning process and thus should contribute, in a playful and accessible education form. On the issue of applicability of the study, we can highlight two characteristics: feasibility and benefits for students.

The feasibility is related to how easy working with Construct2 is, which is focused on the development of games. To use this tool the student does not need to have

programming knowledge for the development of games. The feasibility characteristic is also related to the aspects involving the development of the game, like images and scenarios to be used in the game.

The feasibility is related to how easy working with Construct2 is, which is focused on the development of games. To use this tool the student does not need to have programming knowledge for the development of games. The feasibility characteristic is also related to the aspects involving the development of the game, like images and scenarios to be used in the game.

Regarding the benefits for students, we can highlight: vocation awakening; attract students to the field of computing; work cognitive and social skills that can be explored through games. For example, in the cognitive ability, we can highlight the ability to solve problems, plan, make decisions and think creatively. In social skills, they learn how to work in teams and deal with rules.

With this initial study, it became clear that we still have much to do to innovate teaching and learning of students who are attending the basic level of education, about programming. The implementation of studies that can encourage them to participate more effectively, in studies involving the teaching of programming to students who are not in colleges or universities in the area, may contribute to the formation of new professionals in this area.

Therefore, we conclude that this study, that works with programming concepts, which is housed in what theorists call the computational thinking, in high school, means fostering interest in the computer science area, showing its versatility and relevance in solving problems and demystify common knowledge that computing is a difficult and complicated area. Of course, not all students who participate in studies like this and who are enrolled in high school will graduate in the computing area, but this educational strategy can create and intensify relations with other areas.

In this case, considering the initial results already achieved, and thinking of perpetuate and improve them, there is a proposal to develop a methodology in which students participating in this study, will perpetuate this knowledge in schools.

ACKNOWLEDGMENT

The authors would like to thank the Coordination for the Improvement of Higher Education Personnel (CAPES) and National Counsel of Technological and Scientific Development (CNPq) for partial support to this research. Also, we thank the National Institute of Software Engineering (INES) funded by CNPq, grant 573964/2008-4, the PROEXT - MEC / SESu, and the Graduate Program in Computer Systems - PPGSC / UFRN, for offering all the infrastructure.

Abstract— Linked lists play an important role in learning basic Computer Science (CS) concepts among a number of different data structures. They are the basis for more complex data structures such as tree data structures. Recursion, stacks and queues can be effectively implemented using linked lists. We observe over the years that our students struggle with linked lists more than some other data structures. While students understand the concepts of stack and queue data structures faster, they need more time to understand and visualize the linked list and its operation algorithms. This paper presents a game-like instructional module called *Space Traveler* that aims to assist students to better understand and master the concepts of linked lists. Four CS undergraduate students developed it using GameMaker Studio in three months. The *Space Traveler* game looks like a classic snake game. The game supports practicing the linked list operations such as insertion, search and deletion. This paper presents the game design and implementation in detail and shares our experiences using this module in the CSC2331 Data Structure class at Winston-Salem State University (WSSU) in 2014. This module has been refined based on the feedback from students and instructors. The refined version will be used again in the upcoming semesters. A pretest, a posttest and a survey were developed and used in the evaluation process. In addition, a lab assignment was designed to accompany the game module. Initial assessment outcomes showed very promising student improvements as a result of the use of this game module in the classroom. The module has been made available online to benefit students at other institutions.

Keywords—Computer Programming; Linked List; Game-Based Learning; Data Structures; Motivation

I. INTRODUCTION

A linked list is a non-contiguous data structure composed of nodes. Each node contains a data compartment and one or more link compartments. Links are references to the successor nodes and optionally to predecessor nodes as needed. The linked list nodes are not stored in contiguous memory locations as opposed to array-based structures. Linked list is a dynamic data structure, which expands and shrinks at runtime during every insert and delete operations. Thus, linked list has the capability to utilize the entire fragmented memory unlike array-based structures.

In static array-based structures, insertions and removals may require moving and relocating the following array elements to keep the array organized. On the other hand, insertions and deletions can be made without moving any elements in the linked lists. Only a few corresponding links are altered in case of insertions and deletions.

Linked lists play an important role in learning basic CS concepts among a number of different data structures. They are the basis for more complex data structures such as tree data structures. Recursion, stacks and queues can be effectively implemented using linked lists. We observe over the years that students struggle with linked lists more than some other data structures. While students understand the concepts of stack and queue data structures faster, they need more time to understand and visualize the linked list and its operation algorithms.

Linked list data structure incorporates new concepts and challenges for students such as pointer manipulations or reference operations and list traversals besides other concepts of linked lists. The linked list operation algorithms should satisfy several conditions in order to be correct. We can list the followings among those conditions:

- The head pointer or reference which points at the beginning of the list should not be lost or should always be kept pointing at the first node in the list.
- No node in the list should be made unreachable
- Lists should be free of cycles unless it is a circular list
- The list should be kept in linear structure; it should not be broken or split.

Several researchers in Computer Science Education have addressed the challenges with learning the linked lists concepts for CS students. Fossati et al. proposed an intelligent tutoring system, which is called iList, to assist students with understanding and visualizing the concepts of linked lists [1]. Bloch identified recursion and linked list among difficult data structures concepts for students and proposed a teaching approach without using conditionals and null [2]. Goldwasser proposed a software to assist students in visualizing the linked list and understanding its memory model [3].

This study is funded by a grant from the National Science Foundation (NSF HRD-1137548).

Research studies show that learning difficult programming concepts in the gaming context will create high levels of enthusiasm and excitement about programming which will ultimately help students improve their performance [4]. A model of instructional games and learning that highlights the process of engagement was presented in [5]. Many educational games have been successfully used in helping students learn difficult programming concepts [6-11]. Most of our students who major in CS are minority students. Some of these students are underprepared and it usually presents a challenge for the instructor to engage these students in understanding and using data structure concepts. Many years of our own teaching experiences show that linked list operation is one of those topics that our students struggle with most. The authors have successfully developed and used several game modules in teaching [12-15].

To help our students master the concept of Linked List in the Data Structures' course, we developed the *Space Traveler* game. This game module aims to provide the students with a fun environment to visualize and master the important Linked List operations. The module supports practicing inserting a node at the front of the linked list, inserting a node at a specific location in the linked list and deleting a node from an arbitrary location in the linked list.

To evaluate the potential impact of this game module on student learning, a pretest and a posttest were developed and used in the evaluation process. A lab assignment was designed to use with the module. To collect feedback from students, a survey was conducted after the gaming session. Initial assessment outcomes show promising results and the feedback from students is very positive according to the survey. The module has been made available on the project website to benefit students at other institutions. We believe that this game module will help instructors to engage students in understanding and learning the concept of Linked List presented in class by making the learning process a fun activity.

The rest of this paper is organized as follows: Section II describes the design and implementation of the game module in detail. Section III reports our experiences using the game module in the classroom and presents the assessment results. Section IV presents our conclusions and future work.

II. GAME MODULE DESIGN AND IMPLEMENTATION

A. Game Overview

The *Space Traveler* game was developed in GameMaker Studio, a game development environment that allows developers to create games faster through drag-and-drop features and GML scripting language. Four undergraduate students (three programmers and one artist) developed the game from scratch in about three months. The gameplay time is about fifteen to twenty minutes and it does not require any prior experience in gaming. The tutorial part of the game provides step-by-step guidance.

The *Space Traveler* game looks like a classic snake game, which was used to come with some cell phones. The objective of the game is to keep a space ship alive in the space against its enemies. The space ship grows in length when it collects orbs. The ship is damaged when it is hit by enemies. The player can protect the space ship by purchasing some weapons such as a cannon or booster and adding the weapon after or before specific orbs of the space ship in a docking station. Similarly, the player needs to remove the damaged orbs of the space ship in the docking station to keep it alive longer.

The orbs of the space ship represent the nodes in a linked list. The game supports practicing the following linked list operation algorithms:

- Inserting a node at the front of the linked list
- Inserting a node at a specific location in the linked list
- Deleting a node from an arbitrary location in the linked list

Fig 1. Screenshot of the Space Traveler Game

B. Educational Component

The *Space Traveler* game not only assists students with understanding and visualizing the hard-to-understand concepts of linked lists, but also better motivates them to learn this difficult data structure concept and master its operation algorithms such as insertions or removals of nodes.

The game provides four levels of tutorials as shown in Fig. 2 to train students about the basic game controls, insertion at the front, insertion at a specific location, and deletion. Tutorials cannot be skipped. Upon finishing the tutorials, students are expected to play the game and perform at least three insertions at the front, three insertions at a specific location and three deletions, to be able to successfully complete the linked list lab session with game module. Students are allowed to access the tutorials during the actual game if they need further help. The missing parts of the code come with drop down menus, which list a couple of options including the correct expression to assist students in completing the code.

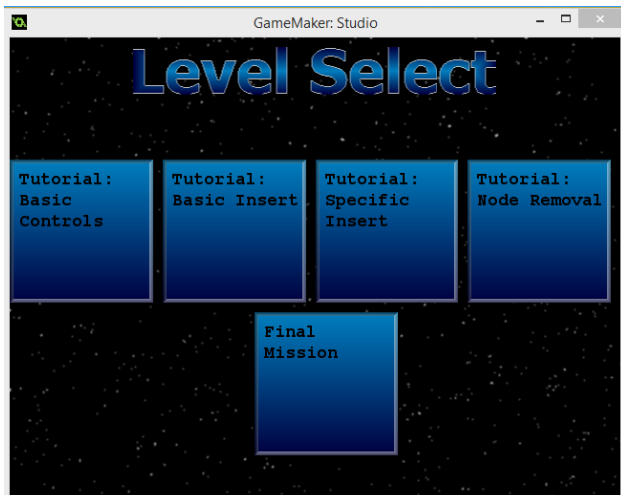

Fig 2. Game Level Select

The pseudo code segments in the game are primarily intended for the students who learn data structures in Java. Therefore, we assume using references rather than pointers. However, the game may still help understanding and visualizing the linked lists for those who learn data structures in a pointer-based language such as C++ even though the pointer operations are not elaborated in the game.

- Inserting a Node at the Front

Fig 3. Screenshot of the Docking Station When Inserting a Node at the Front

A player can add a weapon anywhere in the space ship such as at the front or after a specific orb somewhere in the middle. To be able to attach a weapon successfully at the front of the space ship, the player is expected to complete the missing parts of a pseudo code for inserting a node at the front of a linked list. The missing parts of the code come with drop down menus so students will select one from the menu to complete the statement instead of writing the statements. The player is required to perform this operation three times during

the final mission. The screenshot of the game in Fig. 3 illustrates an insertion at the front. The execution of the following statements by clicking the Run button will insert the Shield node at the front of the list.

```
Node s= new Shield();
s.next = head.next;
head.next = s;
```

- Inserting a Node at a Specific Location

The player is expected to complete the missing parts of a pseudo code for inserting a node at a specific location in the linked list to be able to attach a weapon successfully somewhere in the middle of the space ship. The player needs to perform this operation three times during the final mission. The weapon will be inserted at the specific location once the missing parts are completed and Run button is clicked. The statements are checked line by line. The player can edit the next statement only if the current statement is right. An immediate feedback will be given to explain the errors if there are any. The screenshot of the docking station in Fig. 4 illustrates an insertion at a specific location.

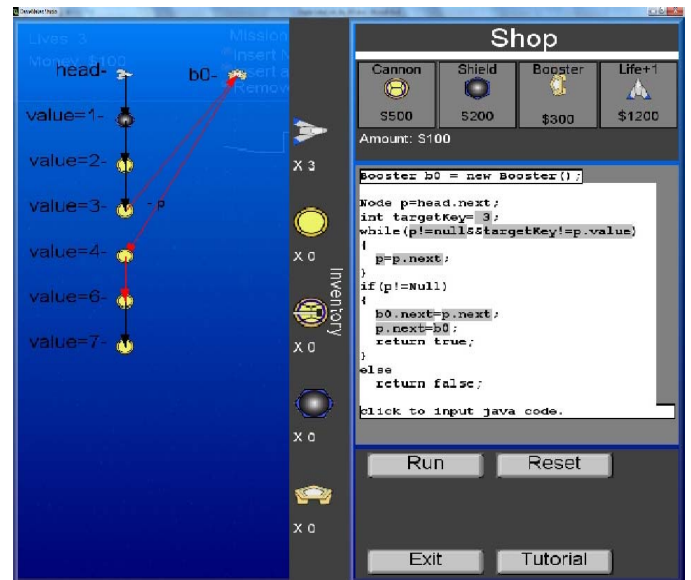

Fig. 4. Screenshot of the Docking Station When Inserting a Node at a Specific Location

- Deleting a Node

The player can remove any damaged orb of the space ship to keep it alive longer. While insertions only need one auxiliary reference/pointer variable, deletions require two auxiliary references/pointer variables, which traverse the list side by side. To be able to remove a damaged orb successfully from the space ship, the player is expected to complete the missing parts of a pseudo code for deleting a node from a linked list. The screenshot of the docking station in Fig. 5 illustrates a delete operation. Final mission requires the player to perform this operation three times as well.

Fig. 3. Screenshot of the Docking Station when Deleting a Node

III. RESULTS AND DISCUSSION

The *Space Traveler* game has been used in the CSC2331 Data Structures class at WSSU in 2014. In order to evaluate the impact of this game module on student learning, we have developed a pretest, a posttest and a lab assignment to use with this module. The module was built into a required lab assignment. Students took a pretest before they played the game during the lab session and took a posttest a few days after playing the game. A survey was conducted as well. The feedback was very positive and the assessment outcomes show promising results.

A. Pretest vs. Posttest

A pretest and posttest were created and used in the evaluation process. The pretest and posttest are very similar as shown in the following table. The pretest is shown in Table I. Each question is worth 10 points and the total possible points are 30 points.

TABLE I. PRETEST QUESTIONS

Questions	
#1	<p>The below code inserts a new node (a new Shield node) at the front of singly linked list. Fill in the missing parts.</p> <pre>Node s= new Shield(); _____ = head.next; head.next = _____</pre>
#2	<p>The below code inserts a new node (a new Shield node) in a singly linked list after the node #3. Fill in the missing parts.</p> <pre>Node s= new Shield(); Node p=head.next; int targetKey=3;</pre>

```
while (p!=null && tagetKey!=p.value){
    p=p.next;
}
if (p!=null){
    _____ = p.next;
    p.next = _____
    return true;
}
else
    return false;
```

The below code deletes the node #4 from a singly linked list. Fill in the missing parts.

```
Node q=head;
Node p=head.next;
int targetKey=4;
while (p!=null&&tagetKey!=p.value){
    q=q.next;
    p=_____;
```

#3

```

}
if (p!=null){
    q.next = _____
    return true;
}
else
    return false;
```

B. Lab

A lab assignment has been designed to use with the game module as shown in Table II. It requires students to play the game, perform the list operations in the lab sheet and answer the lab questions. Thus, students will play the game with a specific goal in mind and the game module will train them to understand the missing code needed to complete their lab assignment. In addition, students are asked to record the game score to ensure that they find the answers by playing the game.

TABLE II. SAMPLE LAB ASSIGNMENT

Task #1: Insert a Shield Node at the Front

```
Node s0= new Shield();
s0.next = _____;
head.next = _____;
```

Task #2: Insert a Shield Node at a Specific Location (e.g., after node #3)

```
Node s1= new Shield();
Node p=head.next;
int targetKey=3;
while (p!=null && tagetKey!=p.value){
    p=p.next;
}
if (p!=null){
    s1.next=_____;
```

```

    }
    else
        return false;
}

```

Task #3: Delete a Node (e.g., delete node #4)

```

Node q=head;
Node p=head.next;
int targetKey=4;
while (p!=null && targetKey!=p.value) {
    q=_____ ;
    p=p.next;
}
if (p!=null){
    q.next=_____ ;
    return true;
}
else
    return false;
}

```

Task #4: Game Score: _____

Fig. 6. CSC2331 Linked List Grade Distribution Pretest vs. Posttest

While Fig. 6 shows the grades distribution for this class, the comparison between the pretest and posttest for this class is given in Table III. These statistics show a very promising student improvement as a result of the usage of the linked list game module in the classroom.

TABLE III. STATISTICS OF PRETEST VS. POSTTEST

	Points Possible	Average	Median	Std. Dev.	Variance
Pretest	30	8.85	5.00	7.12	50.64
Posttest	30	24.62	30.00	8.28	68.59

C. Assessments

The *Space Traveler* game module has been used in CSC 2331 Data Structures course at WSSU in 2014. Understanding the concept of linked lists is among the objectives of this class. Students had the lectures on the linked list before this experiment. The test group was fairly small at thirteen but the results were very positive. Students took the pretest, played the game in one lab session and took the posttest a few days later. The pretest and posttest were very similar and the results of the pretest were not disclosed prior to the posttest. The class consisted of six male students and seven female students. Twelve of the students were African-American.

The results for the pretest were fairly dismal, only two students managed to achieve passing grades (60% or above). The passing rate for the pretest was 15.3%. Eight out of thirteen students were actually either unable to answer any of the questions correctly or only answer one correctly. The class average on the pretest was 8.85 points out of 30 points.

Student scores were improved significantly in the posttest. The passing rate for the posttest was 76.9%. The class average was 24.62 points out of 30 points on the posttest. The class average was improved by 178% from the pretest to the posttest. Eight out of thirteen students managed to get a perfect score on the posttest. While the percentage of A students in the pretest was 0%, it raised to 61.5% in the posttest.

D. Student Feedback

Overall student feedback was very positive. Fourteen students completed the survey online. The survey consisted of nine questions regarding their experiences with the game. The likert scale used on the questionnaire was Strongly Agree, Agree, Neutral, Disagree and Strongly Disagree. Table IV. shows the percentages of students who marked Strongly Agree/Agree for each question. Fig. 7 shows the response distribution for each question on the survey. We are glad to report that 93% of the students thought that they had a better understanding of linked list operations after playing the game. Some students made additional comments on the survey such as:

- “This game is awesome!”
- “Great Game!”
- “This game was fun...”
- “Very helpful to understand link list concept”
- “Great fun working with linked lists!”

TABLE IV. STUDENT FEEDBACK AND PERCENTAGE AGREE

Survey Questions	Percentage Agree
The game is enjoyable to play.	79%
I had a better understanding of how to insert a new node at the beginning of the list after playing the game.	86%
I had a better understanding of how to insert a node at a given position in a linked list after playing the game.	93%
I had a better understanding of how to search a node in a linked list after playing the game.	93%
I had a better understanding of how to remove a node from a linked list after playing the game.	93%
Visualizing the code execution in the game helped me understand the concepts.	79%
The game provided relevant feedback when a mistake was made.	79%
I would like to see more concepts covered by game modules such as this.	93%
This game module improved my motivation to learn programming.	79%

Fig. 7. Survey Response Distribution

IV. CONCLUSION AND FUTURE WORK

The *Space Traveler* game module was designed to help students understand the Linked List operations. A lab assignment was designed and used with the game module. Students have to play the game in order to complete the lab assignment. The module has been used once in Data Structures class. Assessment results based on the pretest and posttest comparison show that the module has a positive impact on student learning. The feedback from students also indicated that they better understood the linked list operations after playing the game. The module has been refined based on the feedback from the students and the advisory board. The refined version will be used in the upcoming semesters. The module has been made available for students at other institutions at <http://compsci.wssu.edu/tip>.

ACKNOWLEDGMENT

The authors thank Emanuel Smith, Casey Lewis, Christopher Benson and Alexis Alvarado-Beltran for their contributions to this paper.

Abstract— According to the U.S. Bureau of Labor Statistics [1], computer science professions are among the fastest growing occupations in the U.S., and computer science occupations will add more than half a million new jobs in the next ten years. Simultaneously, universities in the U.S. and worldwide are seeing poor retention rates in computer science, with a major reason being that students often view the early courses in the subject as uninteresting and dull [2]. We have developed a mobile game that provides an engaging way for students to practice the basic syntax of C, C++ and Java. Learning programming language syntax is a tedious process. Practicing by actually programming is, of course, ideal, but we believe that a game which is fun for students to play in their spare time will help them get used to distinguishing correct syntactical constructs quickly. The initial version of the game was evaluated by a small population of first-year computer science students at Norfolk State University. The results showed that students enjoyed the game, and that a modest improvement in the students' abilities to identify correct and incorrect syntax was achieved.

Keywords—computer science education; mobile computing

I. INTRODUCTION

According to the U.S. Bureau of Labor Statistics [1], computer science professions are among the fastest growing occupations in the U.S., and computer science occupations will add well over a half a million new jobs in the next ten years. Simultaneously, universities in the U.S. and worldwide are seeing poor retention rates in computer science, a major reason being that students often view the early courses in the subject as uninteresting and dull [2].

We have developed a mobile game that provides an engaging way for students to practice (not learn) the basic syntax of C, C++ and Java (since these languages share the same syntax for basic constructs like declarations, selection and iteration). The game gives the player a means to hone her ability to quickly distinguish between correct and incorrect syntax for C, C++ and Java (simply because these languages share the same basic syntactical structures for declarations, iteration and selection). Learning programming language syntax is a tedious process. Practicing by programming is, of course, ideal, but we believe that a game which is fun for students to play in their spare time will help them get used to distinguishing correct syntactical constructs quickly. The intended audience for the game is students taking their first

programming course, either in high school or college. The game should be introduced to students directly after they have covered the appropriate material in class; it is not meant to be a learning tool, but rather a practice tool.

II. BACKGROUND

The importance of computer science as a 21st century skill is becoming accepted by governments and academia, and computer science is being added to the core requirements for high school and university curricula around the world. However, there remains a problem attracting and keeping students interested in the subject. Although there is much more to computer science than just programming, eventually computer science students must study programming.

Some environments have been created to allow students to learn programming concepts without having to be concerned with complex programming language syntax, and they achieve this by generally preventing students from making syntax errors. Examples of these environments include MIT's Scratch [3, 4] and App Inventor [5, 6] and Microsoft's Kodu [7, 8]. In other environments, such as Alice [9, 10] and Greenfoot [11, 12], students do engage with a specific programming language's syntax (Java), but in a controlled and limited manner. These environments all allow students to build games (and many other interesting applications), and have had significant success in helping attract and retain computer science students of all ages. There are also games that attempt to teach programming concepts. In order to progress in the game, the player must program solutions to challenges. Such games include LightBot [13], Robocode [14], a new Doctor Who game [15], and numerous others. As with the programming environments mentioned earlier, some of these games expose the player to the issues of programming language syntax and others do not.

All these environments and games form an effective bridge for students who will eventually learn to program in a language such as C, C++, C# or Java. In our own work, we made significant improvements to the retention of computer science students by using Scratch in an introductory programming course [16]. However, our students still faced the inevitable frustration of learning a programming language's syntax when they reached a later course.

