Conference at a Glance

Wednesday, October 21

11:00 AM - 8:00 PM	Registration Open
1:00 PM - 4:00 PM	Workshop Session 1
5:00 PM - 9:00 PM	Workshop Session 2

Thursday, October 22

8:00 AM - 6:00 PM	Registration Open
8:00 AM - 9:00 AM	Focus on New Attendees Breakfast (<i>included in conference registration</i>)
9:00 AM - 10:30 AM	Plenary Session
10:30 AM - 6:00 PM	Exhibit Hall Open
10:30 AM - 11:00 AM	Exhibit Hall Break
11:00 AM - 12:30 PM	Technical Sessions (T1)
12:45 PM - 2:15 PM	HP Terman and Rigas Awards Lunch (<i>included in conference registration</i>)
2:30 PM - 4:00 PM	Technical Sessions (T2)
4:00 PM - 4:30 PM	Exhibit Hall Break
4:30 PM - 6:00 PM	Technical Session (T3)
7:00 PM - 10:00 PM	Reception (<i>included in conference registration</i>)

Friday, October 23

8:00 AM - 6:00 PM	Registration Open
8:00 AM - 9:00 AM	Breakfast (<i>included in conference registration</i>)
9:00 AM - 10:30 AM	Technical Sessions (F1)
10:00 AM - 5:30 PM	Exhibit Hall Open
10:30 AM - 11:00 AM	Exhibit Hall Break
11:00 AM - 12:30 PM	Technical Sessions (F2)
12:45 PM - 2:15 PM	Lunch (<i>included in conference registration</i>)
2:30 PM - 4:00 PM	Technical Sessions (F3)
4:00 PM - 5:00 PM	Focus on Exhibits and New Faculty Fellows
5:00 PM - 6:30 PM	Technical Sessions (F4)
7:30 PM - 10:00 PM	Reception and Awards Banquet (<i>additional ticket required</i>)

Saturday, October 24

8:00 AM - 5:00 PM	Registration Open
8:00 AM - 9:00 AM	Breakfast (<i>included in conference registration</i>)
9:00 AM - 10:30 AM	Technical Sessions (S1)
10:30 AM - 11:00 AM	Break
11:00 AM - 12:30 PM	Technical Sessions (S2)
12:45 PM - 2:15 PM	Lunch (<i>included in conference registration</i>)
2:30 PM - 4:00 PM	Technical Sessions (S3)
4:00 PM - 4:30 PM	Break
4:30 PM - 6:00 PM	Technical Sessions (S4)

Welcome from the General Chair

2015 is the year of the 45th Annual Frontiers in Education (FIE) Conference. It is good to see that we have been doing this conference for 45 years already and I am personally grateful to be a part of it. As always I am privileged to have the help of the sponsoring entities: the IEEE Education Society, the IEEE Computer Society, and the ASEE Educational Research and Methods Division, through the FIE Steering Committee. Beyond that, I am blessed to have the input from my home institution New Mexico State University and our neighbor, the University of Texas at El Paso.

During your visit here, you can enjoy the warm autumn weather of the Southwest United States as well as the newly renovated downtown area of El Paso Texas.

Our theme this year is “Launching a New Vision in Engineering Education”. This fits well with the latest addition to the southern New Mexico businesses, the brand new Spaceport America, as well as other space related facilities such as the National Radio Astronomy Observatory Very Large Array Telescope and the Apache Peak Observatory, home of the Sloan Digital Sky Survey. It would be my honor to schedule tours of any of these facilities and you can contact me directly to do so. However, you need to be ready for long travel times since the closest of these is two hours from the conference center.

Once again this year we have more than 500 speakers and many pre-conference workshops. These continue a long tradition of some of the best educational innovations and research in engineering and computing. We are thankful to these speakers and to the co-chairs of the Program Committee who have selected and organized the papers submitted: Senay Purzer, ASEE Program Co-Chair; Mani Mina, IEEE Education Society Program Co-Chair; Ari Korhonen, IEEE Computer Society Program Co-Chair; Holly Matusovich, Special Session & Workshop Chair; and James Huff, New Faculty Fellows Chair. I also thank the FIE Steering Committee who guided me through the preparation with much needed professional advice and encouragement.

Finally, I cannot be grateful enough for the logistic support of Assistant to the General Chairs, Kevin Curry, and to Conference Catalysts, for their work on the computer applications and the web site.

Special thanks to our sponsors - New Mexico State University and the University of Texas at El Paso; as well as our other sponsors: Hewlett Packard, VentureWell, and the Markkula Center for Applied Ethics.

I hope you enjoy your stay in the home of cowboys, Native Americans, and Mexican culture, and I look forward to meeting each and every one of you.

Conference General Chair

Michael DeAntonio, NMSU, Las Cruces, New Mexico

Welcome from the Program Co-Chairs

Dear Colleagues,

It gives us great pleasure to welcome you to El Paso, Texas, and the 2015 Frontiers in Education Conference.

As conference programme co-chairs we have had the stimulating challenge of managing the reviewing, selection, and scheduling of submissions for what promises to be a truly outstanding conference. This year we received over 700 submissions, from which we have selected approximately 400 for presentation in different formats. The result is a research and innovation packed programme that commences with a day of pre-conference workshops on Wednesday, followed by three full days of presentations, special sessions, panels, and last, but not least, many opportunities over breakfast, lunch and dinner events to meet new friends, renew old acquaintanceships and engage in inspiring debate and discussion.

We have spent a most exciting six months preparing the technical programme. We hope that you enjoy the fruits of our labour, and find the conference as stimulating and interesting to attend, as we have found the process of putting it all together.

Welcome to FIE 2015 in El Paso!

Senay Purzer
ASEE ERM

Mani Mina
IEEE Education Society

Ari Korhonen
IEEE Computer Society

Message from the FIE Steering Committee Chair

Welcome! And ¡Bienvenidos a El Paso!

The organizers of the 45th annual Frontiers in Education conference are pleased to offer you this opportunity to network and engage in engineering education research that is on the frontier. The FIE Steering Committee welcomes you to El Paso, TX after our successful time in Madrid last year.

If you are like me, you come to FIE to see old friends and find new ideas. I hope you come away from this conference with a renewed sense of commitment to the improvement engineering education and that you have expanded your network of colleagues. For those of you that are “regulars”, I hope you will share your sense of community with those that are new to FIE.

The Steering Committee continues to iterate on ways to improve the conference. This year will be our second time going with a paperless conference. We believe using our resources this way is responsible and keeps us on the frontier. We are also investigating ways to improve the experience of both authors and reviewers in our peer review process within EDAS. Lastly, we are improving the documentation of our processes, so that new FIE volunteers will have a better understanding of their roles. Please continue to provide feedback so we can iterate more effectively.

Below is the list of all current members on the FIE Steering Committee. You can find us at the conference as we will be wearing Steering Committee ribbons on our conference badges. We represent you and your needs for this conference. Please let us know how to improve FIE.

ASCE Educational Research and Methods Division Representatives

- Beth Eschenbach (Chair), Humboldt State University, beth@humboldt.edu
- Archie Holmes, University of Virginia, ah7sj@virginia.edu
- James Morgan, Charles Stuart University, jmorgan@csu.edu.au

IEEE Computer Society Representatives

- Stephen Frezza, Gannon University, FREZZA001@gannon.edu
- Arnold Pears, Uppsala University, Arnold.Pears@it.uu.se
- Deborah Trytten, University of Oklahoma, dtrytten@ou.edu

IEEE Education Society Representatives

- Russ Meier, Milwaukee School of Engineering, meier@msoe.edu
- James Sluss, University of Oklahoma, sluss@ou.edu
- Edmundo Tovar, Universidad Politécnica de Madrid, etovar@fi.upm.es

Next year's conference will be in Erie, Pennsylvania. We will try a new idea where we will have a co-located Saturday conference for K-12 STEM educators. Please invite your K-12 colleagues!

I hope you have a great conference!

Beth Eschenbach, PhD.

Future FIE Conferences

FIE 2016 Erie, Pennsylvania

FIE 2017 Indianapolis, Indiana

Are you interested in hosting a future FIE conference?
Leave your business card at the registration desk, and an
FIE steering committee member will contact you.

Sponsors

Society Sponsors

The **45th Annual Frontiers in Education Conference** is sponsored by the IEEE Education Society, the IEEE Computer Society, and the ASEE Educational Research and Methods Division.

Academic Host Institutions

A comprehensive land-grant institution of higher learning, **New Mexico State University** is dedicated to teaching, research, and service at the undergraduate and graduate levels. NMSU is a NASA Space Grant College, a Hispanic-serving institution and is home to the very first Honors College in New Mexico. U.S. News and World Report ranks NMSU in the top tier among Best National Universities.

The University of Texas at El Paso (UTEP) was founded in 1914 as the State School of Mines and Metallurgy. Today, UTEP is comprised of seven colleges and offers 71 bachelor's programs, 76 master's programs, 20 doctoral programs and 25 certificate programs. With a student population that exceeds 23,000 and a research portfolio that boasts more than \$83 million in spending, UTEP is on track to become the first national public research university to truly serve the 21st-century student demographic.

Diamond Sponsor

Hewlett-Packard sponsors the ASEE Frederick Emmons Terman Award and the IEEE Harriet B. Rigas Award as well as the luncheon where the awards will be presented.

Sponsors (Continued)

Silver Sponsor

VentureWell sponsors the plenary session the morning of Thursday, October 22, and a complimentary workshop which will focus on stimulating science and technology invention, innovation and entrepreneurship on university and college campuses.

Conference App Sponsor

Markkula Center for Applied Ethics, producer of "**An Introduction to Software Engineering Ethics**" by Shannon Vallor, Associate Professor of Philosophy, Santa Clara University with special contributor Arvind Narayanan, Assistant Professor of Computer Science, Princeton University. This ethics module includes a reading, homework assignments, case studies, and classroom exercises, all designed to spark a conversation about ethical issues that students will face in their lives as software engineers.

FIE 2015 Exhibitors

Exhibit Hall Hours

The exhibits will be open in the Mezzanine Level by the Bathroom from 9:30 AM to 5:00 PM Thursday and from 9:00 AM to 4:30 PM Friday.

Exhibitor Showcase Presentations

Again this year, FIE offers Exhibitor Showcases, which provide our exhibitors a longer block of time for demonstrations or presentations. Additional information about the content of each showcase is in the conference app. Please join us for one of these informative sessions.

Thursday, October 22

11:00 AM - 12:30 PM	Cengage Learning	Juarez B
2:30 PM - 6:00 PM	ARM	Juarez B

Friday, October 23

9:00 AM - 10:30 AM	SAS Institutes, Inc.	Juarez B
11:00 AM - 12:30 PM	IonIdea Inc.	Juarez B
2:30 PM - 4:00 PM	MathWorks	Juarez B
5:00 PM - 6:30 PM	ZyBooks	Juarez B

Special National Science Foundation Presentation

On Thursday, October 22, from 4:30 PM to 6:00 PM in the ballroom, the NSF will hold a special session to discuss funding opportunities to cover ENG/EEC and EHR/DUE programs. Additional information about this presentation is in the conference app.

Meetings at FIE

Wednesday, October 21

5:00 PM -6:30 PM	FIE Steering Committee	Boardroom
------------------	------------------------	-----------

Saturday, October 24

8:00 AM - 10:00 AM	FIE Steering Committee	Boardroom
--------------------	------------------------	-----------

1:00 PM - 3:00 PM	FIE 2015 Planning Committee	Boardroom
-------------------	-----------------------------	-----------

Workshops

Workshop 1A

Wednesday, October 21 1:00 PM - 4:00 PM

Integrating Service-Learning into Engineering and Computing Education

Service learning is a rapidly growing pedagogy in higher education and within engineering, technology and computing. Service-learning provides a learning environment that is very well-matched with ABET. Students can learn strong technical skills while developing teamwork, communication and leaderships skills. The community and human context of service-learning provides rich learning experiences for contemporary social, global and ethical issues. Service-learning also provides the kind of curricular efficiency necessary to meet the attributes called for in the National Academy's Engineer of 2020. Evidence suggests that service-learning also has the potential to increase participation among underrepresented populations within engineering, technology and computing. This interactive workshop will provide an introduction to service-learning and allow participants to explore how it could be integrated into their own courses and curricula. Resources, partnerships and potential barriers will be discussed to provide strategies for successful implementation at the participants' own institutions.

Workshop 1B

Wednesday, October 21 1:00 PM - 4:00 PM

Teaching and Assessment Strategies that Value Innovative Thinking

An increasing number of studies point to the issue that engineering students tend to lose their creative edge during their undergraduate education. In our prior studies, we identified three barriers to innovation experienced by students: an overwhelming technical identity that values technical problem solving over creativity, a view of innovativeness as an attribute that is attainable to just few privileged or masterminds, and instructional constraints that demotivate students from taking risks by exploring novel solutions.

This workshop will focus on teaching and assessing in engineering courses so that students see the essential role of innovative thinking for engineers. Examples of student work will be used to illustrate assessment practices that value creativity and innovative problem solving. The participants will develop rubrics to be used in own courses or design projects.

Workshops (Continued)

Workshop 1C

Wednesday, October 21 1:00 PM - 4:00 PM

Process to Draft the Program Educational Objectives for Undergraduate Engineering Degree Programs

This workshop will engage the participants in the process to draft Program Educational Objectives (PEOs) appropriate for undergraduate engineering degree programs at ABET-accredited institutions of higher education. ABET stipulates in its Self-Study Questionnaire under Criterion 2, Category E that there should be a process in place to periodically review and revise PEOs.

PEOs must reflect the Mission Statement of the institution and serve as a yardstick of student achievement three to five years following graduation. The objectives represent the expectations of the department from its graduates and must be crafted such that measurable objective evidence can be obtained through alumni surveys. To be consistent and effective, the entire engineering department must contribute to the discussion, ratification, and eventual adoption of the PEOs. Active participation by the faculty in defining the PEOs yield clear and concise objectives and promotes ownership of the goals of the Department and ABET process. However, not all faculty members are necessarily familiar with the assessment language and the process to evaluate the PEOs. In order to ensure a meaningful contribution from all faculty members involved in defining the PEOs, this workshop presents a framework that facilitates the discussion and the steps taken to define the PEOs that are (1) adhering to the Mission of the University (2) achieving consistent and measurable expectations.

Workshop 1D

Wednesday, October 21 1:00 PM - 4:00 PM

Agile Way of Educating

The goal of this workshop is to help participants explore how Agile development, a management technique borne out of the software industry, can not only change the way that students engage in project-based and team-based course projects, but the Agile mindset can also transform the way that we educate our students. The Agile Way of Working (or Agile) is a collection of principles and practices that supports rapid and flexible response to change. It does this by promoting communication, collaboration, continuous improvement, and reflection within teams of problem solvers. The approach also fosters self-managed teams. Agile accomplishes this by embracing changing requirements, delivering products frequently, using human-centric methods, and engaging the customer in regular collaboration. Agile puts heavy emphasis on articulating goals, facilitating interactions, improving team dynamics, supporting collaboration, and encouraging experimentation and innovation.

There is an increase in interest in how Agile can be applied in higher education settings - both as a topic of study for project management (i.e., Agile Way of Working) and as a pedagogical mindset (i.e., Agile Way of Educating). In this workshop we will: Provide a tutorial overview of Agile; present examples of how Agile has been used for project management for course projects; present examples of how Agile practices has been applied as a pedagogical approach to derive benefit in the areas of encouraging students to take responsibility for their learning (self-managed learning), continuous improvement through reflection, alternative approaches for evaluation, and increased engagement by learners; and engage in activities that demonstrate Agile in practice in order to provide attendees with ideas for applying Agile. Participants will come away with ideas for applying Agile in their courses and resources for a deeper dive into Agile. Participants will also leave the session with resources that will allow them to perform a deeper dive into Agile.