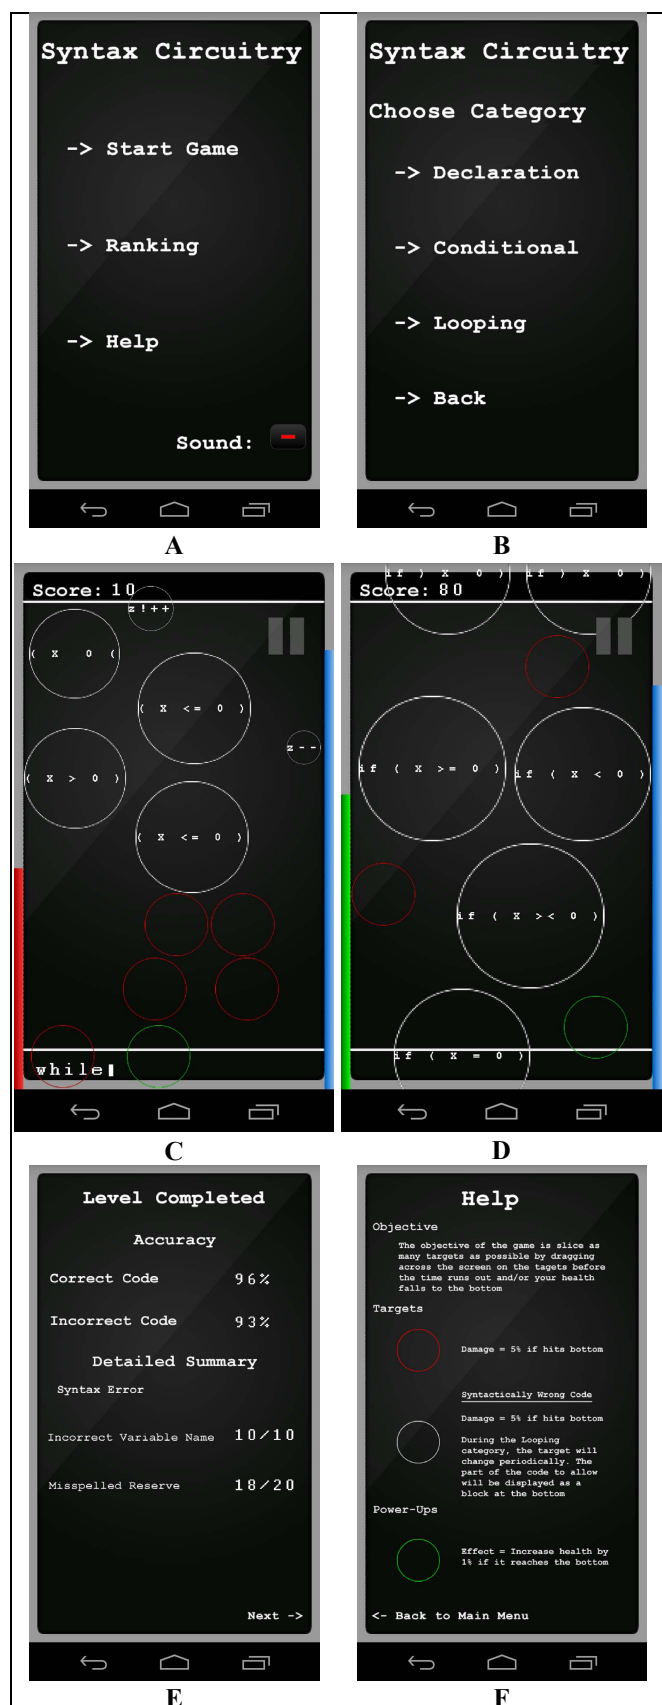

Fig. 1. Some of the game screens

Although modern IDEs do an excellent job of identifying and automatically correcting syntax errors, the necessity for the student to master the language's syntax still remains. Similarly, the autocorrect facility in word processing software does not teach people how to spell, nor does it make it unnecessary for people to learn spelling. Our game is in the same category as other games that aid in memorization, such as those for spelling and basic arithmetic rules. Its role is a practice tool for syntax rules, and it attempts to make the ability to distinguish between correct and incorrect syntax second nature to the player.

III. METHODOLOGY

The game, Syntax Circuitry, has been developed for the Android platform, and is targeted to mobile phones. Android was selected over iOS because of its free and more open development environment.

A. Game Design

The game is designed to look like an old-school arcade game, with highly pixelated fonts and very simple graphics. It has a complementary low-fidelity soundtrack. The color scheme is primarily white on black. The screenshots in Figure 1 show the game's main screens (A and B), some examples of the game play (C and D), and the results and help screens (E and F). The results screen (Figure 1-E) lets the player know how many and what types of errors were made. The game also includes a rankings screen for each category of play.

At the beginning of the game, the player must enter her name; this name is used to identify game results that are stored on a server. Currently, the server database is being used to retain detailed accuracy statistics for each player for the purpose of evaluating the game. The length of time played and statistics including those shown in Figure 1-E are recorded. The scores are also used to create high score rankings.

B. Game Play

The game-play is as follows: bubbles containing small snippets of code float down the screen. Those which contain incorrect syntax must be popped with a slicing motion, similar to that used in the well-known *Fruit Ninja* game, while bubbles with correct syntax must be allowed to reach the bottom of the screen intact. There are also plain red and green bubbles that add more challenge and interest to the game. The red bubbles (injury bubbles) subtract from the score if they make it to the bottom without being sliced, and the green bubbles (health bubbles) add to the score if they make it to the bottom of the screen unharmed.

The game has three categories of syntax (declaration, selection, and iteration), as shown in Figure 1-B. Selecting a category takes the player to a screen to choose a difficulty level, from 1 (easiest) to 3 (most difficult). Code and injury bubbles are created more frequently at the higher levels. The progressively faster play at each level requires that distinguishing correct from incorrect syntax becomes second nature to the student.

In the declaration category, various different errors that might be made in variable declarations are shown, for example: misspelled keywords, illegal variable names, and missing commas. The types of errors in the selection category are misplaced parentheses and incorrect relational operators. For iteration syntax, the context of the problem is shown at the bottom of the screen. The possibilities are the comparison clause of the “while” statement or the initialization, comparison, and increment sections of the “for” statement. Syntax errors in this category include misspelled and incorrect reserved words, incorrect operators, and misplaced parentheses or other symbols.

The game randomly creates correct and incorrect syntax bubbles with equal likelihood. It creates the code using preset examples of correct and misspelled reserved words. It combines these with templates for both syntactically correct statements and commonly made errors to form the numerous variants.

IV. EVALUATION

A. Experiment Design

The evaluation methodology used consisted of pre- and post-tests, the collection of usage and play data from within the game, and surveys about the usability and enjoyment factors of the game. Initially, the study participants were given a unique identifier, and they completed a simple self-assessment (beginner, intermediate, expert) about their familiarity with the three categories of syntax rules.

When the participants signed into the app, and selected a category to play in, they were prompted to take a pre-test on the category syntax. The game app provided the option to open the pre-test form on the server. After playing a certain amount of time in a category, the participants were prompted to take the appropriate post-test. The pre- and post-tests measured the students’ familiarity with the various syntactical constructs and rules that are presented in the game (see Table I). Finally, to measure retention of the information practiced, some of the study participants took a combined post-test again one week after playing the game.

TABLE I. SAMPLE PRE- AND POST-TEST QUESTIONS

Declaration	
Select the syntactically correct declarations:	
a.	int l;
b.	int h_k, title;
c.	char \$a;
d.	float your_name;
Selection	
Correct or Incorrect Syntax?	
	if (x != 0)
Iteration	
Correct or Incorrect Syntax?	
	for (i = 0, i < 10, i++)

At the end of the experiment, participants were given a survey about the game’s usefulness and usability. The participants were given five questions with a 5 point Likert

scale, one question with a numeric answer, and two open-ended questions.

TABLE II. SURVEY QUESTIONS

Q1	How user friendly is the game’s interface?
Q2	How successful is the game with helping you learn syntax rules?
Q3	How useful are the reference documents for the game?
Q4	How useful would this game be to you?
Q5	How likely are you to recommend the game to others?
Q6	How many times did the game freeze or crash?
Q7	What changes would most improve this game?
Q8	What was most difficult about this game?

B. Results

Thirteen people participated in the preliminary study, but not every participant completed the entire experiment. Nine participants were students in the first programming course (CS1) at Norfolk State University. Three participants were students in CS2, and one participant was not taking a programming course and had no programming experience.

The sample was too small to draw significant conclusions from the pre- and post-test data. Most students (those from CS1) participated in the study after having learned declaration and selection syntax, but before having studied loops. In the declaration and selection categories, there was a slight average increase in score (10% and 8%, respectively) from pre- to post-test. However, in the iteration category, there was an average decrease in score (11%) between the pre- and post-tests. Only four participants took the later composite post-test, and the results were inconclusive. Similarly, no correlation could be found between the game statistics (how long and how accurately the game was played) and the pre- and post-test results.

It was the survey that produced the most useful results. Twelve of the study participants took the survey. The results of the Likert-style questions are shown in Figure 2 below, where the question numbers map to the questions shown in Table II. Response 5 corresponds to the most positive response and 1 to the most negative. It is apparent that the general user response to the game was quite positive, and the players felt it was beneficial.

Fig. 2. Survey results

In response to the open-ended questions, the most common response had to do with the graphics. The game's GUI designer, a graduate student, deliberately chose the 80's old-school look-and-feel, and other members of our team (old enough to remember playing 80's games) also liked the retro theme. However, four of the survey respondents mentioned the graphics negatively, one asking explicitly for a "more modern user interface", and another wishing the graphics were more "aesthetically pleasing". Three students also specifically mentioned the difficulty of reading the code on a phone screen, and the screenshots bear out that complaint.

However, the fact that the participants rated the game positively in general, and that all survey respondents answered the first open-ended question with specific constructive criticism and suggestions, showed that they saw promise in the game and really liked the idea of it. Three participants asked for more: one, for more levels, and the other two, for new types of code structures.

V. CONCLUSION

We have developed a game to help students memorize the syntax rules for programming languages such as C and Java. The game is targeted at students in introductory programming courses who are beginning with or transitioning to a programming language such as Java. This is a time when many computer science students become frustrated or overwhelmed and some decide to leave the major. Unlike many games designed to help students learn programming concepts, the game is intended to be simply an engaging practice tool.

Our preliminary evaluation showed that students enjoyed the game and found it valuable; however, many students did not like its *retro* style user interface, and found that the font size and color made it difficult to read some of the code. The students achieved modest improvements in recalling syntax rules that they had already studied in their programming classes. However, the sample size was small, and, at the time of the evaluation, many students had not been introduced to one of the categories (iteration) that the game features.

Since the preliminary evaluation shows the idea has merit, we plan to update the game's user interface to a more modern, colorful look, make sure that the fonts are readable, and create a tablet version. For the next evaluation, we plan to use a

larger sample size and introduce a control group. We will also evaluate the game's effectiveness at the appropriate points in the course as the students learn the different categories of syntax.

New Britain, CT 06050, USA
cwilliams@ccsu.edu

Abstract—Educators and parents alike are seeking innovative ways to introduce young students to computer programming. The hope is to capture children’s attention and foster learning at the same time. The goal of this work was to not only introduce elementary students to the fundamentals of computer programming, but also help them explore more complex concepts in an engaging way. Studies have shown that factors that inspire children’s continued interest can sometimes vary by gender at this age; this work specifically addresses how to incorporate elements that will appeal to these potential differences in motivation. This study describes the design and implementation of a computer microworld game designed to introduce the core constructs and techniques of computer programming. By instructing a virtual robot to complete obstacle courses, students become familiar with core programming concepts such as: algorithms, repetition, conditional logic, debugging, functions, and optimization.

We conducted several interactive sessions with a group of elementary school students in order to evaluate the effectiveness of the game. Our results showed the game effectively familiarized students with both computer language constructs and the essentials of algorithmic thinking. Students were quickly able to learn core-programming concepts and apply these concepts to free form solutions.

Index Terms—Elementary education, Educational software, Computer programming

I. INTRODUCTION

Introducing technology to young students has become a critical objective of STEM education programs in today’s world. Although more students are introduced to computers at a young age, many do not receive the opportunity and encouragement necessary to pursue computer programming as they get older. This challenge in particular requires innovative approaches in order to capture children’s attention while encouraging learning at the same time. The goal of this work was not only to introduce elementary students to the fundamentals of computer programming, but also to help them explore more complex concepts in an engaging way. Studies have shown incorporating elements that appeal to different motivations can be necessary to capture children’s continued interest at this age.

To address these challenges, this work builds upon prior efforts to teach basic algorithmic skills and then aims to leverage students’ creativity and encourage exploration of more advanced concepts. This study describes the design and implementation of a computer game to meet these goals and introduce young students to the core constructs and techniques of computer programming. By instructing a virtual robot to

complete obstacle courses, students become familiar with core programming concepts such as: algorithms, automation, repetition, conditional logic, debugging, functions, and optimization. We conducted several interactive sessions with a group of elementary school students to gauge the effectiveness of the game at teaching these core concepts. In addition to surveying participants to understand their knowledge and motivations before and after playing the game, the team also collected analytical data during game play.

Our results showed the game effectively familiarized elementary students with both computer language constructs and the essentials of algorithmic thinking. Students were quickly able to learn the core programming concepts introduced by the game and apply these concepts to free form solutions. The results demonstrated both males and females enjoyed the game and developed an enthusiastic interest in further learning about computer programming.

II. PROJECT GOALS

The goal of this project was to develop an application that both introduced students to programming, and built upon the latest findings for ways to appeal to eight to ten year old students. A focus of this study was to incorporate ideas that have been shown to engage both boys and girls with potentially different interests and motivations, while also creating an effective learning environment. The objective was for the students to learn core-programming concepts such as automation, parameterization, loops, conditions, functions, and debugging through self-regulated learning while still having fun. We hoped to show that by appealing to different sources of motivation, such as story based advancement, problem solving, and score, we could encourage an understanding of these programming concepts that could be applied to more free form applications. A sub-goal of this study was for the children to understand that in programming there are sometimes multiple ways to approach a problem. We believe such a grasp reflects a deeper understanding of the underlying concepts.

To accomplish these goals, this study describes the design of a robot microworld game, Robot Training, to teach these concepts through structured problem solving. The game focuses on introducing children to the basic concepts needed to write a computer program while trying to help a robot, Robo, collect the parts he needs to get home. The game uses story-based challenges and visual context to motivate

students to understand the mechanics of programs in solving programming challenges and achieving the story goal. The game also provides support for children through the availability of debugging and persona based help functionality.

Based on the success of other research in elementary computer education, our belief was that a game format that incorporated multiple forms of incentives could help guide students in developing a deep understanding of the purpose of programming constructs. The hope was that once introduced to these concepts in this way, the children would be able to demonstrate that they could apply the concepts to more complex problems with less guidance as well as extend their understanding of the concepts outside of the game environment. Although this project specifically targeted younger audiences, this application could likely serve as an introductory lesson on programming to a wider range of students by adjusting the graphics to the target age group.

III. OVERVIEW

The basis of our approach of directed student self-relegated learning is driven by studies showing that children naturally learn through interacting on their own in challenges through creating and extending their thinking to their environment[1]. For example, with Legos, children are often not told the purpose of a specific section of a sequence of picture-based instructions when building. However, throughout the building process, children learn design and construction techniques, reinforced by their own intuition and creativity. Work by Resnick suggests that environments that encourage self-regulated learning can lead children to develop, test, and experiment with their ideas and ultimately help them refine their abilities[2]. As Papert noted, programming can be a very empowering and creative experience for children, which can help motivate engagement[3]. We believe this technique should also work well for children learning computer programming.

In exploring this type of application of learning programming concepts as applied to our target age group, we build upon the ideas of Michalakakis. Specifically, rather than describing a programming concept to children and then asking them to apply it, Michalakakis presented them with the structure and their exploration intrinsically built their understanding[4]. Michalakakis described a unique approach to teaching programming concepts to young children of five to seven years of age. Rather than attempting to describe the abstract inner workings of a computer system, Michalakakis placed the children directly in the role of a programmer. The children and their parents worked together to solve an obstacle course, often in a school gym or other locale. The parents took the role of “robots,” and the children worked to develop instructions for their parents to solve the obstacle course. Michalakakis started the children with a simple “programming language” which consisted of instructions such as “move right foot forward” or “pick up ball.” The child had to develop a set of instructions with which his or her “robot” can navigate the obstacle course, retrieve a ball, and return it to the child. After solving the initial puzzle, the children were encouraged to use their creativity to come

up with new instructions or categorize multiple instructions into higher-level concepts. For example, children might have grouped the “move right foot forward” and “move left foot forward” into a single instruction “take step.” Michalakakis also described how some children quickly discovered the concept of parametrized operations, such as “take 10 steps,” rather than repeating the same primitive instructions many times. Young students quickly displayed an understanding of the core concepts of computer programming through problem solving.

For our Robot Training game, we base the general flow of the game on this same idea. Rather than telling the students specifically what to do, the game sets the context: the child’s role is to help the robot, Robo, recover his lost parts so he can get home. Within this context, the student proceeds through solving puzzles in the form of obstacle courses to get the robot closer to getting home. In the early stages, students are incrementally given new tools necessary to solve the course. Concepts such as combining instructions, constructs such as repetition, and approaches to help them such as debugging are presented for them to learn the benefits of each as they advance through the game. When additional capabilities are added to their environment a brief description of what it is used for is given to the students, but they must then figure out how that tool can help them solve the next puzzle.

For each of the initial obstacle courses, there are constraints that require the students to incorporate the new concept to solve the problem without explicitly telling the child that it is needed. In this way, the levels require the child to think about what the concept adds beyond what they already have in their repertoire. As a result, not only does the student learn how to use the concept, the student also develops an understanding of the new concept’s benefit as compared the other concepts already learned.

IV. LEARNING ENVIRONMENT DESIGN

In structuring the game-based self-regulated learning framework, we looked to Rieber’s findings of the most effective ways to blend learning and play[5]. He suggested the most effective practice was combining elements of Piagetian learning theory with elements of Flow Theory[6], [7]. Specifically, what he termed “microworlds” provide an environment where learners explore increasingly more sophisticated and complex ideas that require little or no training. They provide an environment that is intrinsically rewarding; learners are able to evaluate and monitor their own learning; and individuals can select the environment that best suits their learning style. To realize these traits, we incorporated findings in a couple of key areas. In order to provide an environment that is intrinsically rewarding, we combine different elements of appeal, including gameplay and character-based story involvement. In addition, the latest findings in programming environment development, discussed below, that require little or no training are incorporated to better suit a self-regulated learning style. In addition to these concepts, elements are added to address multiple learning styles and ways for students to self-evaluate their learning without impeding their advancement through the game.

A. Game-based learning

Over the past several decades, research has shown a game-based approach to learning can be engaging as well as effective. Work by Malone and Lepper proposed that by making learning fun, the motivation could lead to effective intrinsic learning[8], [9]. Engaging students' learning through gaming does not only motivate them, but has also been shown to make them more focused and willing to persist over time[10], [11]. More recently, work by Shaffer has shown that computer gaming environments can be both an effective way to engage children, while helping them to learn in the process[12]

While many applications have been developed to address introducing programming concepts to school-age children of various levels through gaming, we believe there remained opportunities to improve the framework for self-regulated learning through better use of a broader range of factors motivating the eight to ten year old age group. Specifically many efforts have been made regarding quick introductions such as those commonly used in The Hour of Code and other programming environments that are aimed at an initial programming exposure. However, the majority of these applications do not incorporate findings of related work in this area that have been shown to help appeal to wider range of interests and motivations.

B. Story and character-based influences

In creating the Robot Training game, a central goal of the application is to design it so that it appeals to all children, but a specific focus was to incorporate elements that interest both girls and boys. Kelleher and Pausch discovered that sociological barriers were more challenging than the technical details of languages and tools[13]. They found that motivation and support for programming was critical for learning, and suggested that motivational stories and students working together in groups helped to provide the necessary context. Furthermore, motivational stories need to be broadly appealing to encourage entire audiences to have interest in programming. For example, battles are not necessarily appealing to all girls, artistic, or musical students. Other work inspiring the inclusion of a character-based storyline, found that students using a story-based environment spent 42% more time engaged in programming than those with a non-storytelling version[14].

To achieve these benefits, a storyline was added as a central element to improve wider student interest and engagement related to student motivation to help the robot get home. Based on this, the motivation to advance through the game is built around helping Robo find the spaceship parts he needs to get home. Students are told that the object of the game is to help teach Robo how to find his spaceship parts by training him with the programs the students create. The story takes the player through a number of different virtual environments ranging from space to the Wild West. A character named Eddy the Alien advances the storyline and acts as a guide, introducing each level. The character explains new concepts, such as repetition, that will be needed to solve the level.

Fig. 1. Eddy at level completion

Within this storyline students are encouraged to figure out what each programming concept means on their own. A further benefit of storytelling in games is it can further motivate children to read what is presented as they complete different levels in a game[13], [14], [15]. To take advantage of this, upon completion of each level, Eddy congratulates the player while articulating the benefits of what the student just discovered on his or her own to help reinforce the reason for that tool and the specific concept (Figure 1). In addition, while these aspects did not affect the student's advancement through the story or gameplay, Eddy provides feedback on the strengths of their accomplishment such as completing the level with the fewest instructions possible. The feedback is designed to allow students to self-assess their learning and encourage them to think about what they are learning in different ways.

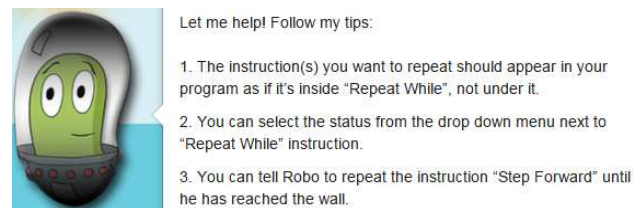

Fig. 2. Eddy when asked for help

Additional components are also incorporated to engage a wider variety of learning styles. In Kahn's study of fourth grade students using the programming simulation game ToonTalk, he found that while some children enjoy struggling through a problem for the satisfaction of finding the solution, others were more motivated and less discouraged when they were assisted by a character named Marty who acted as a coach[10]. To help address this potential factor in Robot Training, if a student ever becomes frustrated with a particular puzzle, they can ask Eddy for help in solving the problem and Eddy will provide tips on how to reach a solution (Figure 2).