Workshops (Continued)

Workshop 2A

Wednesday, October 21 5:00 PM - 9:00 PM

Encouraging Information Rich Engineering Design

Students frequently spend too little time understanding the problem in their design projects and jump to solutions without considering alternatives. This leads to inefficient use of time and suboptimal results in the final design. Instead of re-inventing the wheel, students need to explore and understand the work of others applied to similar situations, using strong information gathering, application, and evaluation skills. Ultimately, these reinforce core skills needed for students to be lifelong learners, i.e., determining where they have gaps in knowledge and determining how to fill those gaps efficiently and effectively. This workshop will provide a conceptual model and examples of activities that will help instructors keep students problem-focused, allowing them to generate and weigh alternatives, and ultimately settle on a solution that is most promising to meet their stakeholders' needs. Participants will take away techniques they can apply to their own engineering design courses.

Participants will learn how to determine the needs of stakeholders, better understand the context of the design problem, and make sure they meet professional standards and legal requirements for their designs. In addition to their own brainstorming, they investigate the prior art of others to enlarge the solution space they explore. Evaluating and synthesizing information gathered or generated themselves, they determine the most promising of their proposed solutions.

Workshop 2C

Wednesday, October 21 5:00 PM - 9:00 PM

Agile Teaching and Learning

Educators are converting traditional and project-base courses to agile in response, but this is a daunting task with few structured teaching resources methods available to reduce the burden on the educator. This workshop will present a comprehensive approach to teaching Agile methods that is itself agile, employing a highly iterative, continuous feedback-driven process. This workshop will convey instructional resources to participants, and provide the scaffolding to conduct an agile project course. Participants will receive materials including Eclipse-based open source labs, project scripts, and pedagogical scripts to adapt to their classrooms. Pedagogical and assessment strategies will be shared, and the presenter will facilitate a best practices interactive discussion to draw out lessons learned from workshop participants. The workshop agenda will include strategies and instructions for setting up Scrum, and supporting XP developer practices including Continuous Integration and Testing using Jenkins, Source Code Control using Git, unit testing, static analysis, and more. The workshop will also encourage interaction amongst participants to share best practices and lessons learned. Research directions related to the application of agile principles to teaching and learning will be discussed. Post-workshop support will be provided through a website hosted by the presenter.

A custom Eclipse install with requisite tools will be available for installation during the workshop via USB stick and the Web. The presenter will record and coalesce information gathered from collaborative sessions on the agenda and make the record available to participants on his university website. Instructions for server-based installations and trial accounts will be distributed to participants. **Laptop Required. Tablets will be of only limited utility.**

Workshops (Continued)

Workshop 2D

Wednesday, October 21 5:00 PM - 9:00 PM

How to Select an Area of Scholarship and Address the Applicable Review Criteria to Publish a Paper in the IEEE Transactions on Education

Engineering education publications are expected to make substantive contributions to the field, but there is a need to clarify expectations of substantive contributions across the global community of scholars in this field. For the purposes of the review criteria, contributions will be defined as clear statements of how work described in the manuscript is expected to influence future directions of the field. Many different types of contributions are possible. Review criteria need to be specific to broad areas of potential contributions. Review criteria for the IEEE Transactions on Education are organized based on the three categories of scholarship described by Boyer: discovery, application, and integration. Workshop participants should expect to learn more about the three areas of scholarship and be able to select the area most appropriate for their manuscript.

Plenary Session

Thursday, October 22, 9:00 AM - 10:30 AM

Ballroom

Plenary session sponsored by VentureWell

Building a Teaching Academy at Your University — What a Faculty Member or Administrator Can Do

Members of Frontiers in Education know much about university teaching that could—and should—be shared with educators across our home campuses. It is especially important to share outside of STEM fields where research about education is not as robust. But how to share such information on one's own campus? Enter: the teaching academy.

A teaching academy is a member-driven organization designed to enhance teaching. A teaching academy can serve as a center for teaching or coordinate with an already established center. It need not have even one paid staff or even a budget in the beginning. Activities that are common for teaching academies include having members offer workshops, lead learning communities, induct new members, honor teaching award winners, host celebrations of teaching, as well as observe and give feedback on colleagues' online or face-to-face classes.

In this plenary session, Dr. Gray will address how to begin a teaching academy at your university as well as how to build upon an existing one. She will discuss how even one faculty or administrator can create a groundswell of support, demonstrate the impact of the academy, and raise money as necessary.

Tara Gray, Ph.D., serves as associate professor of criminal justice and as founding director of the New Mexico State University Teaching Academy. The Academy was established in 2003. In the five years before the Academy was founded, while working as an associate professor of criminal justice, Dr. Gray directed two popular short courses, raised the money necessary to support them and bring in a half dozen speakers per year, and began building the faculty and administrative support for a Teaching Academy. Today, the Teaching Academy is a full-service center, working to improve student learning by providing professional development to New Mexico State educators.

Dr. Gray was educated at the United States Naval Academy, Southwestern College in Kansas and Oklahoma State, where she earned her Ph.D. in economics by asking, "Do prisons pay?" She taught economics at Denison University before joining the Department of Criminal Justice at NMSU. Dr. Gray has published three books, including *Publish & Flourish: Become a Prolific Scholar*. She has been honored at New Mexico State and nationally with eight awards for teaching or service.

Dr. Gray has presented faculty development workshops to 8,000 participants in more than a hundred colleges and universities, thirty-five states, and Thailand, Guatemala, Mexico, Canada, Saudi Arabia and the United Arab Emirates. Workshop participants report that she is "spirited, entertaining, and informative—she's anything but gray!™"

New Faculty Fellow Program

Each year, FIE invites new engineering and computer science faculty to submit applications for possible selection as New Faculty Fellows. A review panel of engineering and computer science faculty from assistant, associate, and full professorship levels completes a rigorous peer review of each applicant's conference paper, nomination letters and professional résumé. The fellowship provides a \$1,000 grant for conference travel expenses.

The purpose of the program is to promote the involvement of new faculty in the Frontiers in Education Conference so they will be exposed to the "latest and greatest" in engineering educational practices and will have the opportunity to exchange information with leaders in education innovations. This year, FIE 2015 will provide registration and travel grants for the awardee to attend the conference.

Focus on New Faculty Fellows

Each fellow will present a conference paper during FIE 2015. Join them in their session and share your thoughts and ideas about the future of engineering education. Also, during the Focus on Exhibits session Friday at 4 p.m., the Fellows will display posters describing their interests and activities and previewing the full papers that they will present as part of the FIE 2015 technical sessions. Below are this year's recipients and the papers they authored or co-authored.

2015 New Faculty Fellows:

Joyce Main

Purdue University

Session T2D: *Using life course theory to frame women and girls' trajectories toward (or away) from computing: Pre high-school through college years*

Session F2F: *Student evaluations of team members: Is there gender bias?*

Session S2C: *The Institutional Environment for Student Veterans in Engineering*

Session S3B: *Examining How International Experiences Promote Global Competency among Engineering Graduate Students*

Session S4E: *Modeling Student Perceived Costs and Benefits to Cooperative Education Programs (Co-ops) and Pathways to Participation*

Noah Salzman

Boise State University

Session S3C: *Effects of Pre-College Engineering Participation on First-Year Engineering Outcomes*

Nathan Canney

Seattle University

Session F3F: *How engineering students define 'Social Responsibility'*

Conference Amenities

Breakfast • Ballroom

Breakfast is included in your conference registration. On Thursday breakfast will include a plenary presentation.

8:00 AM – 10:30 AM Thursday Includes Plenary Session

8:00 AM – 9:00 AM Friday

8:00 AM – 9:00 AM Saturday

Refreshment Breaks • Mezzanine Level

Morning and afternoon breaks will take place daily on the Mezzanine Level, outside the Ballroom.

Lunches • Ballroom

Lunches are included in your conference registration. On Thursday lunch will include the Hewlett-Packard Awards

Frederick Emmons Terman and Harriett B. Rigas Awards Luncheon Sponsored by the Hewlett-Packard Company

12:45 PM – 2:15 PM Thursday

The Frederick Emmons Terman Award is presented annually to an outstanding young electrical engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Harriett B. Rigas Award is presented annually to an outstanding woman engineering educator in recognition of her contributions to the profession.