C. Programming environment

A key goal for Robot Training was to make it easier to focus on the concepts by making the underlying programming environment easily understandable and not distracting from comprehension of the concept. In a study by Kim et al., they found by removing the focus from programming language syntax, middle school students were better able to focus on algorithmic correctness and other learning goals[16]. They

concluded, given the problem context, that students used computers as a tool for problem-solving rather than focusing on specific implementation details. Kelleher and Pausch found teaching children programming could be made easier by simplifying mechanics and syntax and providing support documentation and tools[15]. Thus, helping students focus on learning the programming concepts rather than being bogged down in syntax or intricacies was a key goal. To address this in the Robot Training game, a simplified drag and drop programming language based on block constructs was created. Thus, each robot instruction, such as “Step Forward,” is represented visually rather than typed. The goal was to leverage the findings related to the Scratch programming environment, which suggest such a language allows students to focus on the algorithm correctness rather than syntax or compilation errors[17], [18]. While the Scratch environment has far more capabilities than the language developed for Robot Training, our goal is to provide a more simplified problem-solving environment for an initial introduction to the same concepts.

A somewhat related goal we wish to address in Robot Training is to provide an environment that encourages understanding of why a particular solution works, and to provide easily understandable tools to help when a solution does not work. In Lin et al.’s study of teaching eight to twelve-year-olds programming using Stargate Creator, HANDS and Visual Basic, they found a significant challenge was explaining the reasons for program errors and the result being students resorting to trial and error rather than understanding why a particular instruction did not work[19]. They also observed that in the rush to write code, students frequently included extraneous code without trying to make sense of whether the statement was needed. These findings were a critical factor in developing the game and assisting students to understand the need for certain statements and concepts. In particular, the game provides a strategically limited amount of each instruction type available to guide students’ learning through requiring students to critically evaluate whether a specific instruction is necessary. Furthermore, this was a key factor to provide a visually understandable debugging experience that allows students to investigate their program errors without the complexity of a debugger such as the one found in Visual Basic.

The debugger in Robot Training allows children to run their program step-by-step and observe how the robot executes each instruction just as a typical debugger would. The aspect of it that sets it apart from other work in this area is the “Robot Status” window which lists the current state of the program in a way that is both helpful for finding problems as well as discovering other information that may provide ideas on other types of concepts that may be incorporated into the program. For example, as Figure 3 shows, in addition to the direction of the robot, information is also provided about what conditions are true and false, whether they are being used in the program or not. In this way, the information can help students that are already making use of conditionals as well as present children that are not using conditionals with information about the

environment that can be incorporated in conditionals if they choose to use them.

V. INSTRUCTIONAL DESIGN

The game is structured into two parts: introductory levels and free form challenges. First, introductory levels expose students to different programming concepts and tools in a structured way through the story. Then more free form challenges require the students to apply what they learn to new contexts requiring them to incorporate multiple elements without directly telling them what is needed. This encourages them to explore and find multiple different ways of approaching the problems, thereby learning different concepts in the process of finding the solution.

The game begins with eleven levels, each of which introduce different programming concepts. Challenge levels are then presented, where the children’s task is finding the solution to complete the course using knowledge they acquire from earlier levels. The game interface is composed of three primary components. First, the student is given a “Toolbox” of computer instructions, which they can use to develop a program for Robo. The student drags and drops the toolbox instructions into a window called “Your Program,” which contains the instructions Robo executes. Finally, the main area of the screen features the obstacle course, the goal, and the Robo character. Students can execute their program in the obstacle course by choosing the “Run” option in their program window.

A. Level Design

The first eleven levels each focus on teaching an essential concept of computer programming as follows:

Levels 1 and 2: Computer automation *Once a program starts running, it cannot be altered. It runs in an automated fashion.* In the first two levels, the students build basic multi-step programs. When each level is completed, users are able to see how a program is executed visually. This also emphasizes the importance of having all instructions correct before starting the program.

Level 3: Debugger functionality *A debugger can be used to step through a program, providing developers with additional information that may help in solving problems with a program.* For this level, students again solve the same course as level 2, but this time they must execute the program through the debugger. In doing so, they will see that they can execute their program in a step-by-step fashion seeing where their robot is in relation to which instruction of their program is currently being executed. Having them step through a program they already know introduces them to the additional information that is available regarding the robot’s status at each step of execution. For example, it provides program status such as if Robo detects there is a wall or a part nearby, thus, showing information that may be helpful to a student to begin thinking in terms of conditional statements.

Level 4: Algorithmic thinking *Programming requires you to think about the different ways you can build a program.* The level design is such that there are multiple routes to the finish,

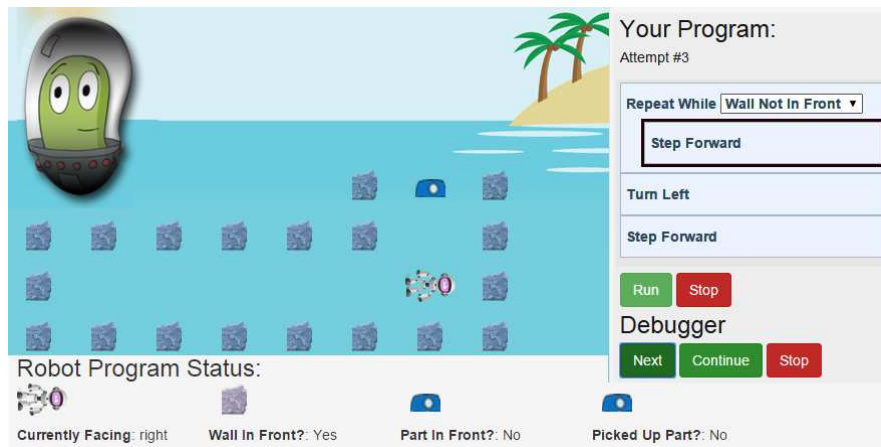

Fig. 3. Step through debugger, visual status and conditions available

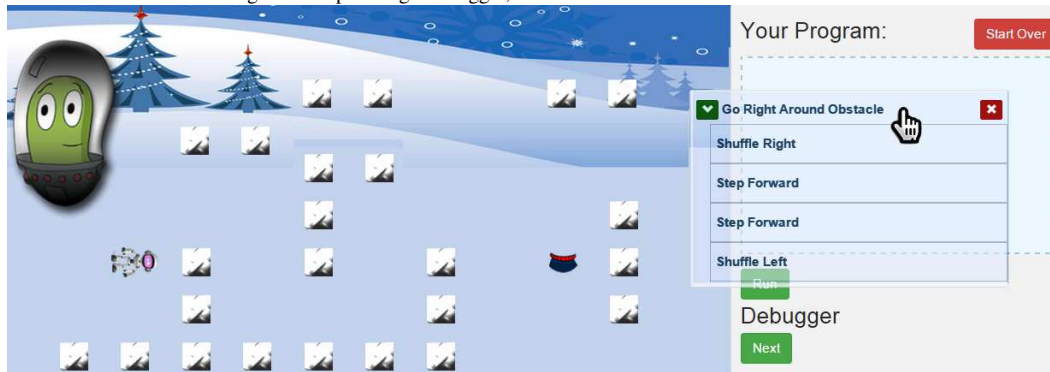

Fig. 4. Incorporating functions

but due to a limit on the number of each instruction, only some approaches actually allow the target to be reached. The goal is for students to realize there may be multiple ways to achieve the same result, but determining which best suits their needs requires them to think through how the program will execute.

Levels 5 and 6: Repetition with parametrization *Loops can simplify a program when a set of instructions should be repeated a number of times.* Level 5 introduces repetition and requires the user to construct a program using a loop to repeat an instruction a specified number of times. This is then followed by a course that requires the students to figure out how to incorporate multiple instructions in a loop.

Levels 7 and 8: Conditional repetition *A condition can also be used to specify how many times a loop should be repeated.* These two levels present problems that once again require the user to incorporate repetition in solving the puzzles, with the second level requiring the user to use two different conditions.

Level 9: Optimization *Simplify your programs.* Level 9 encourages students to look for the simplest way to solve a problem in the fewest number of steps. This level is also intended as a setup for the subsequent levels about functions to demonstrate how functions can reduce the number of steps in a program.

Levels 10 and 11: Functions *Functions can be used to group a logical set of steps.* In Level 10, a course is presented such

that there are two places in the course where the same logical steps need to occur. Specifically, Robo needs to go to the right around an obstacle. A function to perform this action showing the associated steps, is added to their toolbox, and the students must figure out how using this function can help them solve the level. Level 11 builds upon what they learned in the previous level by having the students create their own function to solve the new course in a similar way. Specifically, the intent is for students to see the similarity between the current task and the function they used in the previous problem so that they realize on their own that they can create their own function in order to perform a mirror of that functionality.

Levels 12 through 28: Challenge levels While in the initial levels students are challenged to solve a problem by discovering how to apply a concept on their own, they were guided that to solve the problem they must incorporate a specific concept. After level 11, the goal is for students to determine which concepts they previously covered can be used to solve the challenge. While the obstacle course structure is more open to encourage students to think about multiple ways to reach the goal, constraints are placed on number of times each instruction can be used. The result is that while there are multiple ways to reach the goal, only some of the options are possible due to the limits on instruction use. By doing this, not only does it require students to consider the different ways programs can be written to achieve the same goal, but it also

pushes them to think about how the different concepts they have learned can be applied in multiple ways.

B. Scoring feedback

One of the factors Rieber identified as contributing to effective self-regulated learning, was for the subjects to be able to self-evaluate their progress so that they might look for ways to explore improvement[5]. To provide this feedback we incorporate an idea of bonuses for fewer attempts, simpler programs, and students thinking through the problem on their own. For example, if a student is able to complete a challenge with their first execution they receive more points than if they take three times to reach the solution. In addition, while there is specific help available to students in the form of level specific tips provided by Eddy, to encourage students to try solving the problems on their own first, a student receives a higher score if they solve a level without requesting help.

VI. METHODS

A. Assessment inputs

In order to assess the effectiveness of the game at achieving the goals of this study, the team used a variety of evaluation methods. First, an anonymous online survey collected basic demographic information, prior computing experience, and preliminary opinions at the beginning of the study, and follow up questions were asked at the end of the study to evaluate changes in opinion. The second evaluation technique involved direct observation of participants during the game via anonymous analytics recording of game play. The team recorded a variety of statistics including length of time spent on each level, both successful and unsuccessful level solutions, when the debugger was used, and detailed information about the program elements used to solve each level. Finally, observations and comments made by the students were also used as a third input in evaluation.

B. Procedure

Two after school sessions were designed for the participants.

1) *Session one:* After introducing participants to the research team, the children would be directed to complete an anonymous online pre-survey. Once complete, the project team would ask the students to form groups of three to four. Each student would work on his or her own lab computer, but the students would be encouraged to talk with the members of their team. The team approach was chosen due to studies indicating it is easier to learn programming in groups and gain the benefit of discoveries made by peer teammates[20], [15]. The decision to have each participant work on their own individual lab computer was driven by the hope that this model would encourage the students to try out concepts on their own as well. The children would be given about one and a half hours to play from level one to level thirteen on the first day. These specific levels introduce all of the functionality, controls, and each of the basic programming concepts the game presents. At the end of the first session, students would be encouraged to think about something that they do before

the next session and how they might program a robot to do that activity. This would then be discussed in the next session.

2) *Session two:* In the second session, children would begin playing the challenge levels from level 14 to level 28. For these levels, rather than introducing new concepts, they focus on making students think of different ways they can apply the concepts they have learned. These levels require more in-depth thinking and creative use of the computer instructions available to them. During this session, students would also be asked to write down their program for the activity they were told to think about at the end of session one. After students had played the game for an hour, for a total of two and a half hours over both sessions, they would be directed to complete another anonymous online survey to assess the impact of the game experience.

C. Participants

The experiment took place in November of 2014 in West District Elementary School in Connecticut's Farmington Public Schools district. The research team conducted two sessions of two hours and fifteen minutes each, after school in the school's computer lab. The participants consisted of seven boys and four girls in that school's fourth grade between the ages of eight and ten years old.

VII. RESULTS

A. Pre-survey

The pre-session survey revealed all of the participants used computers frequently for both games and in a learning context (see Table I). In addition to having used computers for homework, all of the students had also used Chromebooks in their classrooms. Furthermore, all students emphatically agreed that they liked using computers. Of the students, 21% indicated they had programmed before, 36% recorded they had not, and the remaining 43% were unsure.

B. Gameplay

Within the first session, each of the first three levels focus on introducing the basics of the environment, building a simple program, and use of the debugger as described above. All students seemed to easily grasp how to play the game. This could be seen in them taking on average only a minute and 13 seconds to complete the level and just over 3 attempts on average for each of the first two levels. In addition, while the introduction to the debugger was brief, we believe usage statistics indicate students learned the benefits of the debugger on their own. Based on the average in-game analytics, for the 14 levels that required 3 or more attempts per completion, the debugger was used an average of 71% of the time. Whereas, on the three levels that averaged fewer than 3 attempts per completions, the debugger was only used 33% of the time, which demonstrates an understanding of the benefit a debugger can provide in solving a more challenging problem.

Level 4 introduces students to one of the central mechanisms used throughout the Robot Trainer application, limits being placed on the number of each type of instruction. This

mechanism is used as a means to introduce epistemic conflict of what the student has discovered to that point, by deliberately requiring them assess and understand the limits of these concepts. This self-reflection and understanding is the requirement for the desired self-regulated learning necessary for students to arrive at how to incorporate the new programming concept[5]. In this level, for the first time, the participants has to solve a challenge where while there appears to be multiple ways to solve the obstacle course, students need to think through the different algorithm possibilities to find a solution that would work given the constraints. This additional complexity resulted in a jump of over two additional attempts per completion and the resulting increase in average completion time by nearly three minutes.

This was then followed in levels 5 and 6 by an introduction to repetition. For example, students had to learn rather than placing three series of “step forward, turn right, step forward, turn left” instructions in their program, they needed to instruct Robo to repeat the group of instructions three times. Based on the amount of time to complete these levels (4.5 minutes) and just over 5 attempts per completion, it appears that it was initially challenging grasping how a multi-step program would repeat a fixed number of times. However, when levels 8 and 9 introduced conditional repetition, students easily applied their gained understanding requiring just 2.5 attempts per completion. We believe this result in part demonstrates how the instruction limiting method of stimulating self-regulated learning allowed students to develop an understanding that they could easily translate into different contexts.

In level 10, the concept of using a function is introduced. Based on the attempts per completion (5.3) and just over 5 minutes average completion time, using a given function appears to have been more challenging to understand compared to the initial exposure to loops. However, when many students solved challenge levels later in the two sessions they chose to use given functions rather than specifying the steps themselves indicating they developed an understanding of their purpose.

One observed weakness in either the approach used in Robot Training, or the way it was presented was observed related to student’s defining custom functions. Level 11 first introduces students to the concept after they have demonstrated how to incorporate predefined functions to solve Level 10. Within this level, while the attempts per completion remained nearly the same as the predefined function level, the average completion time jumped by 60% to nearly 9 minutes. While this by itself does not necessarily indicate a difficulty in understanding, upon examining the student programs in later levels it was clear not all students clearly grasped the concept. While some students demonstrated understanding succinctly encapsulating logic and even using their functions multiple times within a level, other student programs consisted of a single instruction or the entire program solution as a function. This likely indicates understanding the purpose of creating functions was a more difficult concept to grasp without either further repetition or additional ways within the design to encourage a deeper understanding.

In the final “challenge levels,” rather than the application using instruction limits to require the incorporation of a new concept, they are used to require students to figure out which of the multiple concepts they have learned are necessary for a particular solution. The purpose in this change to more free form thinking in problem solving is to require students to understand how the different concepts they have been exposed to fit together. From Level 14 on these challenges became increasingly harder. At first, there was a sharp increase in attempts per completion reaching over 9 for levels 15 and 16, but once students became more familiar with this type of problem solving, the attempts per completion dropped once again to around 4.5 attempts per completion.

We observed that while students were aware no other student saw their scores, the scoring idea still motivated them to continue to try to solve the problem on their own even though they knew help was readily available if they needed it. An example of this was when two students were overheard talking to one another regarding solving a level they were having difficulty with. One student suggested the two of them use the persona for help, but their teammate’s response was that if they did, they would not get as high of a score so they should instead figure the solution out on their own together. In addition, while the debugger was used on 64.8% of levels, help was only used on 12.2%.

C. Learning outcomes

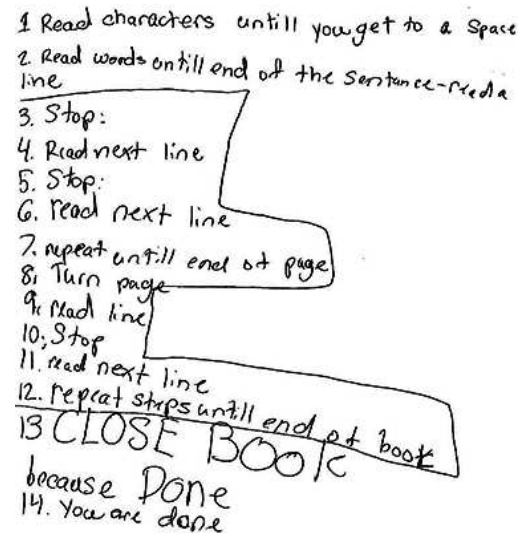

Fig. 5. Student made algorithm

Recall, as described in the procedure, at the end of the first session, students were encouraged to think about something that they do and how they might program a robot to do that activity at the next session. Following gameplay, as a means of assessing how well students could extend the concepts they learned to algorithmic thinking outside of the game environment students were asked about what activity they picked and told to discuss with their group how they would tell a robot to do that activity.

Question	Definitely Agree	Agree	Not sure	Disagree	Definitely Disagree
Pre-session survey results					
I use computers a lot	45.45%	54.55%	0%	0%	0%
I like using computers	100%	0%	0%	0%	0%
I play games on computers	54.55%	45.45%	0%	0%	0%
I use computers for homework	45.45%	54.55%	0%	0%	0%
<i>I know a lot about computers</i>	9.09%	45.45%	45.45%	0%	0%
<i>I think programming computers is fun</i>	54.55%	45.45%	0%	0%	0%
<i>I want to learn more about programming computers</i>	81.82%	18.18%	0%	0%	0%
<i>I want computer programming to be taught more in my school</i>	63.64%	27.27%	9.09%	0%	0%
Post-session survey results					
<i>I know a lot about computers</i>	40%	50%	10%	0%	0%
<i>I think programming computers is fun</i>	80%	10%	10%	0%	0%
<i>I want to learn more about programming computers</i>	50%	40%	10%	0%	0%
<i>I want computer programming to be taught more in school</i>	80%	0%	10%	10%	0%
The game helped me to understand how computers work	60%	30%	10%	0%	0%
I would like to play the game again	50%	40%	10%	0%	0%
I would recommend this game to my friends	70%	30%	0%	0%	0%

TABLE I
PRE AND POST-SESSION SURVEY RESULTS

The programs the students came up with surprised us with how clearly they demonstrated the students' understanding of the core concepts of algorithmic thinking, repetition, and conditional logic. An example of one program two students came up with for telling a robot to read a book can be seen in Figure 5. In all of the student programs, a clear multi-step execution was described that included conditional logic and most also included some form of conditional repetition, such as "brush your teeth side-to-side and repeat for 30 seconds, then move to the other side and repeat."

D. Post-survey

Question (5 = Definitely Agree)	Pre	Post	p-value
I know a lot about computers	3.64	4.30	0.0005
I think programming computers is fun	4.55	4.70	0.02
I want to learn more about programming computers	4.82	4.40	0.01

TABLE II
IMPACT OF SESSION

The lower part of Table I displays students Likert feedback from the post-session survey on the benefit and enjoyment of game. To evaluate the impact of the session there were a number of questions we asked both pre- and post-session (italics). To evaluate the significance of any changes we used a five point Likert scale with "definitely agree" being a five and "definitely disagree" being a one. The p-value was then calculated to determine statistical significance[21]. There were three statistically significant changes. First, there was a huge increase in students' confidence in their knowledge of computers. In addition, there was a increase from an already high opinion that programming computers is fun.

Finally, one result we did not anticipate given the increase in students thinking programming computers is fun, was a decrease in student's agreement that "I want to learn more about programming computers." While the change in the overall average of opinion related to "I want computer programming to be taught more in school" was not significant, the change in distribution of the responses that can be seen in Table I may provide some insight into the previous question.

Specifically, while the overall average remained fairly constant the students that previously were in "Agreement" shifted either positively or negatively. While it is encouraging to see the positive shift and that those in "Definite Agreement" remained there, the negative shift obviously indicates the method of learning introduced in this application was not for everyone unfortunately. It is worth noting however that while it was a small sample size, the four girls shifted from three out of four "Definitely Agree," to all four "Definite Agree" after the gameplay. In addition, all four indicated "Definitely Agree" for the statement "I want to learn more about programming computers" both before and after the game. Thus, while the overall shift was not significant, there is some indication that the game was very successful in encouraging or maintaining high interest in programming for girls.

VIII. CONCLUSIONS

As the results demonstrate, the Robot Training game was successful in teaching many fundamental computer-programming concepts that students were then able demonstrate their understanding in applying the concepts outside of the game environment. Pre- and post-survey results proved that the game sessions had a positive impact on the students' confidence in their knowledge of computers, as well as, their thinking of programming as a fun experience. In addition, the instructional design used in this work of using limited instruction availability as a mechanism to focus concept grasp shows promise for avoiding some of the challenges other studies have observed related to this.

During the sessions, students enjoyed working in teams, discussing different solutions to solve the obstacle course, suggesting improvements on each other's work such as the shortest path to the goal, and enjoyed helping each other debugging their programs. We also observed while they really enjoyed this team aspect, the vast majority still wanted to create their own programs on their machine indicating their desire for personal engagement as well. Finally, all students expressed being very proud of themselves when they successfully completed each level.

Abstract— It seems that education is working fine, especially in several good and traditional Universities around the world. Nokia was also doing very well in a business world until clients' needs change. Are we academics really offering what the students and the labor market need and demand? We have offered the same product for decades, but we haven't realize that the client is different and is demanding another product. Sometimes, we may have the feeling that our students are beyond this world when they are connected in the internet. Some say that the new generation is not using technology in a properly way to study; however are academics using it better? We are not using the new generation's language to communicate with students and to transfer knowledge. Games and competitions is the "language of the new generation" and it may promote a desired long-term learning experience we academics always wished. This paper describes the use of gamification as a tool to support the lectures of concurrent and distributed subjects, for undergraduate students of computer science course. In the game students should create and optimize the production line of a specific product. In the programming class, students should create and balance the same production line to beat competitors. Students have to use concepts of distributed programming and concurrency, and create strategies to organize the threads (production line) in order to be more efficient than the other competitors. The best production lines sell more and get more benefits. This paper discusses the preliminary results obtained from a survey of learning inhibits, which were applied before and after doing the course activity. The study compares the results obtained in both surveys and indicate that with the use of gamification to support class activities the learning inhibits tend to reduce at same time that transversal competences are stimulate on students. The discussion conducted after each round of the game indicated the interest and motivation of the students with this type of class.

Keywords— *gamification, concurrent programming, learning inhibits, programming game*

I. INTRODUCTION

This paper discusses about a business game adapted to teaching concurrency and distributed programming concepts. By using games in class, we expected to make the educational task more realistic, stimulate and motivate students to get involved on their own learning process. McEwen [1] discussed that the introduction of realistic elements into teaching improve motivation and boosts learning effectiveness.

Students' environment is different from decades ago and we need a different method to optimize their performance. Games are part of student's life nowadays and we can take advantage of that making interesting, fun and motivating classes, fostering student's involvement with their own learning process. Maybe we are just not using the potential aspects of all these technologies in class.

Gioia and Brass [2], in the article "Teaching the TV Generation", emphasize that teaching and learning are enhanced when teaching style are commensurate with learning style. At that moment, in 1986, the authors suggested that students who had been raised in an environment dominated by visual images - the TV Generation- should no longer be taught only by verbal stimulus. Proserpio and Gioia [3], on the paper "Teaching the Virtual Generation", say that "we no longer teach a verbal, nor even just visual generation, now it is virtual". They reinforce the idea that optimal teaching and learning occur when teaching styles align with learning styles.

Using game mechanics to non-game environments has been called gamification [14]. This study focus on the use of gamification in class to support theory and practice. Games are part of youth life nowadays and even older people are getting involved on this penchant. The initiative to use a business game to teach concurrent programming could also be defined as serious game according to [15]. The use of the term gamification in this work is appropriate because the business game used to do this proposal was designed to be a board game with the design, elements and characteristics of a game in non-game context.

For Brown and Vaughan [4] say that play is apparently purposelessness, do not seem to have any practical value, but it has inherent attraction, it is fun, it makes you feel good and provides psychological arousal. Although play involves anticipation, expectation, wondering, curiosity, anxiety and uncertainty, the play leads one to surprise, unexpected situations, discovery, new sensations and shifts perspectives, producing pleasure and good feeling [4]. Play gives freedom to improvising, provides a freedom from time when you are fully engaged, makes you stop worrying about many things, makes you even assume a different self [4].

Kapp [5] says that people like playing games because they are fun, engaging and they have the power to inform and educate. When the play is structured by rules, goal oriented,

challenge and promote interaction of the participants it is often defined as "game". A narrow way of understanding what is gamification, according to [5], is visualizing activities where you get points, rewards and badges for doing daily stuff, at work or home, could even be "getting rewards for brushing your teeth". However, [5] says that the real power of the game-based thinking is on the engagement, the storytelling, the visualization of characters, and the problem solving.

Kapp [5] does not try to mislead, he says that gamified learning is difficult, challenging, and stressful, but if well-designed games can help learners acquire in a safe environment skills, knowledge, and abilities in concentrated periods of time with high retention rates, and effective recall. In addition, gamification accelerates the experience curve of the learning, allows reaching complex subjects and provides a systemic view of the whole process [5].

Several studies demonstrate that there is no longer a game player stereotype. Anyone could be game player for several purposes, with several ages, not only kids or teenagers [6] and [7].

Wright, Bitner and Zeithaml [8] said that business schools begun to be criticized, already in the 1990's, for been failing to prepare students for the complex, fast-paced, and global work environments they would face as employees. In [8] it is suggested that students should be taught both new content and new skills in order to meet the changing business needs in U.S. Other studies demonstrate that students involved in experiential learning and subsequently stimulated for reflection on that experience tend to reach effective learning [9] and [10]. Camarero, Rodríguez and San José [11], say that students can approach a task by active experimentation (doing) or by reflective observation (watching). For Hawtrey [12], the experimental learning occurs whenever the student shifts from the role of passive listener to that of active respondent.

II. THE FACTORY GAME AS A PROGRAMMING EXERCISE

On this study it is analyzed the possibility of increasing students' performance by using games to help teaching concepts and stimulate competences. Regarding the knowledge aspect, we focus on the students' understanding, absorption and retention of knowledge. Regarding the students competences, we focus on stimulating skills by games and competitions, instead of classical programming exercises in laboratory.

The "factory game", that was originally used to simulate business and production problems, have been modified to teach computing concepts. The original game has a production line of dices composed by several types of machines, each one for a specific task and different characteristics. Each machine represents a task that students should do. To produce dices on a computational environment, each machine was programmed as a thread. Each thread represent a different machine and each machine has specific characteristics. The threads have inputs that depend on the finalization of the previous thread, which may cause production delays. Different types of products demand different threads on the production line. The market and suppliers send and receive data from the production line through messages in the local network.

A. The Factory Game

At the beginning of the game students are informed about the rules of the production and about the expected market demand.

On the factory game, from time to time (each season - one round), the game stops and the groups have to pay salaries according to the number of employees they have on the team (usually it is charged G\$ 5 (five gramilus) per employee per season). In the programming exercise, one employee controls one machine (one thread). The group directly relates the salary to the number of threads instantiated in each season.

The goal of the game is to maximize the benefit. It is emphasized that this goal cannot overcome ethical and legal principles, like using unauthorized raw material and tool, appropriating things from other competitors, cause damage in the network or other software components of the game, etc. One of the rules previously stated is that the state (professor) decision cannot be questioned.

For the programming exercise purposes, before the game begins, student must write their threads, one for each kind of machine, according to previous programming requirements. Such requirements includes the sequence of machines in order to create the proper production line, the interface between machines to exchange data (interfaces between threads), the data representation of all elements of the game, and the structure of all messages that could be exchanged between each factory and the market.

Suppliers of raw material deliver requirements to the market. Such companies run on a server and are available in the laboratory environment. Students may develop the communication mechanisms between companies as threads that follow the data communication requirements.

It is previously informed that when the game begins the demand per period can oscillate from zero up to 1000 dices per order. The demand must be supplied on time (in each period), placed on client's location (table of the instructor - on the OM game), with a note containing the name or a logotype of the supplier and the bid on it. The Factory programming developed must inform at the end of the order production all data related with the production such as the type and quantity of dice produced, the elapsed time, the number of threads running.

For each order the students may change the strategy plan, i.e., the company is able to buy more or less raw materials (three types of board) and to program machines (template, painting (gluing dots), cutting, folding threads) to begin its production. This means that students may choose to have more threads to increase production, since each kind of dice demands some time to be processed in each machine. In order to study several concepts of concurrency programming such as race condition, critical section and mutual exclusion (mutex), each kind of dice demands different resources about raw material and production time.

The products demanded can be separated in five different market segments or categories, according to the Bowman's Strategy Clock [13] (no frills, low price, hybrid, differentiation, and focused differentiation). It is informed that the:

- "No frills" dice have approximately 30% of the market segment. This category is composed by small dices as dimension criteria (it is provided a number of dice templates that can be done in one board), nor type of raw material or painting color. The price the client is willing to pay for each unit of this product is G\$ 10. The decision criteria of the client when demanding this type of dice is the price.
- "Low price" paper dice have approximately 40% of the market segment. The only criteria this dice have to follow is the minimum size of the dice (again, the number of dice templates in one board), the rest is optional. This dice need to be sufficiently cheap to compete on the market. The maximum price the client is willing to pay for each unit of this product is G\$ 25. The decision criteria of the client when demanding this type of dice is the price.
- "Hybrid" paper dice have approximately 20% of the market segment. The minimum criteria for this dice are: the big size of the dice, the demanded color of the dot painted, and the raw material is optional (it can use the cheap one). This dice need to have a good relation of quality and price to compete on the market. The maximum price the client is willing to pay for each unit of this product is G\$ 50. The decision criteria of the client when demanding this type of dice is the quality/price relation.
- "Differentiation" dice have approximately 8% of the market segment. This high quality dice must have the big size, the good raw material (special paper) and the demanded color of the dot painted. This dice must have good quality to compete on the market. The maximum price the client is willing to pay for each unit of this product is G\$ 100. The decision criteria of the client when demanding this type of dice is the quality.
- "Focus differentiation" dice have approximately 2% of the market segment. This high quality dice must have the big size, the good raw material (special paper) and the dot painted is specific (forcing the company to postpone the painting). This dice must have good quality and attend to the customized dot criteria to compete on the market. The maximum price the client is willing to pay for each unit of this product is G\$ 250. The decision criteria of the client when demanding this type of dice is the customized quality.

In the programming class, each kind of dice represents the type of material that the factory must take from raw material supplier, a production time for each machine (thread) and the cost of each machine to produce the order. In the general situation, the time to produce a "no frills" dice in each machine is lower than to produce a "low price" dice, and so on until the "focus differentiation" dice. Any machine can produce all kind of dices, since it is programmed to do so. For that, the thread must be programmed with all production times related with each kind of dice.

B. Programming Strategies Examples

During the game, the demand changes each round. At each round, all factories receive an order and cannot offer anymore the previous request. The student has up to 10 minutes to organize how many threads they will launch to attend the order as best they can according to price and quality criteria of the product demanded. The consumer must buy an amount of dices in each round or can buy all produced dices off all factories in a certain elapsed time.

Any order is presented to students as depicted in figure 1 and 2. For each one of the order students may organize their production line launching any quantity of each kind of machine to best fit the order. Figure 3 presents one possible strategy to fit the first demand (figure 1) in which it was launched four threads, one of each machine and one thread to buy raw material. Figure 4 presents another strategy in which students launches more threads to slower processes and creates intermediate stocks. Each one of the strategies present concerns about concurrency concepts.

<div> <div>1</div> <div> Consumer criteria: All dices produced to any factory in the next 5 minutes Hybrid consumer price 50 G\$ (big size – cheap raw material – black dot color) </div> </div>				
Type of strategy	Dice template marking	Painting or gluing dots	Cutting	Folding
Focused Differentiation	t=1s per dice 5 dices/board	t=1s per dice	t=1s per dice	t=1s per dice
Differentiation	t=1s per dice 5 dices/board	t=0,5s per dice	t=1s per dice	t=0,2s per dice
Hybrid	t=0,5s per dice 10 dices/board	t=0,3s per dice	t=1s per dice	t=0,2s per dice
Low price	t=0,2s per dice 20 dices/board	t=0,2s per dice	t=1s per dice	t=0,2s per dice
No frills	t=0,1s per dice 40 dices/board	t=0,1s per dice	t=0,5s per dice	t=0,2s per dice

Fig. 1. Order example – time criteria

<div> <div>2</div> <div> Consumer criteria: Market will buy the first 500 dices and will pay the consumer price Low Price consumer price 20 G\$ (big size – cheap raw material – black dot color) </div> </div>				
Type of strategy	Dice template marking	Painting or gluing dots	Cutting	Folding
Focused Differentiation	t=1s per dice 5 dices/board	t=1s per dice	t=1s per dice	t=1s per dice
Differentiation	t=1s per dice 5 dices/board	t=0,5s per dice	t=1s per dice	t=0,2s per dice
Hybrid	t=0,5s per dice 10 dices/board	t=0,3s per dice	t=1s per dice	t=0,2s per dice
Low price	t=0,2s per dice 20 dices/board	t=0,2s per dice	t=1s per dice	t=0,2s per dice
No frills	t=0,1s per dice 40 dices/board	t=0,1s per dice	t=0,5s per dice	t=0,2s per dice

Fig. 2. Order demand example – quantity criteria

After stimulating a healthy competition, compliance with the deadlines during the game and finding the best possible performance from each team and before saying what was the winning team, stands out the most important activity is the learning and carry it. Teams are requested to comment on their strategies, successes, mistakes, and think what would change if

done similar to this activity. The amount of money each company got (selling dices) at the end is dividing by the number of threads of the company (number of employees). The winner is the company that -at the end- gets more money by thread used on production.

Fig. 3. Dice factory programming example 1

At each round students could rethink their strategies, evaluate the effect of race condition, critical section and mutex in their production line. Students should also evaluate in each the “computational effort” for each order when launching several threads and evaluate the effect in the production time and amount of dices produced.

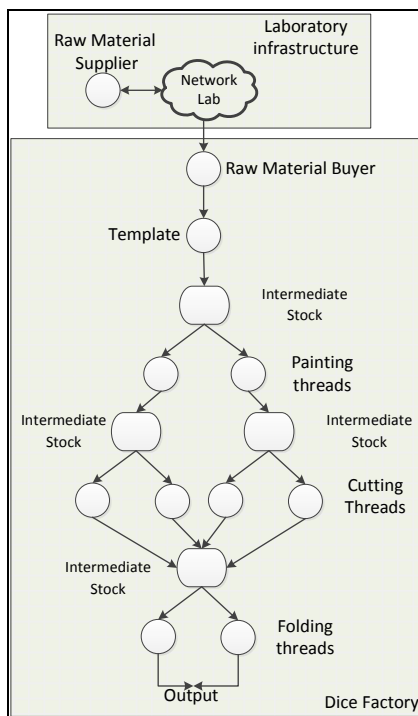

Fig. 4. Dice factory programming example 2

III. RESULTS

A survey has been conducted trying to measure if the simulation can reduce students' learning inhibitors. The questionnaire has been conducted in class, before and after doing the game. The questionnaire asks how much each factor affected students' learning with traditional speech classes (before the game) and with the use of the game to teach (after

the game and it discussion). The student have to answer with "1" if he/she considers that the factor affects very few on his learning; "2" if it affects few, "3" if it affects moderately, "4" if it affects a lot, and "5" if it affects extremely.

The topics measured are (number indicates the question number):

- 1 - Tiresome topic;
- 2 – Topics are difficult;
- 3 - Boring teacher;
- 4 - Boring lecture material;
- 5 - Teacher not been clear in his explanations;
- 6 - Student doesn't realize the practical utility of the topic;
- 7 - Student doesn't remember the content of previous lessons;
- 8 - Student is very tired;
- 9 - Colleagues talking during class disturb learning;
- 10 - Poor conditions of the environment disturb learning;
- 11 - How long do you think you will remember the topic explained? The options for this question are: (a) more than 15 years, (b) between 5 and 10 years, (c) between 3 and 5 years, (d) between 1 and 2 years, (e) less than 1 year.

The results of the survey is depicted in figure 5

An important point is that students have classes at night and in most cases are employees or interns in companies during the day.

The question one indicates that the computer programming classes became more interesting for 73% of students, as the same way the explanations of the teacher were more interesting (question 3) for 81% of them. The class were dynamic (question 8) since at least 36% of the students did not felt tired.

The content of the discipline was complex after doing the game for 18% of the students compared to 36% of them before the game. That indicates the game were useful to better understanding of the topics. One possible reason for such improvement of better understanding of the contents is that game helped teacher in the explanation, since the game was an example for several topics and student could analyze them in the lab. Students also report that could better understand the practical application (91%) of the concepts through the game, which is considered a quite important result since it is possible to estimate that students will be able to apply the studied concepts outside the classroom in related problems.

Question 11 suggests that students can remember the contents for long term using this type of class (9% answered - for more than 15 years, 27% between 5 and 10 years) compared to traditional classes (18% answered that won't remember for longer than one year).

Another important part of the survey measure the students' perception of the learning skills used on the game (the competences). The student have to answer with "1" if he/she considers that the game does not stimulate competences at all; up to "5" if it stimulates the competence very much. Students were invited to answer the competence development the following subjects:

- 12 - Negotiation;
- 13 - Leadership;
- 14 - Communication;
- 15 – Team working;
- 16- Organization

Fig. 5. Students' perception of increasing or decreasing learning inhibits with the game

Fig. 6. Students' perception of competences stimulated with the game

The results depicted in figure 6 indicate that the students perceived improvements in all competence through the game compared to classroom. During the game students needed to discuss (negotiate) how the production line should be built on each round, the leadership was developed when the work should be organized, the communication was relevant to better understand the objectives and reach the goals of each round and the organization of work, which means that each student should develop his job to complete the production line.

IV. CONCLUDING REMARKS

Games can enable students to learn in an entertaining and unforgettable way, putting in practice the theory and connecting knowledge. Traditionally, the unstructured problems, the time constrain, working in groups, the competition, the collaboration and other characteristics of the game stimulate the development of entrepreneurship competences on students. This work got evidences that working with games to learn computer-programming techniques is effective and may improve the quality of class and a better understand of the concepts. The game helped to develop skills valuable to students such as teamwork, communication, critical thinking, problem solving, creativity, initiative, holistic view, setting up plans, self-confidence, motivating oneself and others.

The results on the survey revealed that after the simulation game, the students' perception about the negative impact on the learning inhibits usually decrease. Additionally, most students mentioned that using the game to support learning have helped them to retain the knowledge for longer.

The simulation done in class generate worthy discussion about different strategies to develop and organize the code to reach a dice production goal. During the discussions, students could analyze different methods and ideas to model the proposed problem, represented by the production order of each round. The concepts about concurrent programming and their effects became clear in each strategy and as consequence; it became clear why one of the strategy was more feasible for a production order, or specific application scenario.

Discussing the organization of the threads to attend to production strategies adopted by each group, the students demonstrate a deep and mature critical thinking, connecting concepts from different business areas that they studied previously on their engineering courses.

This study contributes to a new approach of teach and learn concurrent programming and offering an initial attempt to measure the impact of gamification on the learning inhibits. The gamification has been helping us to make our teaching task more attractive and effective to the students.

Towards a Flipped Cyber Classroom to Facilitate Active Learning Strategies

Stephen W. Turner, Mark Allison, Zahid Syed, and Michael Farmer

Abstract—Success within the distance learning paradigm typically requires a strong intrinsic motivation on the part of the learner. This motivation needs to be matched with effective delivery of engaging course content. Developing an active engagement environment for deep learning is a nontrivial task as the instructor is not physically present.

To address the concern in an online/blended delivery model, we had developed and examined our first *cyber classroom*, in which lectures are automatically recorded and posted to a website for subsequent online consumption. The observed limitations of this approach were twofold: (1) online student participation in onground classroom activities was unfeasible; and (2) onground student collaborative activities were severely curtailed by the classroom layout.

In this work in progress we present our revised concept grounded in active learning scientific principles combined with lessons learned from our prior approach. By leveraging classroom spatial layout best practices combined with the apropos technology, we seek to address the aforementioned two concerns. Specifically we present a description of our revised cyber classroom, along with plans for future application involving integrating online learning with the flipped classroom concept.

I. INTRODUCTION

The concept of a classroom has evolved to blur geographic and temporal constraints. Innovations in teaching and learning technologies has facilitated a classroom that extends to the internet, expanding access to education in an unprecedented manner. The progress of these cyber classrooms, however, is not without challenges as we strive towards a merger of technology and pedagogical principles in support of the digital native cohort in a blended environment. Research into these challenges support the existence of a clear disparity between the quality of education available when comparing on-ground and distance-learning (DL) environments [1]–[4]. These studies explored technical solutions to DL problems and collectively support the following as best practices in the design of a active learning online classroom: Internet delivery of audio and video course content; combining real-time student feedback with streaming delivery of audio and video lectures; and the integration of natural handwriting into online slides. With these in mind we sought an approach which would leverage these concepts while infusing an active learning environment for onground students; a best of both worlds solution.

Spurred by a changing student cohort that demanded increasing flexibility, Farmer and Turner [5] described the initial

attempt at a viable solution by repurposing the classroom. This solution combined best practices of interactive distance learning with a traditional classroom experience. Courses in a brick-and-mortar environment are video-captured and delivered via web servers to support both the traditional and online students. The focus was on the technical component that is primarily automated, allowing course instructors to schedule recorded lectures and initiate the recordings with a “one button push”. An underlying pedagogical model being satisfied is that of a *Flipped* classroom whereby traditional lecture and practice components are reversed. Typically students may watch lectures at home and do homework during classroom.

The emerging limitations of this early approach occurred along two primary dimensions. First, the spatial layout of the classroom followed the traditional auditorium design, confining interaction between learners and hindering active learning strategies, such as cooperative learning and peer instruction. The legacy layout, while fitting for passive engagement (typically a lecture), needed to evolve [6]. In terms of the distance learners, the effect was essentially lackluster, as the classroom recording essentially became a video to be endured with great effort.

The second component, which relates to the technology, is that the initial cyber classrooms were not designed to facilitate remote interaction with distance learners. Synchronous interaction could only be accomplished with add-on disparate technologies, which did not lend themselves to smooth integration within the classroom.

These challenges resulted in some frustration within the students and a reluctance of faculty to fully employ all that the classroom had to offer. This meant that any subsequent approaches had to consider as driving classroom design factors:

- An active learning spatial layout capable of peer collaboration.
- Technological infrastructure capable of synchronous communication
- The technologies used should seamlessly integrate and be relatively intuitive to use.

To this end, we redesigned the spatial and technology components based on [7], which proposes a highly cooperative and collaborative environment, along with guidelines for delivery. In this paper we expose our design and overview our

consideration for future application and integration within the current curriculum.

The remainder of the paper is organized as follows: Section II discusses related approaches and Section III describes the classroom in term of spatial layout and supporting technology. We discuss future application and consideration in Section IV and conclude in Section V.

II. RELATED WORK

Related literature suggests that effectively organized distance learning increases learning opportunities and accommodates multiple learning styles [3], [8], [9]. Pedagogically, the cyber classroom allows students who respond to different presentation styles to take advantage of varying content and modalities. Logistically, it has improved the distance learning experience for both our students and instructors; our students have the option of attending class or watching from home/work, and our instructors are able to deliver class without having to substantially adjust their “normal” classroom style of delivery.

The contention that video recordings are effective as a pedagogical tool, as studied in our prior work [5], is supported in a study that examines the use of an online library of video recordings of faculty lectures [10]. Here, the authors came to similar conclusions: students use video recordings as a pedagogical aid, i.e. to review concepts they struggle with and as a back up in case they miss class.

The use of videos have also been explored in the context of flipped classroom pedagogies. Bishop and Verleger [11] explored the use of video lectures coupled with active learning techniques in the classroom. Smit and Goede [12] explored the use of videos to provide supplemental instruction on difficult concepts within a system analysis and design course. In both cases, the authors found that videos are useful as a supplemental instructional aid if properly paired with additional effective instructional techniques.

A study of the use of technologies in the flipped classroom model is presented in [13]. Here, the authors examined the use of video lectures viewed at home, combined with exercises and group activities employed within the classroom. Our approach is similar in that our cyber classroom could support their methodologies, but we intend to extend the pedagogical approaches to include support for distance learning students participating in real-time.

Other work related to distance education paradigm examined the use of virtual laboratory infrastructure [14]–[16]. In these studies, the authors examined mechanisms by which virtual machines are used to deliver laboratory content for use in networking courses. The VMs are coupled with virtual networks built within the VMWare software, allowing our distance students to experience laboratories *equivalent* to in-person.

Active learning strategies are explored extensively by Beichner in the Student-Centered Active Learning Environment with Upside-Down Pedagogies (SCALE-UP) project [6], [7], [17]–[19]. Students learn in spaces designed to facilitate interactions among teams of students, as well as with the instructor. Instead of spending the duration of class in lecture, the goal is

to flip the classroom so that students spend much of their class time engaged collaboratively in a series of short, interesting tasks designed to enhance their learning.