Luncheon

12:45 PM – 2:15 PM Friday

Includes Plenary Session

Luncheon

12:45 PM – 2:15 PM Saturday

New Faculty Fellows • Exhibit Area • Mezzanine Level

4:00 PM – 5:00 PM Friday

A special session focusing on the New Faculty Fellows will be held on Friday. This session will provide an opportunity to meet this year's New Faculty Fellows, a group of new CSET educators who were selected based on an application and a full paper being presented at this year's conference. There will also be an opportunity to view their poster presentations at this time.

Focus on Exhibits • Exhibit Area • Mezzanine Level

4:00 PM – 5:00 PM Friday

Visit the FIE exhibits and check out the latest textbooks, computer software, lab equipment, and other innovations while enjoying refreshments.

Awards Banquet • Ballroom

7:30 PM – 10:00 PM Friday

Thanks to our sponsor, the IEEE Education Society, the Frontiers in Education Conference annual gala networking dinner and awards program is only \$30 per person. An opening reception will be followed by a full-service plated meal. This business formal event is sponsored by the IEEE Education Society - a group of more than 3,000 engineers and academics dedicated to advancing the scholarship and practice of engineering education. You do not have to be an IEEE Education Society member to attend. Tickets can be added to your registration on site.

FIE Registration Conference Desk • Mezzanine Level by the Elevators

Registration will be open during these times:

Wednesday	11:00 AM – 8:00 PM
Thursday	8:00 AM – 6:00 PM
Friday	8:00 AM – 6:00 PM
Saturday	8:00 AM – 5:00 PM

Award Selection Committee Chairs

Frontiers in Education Conference

Benjamin J. Dasher Best Paper Award	Diane Rover
Helen Plants Award	Mats Daniels
Ronald J. Schmitz Award	Cynthia Finelli

ASEE ECE Division Hewlett-Packard Frederick Emmons Terman Award

*For being the principal author of **Fundamentals of WiMAX**, 449 pages, Prentice-Hall, 2007, a leading textbook in wireless communications, and for research, teaching, and professional service in the discipline of wireless communications.*

Jeffrey G. Andrews (S'98, M'02, SM'06, F'13) received the B.S. in Engineering with High Distinction from Harvey Mudd College, and the M.S. and Ph.D. in Electrical Engineering from Stanford University. He is the Cullen Trust Endowed Professor (#1) of ECE at the University of Texas at Austin and the Editor-in-Chief of the IEEE Transactions on Wireless Communications. He developed Code Division Multiple Access systems at Qualcomm from 1995-97, and has consulted for entities including Apple, Samsung, Verizon, AT&T, the WiMAX Forum, Intel, Microsoft, Clearwire, Sprint, and NASA. He is a member of the Technical Advisory Board of Fastback Networks, and co-author of the books *Fundamentals of WiMAX* (Prentice-Hall, 2007) and *Fundamentals of LTE* (Prentice-Hall, 2010).

Dr. Andrews is an ISI Highly Cited Researcher, received the National Science Foundation CAREER award in 2007 and has been co-author of eleven best paper award recipients including the 2010 IEEE Communications Society Best Tutorial Paper Award, the 2011 IEEE Heinrich Hertz Prize, the 2014 IEEE Stephen O. Rice Prize, and the 2014 IEEE Leonard G. Abraham Prize. He is an IEEE Fellow and an elected member of the Board of Governors of the IEEE Information Theory Society.

The Frederick Emmons Terman Award is presented annually to an outstanding young electrical or computer engineering educator by the Electrical and Computer Engineering Division of the American Society for Engineering Education. The Terman Award, established in 1969 by the Hewlett-Packard Company, consists of \$5,000, an engraved gold-plated medal, a bronze replica of the medal mounted on a walnut plaque, and a parchment certificate.

The recipient must be an electrical engineering educator who is no more than 45 years old on June 1 of the year in which the award is presented and must be the principal author of an electrical engineering textbook published before June 1 of the year of his/her 40th birthday. The book must have been judged by his/her peers to be an outstanding original contribution to the field of electrical engineering. The recipient must also have displayed outstanding achievements in teaching, research, guidance of students, and other related activities.

About Frederick Emmons Terman

Frederick Emmons Terman received his A.B. degree in chemistry in 1920, the degree of engineer in electrical engineering in 1922 from Stanford University, and his Sc.D. degree in electrical engineering in 1924 from Massachusetts Institute of Technology. From 1925-1965, he served as instructor, then professor of electrical engineering, executive head of the Electrical Engineering Department, dean of the School of Engineering, provost, vice president, and finally, as acting president of Stanford University.

Among the many honors bestowed upon him were: the IEEE Medal of Honor; the first IEEE Education Medal; the ASEE's Lamme Medal; the 1970 Herbert Hoover Medal for Distinguished Service to Stanford University; an honorary doctor's degree by Harvard; a decoration by the British government; the Presidential Medal for merit as a result of his war work; and the 1976 National Medal of Science from President Ford at a White House ceremony.

Dr. Terman was a professor at Stanford University when William Hewlett and Dave Packard were engineering students there. It was under Dr. Terman's guidance in graduate work on radio engineering that Mr. Hewlett built the first tunable and automatically stabilized Weinbridge oscillator. Partially through Dr. Terman's urging, Hewlett and Packard set up their partnership in an old garage with \$538 and the oscillator as their principal assets.

Dr. Terman died in December 1982. It is in appreciation of his accomplishments and guidance that Hewlett-Packard is proud to sponsor the Frederick Emmons Terman Award.

IEEE Education Society Hewlett-Packard Harriett B. Rigas Award

For exceptional contributions to electrical and computer engineering education and the global engineering community through student and faculty development, transformational and inclusive institutional and professional leadership, and engineering accreditation service.

Sarah Rajala, who has been a pioneer for women in electrical engineering, graduated with a bachelor's degree in the field.

She is currently serving as dean of the Iowa State University College of Engineering and holds the James & Katherine Melsa Professorship in Engineering. Prior to this, Rajala served as the named dean of Mississippi State University's Bagley College of Engineering and head of the Department of Electrical and Computer Engineering. She earned both master's and doctoral degrees from Rice University, taught at North Carolina State University and Purdue University, and served as an adjunct research faculty member at the Wake Forest University Bowman Gray School of Medicine.

Rajala joined the faculty at NC State in 1979, where she was the first female professor in the Department of Electrical and Computer Engineering. Throughout her career at NC State, she served as a center director, Associate Dean for Academic Affairs, and Associate Dean for Research and Graduate Programs.

She is a Fellow of the American Association for the Advancement of Science and the Institute of Electrical and Electronic Engineers; she served as president and is a Fellow of the American Society for Engineering Education. She served as the chair of the Global Engineering Deans Council and is currently Chair of the Engineering Accreditation Council of ABET. A native of Skandia, Michigan, she was only the third woman to graduate from Michigan Tech with an electrical engineering degree.

At Michigan Tech, Rajala is a member of the Presidential Council of Alumnae and the Electrical Engineering Academy and was the first alumna to receive Tech's Outstanding Young Alumni Award (1986). She was recognized again in 2008 with the Distinguished Alumni Award.

About the Rigas Award

The Harriett B. Rigas Award is presented annually to recognize outstanding faculty women who have made significant contributions to electrical and computer engineering education. The award consists of an honorarium, plaque, certificate, and Frontiers in Education Conference registration.

The recipient must be a tenured or tenure track woman faculty member in an ABET-accredited engineering program in the United States, with teaching and/or research specialization in electrical or computer engineering.

About Harriett B. Rigas

Dr. Harriett B. Rigas (1934-1989), an IEEE Fellow, was an electrical engineer with an international reputation for her hybrid computer and computer simulation research. At Washington State University between 1966 and 1984, she was eventually both full professor and chair of Electrical and Computing Engineering School. Later she chaired larger departments at the Navy's Postgraduate School in Monterey and, at the time of her death, Michigan State University.

Her achievements in engineering research, administration, and service were widely recognized. In 1975-76, Harriett was a Program Director at the National Science Foundation and, over the years, a member of numerous panels and advisory committees at both the NSF and the National Academy of Sciences.

Professor Rigas' success was achieved within a profession and within university administrative structures where there were very few women. Her character and courage were both evident in her strong advocacy of advancement for women. She was involved both locally and nationally in the Society of Women Engineers.