III. THE FLIPPED CYBER CLASSROOM

This cyber classroom consists of two primary systems: the technological component responsible for the recording of lectures and posting them to our department’s web server; and the active learning components based on the SCALE-UP project. Although these concepts are somewhat blended for the purpose of computer science instruction, they primary divide the room into electronic components and physical, architectural features.

A. Spatial Considerations

Fig. 1: Active Learning Layout

Figure 1 shows the layout of the classroom. Student huddles of six are capable of collaboration in close proximity. Each table is designed according to the SCALE-UP paradigm, such that students face or nearly face each other with the u-shaped configuration. The huddle size was chosen in accordance with research that suggests optimal group sizes for collaborative learning [20]–[22]. In addition, the instructor is able to easily move about and interact more closely with individuals and groups, a feature sorely lacking within the auditorium style classroom.

Fig. 2: The Cyber Classroom

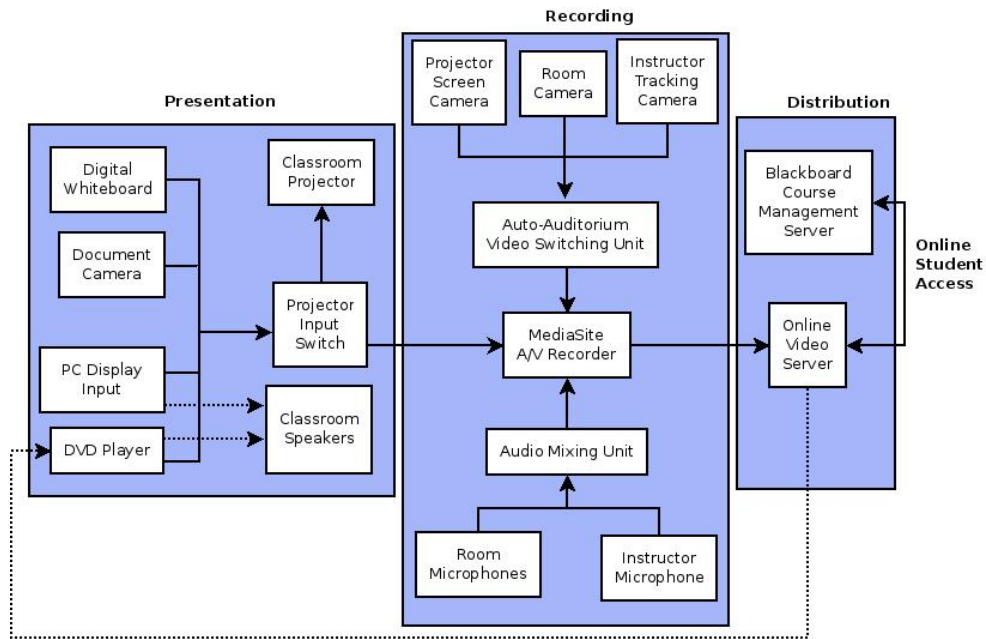

Fig. 3: Supporting Technology Infrastructure

B. Supporting Technologies

The generic technical architecture of the cyber classroom is provided in Figure 3. Here, the system is divided into three general subsystems: (i) presentation, (ii) recording, and (iii) distribution. The system is fully automated, requiring instructors only to schedule a recording, ensure the system power is on at the start of each class, and press the record button on the control screen. The ease of use makes the system suitable for a wider variety of faculty having varying levels of technology comfort.

The automation of the recording mechanism is accomplished by use of MediaSite [23] and AutoAuditorium [24] products. The MediaSite device is responsible for scheduling, recording, and storage of the recorded lectures. The AutoAuditorium acts, using an AI, as a computerized camera operator, determining when to follow the instructor as he/she walks around the room, and determining when to switch among various sources, including a tracking camera, a fixed camera that focuses on the screen, the room camera, and the presentation inputs. Further details of the operations of the subsystems are described in [25].

Figure 4 presents the control screen, used to control operation of the entire room. Note how closely it maps to the actual layout of the classroom. This allows for a more intuitive feel. The controller has the capability of routing feeds among various components, including sending the instructor's video feed to all PCs, routing from one PC to other PCs and/or tables, and controlling feeds to individual tables. As the screen shot shows, there are five *huddle tables* within the room, designed for collaborative activities.

The huddle tables are shown in Figure 2. All PCs on the table are connected together via a local switch such that they can be controlled by an interface local to the table, shown in

Fig. 4: Video Routing Control Interface

Figure 5. Under control of the instructor, individual tables can be independently operated to facilitate close group interaction among students. Outside interaction through Skype or similar real-time communication software, is fully supported.

Fig. 5: The Table Controller Interface

IV. FUTURE APPLICATION

Our intended future uses of this cyber classroom are to further combine the inquiry-based learning techniques advocated in the SCALE-UP project with the best aspects of our video course delivery capabilities. The initial use of the classroom was to teach computer architecture using project based learning as the pedagogical backbone. Our initial results are very promising, as students and instructor alike seemed to take to the technology. We will endeavor to seek a more empirical analysis as to the effectiveness of the classroom in the short term using qualitative methods.

We intend to expand our use of the classroom to teach software engineering as the small collaborative group requirement for agile purposes is a very close fit. In addition, the practice of *pair programming*, which was not easily implementable in our prior cyber classroom, is now an option for learners.

As we expand offering, we intend not only to produce a quick start guide for faculty but guidelines on integrating a syllabus to maximize learning.

V. CONCLUSION

The construction of this room was initiated due to needs within our program to revisit our cyber classroom space design. We used it as an opportunity to add features conducive to Computer Science related coursework. In this paper we exposed our preliminary implementation and consideration for future considerations.

This concept demonstrates promise for teaching and learning augmentation and expansion into other disciplines being taught within our institution.

Evaluating the effect of thoughtful design of in-class time for a flipped classroom

C.J. McClelland

Petroleum Engineering Department
Colorado School of Mines
Golden, Colorado, USA
cmcclell@mines.edu

Abstract— A lot of attention has been given to the pedagogical method referred to as "flipping" the classroom. Many previous studies and conference presentations have shown that while students do not perform any worse in flipped classrooms than in a traditional format. However, a thoughtful design of the time spent in class can improve performance. This work-in-progress paper is a narrative of one course's journey over several semesters from traditional lecture to flipped classroom, and the observations of the impact that in-class and out of class activities had on overall performance of students. Brief descriptions of many course assignments and activities are included. In addition, the preliminary plan for evaluating how to create an inverted classroom that can support building lifelong learning skills is presented.

Keywords— engineering education; flipped classroom; active learning; effectiveness

I. INTRODUCTION

Inverted, or Flipped, classrooms have been gaining popularity in both K-12 and higher education. Inverted classrooms are a pedagogical method that allows for the combination of behaviorist and constructivist learning theories that were once considered incompatible with each other [1]. In this method, pre-recorded video lectures and individual activities are assigned before class, reducing or eliminating the amount of time spent in lecture during class. As a result, time can be spent in class employing active, open-ended, and group activities. More simply, Lage, Platt, and Teglia explain the flipped classroom by stating, "...events that have traditionally taken place inside the classroom now take place outside the classroom and vice versa" [2].

Many studies that have tried to gauge the performance of achieving course outcomes in flipped courses have found that there is either inconsistent or no significant differences between the performance of students in flipped courses versus students in lecture-based courses [3,4]. In general, studies have shown that students typically like this method, with there always being a few who would prefer a more traditionally structured class [1, 2, 5, 6]. Instructors, including the author, also are satisfied with the flipped classroom format. Faculty can provide more instructional opportunities (such as guest speakers, field trips, deeper discussions) and interact more

with the students [7], and many students are better prepared for class [2].

Because it has been shown to be at least as effective as lecture-based courses, and students and instructors are satisfied with it, the inverted classroom is a pedagogical method that will continue to be used. In addition, it has great potential to be a highly effective pedagogy. Therefore, it warrants further use, experimentation, and refinement. There needs to be more work showing how this pedagogical method can be consistently highly effective and help students achieve outcomes in ways that are supported by educational science. There also needs to be more information provided in publications that share details and descriptions of the assignments and activities used for the inverted courses [1].

This work-in-progress paper aims to help meet these needs, and outlines how one course has progressed from a lecture-based-turned-inverted course to a thoughtfully designed course that aims to support students' learning. Brief descriptions of many course assignments and activities are included, along with a qualitative evaluation of the effectiveness of the course overall and specific assignments and activities.

II. PROGRESSION OF AN INVERTED COURSE

A. The Original Study that is the Basis of this Narrative

In 2012, a high-enrollment (n=146) fluid mechanics course was converted by the author to an inverted classroom format. The impetus for this change centered on the desire to create a course that helped students to learn the course content more effectively while also acquiring some skills to become lifelong learners. After the initial semester, performance on the final exam (which was common between the two semesters) was compared between the inverted classroom in 2012 and a lecture-based section taught by the same instructor the previous year. The results of the comparison showed that the lecture based course had a statistically significant higher final exam score than the inverted classroom section for the overall grade and two course topics. What this analysis does not consider is the gap in the depth of content coverage for one of

those topics, which resulted in a very large difference in scores on the common final exam.[8]

B. Many Course Design Iterations - Striving for Effectiveness

After that first semester of the inverted course, despite the difference in performance, I chose to continue using the flipped format. The potential for “deeper” learning is great, and the extra time spent interacting with the students is invaluable for developing relationships with students when enrollment is high. In addition, educational research has concluded so much that can be supported by having an inverted classroom. For example, the levels of Bloom’s Taxonomy of Learning [9] are addressed by structuring course work such that the lower order thinking and tasks are accomplished by the student outside of class. Doing so leaves time for the instructor to facilitate the higher order thinking and activities in class. Vygotsky’s Zone of Proximal Development [10] is accounted for by designing assignments and activities that will support students learning and help them to learn more than what would have been possible without that support. The extra in-class time that an inverted classroom affords is essential for this. In order to address students who are both intrinsically and extrinsically motivated [11] there needs to be activities that offer choice, and also activities that result in a grade that applies to the final course grade. Providing a wide assortment of activities allows for the many learning preferences [12] of students to be addressed and all students have offerings that will help them to be successful. Time to reflect on the material and then engage with it again is also necessary. These considerations were applied in conjunction with the instructor’s objectives, which are as follows:

- Ensure that students meet the course outcomes and learn the technical concepts necessary to succeed in future courses and their careers
- Develop student ability to use the course concepts as they solve problems and apply them to their chosen careers
- Help students learn how to learn and eventually be lifelong learners
- Provide time for students to have interpersonal interactions and develop teamwork skills
- Have students enjoy learning the course material

Over the 5 semesters that the course was taught after the study discussed above [8], the desired outcomes, assignments and activities have been incrementally changed, integrating aspects of other pedagogies that have been successful. For example, some components of the Team-Based Learning model [13] are incorporated, along with computer simulations and other active learning activities. When the course was first inverted, it followed a regular schedule of student preparation using videos and the text before class, and working problems in class with a few spurratic mini-lectures and demonstrations. More structured in-class activities were needed in order to help make the course more effective.

C. Second and Third Offering of the Course

The following two semesters after the first study, a few in class “labs” using computer simulations were assigned, and team quizzes and multiple choice exams were given using the IF-AT scratch cards first made popular for the Team-Based Learning [13] pedagogy. The computer simulation “labs” were quite effective for letting students “play” with the major concepts involved and were well-received by the students. The scratch card exams gave a lot of people anxiety, and the test was too long if the students didn’t get most of the answers correct on the multiple choice exam the first time around. As a result, the average on the final exams, which used many of the same questions and covered the same topics, was a 72%, which is a letter grade lower than the averages from the lecture based course and the first iteration of the flipped course. In addition to the anxiety that the scratch cards caused, upon self-reflection, the lower performance may also be due to the difficulty of the exams, which have been getting progressively more difficult as I mature as an instructor.

D. Fourth and Fifth Iterations of the Course

Over the next couple of semesters, small changes were made with the intention of improving the learning experience. More computer simulation “labs” and demonstrations were added, and more time was spent working examples together to help model problem solving skills. In addition, many of the students were not comfortable with the small quantity of graded homework, so some graded homework problems were added.

E. Sixth Time is a Charm?

By the time the inverted format had been taught for six semesters, the class was structured around seven key groups of concepts. Each group of concepts went through at least one iteration of the following sequence of carefully sequenced assignments and activities to allow multiple opportunities for students to interact with the course material at steadily increasing levels of difficulty.

- Exposure Level 1 – Introduction and low stakes exploration
 - Online lectures – introduce to topics, give initial chance to organize information, form questions, begin to practice with simple problems and examples
 - Reading quizzes online before class – self-assess whether basic level of understanding has been attained – very low stakes
 - In class demonstrations to illustrate concepts
- Exposure Level 2 – Practice
 - Think aloud examples presented illustrating how to do more complex problems
 - In class “labs” using online physics simulations

- Practice problems – (not for credit) answers given but no solutions. Hints and Steps provided after a week to help with review and build confidence that they are working problems correctly
- “Teach your Team” – students are assigned a practice problem that they work out, write a script explaining the solution, and then teach to a small group of other students.
- Exposure Level 3 – The stakes get higher
 - Homework problems assigned for credit
 - Group Quizzes –
 - in class multiple choice quiz using IF-AT scratch cards [13]
 - Students work together to answer questions
 - Must work until correct answer is determined
 - Credit awarded decreases with each incorrect answer
- Exposure Level 4 – Individual high stakes exam – written, open answer problems; conceptual questions

The final exam given to this sixth group of students was similar to that given to the first inverted section and the lecture based section (final exams are not handed back), with some questions being of higher difficulty. The student performance on this exam was higher than both the original lecture-based section and the first inverted section, for the total score and several topics. This may indicate that the structure of the course contributed to improved outcomes for the students. However, no controlled study was conducted to support this claim.

F. *The Not-So-Lucky Number Seven*

Encouraged by the results in the sixth semester, a similar course design was used again the following (7th) semester, with a few key differences. The number of students increased from 50 to 205. More “labs” were added, and at the request of the students, the amount of graded homework problems from the textbook was increased dramatically. However, contrary to my expectations, the average on the final exam was seven percentage points lower than the previous semester. Upon reflection, these are the reasons that performance was lower for this particular iteration of the course:

- The departure from mainly practice problems and switching to mostly graded problems had a seriously negative effect on the quality of learning. Because the assigned problems were from the textbook (even though it was the first semester of a first edition), the solutions were easily accessed and widely used by the students. As a result, many replicas of the solutions manual were turned in and the quality of engagement with the course material was very low. This is an illustration of how much more this group

of students was motivated by grades instead of having the desire, or motivation, to learn.

- The prolific use of the solutions manual also led to bi-modal exam score distributions. Typically, those who did not engage with the material earned below a 70% of the exams. Those who watched the videos, prepared for quizzes and classes, did the practice problems and truly worked the homework problems performed higher, usually above an 80%. There were very few traditionally average C’s.
- The “personality” of this class was notable in the respect that they were the least self-directed group of students that I have had to date. In addition, many did not have the necessary study skills and or self-reflection skills. The main concern of most was knowing what was going to be covered on the exams. In response to this observation, I added some activities and assignments to help students acquire these skills while working within the confines of the actual course material [14]. These included learner-centered activities such as a participatory exam review [14], a self-evaluation of performance on exams [14], determining individual learning preferences [12], providing instruction on various note-taking techniques, and providing an overview of many sources of course-related information. Many students appreciated these additional activities and commented that no one had ever taught them those aspects of learning before.

III. FUTURE IMPROVEMENTS AND PLANS

In the next offering of this course, a structure similar to the sixth offering is planned, along with integrating the learner-centered material and assignments used in the seventh semester. There will be a return to having more ungraded practice problems and fewer problems turned in for a grade. This is to encourage students to work toward getting a correct answer instead of working to meet a deadline. To help encourage more students to come prepared to class, the reading quizzes will be converted to a take home version of the individual readiness quiz that is part of the Team-Based Learning system [13].

In addition, one of the key outcomes identified for the fluid mechanics course discussed in this paper is to help students attain the skills necessary to be lifelong learners. The structure of an inverted course makes it a great forum for helping students become lifelong learners. Students must be able to acquire knowledge outside of the classroom in order to arrive prepared. They also must be aware of what they know and what they still need to learn in order to be successful. Thus, future iterations of this course will also include more aspects that are structured to directly support developing lifelong learning skills. One such way to accomplish this may be to offer multiple sources and have students be responsible for finding the applicable information, rather than assigning

readings. This may be too much to ask of sophomores, however.

There may even be an opportunity to add to the body of research on the effectiveness of the inverted classroom by evaluating how the pedagogical method contributes to attaining life-long learning skills. A possible design for one such study would be to use in class assignments, surveys, and possibly a validated survey to assess the effectiveness of the course formats and particular activities and assignments. Select participants could also be interviewed either individually or as part of focus groups to learn about their impressions both before the course and after it was completed. Additionally, anonymous comments that are part of the university faculty evaluation system can be used when possible.

For a study such as this, comparisons can be made between at least five cohorts. The first cohort has already finished the course, but is still at the university as seniors. These students

had fluid mechanics as an inverted course, but received no specific instruction regarding lifelong learning skills. The second and third cohorts are groups of alumni who received no related training or assignments as part of their fluid mechanics course: one completed fluid mechanics as a lecture-based course, and one completed the course as an inverted course. The fourth cohort consists of juniors who had the inverted course with some learner-centered activities incorporated into the curriculum. The final (fifth) cohort could be next year's sophomores who will have the inverted course with the learner-centered activities and some additional skills training and assignments. These cohorts are composed of students who are part of a specific department who all aspire to the same profession and have entered the course having completed the same core courses. In addition, the fluid mechanics course is taught by the same professor. Therefore, they are similar even though the experiences of these cohorts have been spread over many semesters and years. The difference between the cohorts is summarized in Table 1.

Table 1. Division of Cohorts for possible study

Characteristic of Cohort	Cohort 1	Cohort 2	Cohort 3	Cohort 4	Cohort 5
Completed lecture-based course		x			
Completed inverted classroom course	x		x	x	x
Completed learner-centered assignments focused on meta-cognition, study skills, and skills assessment				x	x
Completed assignments with lifelong learning skills acquisition embedded					x
Interviews, Focus groups, and/or Survey	x	x	x	x	x
Interviews, Focus groups, and/or Survey as seniors	x			x	x
Interviews, Focus groups, and/or Survey as juniors				x	x
Interviews, Focus groups, and/or Survey at the beginning of term					x
Interviews, Focus groups, and/or Survey at end of course					x

IV. CONCLUSION

Inverted classrooms provide many opportunities to support student learning beyond what most lecture-based courses can. Many studies have shown that students perform comparatively well despite the format. However, the method offers the opportunity to be more effective for learning both content and professional skills. This paper outlined the progression of how this course was designed in pursuit of an inverted course that is more effective than a lecture-based course, which also offers the additional benefit of going beyond course content and to help students be lifelong learners and members of a team. Careful structuring of the time both in and out of the classroom can lead to an effective educational experience for students that will serve them well both during their time in school and as professionals.

Abstract—A concept of framing is adapted for analyzing how students learn in problem-centered group learning. Students' contributions to discourse are analyzed and associated with their conceptual understanding and growth. Characteristics indicating conceptual understanding, along with factors influencing classroom interactions for conceptual growth are reported. Resources that support designing and conducting learning activities in “flipped classrooms” are discussed.

Keywords—group problem solving; positioning; cognitive development; conceptual understanding

I. INTRODUCTION

We have applied the Four-Practice Model in flipped engineering classrooms for the past three years and found that problem-centered collaborative learning has been effective in supporting quality teaching for flipped classrooms [1-3]. The four-practice model, shown in Table I, emphasizes the redefined roles of instructors as well as accountability for students in learning. These studies were conducted in an upper-level undergraduate electrical engineering course offered once a year. By problematizing content, we have engaged students in group problem solving that has improved students' learning of content knowledge and development of problem solving skills. Other positive influences, including better understanding of what knowledge is counted toward learning, as well as improved learning habits have been observed [2, 3]. Discourse in group discussions influenced conceptual growth through peer interactions during small group discussions. Many students commented that replacing traditional lectures with problem-centered learning provided them with exciting and authentic learning opportunities. They wished that more engineering classes would make similar changes. Some students reported that the instructor influenced areas of growth, specifically the ability to ask quality questions.

Despite many positive changes in teaching and learning in flipped engineering classrooms, we continue to encounter teaching and learning challenges while integrating collaborative learning with cognitive development. Many factors, including group discussions, classroom discourse,

learning materials, and others influence collaborative learning. These factors can be multi-faceted due to the complex nature of learning. To ensure that the instructional model in a flipped classroom, particularly group problem solving, significantly improves learning outcomes, it is critical that we understand how students learn in groups and how we can best support students to achieve conceptual understanding and growth in the subject domain. Given the reliance on group activities, it is crucial that we assess what aspects of peer-to-peer dialogues facilitate or hinder learning.

In this study, we adapted a concept of framing to explain two cases of small group problem solving, and expanded verbal discourse analysis to include “Big D” Discourse analysis for language and other artifacts used in flipped classrooms. We analyzed students' conversations during a group problem-solving exercise. The content of the group talks was analyzed using a developed scheme supported by the revised 2-D taxonomy [2, 4]. We then applied a general situative framework of framing proposed by Greeno and others [5-7]. We found that the way students position themselves throughout a conversation, as either a source or receiver of information, influences the development of conceptual knowledge.

TABLE I. THE FOUR-PRACTICE MODEL FOR PROBLEM-CENTERED LEARNING IN “FLIPPED CLASSROOMS” [1]

Instructional Practice	Description
Anticipating	<ul style="list-style-type: none">• Select content topics that are important for learning the course in coherent ways• Anticipate demands and possible responses to learning tasks
Monitoring	<ul style="list-style-type: none">• Probe students' responses• Engage in conversations with students• Keep group discussions on track by providing probing and driving questions and hints
Connecting & Contrasting	<ul style="list-style-type: none">• Contrast students' views to discipline norms• Elicit questions and encourage “dialogic inquiries” targeting key concepts• Q & A in a big group
Contextualized Lecturing	<ul style="list-style-type: none">• Lecture based on students' responses

II. BACKGROUND

A. “Big D” Discourse in Flipped Classrooms

“Big D” Discourse, termed Discourse in this report, is a distinctive way of saying, doing, and being, because Discourses are always language plus ancillary material and effects [8]. Applying Discourse analysis combines and integrates languages, actions, interactions, ways of thinking, believing, valuing, and the use of various representational tools to evaluate learning activities. Decades of research on discourse has supported the fundamental role of classroom talks in education. As Halliday puts it, “language is the essential condition of knowing, the process by which experience becomes knowledge” [9]. Much research, for example the study by Chin and Osborne, discusses the potential of students’ “utterances” as an epistemic probe and a heuristic for how students are constructing knowledge collaboratively in classrooms. Other studies indicate that the nature and the quality of the classroom talks are central to whether and how learning occurs [10].

Our previous studies on students’ verbal utterances in group discussions consistently showed evidence that supports these findings [3]. Drawing on the revised 2-D taxonomy for science and engineering instruction, we developed a scheme to analyze content of group talks along the dimensions of “knowledge type” and “cognitive ability” [2, 4]. The coding scheme shown in Table II for discourse analysis allowed us to characterize the nature of group talks and provided indicators of student engagement in learning. We found that students’ group talks shifted from factual knowledge to conceptual and procedural knowledge when deep learning and critical thinking took place. We have also found that some problems posed by the instructor engaged students well while others failed to do so [3]. Building on this first step, we expand to include Discourse analysis to connect saying with doing and being in cognitive development.

TABLE II. KNOWLEDGE DIMENSION OF CODING SCHEME [2]

Knowledge Type	Sample Verbal Data
Factual (F): Terminology; Specific details and elements.	<i>“Isn’t P mechanical tau times omega?”</i>
Conceptual (C): Classifications and categories; Principles and generalization; Theories, models, and structures.	<i>“So, what if we assume the total power we get is some torque times speed. So that torque is going to be applied by the motor no matter what.”</i>
Procedural (P): Subject-specific skills and algorithms; Subject-specific techniques and methods; Criteria for determining when to use appropriate procedures.	<i>“We’re trying to find mechanical power; we have to use mechanical speed.”</i>
Metacognitive (M): Strategic; Cognitive tasks including appropriate contextual and conditional knowledge; Self-knowledge.	<i>“I first did it using P(power) and then added it to the answer and had it wrong.” “Oh! That’s where I got mixed up. It’s not omega synchronous. If you just say omega...”</i>

B. Concept of Framing

Framing generally refers to the way in which participants understand the activity in which they are engaged. Three interrelated aspects of framing, i.e. positional, epistemological, and conceptual framing have been described [6]. Positional framing refers to the way in which participants understand themselves, their relationship to others, and their contributions to group activities. Epistemological and conceptual framings are two parts of cognitive framing. Epistemological framing refers to participants’ understanding of kinds of knowledge that are counted while conceptual framing refers to participants’ understanding of information structure and organization pertaining to domain content knowledge. In general, cognitive framing refers to how different aspects of the information are recognized and organized during group discussions. It is used to consider “knowing, understanding, and learning concepts and conceptions as processes that occur in individual minds” [5].

The current study stresses how students’ interactions influence their learning by connecting positional framing to cognitive framing. The goal is to study ways in which students’ mental processes are supported, facilitated, or hindered by conditions of social interaction described by positional framing in group discussions.

III. RESEARCH QUESTIONS AND DATA COLLECTION

A. Research Questions

The study focused on two research questions: (1) What are the factors that influence students’ interactions with assigned problems as a group? (2) What are the resources in facilitating students to reach common understanding during group discussions?

B. Data Collection

The study was conducted in Electric Drives, one of the three core courses in the curriculum of electrical energy systems. Data collected in spring 2014 included

- (1) students’ verbal discourse while working within a small group on problems posed by the instructor. Student talks were observed by researchers and audio recorded weekly. The recorded voice data were transcribed, coded, and analyzed using the developed scheme (Table II). The coded verbal discourse was quantified to facilitate data analyses.
- (2) students’ team worksheets in group discussion during in-class lecture periods, and for three “mock test” group problem-solving exercises right before midterm exams.
- (3) copies of students’ midterm exams. These were analyzed and referenced in conjunction with the data described above.
- (4) two online surveys. One conducted at the beginning of the semester and one at the end of the semester. Two focus group meetings were conducted at the end of the semester.

For the current study, we analyzed the verbal discourse and written work from two student groups (OR and MN) while they worked on the problem presented in Fig 1. The

problem was one of two problems that were part of a closed-book and closed-notes “mock-test” group problem-solving exercise. Students were asked by the instructor to work in groups to solve the problem. The intended conceptual framing, equations (1) and (2) for steady state, is also shown in Fig 1.

C. Data Analyses

- Using the coding scheme in Table II to identify group talk content;
- Applying positional framing to analyze how students interact with each other in problem solving group activities;
- Employing the extended cognitive framing to examine students’ learning outcomes in conceptual understanding of content knowledge.

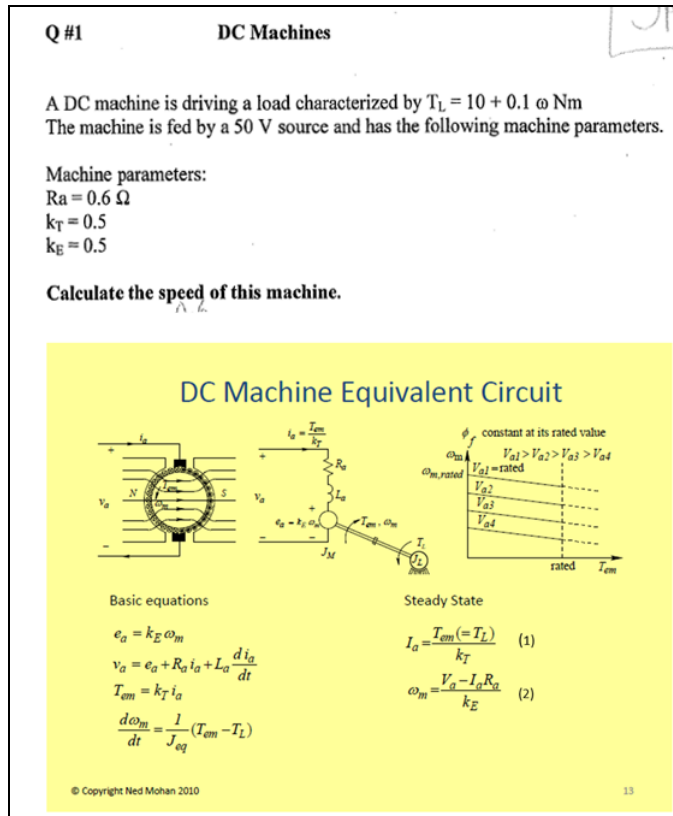

Fig. 1. Problem 1 in the “mock test” and intended conceptual framing [11].

IV. RESULTS AND FINDINGS

A. Positional Framing

Table III displays verbal utterances from Group OR. Four students participated in the group problem-solving exercise. Their conversations were coded using the knowledge dimension coding scheme (Table II). The progression of talks is displayed in Fig. 2.

Patterns of group talks observed are consistent with positional framing, namely that the dialogue progressed involving joint efforts from group members. Multiple students engaged in problem solving by sharing understanding, asking

questions, providing explanations, and reviewing their own and others’ opinions publicly. Prolific dialogues during learning activities such as problem solving often involve negotiations. It requires that two or more participants play roles more than simple “presentation-acceptance” pairs. Because students brought different perspectives into the activity, they were expected to take turns to initiate topics and contribute to dialogues differentially in productive discussions. Participants need to listen critically as well as act as a source of information to achieve mutual understanding for communicative purposes.

Changes in the positioning of each participant in Group OR were observed, which resulted in unique and inhomogeneous contributions from each member. For example, while discussing the proposal “if ω is a constant”, three students repeatedly alternated their roles as critical listeners with their roles as a source of information. Eventually, one idea was accepted after a lengthy discussion. Characteristics in the discussion for Group OR included uneven contributions from members of the group over the course of the conversation due to different positioning. This likely supported their cognitive development in significant ways, which will be discussed in the following.

B. Cognitive Framing: Epistemological and Conceptual

Students in Group OR considered the activity of problem solving to be an opportunity to test their understanding and capability to apply relevant formulas under study. One student, student P1, who initially focused on identifying an equation, ultimately came to understand the meaning and structure of the problem by working with others. The alignment of epistemological framing, i.e. understanding what kind of information and knowledge is needed and counted toward learning is the foundation of conceptual framing, in which students organize the solution activity around the structure of the problem.

Tables included in Fig. 3 provide detailed accounts of students’ conceptual framing and reveal how knowledge is distributed across group members and its resources, and how group communication and collaboration leads to the development of conceptual understanding. We divided the group talk into four episodes to explain what conceptual framing and reframing mean and how they contribute to improved learning. Following [6], we focused primarily on two items: “foreground components” and “relations between these components”. Students’ misconceptions were indicated.

1) Episode 1 (Lines 1-12, Table III)

In the initial framing, it was clear that students knew that finding ω was the goal of the task. Student P1 initiated the discussion and put some components, such as k_T , ω , and T_L , into the foreground. He did not attend to the meanings of these components. Student P2 responded and acted as a source with some explanations and immediately suggested that “the motor is in steady state.” Student P3 joined the conversation with the idea of “finding ω ” in mind. Each participant identified some required components, but none was able to connect these pieces. The left columns in the top table in Fig. 3 show

students' framing in Episode 1. There are gaps in their understanding of content.

2) Episode 2 (Lines 13-27, Table III)

The focus of the discussion in Episode 2 was on "if ω is a constant" and its implication. Student P3 visited and revisited the idea three times and stressed that acceleration was zero as a result of constant ω . While student P2 was uncertain about the claim, because it was not explicitly stated in the problem, he eventually accepted the idea. These utterances revealed that an initially missed connection between "steady state" and "constant ω " was repaired through dialogues. Students P2 and P3 achieved mutual understanding and foregrounded a few more components and their relationships. As illustrated in the right columns of the top table in Fig. 3, they aligned their conceptual framing and were able to bring information into the common ground. Although, student P1 was not yet in agreement, he followed and was involved.

3) Episode 3 (Lines 28-47, Table III)

This part of the discussion showed that students P1 and P4 were able to communicate between themselves and with others after they reframed their conceptual understanding. The component T_{em} along with V_R and e_a was in the foreground, and relations for all foregrounded components became explicit to all in the group. Students evaluated their own work and compared it with works of their peers. As shown in the left columns of the lower table in Fig. 3, after adding two equations, students' conceptual framing was in line with the framing intended by the instructor, Equations (1) and (2). Students were also able to provide explanations for why these equations were applicable in their conversation.

4) Episode 4 (Lines 48-83, Table III)

The group continued to refine their conceptual understanding while evaluating and comparing their work. Because they aligned their conceptual framing, they were able to communicate effectively, and helped each other correct mistakes and consolidate understanding while applying formulas that they identified together. See the right columns of the lower table in Fig. 3. We followed [6] and used refining instead of reframing to infer that discussions at this stage did not change their conceptual understanding. Student P4 misused the equation for I_A , but was able to communicate with his peers. The episode showed that students were able to reflect on the process while strengthening their conceptual and procedural knowledge. As shown in Fig. 2, it is important to offer students time and space that allows them to gain metacognitive knowledge.

TABLE III. EXCERPTS OF GROUP DISCUSSION VERBAL DATA

Line No.	Verbal discourse (Group OR, 4 students)	Code
1	P1: k_T is K Omega, right?	F
2	P2: Yeah. Yes, it is.	F
3	P1: Omega equals T_L minus... (mumbling)... is it 10? It has something to do with current.	F/C/P
4	P2: The motor is in a steady state.	C
5	P1: Right.	C

6	P2: It doesn't say. Oh, wait, it's $10 + 0.1 \Omega$.	C
7	P3: From that can't you figure out the frequency?	P
8	P2: No, you're actually better than most of us at torque stuff.	P
9	P1: Well, because we have that Omega wouldn't we be able to figure out the beginning?	F/P
10	P2: Right, so the beginning DC?	F/C/P
11	P1: Yeah, that's what I mean.	C/P
12	P2: We're trying to find Omega from DC?	C/P
13	P3: If the acceleration is 0, meaning the speed is constant, right?	C
14	P2: Right. Omega equals 10 times T_L ... (mumbled at 1:42)	C/P
15	P3: If the speed is a constant, does that imply that?	C
16	P2: I don't even think it's a constant.	C
17	P3: If it's a constant we can say acceleration is 0.	C
18	P1: Do you guys know how to get an actual number?	P
19	P2: It's the other K , k_T .	P
20	P2: You can make that assumption if acceleration is 0.	C
21	P3: Okay, so let's assume acceleration is 0.	C
22	P2: If acceleration is 0 then T_L equals $k_T I_A$. So, that would mean T over I_A or T over .5 is I_A .	C/P
23	P1: I_A equals T_L over 0.5. Alright.	P
24	P2: Then V_R is that times...	P
...		
28	P2: Oh. We don't have I_A though, right?	P
29	P4: You have T_{em} .	P
30	P2: Oh! Because T_L is in the variant.	C/P
31	P4: Do you agree with that?	C/P
32	P1: Yeah, because it's in a series. Or because we are in steady state.	C/P
33	P3: V_A equals V_R plus e_a , right?	P
34	P1: Yeah.	P
35	P1: $V_R V_L$.	P
36	P2: Let's go back. 50 minus 0.6.	P
37	P3: Oh, okay! 0.6.	P
38	P4: So, you have an equation in terms of ω_m .	C/P
...		
46	P2: That's really easy! When you multiply this you'll have .6 times .05 and subtract that from here and you will just divide it. We have Omega! Well we do anyway.	P/M
47	P4: What did you get? I got 100 radians per second.	P
48	P3: I don't think we did it right.	P/M
49	P4: Here's what I did.	P
50	P1: Here's what I did.	P
51	P4: 100 minus 0.6 minus 5. But I_A is not e_a over Omega.	C/P
52	P1: Hm?	P
53	P4: This isn't right.	P/M
54	P1: Why not?	M
55	P4: Isn't that e_a over Omega?	P/M
56	P2: No, it's not equal to it. That's I_A .	C/P/M
...		
60	P2: Yes, yes. T_L equals T_{em} , yes. I_A equals... that divided by that. Yes.	C/P
...		P
65	P1: I don't know. I'm getting 94. It's probably a calculation error	P/M
66	P4: I'm sorry, what are you trying to do?	p
...		
70	P4: What did I do mathematically wrong?	P
71	P1: I'm saying one of us did something mathematically wrong.	P/M
...		

77	P3: We don't know what V_R is, right?	C/M
78	P1: Well, kind of. We have to solve for I_A and then we get V_R .	P/M
79	P2: I don't like this problem.	M
82	P4: Yeah, but my idea was... (mumbled)...	M
83	P2: You can try that. Okay, I think I just got rid of I_A in the first place.	P/M

Fig. 2. Group OR discussion content and progression. “Concurrent code” refers to coding with more than one type of knowledge shown in Table III.

C. “Big D” Discourse Analysis

Fig. 4 shows the written work from Group OR. Although they did not show a final numerical solution explicitly, the problem-solving worksheet includes their reconciled and improved understanding about the steady state of DC machines. Fig. 5 displays samples of work by individuals in Group OR in the exam right after the mock team test. The problem is included. The four Group OR students displayed their ability to apply appropriate equations with understanding of the steady state that they co-constructed and strengthened in their team discussions.

Conceptual framing for Episodes 1 and 2

Fig. 3. Conceptual framing for Episodes 1&2 (top) and 3&4 (lower).

D. A Case of Group Discussion That Hindered Learning

The majority of the class (more than 90%) showed conceptual understanding of “steady state for DC machines” in their work for the midterm exam. Yet, a few were not able to apply the concept. Even though factors that negatively influenced their learning are expected to be complicated, we were able to identify a few from their dialogues during group problem-solving. Fig. 6 displays Group MN’s work in the same exercise and midterm test. Fig. 6(a) shows the written worksheet; (b) and (c) show individuals’ work in the midterm. The group discussion utterances are shown in Table IV, and the progression is shown in Fig. 7. Patterns displayed for Group MN are in sharp contrast to what are shown in Table III and Figs 2 and 3 for Group OR. Contributions to group discussions in group MN were short, linear, and straightforward. Two main participants, students P1 and P2 had fixed roles of “presenting” and “accepting” respectively throughout the discussion. Because the concept of framing recognizes several important aspects of discourse practice including positioning of individuals, joint efforts of the group, and conceptual resources from individuals, it is problematic that student P2 did not question any proposals that student P1 presented. In addition, student P2 never presented his own conceptual framing, i.e., relationships for foregrounded components. As shown in Fig. 8, student P2 (Mn2) did not get an answer to the question of what I_A is. By positioning himself as a passive information receiver, student P2 failed to show learning gains. This is evidenced by his poor performance in the individual work for the midterm (shown in Fig. 6(c)).

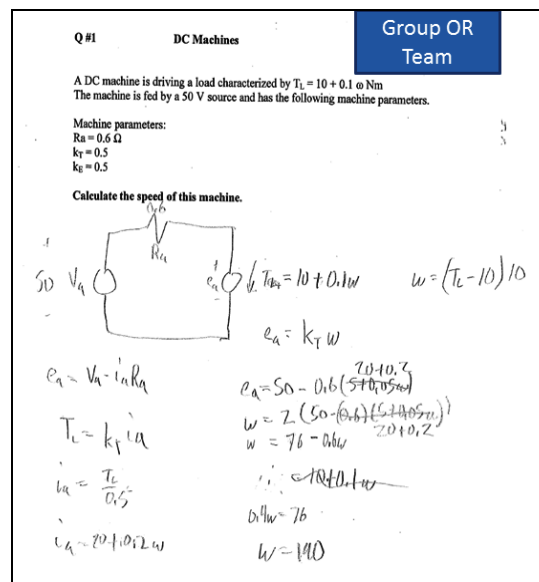

Fig. 4. Team written work of Group OR.

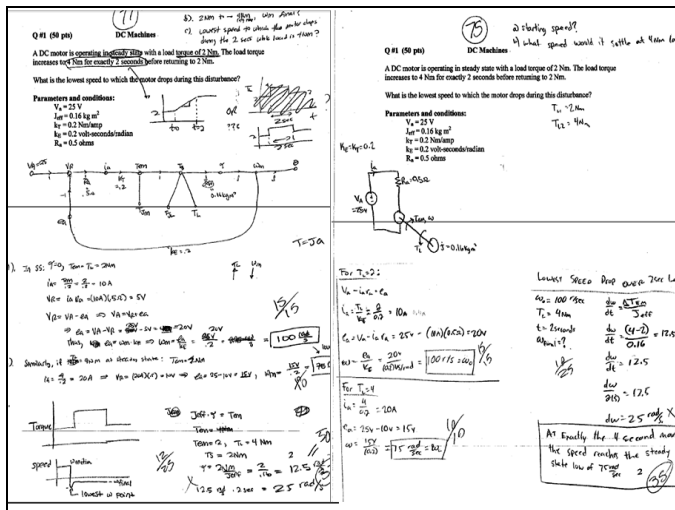

Fig. 5. Samples of individuals' work in the midterm. (Group OR).

Fig. 6. Group MN discussion content and progression. "Concurrent code" refers to coding with more than one type of knowledge shown in Table IV.

TABLE IV. EXCERPTS OF GROUP DISCUSSION VERBAL DATA

Line No.	Verbal discourse (Group MN, 3 students)	Code
1	P1: I would kind of like to start with this one. T_L equals 10 plus I_A is $V_A R_A$?	F
2	P2: I_A ? Or V_A over R_A , I_A .	F/P
3	P1: Well, you just confused me. Oh!	F/P
4	P2: Well, is that I_A ? Is that the equation? I'm not sure if that's how it works.	F/P
5	P1: Well, it's $e_a + R I$, so here's R .	F/P
6	P2: Yep.	F/P
7	P1: And I is $-T_{EM}$ over k_T over 5.	F
8	P2: T_{EM} equal k_T ...	F
9	P1: I think if we're at a constant speed then T_L is equal to T_M . I think.	C
10	P2: Sure.	C
11	P1: So, we have the total voltage, --- is the total voltage, which is the voltage across the resistor, plus that thing (e_a), which is .5 Omega. Well, then we just have one variable.	C/P
12	P2: Yeah, we can solve already! Oh wait, no we do because T_{EM} equals 6.	P
13	P1: There it is.	P
14	P2: Awesome. Do you think that's right? I don't see any other way to do it.	P/M
15	P1: Seems reasonable.	M
16	P2: Sure.	M

17	P3: Is that right?	F
18	P1: Yeah.	F
19	P3: Alright.	F
20	P1: 38 divided by .17.	F
---		P
24	P2: Is it .5?	P

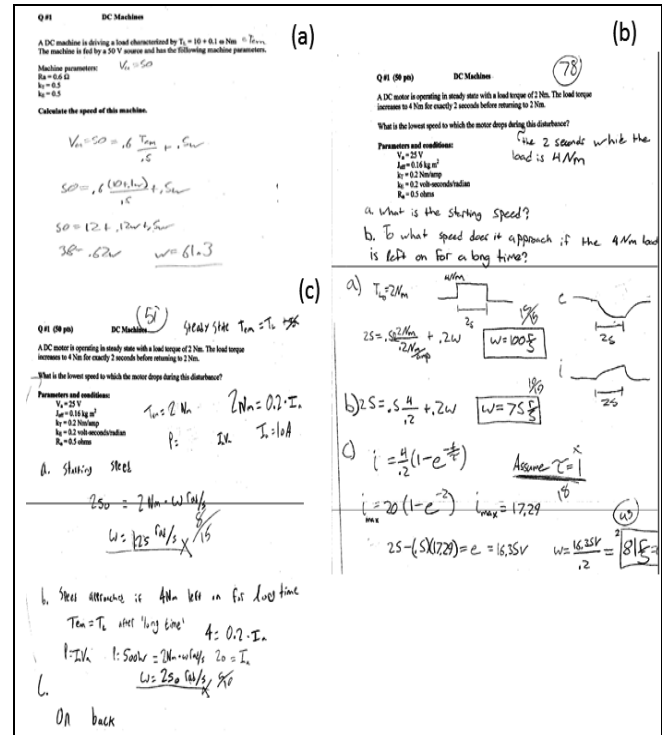

Fig. 7. (a) Group MN written team work for the mock test; (b) Individual work in the midterm by student P1; (c) Individual work of student P2.

Framing	Mn1	Mn2	Notes
Components in foreground	V_a , e_a , T_L , ω , R_a , I_a , T_{EM} , k_T	V_a , R_a , I_a , T_{EM}	
Relationships between components	$V_a = I_a R_a + e_a$; $\omega = \text{constant}$; $T_L = T_{EM}$	None was stated explicitly	Mn2 never stated clearly what I_a was, and only mentioned if $\frac{V_a}{R_a} = I_a$ (?)

Fig. 8. Conceptual framing for Group MN discussions.

V. CONCLUSIONS AND IMPLICATIONS

We introduced two case studies of group discussions and used the adapted concept of framing to analyze students' discourse and written work. The study revealed processes with which students created solutions and provided insights into how students interact in ways that facilitate learning. The study also suggested several factors that hindered productive

group learning. The two main factors that influence productive interactions, indicated by this study, include (i) if an individual and his/hers peers recognize gaps/discrepancies in views toward the subject under study; (ii) if an individual and his/hers peers are able to reconcile the revealed differences in understanding through conceptual framing and reframing. The quality of classroom discourse while solving problems within a small group is critical for effective learning in problem-centered flipped classrooms. Applying the concept of framing allowed us to analyze students' verbal utterances along with other artifacts such as written work, etc. from two dimensions of social interactions and cognitive development. The two dimensions are combined through Discourse analyses, which revealed whether students' interactions support or hinder their learning. We observed characteristics indicating cognitive growth and learning gains for an individual: (1) changes in his/her contribution to discourse practice; (2) changes in his/her ways of defining goals of the task; (3) changes in understanding of the nature of knowledge; and (4) changes in understanding of information structure and organization.