Lecia Barker
University of Texas

Jane Gruning
University of Texas

Frontiers in Education Conference Benjamin J. Dasher Best Paper Award

The Student Prompt: Student Feedback and Change in Teaching Practices in Postsecondary Computer Science by Lecia Barker and Jane Gruning FIE 2014, Proceedings pp, 2873-2880

Lecia Barker is an Associate Professor in the School of Information at the University of Texas at Austin and a Senior Research Scientist for the National Center for Women & Information Technology. Lecia conducts research in attracting, retaining, and advancing groups underrepresented in professional computing and science careers; these studies focus on social climate, identity/belonging, faculty adoption of teaching and curricular practices, and sustainable organizational change. She advises several research and implementation projects intended to advance knowledge about computer science education. She is a co-PI of the NCWIT Extension Services program, which provides customized consulting to support systemic reform of computing and engineering departments. Lecia is currently studying faculty adoption of teaching methods in computer science. Lecia holds a Ph.D. in Communication from the University of Colorado at Boulder, a Master of Business Administration from San Diego State University, and a Bachelor of Arts from the University of Iowa.

Jane Gruning is a doctoral student in the School of Information at the University of Texas at Austin. In addition to her research on retaining underrepresented groups in undergraduate computer science programs, Jane conducts research in the area of human-computer interaction investigating the importance of objects in everyday human life and how this differs between physical and digital objects. Her research has focused on various aspects of this subject, from digital objects in causal gaming, to objects on obsolete media in a workplace, to how people share objects in home settings (study conducted during an internship at Microsoft Research Cambridge). She holds an MSIS from the University of Texas at Austin, an MA in Philosophy from Tulane University, and a BA in English Literature from Loyola University in New Orleans.

About the Dasher Award

The Benjamin Dasher Best Paper Award is given to the best paper presented at the annual Frontiers in Education Conference, as demonstrated by technical originality, technical importance and accuracy, quality of oral presentation, and quality of the written paper appearing in the Conference Proceedings. Papers are nominated for the award by reviewers.

A committee with representation from each of the organizing societies (ERM, IEEE Ed. Soc., IEEE Comp. Soc.) is formed to review nominated papers. During the FIE meeting, the committee attends presentations of the nominated papers. The committee then makes a final recommendation to the FIE Planning Committee for the Ben Dasher Award winner based on the overall quality of both the paper and the presentation.

About Benjamin J. Dasher

Benjamin J. Dasher was born December 27, 1912 in Macon, Ga. He earned his bachelor's and master's degrees in electrical engineering in 1935 and 1945, respectively, and graduated with a doctorate in electrical engineering in 1952 from the Massachusetts Institute of Technology. At MIT, Dr. Dasher worked on the electronics of instrumentation of electromechanical transducers and analog-to-digital converters. He was the author of "Dasher's method" for synthesis of resistance-capacitance two-port networks, which is found in standard textbook treatments.

While at Georgia Tech, Dr. Dasher served as a graduate assistant in 1936, then as an instructor in 1940, and became an assistant professor in 1945. While earning his PhD at MIT, he was an instructor from 1948-51. Before finishing with his PhD, he became an associate professor at Georgia Tech in 1951, was promoted to professor in 1952, and became director of the School of Electrical Engineering in 1954, where he served in that capacity until 1969. In 1968, Dr. Dasher was appointed associate dean in the College of Engineering. At Georgia Tech, Dr. Dasher served as director of network synthesis projects and transistor oscillator projects. His fields of interest included advanced network theory, electronic theory, electronic circuits, electrical engineering education, machine translation, speech analysis, and pattern recognition. He was credited for bringing undergraduate engineering education to the forefront at Georgia Tech and for increasing interactions between undergraduates and industry.

Dr. Dasher was a member of Phi Kappa Phi, ASEE, Sigma Xi, and the American Association of University Professors; he was a Fellow of both the IEEE and the Institute of Radio Engineers. He served as a regional director for IEEE and as the chair for the Atlanta section of IEEE; he was on numerous committees for IRE, AIEE, and IEEE. He served as President of the IEEE Education Group in 1970-71.

Ben Dasher organized the first Frontiers in Education Conference; it was held in Atlanta in 1971, and attracted 100 participants. There were 34 papers in six technical sessions.

Dr. Dasher died of congestive heart failure on December 13, 1971 in Houston, Texas.

Frontiers in Education Conference Helen Plants Award Best Nontraditional Session at FIE 2014

For their Special Session “Agents for STEM Change –Articulating the Goals of Our Community”, Proceedings, 2014 Frontiers in Education Conference, pp. 1942-1943

The EER Leaders NetWorkshop was formed in 2013 through funding from the National Science Foundation (EEC-1314725 and 1314868; Rebecca Bates and Lisa Benson, co-PI's). Our goal is to provide a mechanism for mentoring and supporting mid-career faculty across distributed locations who are not far enough along in their careers to have administrative or leadership experience, but are frequently stepping into these roles. We seek to develop advocates and future leaders for our emerging discipline of EER by focusing on building community, developing skills to communicate across organizational boundaries and identifying strategies for moving the emerging field forward and supporting rising EER leaders. As a group of about 25 mid-career EER faculty, we have had held face-to-face workshops at and around engineering education conferences. We have also had monthly virtual meetings to learn about ways to influence those outside of our discipline, and ways to navigate important conversations across administrative boundaries within universities. We have learned about sources of influence (such as structural, social and personal), barriers to achieving influence, and change models that are appropriate for engineering education.

Rebecca Bates is a Professor and Chair of the Department of Integrated Engineering at Minnesota State University, Mankato. She directs the Iron Range and Twin Cities Engineering programs, project-based learning programs that provide pathways to four-year engineering degrees for community college graduates. Her research background has focused on speech recognition and understanding as well as engineering and computer science education. Her degrees are in biomedical engineering (B.S., Boston University), electrical engineering (M.S., Boston University, Ph.D., University of Washington) and theological studies (M.T.S., Harvard University).

Lisa Benson is an Associate Professor of Engineering and Science Education at Clemson University, with a joint appointment in Bioengineering. Her research focuses on the interactions between student motivation and their learning experiences. Her projects involve the study of student perceptions, beliefs and attitudes towards becoming engineers and scientists, and their problem solving processes. Other projects in the Benson group include effects of student-centered active learning, self-regulated learning, and incorporating engineering into secondary science and mathematics classrooms. Her education includes a B.S. in Bioengineering from the University of Vermont, and M.S. and Ph.D. in Bioengineering from Clemson University.

Alan Cheville studied optoelectronics and ultrafast optics at Rice University, followed by fourteen years as a faculty member at Oklahoma State University working on terahertz frequencies and engineering education. While at Oklahoma State he developed courses in photonics and engineering design. After serving for two and a half years as a program director in engineering education at the National Science Foundation, he took a chair position in electrical engineering at Bucknell University. He is currently interested in engineering design education, engineering education policy, and the philosophy of engineering education.

Frontiers in Education Conference Helen Plants Award Best Nontraditional Session at FIE 2014 (Continued)

Cynthia Finelli is Director of the Center for Research on Learning and Teaching in Engineering and associate professor of electrical engineering at University of Michigan. At U-M, she actively engages in engineering education research, assists other engineering faculty in accomplishing their educational research endeavors, and promotes institutional change through faculty professional development. She currently studies student resistance to active learning, faculty adoption of evidence-based teaching practices, and ethical decision-making in undergraduate engineering students. Dr. Finelli leads an international initiative to create a taxonomy for the field of engineering education research, and she is a Fellow of the American Society for Engineering Education.

Jennifer Karlin is a professor of industrial engineering at the South Dakota School of Mines and Technology. She received her undergraduate degree from Washington University in St. Louis and her Ph.D. in industrial and operations engineering from the University of Michigan, specializing in engineering management. Jennifer studies colleges and universities as organizations and change management to improve learner development and university-based economic development. She has been active in FIE, serving as conference general co-chair for the 2011 conference and an ERM representative on the FIE steering committee. She also served as an ERM Board Member.

Susan M. Lord is Professor and Chair of Electrical Engineering, University of San Diego. She received a B.S. from Cornell University and the M.S. and Ph.D. from Stanford University. Her research focuses on the study and promotion of diversity in engineering including student pathways, diverse populations including Latinos and military veterans, and cross-cultural studies with non U.S. students. Dr. Lord is a Fellow of the IEEE and ASEE and is active in the engineering education community including serving as General Co-Chair of the 2006 Frontiers in Education (FIE) Conference, on the FIE Steering Committee, and as President of the IEEE Education Society for 2009-2010.