Because knowledge and cognition in general is distributed across members of the group, group talks involve levels of information that is "expected or required for mutual understanding, and for the kinds of questions or challenges that are appropriate" [5]. Variations in an alignment imply that it is significant to provide resources that support students to place their framings, including both positioning and cognition, in line with others.

There are two implications for directing resources to designing and conducting group learning activities in student-centered classrooms such as flipped classrooms. First, it can be useful to support students' positioning themselves in multiple ways during group conversation. Although it is often difficult to anticipate the ways students will engage in conversations that involve turn taking, one resource for encouraging turn taking in group discussions is to formulate a set of sub-goals for students. These sub-goals should be defined in ways leading to an ultimate goal. They should help to highlight misconceptions thus motivate each participant to contribute by rotating roles with others during group discussions. Working on a large overall goal at the front end is sometimes to the disadvantage of student groups who are not able to identify gaps in understanding within the group. In these situations, participants often do not know how to make inquiries or to initiate dialogues, and cannot sense if one or more group members lack understanding. Participants will unsurprisingly place themselves at a fixed position, either as a presenter or a follower, due to a lack of negotiation and opportunity to pause the conversation. It is difficult for participants to improve their contributions to discourse practice unless they improve their understanding. What happened in Group MN illustrated the situation. Two participants, students P1 and P2, seemed to work and solve the problem together. Yet, student P1 never recognized that student P2 lacked a significant level of understanding. Student P2 did not show improved comprehension, and his simple acceptance was merely for communication purposes. For both

students, there was no need or context for negotiation. It is essential that instructors develop pedagogical strategies to help students recognize their misaligned framings in group activities. It is also important that students are provided with time, space, and opportunity to notice misalignments and to negotiate before they establish a common ground.

Second, it is important to support processes by which students come to understand concurrent limitations and reasonable information structures when one and more group members have not developed sufficient strategies such as the application of relevant formulas. Instructors should provide guidelines to help students connect "knowledge pieces" and repair misconceptions during the process. For example, during Group OR discussions, students took turns making inquiries, providing explanations, and critically reviewing their own and others' opinions. The students improved their understanding of content knowledge while negotiating the proposal "the motor is in steady state". Together they created an appropriate equation for the target quantity ω . The problem posed by the instructor provided resources that helped the group and individuals to pay attention to limitations and resources for information organization, i.e. an equation for ω in a steady state. Because the problem did not explicitly state the condition and required students to make assumptions, it did not undercut learning. Instead, it confronted individuals' misconceptions and engaged students in discourse practice. It improved their learning through constructing understanding that was situated in group problem solving and was supported by the domain concept knowledge.

We believe that results from the current study have contributed to general understandings of how students gain conceptual understanding through productive interactions in classrooms. Two factors that influence group problem solving discourse are identified by adapting the concept of positional and conceptual framing. Resources that engage students in group discussions to facilitate learning include instructional interventions, helping students confront misconceptions, and, if needed, providing a set of sub-goals for a designated learning task.

ACKNOWLEDGMENT

Support for data collection from the College of Science and Engineering at the University of Minnesota is acknowledged.

Evaluating Flipped Classrooms with respect to Threshold Concepts Learning in Undergraduate Engineering

Elaine Khoo, Jonathan Scott, Mira Peter, & Howell Round

University of Waikato
Hamilton, New Zealand

Abstract—This paper reports on the initial findings from a two year (2015-2016) investigation of the impact of the flipped classroom on student learning of threshold concepts (TCs) in a large introductory undergraduate engineering course at a New Zealand university. As part of the flipped class intervention trialed over a three-week period, a series of short themed video lectures were developed as a replacement for the traditional weekly lectures. The weekly practical lab session were redesigned to incorporate small-group problem solving tasks and assessment. Data from student surveys, interviews, class observations, and video analytics were collected and analyzed. Findings revealed that students were familiar with online videos as a learning resource; they had positive past experiences with using them and were willing to participate in a flipped classroom. However, most students did not watch all assigned weekly videos, including ones crucial to their TC learning. There is indication they thought learning strategies involving interactions with real persons to be more useful to their learning. This suggests that current strategies for motivating students to access and engage with the prepared videos need to be revised to maximize students' learning opportunities.

Keywords—engineering education; threshold concepts; flipped classrooms; university students; electronics engineering

I. INTRODUCTION

This paper reports on the initial findings of a two-year (2015-2016) longitudinal case study exploring whether and to what extent a flipped classroom model of teaching and learning enhances student learning of hard to master threshold concepts (TCs). TCs are concepts students need to master in order to think like a subject specialist [1] and have been evidenced as an effective theoretical framework in facilitating student learning [2, 3].

The flipped classroom is a variant of student-centred learning where lecture materials are assigned as take-home tasks, typically in the form of online videos [4]. By freeing up class time for instructor-student class contact a flipped class provides more flexibility for instructors and students to partake in discussions, collaborative and guided problem solving

activities to address student misconceptions, and, is claimed to support the mastery of TCs and the development of the skills needed for 21st century graduates [5]. We postulate that a TC-based flipped-class pedagogical approach to teaching and learning can enhance first year students' learning of TC content in an undergraduate engineering course which had a large enrolment and a strong lab component.

II. RESEARCH CONTEXT

The "Introduction to Electronics" course is a core undergraduate engineering paper compulsory for EE and ME students. In 2015 approximately 150 students were enrolled in the course and about 30% of the students were from Software Engineering, Computer Science, Education, and other disciplines. The organizational model for this paper has traditionally consisted of three one-hour long lectures, an hour-long tutorial session, and one three-hour laboratory session each week of the semester. It is expected that all students would attend all lectures. Each student is expected to attend one of 5 parallel laboratory streams which run once a day on each day of the week. The laboratory space is set up for pairs of students to work at one of 18 identical benches, each bench equipped with a PC, oscilloscope, function generator, power supply, soldering iron and DMM (Digital Multimeter).

The Introduction to Electronics class differs from many university classes in its "engineering" style predominance of laboratory learning time. Much of the learning revolves around tacit knowledge and practical skills that are picked up in the lab sessions. Notably the paper differs in having a high level of conceptual difficulty, representing a relatively heavy conceptual load. It is regarded by many students as the most challenging paper of the semester.

Our project team had investigated ways to enhance the pedagogical approach for teaching this course since 2011. In 2011, the course syllabus was rigorously analyzed to identify TCs that it seeks to teach [6, 7, 8] which led to a refinement of the course curriculum and assessment to emphasize student understanding of TCs [9]. In 2013, the face-to-face tutorials were replaced by an online system which was well received by students and credited with an increase in learning [10, 11]. Student achievement data showed that the 2013 student cohort did significantly better than previous cohorts, and students

reported liking the flexibility and accessibility of the e-tutorials. This affirmed the value of incorporating online resources in support of student learning in the course. During these changes the cohort was observed extensively and student performance was carefully benchmarked.

A problem inherent in the lecture-plus-lab model is what we term "the phase problem". Typically, students attend lectures spread throughout the week. All students also attend one (out of five parallel) lab streams during the week. Some students have their lab on Mondays—the last group of students has it on Fridays. This means that the theoretical material is covered in lectures from 3 up to 11 days before a student may put it into practice in a corresponding lab (i.e., Friday group). This delay is undesirable. We realized that this delay could be eliminated if the material presented in lectures was made available through instructional videos. The question that arises is: Would the same flexibility and availability that enhanced e-tutorials be as welcomed and as effective in the case of making the instructional materials available in video format?

Currently in 2015, we are trialing a flipped-classroom model for 3-weeks (Weeks 2 to 4 out of the 12-week semester) by replacing the three 50-minute weekly lectures with a suite of short videos which are accessible from the course Moodle website (Moodle is our university online learning management system). The videos, each between 4 to 13 minutes long were created with careful reference to recommendations from cognitive models shown to be effective in online learning [12] and strongly resembled the style found in Sal Khan's work on khanacademy.org. The videos targeted the teaching of two key TCs in the course (i.e., Thevenin's theorem and dynamic resistance). As these TCs are mostly taught using circuit diagrams and solving equations, the videos allowed the lecturer the flexibility to draw, modify and elaborate on circuit diagrams using a drawing tablet to replicate the way he usually teaches in his face-to-face class. Smoothdraw and Quicktime were used for the video screen capture of the lecturer's explanation and illustrations. There is evidence that interactive online instructional videos can be effective in fostering university student learning [13], including in the Engineering discipline [14, 15] and even in the learning of TCs [16].

Students were expected to watch the assigned videos in preparation for each week's practical activities. We anticipated that the video materials would allow students more flexibility in viewing and reviewing the course material before the lab sessions in which the learning would be put into practice. The three-hour laboratory sessions were extended to four hours to allow for small-group problem solving activities and more personal interaction with the instructor and demonstrators.

III. DATA COLLECTION AND ANALYSIS

In the project, a design-based research approach [17] with practitioner-led cyclical processes of planning, design, and implementation is used to refine the pedagogical tasks. Multiple data are currently collected from: (1) instructor and student interviews, (2) student surveys, (3) class observations, (5) video analytics, (6) student online usage logs, and (7) student achievement data. The research project received formal university-level human research ethics approval. All

participants participated in the project on a strictly voluntary basis.

As data collection is still underway, we will report only on results from the student pre-intervention survey, and, weekly surveys and video analytics of student viewing patterns during the final week of the flipped class (Week 4). Week 4 was selected for analysis because the TC, Thevenin's equivalent circuit theorem, was introduced in this week. Students were expected to watch 11 videos (9 created by the instructor and 2 were from YouTube) related to Thevenin's theorem before attending the lab. Of these videos, we identified and analyzed three that were crucial for student learning of this TC. The pre-intervention survey and Week 4 student evaluation of the intervention quantitative data are analyzed using the SPSS software while qualitative data are coded and categorized to identify emerging themes.

IV. FINDINGS

One hundred and fifteen students completed the pre-intervention survey voluntarily. The survey was distributed during the first week of lectures prior to the flipped class intervention. A majority of the student respondents were 18 years old (64%); most were males (90%); 15% were international students, and 17% were second language speakers of English.

As can be seen in Figure 1, when asked about their preferred ('useful' and 'very useful') learning strategies when learning for formal qualifications, students reported asking the teacher as the most frequent option (95%), followed by watching live demonstrations (93%), referring to the laboratory notes (86%), asking their friends (79%), watching Internet-based videos (76%), learning through trial-and-error (74%), and reading Internet-based text (73%). Reading a textbook was the least favoured strategy (59%). It is noteworthy that students prefer learning strategies in which they can interact with a real/live person be it a teacher, demonstrator or a friend.

Fig. 1. Strategies students considered when learning for formal qualifications (collated 'useful' and 'very useful')

A majority of students (79%) had used online videos as a learning resource and had positive experiences when using them. Another 14% had also used online videos in the past but did not like the experience. This indicates most of the class are

familiar with online videos as a learning resource and had positive experiences with using them.

Most students, 86%, were not familiar with a flipped classroom prior to enrolling in the course, 9% have had some experience with flipped classes, while 3% had only heard about it. Since most students were unaware of the flipped class concept, it was no surprise that when asked if they thought a flipped class could help them learn better in the course, 70% were not sure, 17% thought it would, while another 14% did not think so. However, 93% of students were willing to participate in and experience a flipped class. General themes from the open-ended survey question support this broad trend to reveal students generally lacked prior experience with a flipped class (36 responses), were open to the potential a flipped class could offer to enhance learning (16 responses) but were reluctant to lose the structure that regular lectures offered (8 responses), and, a (mis)assumption about losing the human interaction factor found in traditional lectures (6 responses). Some key illustrative quotes include; ‘I am new and adapting to the new environment, so I have no relative intention on what it takes to learn’, ‘Its (Flipped class) very self-directed. If you put in the work it should be very beneficial’, ‘It kind off becomes me delaying watching the videos till the last minute because I have other assignments to work on’, and, ‘I believe flipped classwork would result in slightly less success due to the lack of commitment to lectures and inability to ask the lecturer questions’.

During the final week of the flipped class (Week 4), 141 students completed a weekly survey on their learning experiences. Less than half of the class (44%) reported watching a few videos assigned for the week, 39% had watched most, 10% had watched all videos, while 7% did not watch any. Overall, 93% of students had watched the assigned videos albeit to different extents.

A majority of students (74%) thought the length of the videos were just right, 24% thought they were too long while only 3% thought they were too short.

As can be seen in Fig. 2, over half of the students did not watch all of the three key videos related to Thevenin theorem (e.g., 61% did not watch ‘Finding Thevenin Equivalent Circuit’, 54% did not watch ‘Thevenin Equivalent Circuit Example’). Interestingly, almost all students (97%) watched the video titled ‘Thevenin Equivalent Circuit and Measuring It’. Remarkably, 41% of students watched this video once, almost 30% watched it twice, and 2% of students viewed it up to eight times compared to the other videos.

Fig. 2. Student viewing patterns of the three key videos for TC learning in Week 4.

The high student regard for this particular video was corroborated by the fact that over half of students (57%) thought this video to be the most engaging for their learning (Fig. 3). Conversely, the other two key videos associated with TC learning (‘Thevenin Car Battery Equivalent Circuit Example’ and ‘Finding Thevenin Equivalent Circuit of a Network’) had less than 40% of the class watching them at least once (Fig. 2) and were rated to be engaging by only 30% and 20% of students respectively (Fig 3).

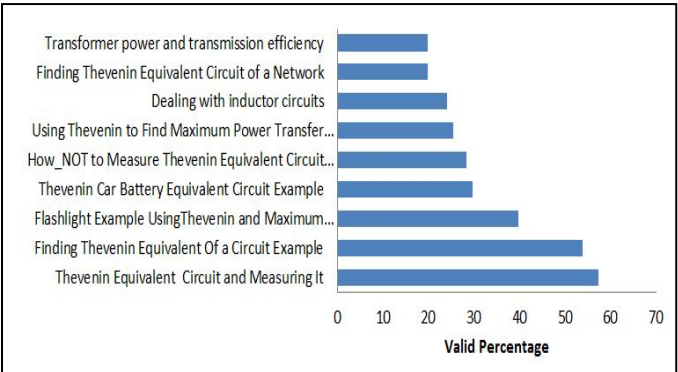

Fig. 3. Videos reported to be most engaging for TC learning in Week 4

Further examining of the characteristics of this "most engaging of the videos" (‘Thevenin Equivalent Circuit and Measuring It’) revealed it importantly contained footage of practical ideas—making measurements in the lab, which was integrated into a lecture of the theoretical concepts. Students probably found the practical demonstration helped to exemplify the conceptual ideas in a manner that was useful and engaging to their learning which the other videos did not.

When asked about the extent they thought the instructor prepared videos had helped them learn about Thevenin's equivalent circuit, 96% of students reported ‘somewhat’ or ‘very much so’, while only 4% thought the videos did not help them learn; this responses included students who did not watch the prescribed videos. This finding suggests that when students watch the videos, almost all of them find them to be helpful to their learning of the TC. Future analysis of the student achievement data may provide further evidence of the effect of (timely) video watching on learning the TC.

V. DISCUSSION AND CONCLUSION

In our study we integrated a TC-based curriculum with a flipped class model of teaching and learning in an engineering course to investigate if and how a TC-inspired flipped class can facilitate student learning. It is novel as no other studies have attempted to integrate a TC-based flipped class approach in engineering education. The results thus far show that students report to prefer learning from a real person (teachers, demonstrators, peers). The video analytics data reveal that students are not fully engaging with the assigned weekly videos. Importantly, when students do watch the videos, they find them to be useful to their learning of the TC.

From past experience, we observed that students generally find learning TCs to be more difficult than non-TCs and we assumed this would still be the case even if the form of course delivery had changed to online videos instead of lectures. The fact that over half of the class did not watch two of the three key videos relevant to TC learning prior to the practical lab session leaves us in doubt as to whether students had understood the TC. This poses a question about when and if students will have a chance to learn the TC. Students' hesitancy/failure to watch the videos (on time), despite their familiarity and past positive experiences with learning from online videos and their being open to the notion of a flipped class, may point to a limitation of a flipped class approach designed for the first semester of a large undergraduate course. We had also foreseen the possible loss of pedagogical responsiveness and group momentum without any scheduled course event that brings the whole class together (such as lectures) as another potential limitation of our intervention. This suggests a need to look into possible revision of current strategies for motivating students to watch the videos and come to the face-to-face class sessions prepared to participate in active learning tasks and ask questions. Another possible way forward is to closely examine the characteristics and content of the instructor prepared videos that students found particularly engaging and useful to their learning to inform our (re)design of future teaching videos.

In conclusion, as universities continue to explore and adopt e-learning platforms including Web 2.0 and mobile applications to provide for more flexible and innovative teaching and learning approaches, our study highlights the need for further investigation into the learner perspective to maximize their learning opportunities and outcomes.

A Letter to the Future Engineer: Exploring cross-cultural engineering identities through practitioners' letters of advice

Héctor E. Rodríguez-Simmonds, Matilde Sánchez-Peña, S. Zahra Atiq, Genisson Silva Coutinho, Brent K. Jesiek
School of Engineering Education
Purdue University
West Lafayette, IN, USA

Abstract— Engineering education researchers have been trying to improve the quality of engineering education. Related to these efforts, it is important to revisit and better understand the definition of engineering education. As part of our PhD coursework, we were required to create a short video depicting our understanding of the definition of engineering education. For this purpose, we created “*a letter to the future engineer*” that presented a holistic view of the challenges and opportunities involved in the professional practice of engineering. To write our letter, we collected real letters of advice from practicing engineers with varying demographic characteristics and experiences. Thematic analysis of the letters uncovered some country-level differences in terms of priorities, perceptions, and the professional life of the contributing engineers. The aim of this work-in-progress paper is to describe our experience of generating this letter of advice and to comment on the patterns we identified during this process. This idea calls for more in-depth studies to reveal the influence of culture and geographic regions on the engineers' perceptions of their profession.

Keywords—*engineering practice; ontology; cross-national; engineering identity; global engineering; letter; advice*

I. INTRODUCTION

This work-in-progress paper came into being as a class project for a graduate-level engineering education course, ENE 502: “History and Philosophy of Engineering Education” [1]. For this project, students were required to depict their understanding of and inquiry into the definition of engineering education in the form of a short video. Some of the guiding questions that shaped both the class in general and this assignment in particular were: “*What is (and should be) engineering?, what is (and should be) the purpose and process of engineering education?, who gets to be an engineer (and who should get to be)?...*” As our project group comprised people from multiple cultures and ethnicities, we decided to portray our vision of this task within a global framework. Rather than focusing on descriptive or normative definitions of engineering education, we preferred to focus on sending a positive message, one full of hope in the future of engineering practice. To make our vision a reality, we decided to create a video for the future generation of engineers which could serve to advise them during their learning process and future

practice. Without ignoring requirements by different national accreditation bodies [2], [3], we opted to capture the messages that current practicing engineers would like to send to their successors. Moreover, to make the content of the video as realistic as possible, we decided to ground the video in the perspectives and experiences of practicing engineers.

In order to make the letter more personal, we asked practicing engineers to write letters to someone who was close to them (a son or a daughter, a niece or a nephew, a younger friend, etc). We asked them to assume that the intended recipient of the letter would be starting their engineering training soon and that this letter would serve as a means to guide them throughout their journey. A variety of prompts were given to the letter writers, the intent of which was to capture the following questions:

1. What advice can an experienced engineer give to an incoming generation of students?
2. What aspects of their training and practice should they pay special attention to?
3. According to their perception, what facets were missing in their own training, which they wished these new generation of engineers to experience?

We collected 21 letters from practicing engineers located in U.S., México, Pakistan, Canada and Brazil. We analyzed these letters to identify themes and topics which were then used to create a unified letter of advice to the future engineers. During this process, we had some interesting and meaningful insights, which motivated us to write this paper. Since this endeavor was initiated as a class project, our motivation was merely exploratory and was not supported by an extensive literature review. Similarly, there was no theoretical framework shaping this work. However, the next sections will discuss the process of letter development and our resulting insights, including some suggestions for future research that can potentially be derived from this preliminary effort.

II. LETTER DEVELOPMENT

The first four authors independently sent an open invitation to their personal network of engineers. This

network consisted of parents, siblings, friends, cousins, colleagues and acquaintances in general. As one of the instructors of this course, Dr. Jesiek provided support and feedback about the original idea and venues of letter collection and analysis.

From the 21 engineers replying to the invitation, only three were women. Respondents ranged in ages broadly, from early 20's to late 70's, implying all levels of experience. They had experience in industry, academia or both. Many of these engineers had international working experiences in addition to working in their home countries. Others were working or conducting graduate studies outside of their home country.

Letter writing as our method of data collection gave the engineers freedom to express their views without any constraints, the intention of which was to ground the letter in realistic, practical, and meaningful experiences.

The thematic analysis of letters resulted in four broad themes that are summarized in Table 1. The columns denote two main phases of engineering life as mentioned by the writers: 1) college experience/training, and 2) professional practice. The rows denote themes corresponding to their academic and personal life. During analysis, we identified some themes that emerged consistently from engineers practicing in the United States and those practicing outside the U.S.

From Table 1, it can be seen that the most common themes across countries were those related to academic college experiences. Letter writers suggested future engineers not get frustrated by courses if they could not make sense of or connect with them initially. They encouraged students to acquire communication, teamwork and critical thinking skills, which they found more useful than pure academic skills. A recurring theme was advice on understanding that engineering training should be focused more on 'learning how to learn' rather than preparation of specific skill areas. In terms of personal life, letter writers from all locations suggested that future engineers should proactively get involved in extracurricular activities.

In the professional realm, engineers based in the U.S. offered more advice in terms of how to get a good job and being prepared for it. Engineers from other countries were focused more on continuous learning and ethical considerations in engineering practice. However, both groups were aware of the variety of possibilities that a future engineer could possibly pursue, e.g., in industry, academia, and research. Some advice provided for the personal life by U.S. engineers was to keep a work-life balance, while non-U.S. engineers suggested a more holistic growth, ego control, and caution against discrimination. The following section will consider the value found in this letter writing process and how this effort is envisioned to generate valuable new inquiries to identify trends in different identities of engineering across countries and cultures.