About the Plants Award

The Helen Plants Award is given for the best special (non-traditional) session at the FIE conference, as demonstrated by originality, session content and presentation including the use of written materials and visual aids, and participation of session attendees.

About Helen Margaret Lester Plants

Helen Margaret Lester was born in Desloge, Missouri, in March 1925, the only child of Rollo Bertell and Margaret Stephens Lester.

She entered the University of Missouri as a journalism major, but soon switched to Civil Engineering. She received her BSCE in 1945. She joined West Virginia University in 1947 as a graduate student and Instructor in Mechanics, and received her MS in Civil Engineering in 1953. She was a Professor of Theoretical and Applied Mechanics and of Curriculum and Instruction in the Division of Education at WVU. She became Professor Emeritus, Mechanical and Aerospace Engineering in 1983. From 1985 to 1990 she served as Chair of Civil Engineering Technology at Indiana University-Purdue University - Fort Wayne.

Her husband Ken Plants had been a "bureaucrat" with the US Bureau of Mines in Morgantown - a chemical engineer with great expertise in cost estimation. Some of their "courting" evenings were spent manually checking the design calculations on the Star City, WV Bridge, designed by the Dean and State Bridge Engineer. While in Morgantown, Helen was active in Trinity Episcopal Church where she served as a Vestryman and Bishop's Man. For many years she was a Girl Scout leader. Helen died in Tulsa, Oklahoma in September 1999.

From the beginning of her academic career, she was a gifted teacher and a role model for the few women students at West Virginia University at that time. Later, she became an advocate of programmed and individualized instruction. She and Wally Venable wrote series of papers on these topics and several texts: *Introduction to Statics, a Programmed Text*, (1975), *A Programmed Introduction to Dynamics* (1967), and *Mechanics of Materials, A Programmed Textbook* (1974). She established the first doctoral program in Engineering Education at West Virginia University.

In 1975, the University of Missouri at Columbia recognized her with the Missouri Honor Award for Distinguished Service in Engineering. She became an ASEE Fellow in 1983 as a member of the first class of Fellows. She also received Distinguished Service Award, Western Electric Fund Award, and was an ASEE Vice-President (1974 – 1976).

Frontiers in Education Conference Ronald J. Schmitz Award

For contributions to the Frontiers in Education Conference through developing and maintaining a comprehensive program of informative educational exhibits.

Robert J. Hofinger holds the title of Professor Emeritus from the Electrical and Computer Department in the College of Technology at Purdue University. He received his BSEE and MSEE degrees from the Brooklyn Polytechnic Institute (now the NYU Polytechnic School of Engineering).

Before starting his academic career at Purdue University, he worked as an electrical engineer for over 30 years. His experience included work in the military/aerospace industry with LITCOM electronics, a division of LITTON Industries and RCA Astropace Division where he designed digital circuitry for the decoding and control of hydrogen gas thruster engines on commercial telecommunication satellites; in the gasoline industry with GILBARCO, at the time an EXXON subsidiary, in the design of ultrasound underground metering systems and specialized switching power supplies for gasoline dispensers; in the electric metering industry with LANDIS & GYR, in the design of analog current dividing circuits for accurately measuring the in-phase and quadrature-phase currents for electronic watt-hour metering systems; and the automotive industry with DELCO Electronics (now DELPHI Electronics) in designing Electronic Control Modules (ECMs) for OPEL Motors, a General Motors European subsidiary.

After retirement from full time teaching, he is teaching part time as an Adjunct Professor for the IvyTech Community College of Indiana in the School of Applied Science and Engineering Technology.

He has been active in the American Society for Engineering Education (ASEE) for many years, serving as the program chair for the Instrumentation Division. He was elected to and has held all executive positions in the IL/IN section of the ASEE. He has also held the office of treasurer of the Greensboro, N.C. chapter of the IEEE.

About the Schmitz Award

The Ronald Schmitz Award is given to recognize outstanding and continued service to engineering education through contributions to the Frontiers in Education Conference.

About Ronald J. Schmitz

Ronald J. Schmitz was born near Ionia, Iowa on April 25, 1934. He attended a one-room country school through the eighth grade and then, as was not uncommon at the time, decided to forgo high school and work on his father's farm. At age 18, he joined the United States Navy. He served as an Electricians Mate, spending much of his enlistment at sea and made a round-the-world cruise aboard the USS Saipan.

In the Navy, Ron found an interest in and an aptitude for technology and recognized the need for further education. He completed a GED program in the Navy and, when he was discharged, enrolled in electrical engineering at Iowa State University. He received all his degrees there, finishing his doctorate in 1967.

In the fall of 1967, he accepted appointment as Assistant Professor in the Department of Electrical Engineering at the South Dakota School of Mines and Technology in Rapid City. He was involved in various research activities and directed both masters and doctoral students, but his strongest interest was always in teaching. Ron was a consummate teacher, patient with students who were having difficulty but intolerant of sloth. He received the School of Mines Teaching Award in 1975 and the Western Electric Fund Award for Excellence in Teaching in 1981.

Dr. Schmitz was very active in the IEEE, especially the Education Society, and served as Secretary Treasurer of the Society. He was also active in ERM and attended, and contributed to, many Frontiers in Education Conferences. He served as general chair of FIE 1981 in Rapid City.

Ron was an avid hunter and fisherman, a devoted husband and father and a faithful friend. He served his church as Lector and Lay Minister and was active as a Boy Scout leader.

Ron contracted cancer in 1983 and died on July 19, 1984.

IEEE Education Society William E. Sayle II Award for Achievement in Education

For continuously introducing project-based learning into the engineering curriculum and promoting professional development of the faculty

Marco Winzker (M'10-SM'11) is Professor for digital design and fundamentals of electric circuits at the Bonn-Rhein-Sieg University in St. Augustin, Germany. He joined the faculty in 2004 and was associate dean of the Engineering department from 2007 to 2011. Since 2011 he has been the project manager for Pro-MINT-us, the university project of the German Teaching Quality Pact initiative ("Qualitätspakt Lehre"). Marco studied Electrical Engineering at the University of Hannover, Germany and received his Ph.D. for work on low-power CMOS design. As Design Engineer and Group Leader he developed image processing systems with ASICs and FPGAs. He worked for Philips Semiconductors (now NXP) in Hamburg, Germany and Eindhoven, The Netherlands, for Liesegang electronics in Hannover, and for Silicon Optix (now IDT) in Hannover and Toronto, Canada.

At the Bonn-Rhein-Sieg University he was the Program Director of the first bachelor curriculum in electrical engineering which introduced a new 4-1-4-1-4-1 semester structure. Three weeks of each semester are reserved for project-based learning and self-learning exercises and these project weeks alternate with four weeks of regular lectures, classroom exercises, and hands-on labs. He successfully applied for funding from the Teaching Quality Pact initiative to extend project-based learning to 1st-year students and to strengthen STEM-subjects in the initial study phase. Marco promotes professional development within the faculty by organizing workshops, "education evenings" where professors dine at a restaurant and discuss an education topic and "teaching days" with talks from university staff and external speakers. In the university canteen he enthusiastically reports from education conferences like Educon and invites colleagues to join him at future events.

Marco was selected as participant for the excellence in education program "Lehre-hoch-n". He received an IEEE Educon Best Paper Award and the award for innovation in teaching at the Bonn-Rhein-Sieg University. He wrote an interdisciplinary textbook about electronics for non-engineers ("Elektronik für Entscheider") for a degree course of technical journalism. He was guest editor of the Austrian journal for higher education development ("Zeitschrift für Hochschulentwicklung") and was invited to speak as well as to chair workshops at several national and international education conferences. He regularly participates in summer schools of his university and has accompanied students to Finland, Spain and The Netherlands. He was also guest lecturer at the National Technical University of Argentina in Buenos Aires.

About the Sayle Award and William E. Sayle II

The William E. Sayle II Award is presented to recognize a member of the IEEE Education Society who has made significant contributions over a period of years in a field of interest of the IEEE Education Society. The award consists of a plaque, a certificate, and paid registration to the Frontiers in Education Conference.

Dr. William (Bill) E. Sayle received his BSEE and MSEE degrees from the University of Texas at Austin and his Ph.D. from the University of Washington. He joined the faculty in electrical engineering at Georgia Institute of Technology in 1970, just as Georgia Tech was beginning the transition from an undergraduate institution to a research university. He was the ECE associate chair for undergraduate affairs from 1988-2003 and, following retirement in 2003, served as director of undergraduate programs at Georgia Tech-Lorraine in France until 2007. Bill was a tireless advocate for students, putting in countless late night and weekend hours in addressing student issues, assigning teaching assistants, and meeting with prospective students and parents.

Throughout his career, Bill touched the lives of many people in the worldwide academic community. He was a leader and a pioneer in many areas. In the 1970s, he was a founding member of the IEEE Power Electronics Society, where he served in many leadership roles over the years. He was a champion of diversity and in recruiting underrepresented minorities and women to engineering and science, long before it became a national issue. He visited many high schools on behalf of the Southeastern Consortium for Minorities in Engineering, a role where he made many friends for Georgia Tech among high school administrators and students in the southern part of Georgia.

In his 30-year career at Georgia Tech, Bill received the ECE outstanding teacher award twice, as well as the Georgia Tech outstanding teacher award and outstanding service award. Bill lent his voice and efforts to Georgia Tech faculty governance throughout his career, serving as an elected member of Institute-level committees, the Academic Senate, and the Executive Board.

Bill was a long-time member and active volunteer in the IEEE Education Society and the Electrical and Computer Engineering Division of ASEE. He was a Fellow of both IEEE and ASEE. He was the recipient of the Education Society's 2001 Meritorious Service Award and 2004 Achievement Award and of the ECE Division's 2001 Meritorious Service Award and 2006 ECE Distinguished Educator Award. Bill was the General Chair of the 1995 Frontiers in Education (FIE) Conference, which is still remembered for its all-vegetarian menu, and received the 1996 Ronald J. Schmitz Award for outstanding service to FIE.

Much of Bill's professional career was devoted to engineering accreditation, serving at various times as member and chair of the IEEE Committee on Engineering Accreditation Activities and the IEEE Accreditation Policy Council. He participated in more than 20 visits as a program evaluator, in addition to serving as a team chair and member of the Engineering Accreditation Commission of ABET for more than five years. Bill received the IEEE Educational Activities Board Meritorious Achievement Award in Accreditation Activities in 2004.

Dr. Sayle passed away on February 2, 2008.

IEEE Transactions on Education Best Paper Award

Presented to: Raghu Raman, Krishnashree Achuthan, Prema Nedungadi, Shyam Diwakar, Amrita University, and Ranjan Bose, Indian Institute of Technology New Delhi, for their paper "The VLAB OER Experience: Modeling Potential-Adopter Student Acceptance", IEEE Transactions on Education, 57:4, November 2014, pp. 235-241.

Raghu Raman (M'08, SM '12) received his MBA from Haas School of Business, Berkeley in 2003. He is the Principal Investigator for the National Mission on Education through ICT EdRP Project, Measuring Learning under the HP Catalyst Global Innovation with Carnegie Mellon University and for the Medical Simulation initiative under the Ministry of IT. Currently Raghu is guiding research projects in the areas of learning analytics, serious games and virtual interactive learning environments.

Raghu has over 14 years of product design and architecture experience from NEC Research Labs and IBM and is recipient of the President of India Gold Medal. He is Immediate Past Chair of the IEEE Education Society, India, and recipient of IEEE Outstanding Chapter award for 2013.

Prema Nedungadi (M '12) is the Joint Director of Amrita CREATE (Center of Research in Advanced Technologies for Education) and faculty in School of Engineering. She has coauthored numerous scientific publications. Her research interests are in personalized e-learning solutions using computational intelligence methods, multimodal and virtual reality systems for STEM learning and language learning. She is Principal Investigator for the Online Science Labs and Adaptive Continuous and Comprehensive Evaluation research grants from Govt. of India and Co-Principal Investigator for the Virtual Labs project under National Mission in Education through ICT.

Krishnashree Achuthan holds a Ph.D. in chemical engineering and heads the Center for Virtual and Accessible Laboratories Universalizing Education (VALUE @ Amrita) at Amrita University. VALUE @ Amrita has built over 30 virtual laboratories that are simulation-based, interactive and/or remotely triggerable with over 300 experiments in the areas of Physics, Chemistry, Biotechnology, Computer Science and Mechanical Engineering. She is Principal Institute Coordinator for National Mission on Education through ICT at Amrita University. Her research interests include Science and Engineering under-graduate education amongst others. She has over forty research papers and publications in peer-reviewed conferences and journals. She is also the author of 29 U.S. Patents.

Shyam Diwakar (M '01) received his Ph.D. in computational sciences from the University of Milan, Italy in 2008. Currently, he is an assistant professor at the School of Biotechnology where he is the head of the Computational Neuroscience laboratory. Prior to that he worked as a postdoctoral researcher in the department of General Physiology, University of Pavia, Italy. His research uses principles from electrical engineering and informatics to study the cerebellum and its functioning. Dr. Diwakar is also a member of Indian Academy of Neurosciences, Organization of Computational Neuroscience Societies (OCNS) and the IACSIT.

Ranjan Bose (SM '11) received his B.Tech. degree in electrical engineering from the Indian Institute of Technology (IIT), Kanpur and the M.S. and Ph.D. degrees in electrical engineering from the University of Pennsylvania, Philadelphia. Currently he holds the Microsoft Chair Professorship and heads the Wireless Research Lab in IIT Delhi. His research interests lie in the areas of ultra-wideband (UWB) communications, broadband wireless access and coding theory. He has held guest scientist positions at the Technical University of Darmstadt, Germany, University of Colorado at Boulder, USA and UNIK, Norway. He has published over one hundred research papers in refereed journals and conferences, and holds ten patents.

Rosanna Yuen-Yan Chan
The Chinese University
of Hong Kong

Distinguished Chapter Leadership Award

For her exceptional contribution to the IEEE Education Society and for distinguished leadership in engineering education over a sustained period.

Dr. Rosanna Yuen-Yan Chan is a Senior Member of the IEEE and an Adjunct Assistant Professor at the Department of Information Engineering, The Chinese University of Hong Kong. She has a multidisciplinary background in engineering, education, and learning science. Rosanna is the Founding Chair of the IEEE Education Society Hong Kong Chapter, the Educational Activities Chair of the IEEE Hong Kong Section, and a committee member of the IEEE Educational Activities Board (EAB) Student Educational Resources Committee (SERC) as well as the Chapter Committee of the IEEE Education Society. Rosanna is elected the New Faculty Fellow of the Center for the Advancement of Scholarship on Engineering Education (CASEE), National Academy of Engineering (NAE), USA.

IEEE Education Society Edwin C. Jones, Jr. Meritorious Service Award

For service to the Education Society through maintenance, improvement, and implementation of the by-laws and related activities, for overall service to the society, and for service to all of IEEE, ABET, and ASEE.

Victor P. Nelson is a Professor and Assistant Chair of Electrical and Computer Engineering at Auburn University, where he has been on the faculty since 1978. His primary research interests include embedded systems and computer-aided design and testing of digital systems and application-specific integrated circuits (ASICs). He is co-author of the textbook *Digital Logic Circuit Analysis and Design* and IEEE tutorial book *Fault-Tolerant Computing*. He is past chair of the ECE Curriculum Committee and coordinator of the ECE Graduate Program, and served one year as Associate Dean for Assessment in the College of Engineering. He was a co-winner of the 2005 "Wireless Educator of the Year" award from the Global Wireless Education Consortium for his role as one of the developers of the Bachelor of Wireless Engineering program at Auburn University, which is the first of its kind in the U.S., and currently serves as the director of that program. He received the Birdsong Merit Teaching Award in 2000 and the Walker Merit Teaching Award in 2002 from the College of Engineering, and was named outstanding member of the Graduate Faculty in 2004.