TABLE I. THEMES IDENTIFIED IN LETTERS WRITTEN BY PRACTICING ENGINEERS

	College Experience/Training	Professional Practice

III. INITIAL INSIGHTS

A. Value of a personal letter

Although Creswell cites the use of letters as a way to collect research data [4], their use is very limited due to logistical issues related to time elapsed between prompts and answers provided using conventional mail. However, technology now makes this process easier. In a few seconds we can reach thousands of people from all over the world through electronic communications [5]. Additionally, the use of letters may allow a deeper understanding of the individuals' perceptions of engineering. Since writing normally involves a deeper, organized, and more purposeful thinking and reflection process, it may reveal deeper thoughts in terms of facts, opinions and ideas [6]. Some of our letter writers reported seeing value in the writing process of the letter; some of them even considered it as a venue to expose hidden feelings towards their experiences, which further supports our argument.

B. Value of a global perspective

Another important aspect of this novel approach is the diversity of our sample. In fact, using letters, we can reach engineers in the most diverse cultures and countries, not only those already engaged in engineering education research, but also those most likely to be affected by cross-cultural aspects of engineering. Lucena et al. conducted rigorous research about the re-organization of engineering education in US, Europe and Latin America [7]. They collected data from different sources such as international conferences, workshops, meetings and interviews with people already engaged in engineering research. In this sense, our work complements this research by bringing information from engineers who are engaged in the day-to-day rigor of the profession, and more likely will reflect the common culture that pervades the engineering profession of a certain country. One of our future goals would be to further analyze how engineering identities reflect the historic and socio-cultural processes that shape them within countries, and also evaluate the impacts of globalization on such identities all over the world.

Our results so far are in consonance with the findings from other studies. Downey and Lucena [8] show us how historical and cultural factors have shaped different engineering identities in France, U.S., Germany and England, defining or influencing values, beliefs and metrics of progress. According to the authors, for U.S. engineers, the metrics of success were associated to the corporate and industrial world. Lucena [9] described the process of construction of engineers' identities in Mexico and revealed that at least part of the engineering community has a great concern with societal issues other than the corporate world.

IV. DISCUSSION AND FUTURE WORK

Even though the insights from this exercise are limited, they prompt a variety of questions that would be interesting to keep exploring such as: 1) By means of the advice given to the future engineers, how can we investigate the engineering

identities in different cultures?, 2) How do cultural differences of practicing engineers influence the advice given to future engineers?, 3) What would be an effective way to deliver a concise yet powerful message to future generations of engineers worldwide?

We see value in the use of letters as our primary source of qualitative data in order to build a cohesive, unified letter. This approach offers a way to portray real feelings and experiences in a more authentic way. The method we used to invite the professionals to write the letters could be improved through the development of a uniform protocol that gives the same prompts to all the potential writers. This uniformity could result in stronger conclusions when comparing letters from different countries and drawing conclusions about their differences regarding the engineering profession in a qualitative way.

The original letters can also be used as a starting point for a potential longitudinal study where the professionals project their thoughts at a point in time, and after some time they can be monitored through this or other venues of data collection to detect their evolution of thinking. Additionally, we can investigate engineering identities within the same country. Other inquiries could involve identifying the level of development of communities of practice of engineers among and across countries. This methodology can be a powerful way of assessing engineering identities over time.

It is envisioned that the effort of building a strong holistic message can open conversations about how different factors interact with the advice experienced engineers want to give to novices. In an educational setting, the letter has the potential to promote awareness of the multifaceted nature of engineering as well as to motivate the persistence and success of those aiming to join the field.

The appendix contains the final letter we composed from those we received, which was finally used in our video. The corresponding video can be accessed from the following URL: <https://www.youtube.com/watch?v=R3XBclouVxI>.

V. APPENDIX: "DEAR FUTURE ENGINEER"

Congratulations on your admission to your engineering program! I am honored by your decision to join the profession I have devoted my life to. Because of my experience, I will offer you some advice for your journey to begin.

First of all, engineering education is composed of all the different aspects that aim to build the knowledge, skills, and attitudes required to execute the possible roles of engineers in a society. It comprises a lifelong process that you may have already started in your experiences during your basic education. This process won't end with obtaining your degree but will keep going as you mature professionally.

As you start this new journey, be aware that you will be challenged. This is not meant to scare you off, but rather to ground you so that you remain motivated and enjoy the experience you are about to embark on. Smile, keep your head up and enjoy the challenges that come your way. Know that

you will be able to resolve those challenges only with conviction and interest. Problem solving in Engineering is not about knowing the solution, it's about having the confidence that there is a solution, and knowing where to start looking for one. Getting good grades is important, but focusing solely on them can take away the joy from the learning experience. Do not become a slave to grades. Learning combined with hard work will result in success.

When you start college, you will take courses you may not consider relevant. Researchers, professors, and even industry members are aware of this, and they are working on making the engineering education experience more meaningful. I would urge you to be patient, see math and science as tools in a holistic problem solving strategy. Keep on growing your toolbox, and be rest assured that you will find all of these tools handy somewhere down your journey.

As you get through the courses involving problem solving and design skills, you will be expected to develop critical thinking skills. Problem solving and designing for others and with others is important in creating meaningful and impactful solutions. In order to make the most of your precious time and effort while solving a problem do not try to "reinvent the wheel", we are standing on the shoulders of giant; take advantage of this.

The importance of good written and verbal communication skills cannot be ignored. You will have opportunities to develop these skills in part through engineering coursework. However, you must strive to take courses outside of your area. These courses will help you broaden your perspective and will help you build intellectual connections required to translate engineering to the outside world.

Teamwork skills are essential to engineering. Find opportunities to practice these skills, be a good team member, and do not shy away from opportunities to work with difficult people. These experiences can cultivate sound professional connections and in some cases long-term friendships.

You will be working in a community of people with diverse backgrounds and cultures. Be aware that engineers are trained differently in different countries. As part of society, engineers should appreciate differences and avoid segregation and discrimination at all levels. Value the contributions of others, regardless of their gender identity, sexual orientations, culture, ethnicity, religion, language, nationality or any other difference. Diversity brings with it tremendous value. Developing these skills will enrich you and help you become a more competent global engineer.

Balance is essential in all stages of your life. While in college make time for yourself and the rigorous demands of school. Carry this trend forward after graduation so you are able to live a happy and healthy professional life.

"Scientists discover the world that exists; engineers create the world that never was." As an engineer you will be responsible for creating this new world in a sustainable way and you must be conscious of social, ethical and moral issues. Avoid unethical decisions as they discourage the ingenuity of

a solution. The value of your contributions will not be measured by money but by the betterment of society.

Your engineering education will teach you a way of thinking - a way of approaching problems. You will need to find ways of connecting course content with real world applications. The skills you acquire along your journey are just as important as the content itself. By virtue of our educational journey, as Engineers we are meant to become life-long learners.

The community of Engineers you will belong to is constantly innovating and developing new technology. You must keep abreast of these newest developments as well as ways to use them by participating in communities of practice.

Again, I would like to conclude by congratulating you on picking such a rich, challenging and fulfilling field. Engineering offers limitless opportunities. Engineering plays a big role in society and on the shoulder of an engineer lays the responsibility and consequences of all their decisions.

Your journey into engineering education is sure to be filled with challenging, rewarding, and enjoyable experiences. These experiences will be what you make of them. Now it's time for you to start thinking about what you will do with your engineering education.

ACKNOWLEDGMENTS

We would like to thank Emma Simmonds who proposed the idea of sending letters to practicing engineers. We would also like to thank the feedback from the other two course instructors, Profs. Alice L. Pawley and Robin S. Adams, on the development of the idea for the video. Thanks also go to all the engineers contributing their letters, and the people participating in the actual recording of the video.

Abstract— A Bachelor of Engineering in Precision Engineering programme at Limerick Institute of Technology (LIT) has been created in a collaborative response to the needs of the industry. This new one year duration add-on programme was developed and implemented in an eight month period. The programme differs from the norm in the nature of its development, the integration of industry requirements and the balance of academic requirements. This unique programme offers a flexible mode of delivery where a key attraction for industry is that student may attend two consecutive days per week and work three days per week. Students choosing this option take two years to complete one academic year while gaining professional experience in a world class manufacturing environment. Students not employed in industry may attend on a full time basis. As a result of this collaboration, industry has committed to provide €100,000 to assist LIT in equipping the programme. This coming together of industry and academia has resulted in forming the greater ambition of creating a National Precision Engineering Centre of Excellence to address the long term goals of Ireland's manufacturing industry to develop a constant stream of competent, technical and practically orientated engineers.

Keywords—*component; precision engineering, industry collaboration, engineering education, training, curriculum development.*

I. INTRODUCTION

Collaboration with industry in the development of curricula is encouraged to ensure excellence and relevance is achieved in third level programmes. The need to develop engineering graduates that are ready for employment upon graduation is a key focus for industry. However, balancing the educational and training needs of students and the specific requirements for employers creates a need for the development of trust and understanding between academia and industry. A shortage of skilled, educated engineers in the precision manufacturing sector in Ireland was identified by the Precision Turned parts Manufacturing Association (PTMA) and an expert industry focus group brought together by the Department of Jobs, Enterprise and Innovation in response to a report from Forfás. Forfás is Ireland's policy advisory board for enterprise, trade, science, technology and innovation. A serious deficit in the

availability of human resources in the precision manufacturing sector and the potential to meet current demand and the future expansion of business in Ireland was highlighted as a serious problem. Limerick Institute of Technology (LIT) was selected by the Industry focus group and the PTMA as a possible partner to collaborate with in the development of a new Precision Engineering programme in Ireland.

II. ECONOMIC BACKGROUND

Ireland as a small open economy on the west of Europe depends greatly upon the ability to satisfy an international market with products, systems and services that are in demand. As a country emerging from an economic crises, with a relatively high but decreasing unemployment rate, it is essential for the future development of the economy that existing areas of excellence and new areas to be explored to remove the past reliance on one major economic sector.

Manufacturing plays a crucial part in the Irish economy and is a driver of innovation and technical advances with a broad range of employment and skill levels. Associated with these activities are a range of additional indirectly related jobs in the economy [1]. In 2012 manufacturing contributed significantly to Ireland's exports at €78.5 billion [2]. In Ireland, manufacturing can be divided into two main categories; Irish owned manufacturing and service companies which in 2012 were responsible for €27.59 billion in sales and secondly, foreign-owned agency assisted manufacturing companies were responsible for €68 billion in sales. Within the export sector, traditional manufacturing represented €5.3 billion in sales from foreign owned agency assisted operations, yet €5.7 billion was also achieved from Irish-owned agency clients.

One of the major concerns of the manufacturing sector was the need for a detailed assessment of the skills required industry up to 2020. This need was articulated in the 2012 Government "Action Plan for Jobs in 2012". This report highlighted that manufacturing accounts for less than 10% of total employment but it accounts for over 30% of GDP and remains a fundamental 'engine' of the Irish economy [3]. The challenges for manufacturing in Ireland are, for example reducing costs and moving to sophisticated knowledge based systems with

economies of scale in a globally competitive market. The need for upskilling across the manufacturing sector so that workers are proficient in the most up to date tools, technologies and systems within their specific sector is a clear requirement. A further need to develop the capacity of indigenous and multinational manufacturers for research and innovation from publically funded research in universities and colleges is also stated.

III. INDUSTRY DEMAND

Enterprise Ireland (EI) was tasked with determining the needs of the indigenous Irish manufacturing sector. In June 2013, an EI Manufacturing Focus group met to determine the challenges facing the industry. The key challenge facing industry identified by this grouping was a lack of qualified, competent and skilled personnel to drive business forward. An unpublished report [4] identified the need to collaborate with a third level partner to develop a programme to meet the specific needs of the precision manufacturing sector in Ireland. A parallel discussion within the PTMA had also been ongoing. Both the PTMA and EI focus groups share common membership and this led to discussions around the development of a degree programme in Precision Engineering. LIT was identified as producing quality graduates that are close to meeting the requirements of industry due to the fusion of theory and practice through applied active learning that LIT promotes [5]. Both groupings expressed their interest in developing a programme with emphasis on the mid-west of Ireland region and specifically LIT as a centre of excellence in precision engineering

The EI Manufacturing Focus grouping had access to an out of date version of the Bachelor of Engineering Mechanical Level 7 Degree Programme in LIT. This formed the basis for the development of a new programme by highlighting the following:

- Areas that are relevant and should be retained.
- Areas that are not relevant and should be replaced by new content.
- Content that should be included in a new programme

IV. COLLABORATION WITH LIT

Collaboration between the PTMA, the EI Manufacturing Focus group and LIT was initiated through a series of meetings to establish common ground. It was evident through these discussions that the industry understanding of qualifications levels was very poor. For example, Quality and Qualifications Ireland (QQI) has 10 levels on the National Framework of Qualification (NFQ) [6] with overlapping levels at Level 6 as shown in Figure 1. Level 6 to Level 10 are regarded as higher or third level education. The structure of the NQF in Ireland needed explanation to the industry representatives to ensure a clear understanding and direction on the level of qualification that was required. Apprenticeship and Higher certificates share level 6 but with differing levels of Mathematics and Science being one major differentiating factor.

Clarification of the difference between training and education was also required. In the Irish context Garavan [7] utilises the definition of training as a practical education in a profession, art or craft.

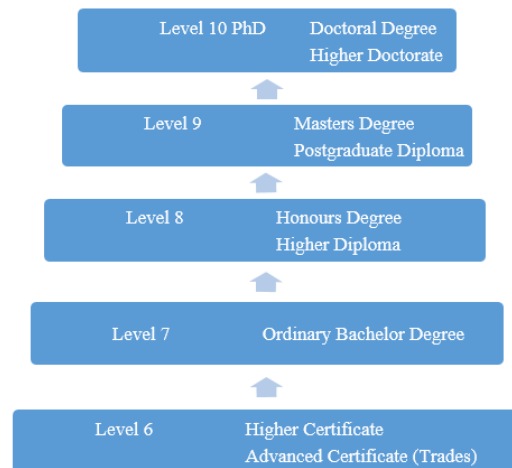

Figure 1 National Framework of Qualifications Ireland [6]

Garavan regards training as a planned and systematic effort to modify through learning experiences to achieve effective performance. In human resource development education is regarded as teaching general skills and knowledge for the sake of field or discipline rather than having a specific job focus. This difference between training and education is an area of continuing discussion with industry. A long discussion and exchange of knowledge/views relating to the current programme provision and the needs of industry to meet a skills shortage/education gap and how this could be accommodated was held [8]. The outcomes of this discussion were that;

- A Level 6 and 7 programme with shared/common modules with the mechanical engineering be developed
- The level 7 programme would be populated by students selected by industry as programme partners and the modules would be delivered on-site in LIT.
- A level 7 add-on programme where students could work for three days per week in the sponsoring company and attend college two days per week.
 - This would allow a student to complete a level 7 one year add-on Ordinary degree over two years.
- A part-time work-learn model mode of delivery was viewed favourably by industry as a where engineers are graduating with real experience.
- Entry to the level 6 or 7 programme could be from any relevant third level programme subject to the programme prerequisites being met.
- A student may have to take qualifying modules to gain entry if they have not met prerequisites.
- Industry to directly support this programme for the first five years in a variety of ways i.e. sponsoring students travel and subsistence, seeking tax breaks for students.
- Electives could be offered where there is a need from a particular sector in engineering .

- Equipping the programme could be achieved by working with suppliers and perhaps the sponsoring of equipment.
- Infrastructure and capital equipment will be required to meet the shortfall in equipment/resources available.

As part of this process a request was made to industry by LIT for evidence of demand for the programme. Over 40 letters of support from industry were received thereby reinforcing to LIT management that the base of support that would lead to student registrations on the programme.

V. ACADEMIC PROGRAMME DEVELOPMENT

In October 2013 a collaborative process was set in motion between the Industry representatives and LIT as the educational provider. The need for a rapid response to the requirements of industry was clearly stated and this led to the unusual step of developing a one year duration Level 7 add-on degree programme first. Putting in place the third year of a degree programme before the first two years are in place appears to counter intuitive but the need to convert existing trade staff, technicians or degree students as specialist engineers in the precision sector to address the needs expressed in government policy was a key deciding factor. A time frame of eight months was deemed achievable for this response. A level 6 programme of two years duration would be added in the 2015/16 academic year with wider consultation on content. A level 8 Programme to follow in the 2016/17 academic year.

In November 2013 an Industry/Academic brainstorming session was held to determine the curriculum content of the one year duration Level 7 Add-on programme. A clear direction emerged from the discussions and preferred content was listed under various headings. The brainstorming meetings followed this process firstly by determining the type of role that the graduate would grow into, the second step was to determine the types of activities undertaken in industry and thirdly the skills and knowledge deficits identified need to address the shortcomings.

The danger of this approach is similar to that of a teacher-centred approach highlighted by Kennedy [9] where teachers decide on content of a programme, plans how to teach this content and then assesses the content. In this case, the concern was the creation of a narrow outcomes-based industry centred programme, with industry deciding the content, and deciding how the content was to be taught and assessed. A balanced programme is needed to ensure the students achieve verifiable learning at the end of a programme or module to an appropriate educational standard. The outcomes-based approach needed in third level programmes must also incorporate a variety of outcomes including the higher level skill, knowledge and understanding outlined by Gosling and Moon [10] and in this case to address more than just a skills shortage.

In December 2013 Academic staff in LIT then undertook address these issues by differentiating, organising and developing the industry led content into programme learning outcomes (PLOs) and coherent modules. Under the European Credit Transfer and Accumulation System (ECTS) Learning Outcomes (LOs) are defined as statements of what the individual knows, understands and is able to do on completion of a learning

process [11]. Balancing industry requirements against this was crucial, Gosling and Moon present an ideal sequence for module development but acknowledge that although it is rarely followed, it does provide a basis for a quality assurance process. The main components of this are:

- level descriptors
- learning outcomes
- assessment criteria
- assessment procedures
- teaching strategies.

The programme development followed the frameworks and regulations required by LIT's Academic Council Regulations and Procedures for Taught Programmes [12] which generally follows this ideal process. In reality programme development, while controlled by frameworks, is a much more dynamic process. The need to develop students beyond the short terms skills deficit urgently required by industry and the longer term need for knowledgeable intelligent engineers is the responsibility of the academic staff. It was agreed to meet industry in January 2014 to present the PLO's, the modular structure and content to industry for consideration.

During the period between the industry meetings, an evaluation of the balance between training needs of the employers and the education needs of the students was undertaken Using the experience and knowledge acquired from industry, a process similar to the three-circle method used by Harden et al. [13]. The focus being to determine the:

1. Role the engineer is expected undertake.
2. Tasks to be achieved by the engineer
3. Attributes of the individual being trained/educated and registered on the programme.

The programme was subjected to an internal review and an external review before being approved in June 2014 and the first cohort of students were enrolled in September 2014.

VI. PROGRAMME STRUCTURE

The outcome of the collaborative process led to a clear direction for the academic development of the programme. This led to the development PLOs utilising the QQI Awards Standards for Engineering [14] and from these outcomes a set of modules were developed.

Three modules currently offered in LIT's Level 7 Mechanical Engineering programme are included in this programme. These modules form a broader base to the learner's education giving a strong academic aspect to the programme. The existing modules to be utilised are:

- Mechanics and Materials,
- Mathematics and Statistics
- Project

Three new modules were developed to respond to the need for high level graduates that are not currently available. These modules enable graduates to work safely with mechanical, electrical, control and automation systems with a special

emphasis on manufacturing with CNC equipment. These new modules are;

- Metrology and Statistical Process Control
- Advanced CAD/CAM
- Advanced Engineering Technology and Process Planning

Figure 2 was created to illustrate to industry the structure and focus of the programmes. A project based module was not listed in this graphic as it is expected that the students will utilise elements from each module as part of the project based work.

Figure 2: Programme focus and content.

VII. PROGRAMME IMPLEMENTATION

The programme was created as one year add-on Level 7 programme on a full time basis. This is equivalent to the third year of a four year ab-initio degree programme with an exit award. Access to the programme is available to those with a minimum NFQ Level 6 award at Technician level in a related cognate area or those with a trade qualification who have also improved their mathematical and science qualifications sufficiently to move to Level 7.

As a result of the rapid programme development it was not possible to have the all resources, including staffing, in place to deliver all six modules for the September 2014 deadline. It was decided to offer the programme on a part-time basis initially with three modules being offered utilising existing resources and the purchase of additional equipment. In the 2014-15 academic year the following were offered;

- Mechanics and Materials,
- Mathematics and Statistics
- Metrology and Statistical Process Control

From September 2015, all six modules will be on offer allowing both part-time and full time students to register on the programme.

- Advanced CAD/CAM
- Advanced Engineering Technology and Process Planning
- Project

As the programme was offered part-time, a small cohort of eight students from industry were registered thereby allowing the programme to become established and credibility gained with industry. All of the students are working in industry three days per week and attending LIT on two consecutive days per week.

A Level 6 programme has now been developed that will provide graduates to industry not currently available. The development of a Level 6 Higher certificate programme would normally precede a Level 7 programme but in this case the need from industry required the opposite approach be taken. A Level 8 Honours degree programme will be added in 2016 as shown in Figure 3.

Figure 3 Academic Progression Ladder

VIII. INDUSTRY SUPPORT AND SUPPORT TO INDUSTRY

In response to the development of the programme four companies were approached to make a charitable donation to help fund the programme. Approximately €100,000 over a five year period has been pledged to LIT to support the development of the programme. Equipment suppliers from industry have also committed to supply equipment to the programme. As a result of this unique level of collaborative engagement, LIT are in the process of developing a Precision Engineering Hub with the aim of become the National Centre of Excellence in Precision Engineering and Manufacturing Technology.

IX. CONCLUSIONS:

The development of a Precision Engineering programme at LIT has been created by a unique Industry-Academic collaboration and an innovative response to the needs of industry. The PTMA, EI Manufacturing Focus group, LIT academic staff and management successfully implemented a common approach to programme development. This approach proved successful, even though a little unusual, by creating one Year Level 7 add-on programme before a Level 6 programme and Level 8 had been created. The rapid and successful development of the programme could only occur where a clear meeting of minds had occurred and a balanced approach to the immediate training needs of industry against the long term desire to educate engineers to drive the industry was achieved. The work-learn model where a student may attend LIT two days per week on a part-time basis while working at the same time has also proved innovative in an Irish context. The financial investment by industry into the programme has also been a new development and is also seen as a key factor in the proposed development of a new dedicated Precision Engineering Centre of Excellence at LIT. The plans for this new facility are evolving rapidly with a predicted opening date for September 2016.

Localized Open Source Collaboration in Software Engineering Education

Kevin Buffardi

Computer Science
California State University—Chico
Chico, California, USA
kbuffardi@csuchico.edu

Abstract—Involving computer science students in open source software projects provides opportunities for them to contribute to real products with more authentic scope than typical computer science assignments. However, the environment of collaborating with external, distributed teams also poses unique challenges and may distance students from the potential for valuable, direct contact and mentorship from software professionals.