He is a member of the IEEE Education Society, in which he has served as a member of the Board of Governors, chair of the Constitution and Bylaws committee, and previously as an associate editor of the *IEEE Transactions on Education*. He was a member of the IEEE Computer Society/ACM Task Force that developed the Computer Engineering 2004 (CE20014) report on model computer engineering curricula, and is a member of the task force updating that report for CE2016. He is active in accreditation activities, having served as an ABET program evaluator and a current member of the ABET Engineering Accreditation Commission, and previously as a member and mentor coordinator of the IEEE Committee on Engineering Accreditation Activities (CEAA). He is also a member of ASEE, and previously served as chair of the ASEE ECE Division.

About the Edwin C. Jones Award

The Edwin C. Jones Meritorious Service Award is presented to recognize a member of the IEEE Education Society who has made pioneering contributions to the administrative efforts of the IEEE Education Society over a period of years. The award consists of a plaque, a certificate, and registration to the Frontiers in Education Conference.

About Edwin C. Jones

Professor Jones served as a Society officer from 1970 through 1976; this service included two years as president. He served as Editor-in-Chief of the IEEE Transactions on Education from 1982-84. Since he first became involved in the Society in the late 1960s, he has held virtually every office in the Education Society. Professor Jones also serves the IEEE as a member of the IEEE Committee on Engineering Accreditation Activities. Dr. Jones is University Professor and Associate Chair, emeritus, Department of Electrical and Computer Engineering, Iowa State University. Prior to joining Iowa State in 1966, he was an Assistant Professor at the University of Illinois from 1962-66. He received his PhD in 1962 from the University of Illinois; the DIC in 1956 from Imperial College of Science and Technology, London; and the BSEE in 1955 from West Virginia University. Dr. Jones' honors and awards include: Fellow, Institute of Electrical and Electronics Engineers; Fellow, American Society for Engineering Education; Fellow, American Association for Advancement of Science; Fellow, Accreditation Board for Engineering and Technology; IEEE Centennial Medal, 1984; ASEE Centennial Medal, 1993; and the Grinter Distinguished Service Award from ABET in 2001. Some of his students founded a scholarship for Electrical and Computer Engineering students at Iowa State University in his honor.

IEEE Education Society Mac Van Valkenburg Early Career Teaching Award

For leadership in engineering education innovation and outstanding classroom teaching, providing students hands-on experience during classes and research, and helping them understand fundamentals using practical examples.

Dr. Chengying “Cheryl” Xu is currently an Associate Professor at the Florida State University, Tallahassee, Florida. She received her Ph.D. in 2006 in mechanical engineering from Purdue University, West Lafayette, Indiana, and her M.S. in 2001 in mechanical manufacturing and automation from Beijing University of Aeronautics and Astronautics, Beijing, China.

Her research interests include manufacturing of advanced materials, manufacturing process optimization and control, high temperature sensor design. Dr. Xu has co-authored a textbook with her doctoral advisor: *Intelligent Systems: Modeling, Optimization and Control* (CRC Press, 2008, 433 pages), and four book chapters. She has authored and coauthored more than 30 journal papers and around 30 refereed conference proceedings.

Dr. Xu is the Journal Guest Editor for *ASME Transactions, Journal of Micro- and Nano- Manufacturing (ASME JNM)*, an Associate Editor of the *International Journal of Nanomanufacturing (IJNM)* from 2008 to 2010, and has been on the Board of Editors for *Journal of Aviation and Aerospace Perspectives (JAAP)* since 2010, and *International Journal of Computational Materials Science and Surface Engineering* since 2007. She served on the Conference Organizing Committee for *ASME Dynamic Systems and Control Conference (DSCC)*, *International Symposium on Flexible Automation (ISFA)*, *SPIE Conference, Smart Structures/NDE, Sensors and Smart Structures Technologies for Civil, Mechanical, and Aerospace Systems*. She won the Office of Naval Research Young Investigator Award and Society of Manufacturing Engineers’ (SME) Richard L. Kegg Outstanding Young Manufacturing Engineer (OYME) Award in 2011.

She is actively in conducting research in manufacturing field and has attracted an impressively high level of research funding (total > \$4M, where her share > \$2.8M). She has secured significant support from National Science Foundation (NSF), Department of Energy (DoE), Office of Naval Research (ONR), Florida State, international/national companies, and her university to conduct research. She has graduated five Ph.D. and nine M.S. students.

IEEE Education Society Distinguished Member Award

For leadership in promoting innovation in STEM education, including service as project director for the Foundation Coalition, service as an ABET program evaluator, and service to the IEEE Education Society as Editor-In-Chief of the IEEE Transactions on Education and past-chair of the Frontiers in Education Conference.

Dr. Jeffrey E. Froyd is a TEES Research Professor in the Office of Engineering Academic and Student Affairs at Texas A&M University, College Station. He received the B.S. degree in mathematics from Rose-Hulman Institute of Technology and the M.S. and Ph.D. degrees in electrical engineering from the University of Minnesota, Minneapolis. He was an Assistant Professor, Associate Professor, and Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. At Rose-Hulman, he co-created the Integrated, First-Year Curriculum in Science, Engineering and Mathematics, which was recognized in 1997 with a Hesburgh Award Certificate of Excellence. He served as Project Director for a National Science Foundation (NSF) Engineering Education Coalition in which six institutions systematically renewed, assessed, and institutionalized innovative, integrated undergraduate engineering curricula.

He has authored over 70 journal articles and conference papers and offered over 30 workshops on faculty development, curricular change processes, curriculum redesign, and assessment. He has served as a program co-chair for three Frontiers in Education Conferences and the general chair for the 2009 conference. He also serves on the IEEE Curricula and Pedagogy Committee, which is part of the University Resources Committee, which is part of the Educational Activities Board. Prof. Froyd is a Fellow of the IEEE, a Fellow of the American Society for Engineering Education (ASEE), an ABET Program Evaluator, the Editor-in-Chief for the *IEEE Transactions on Education*, a Senior Associate Editor for the *Journal of Engineering Education*, and an Associate Editor for the *International Journal of STEM Education*.

German Carro Fernandez

Past Recipients

- '09 Seiji Isotani
- '10 Emmanuel Gonzalez and Kai-Pan Mark
- '11 Dario Schor
- '12 Elio San Cristobal Ruiz and Sergio Martin
- '13 Subhamoy Mandal
- '14 Liang-Bi Chen

IEEE Education Society Student Leadership Award

For Student Branch leadership advocating and facilitating the activities of the UNED Student Branch and collaborations in Spain and Portugal to sustain IEEE Students Branches.

German Carro Fernandez is Doctor, Cum Laude, in Industrial Engineering (UNED, 2014), Master in Research on Electronics, Electricity and Industrial Control (UNED, 2012), Bachelor degree on Computer Systems Engineering Tech. (UNED, 2010), Master on Business Administration and Taxes (UDC and Spanish Public Tax School, Spanish Treasury, 1997) and Bachelor degree on Economics Science and Financial Markets (UDC, 1996). He is on the Board of Directors of Pre-University Activities Sub-Committee of EASC Region 8, was Treasurer of IEEE Spain Section, Chair of Spain Section AG GOLD/YP, Chair of IEEEsb of UNED, Chair of Student Chapter of IEEE Education Society on IEEEsb of UNED, and Member of several IEEE Societies.

He has worked as a freelance economist and engineering consultant for industries and enterprises since 1994. Since 2012 he is working as Professor and Researcher on several projects with main focus on Remote Laboratories, Telematics Control, Robotics and IoT, at UNED, and since 2015 he is Director of the UNED Associate Center on A Coruña (Spain). Since 2006 he has been working as volunteer at IEEE to spread technology on several education areas and promoting the engineering and science on Schools, Universities and Academia receiving several appreciation certificates like "Certificate of Appreciation from IEEE", 2010/2011, and "Certificate of appreciation from IEEE Spain Section", 2012/2013.

IEEE Fellow Award

Susan M. Lord, University of San Diego

For professional leadership and contributions to engineering education

Susan M. Lord is Professor and Chair of Electrical Engineering, University of San Diego (USD). She received a B.S. from Cornell University and the M.S. and Ph.D. from Stanford University. Her research focuses on the study and promotion of diversity in engineering including student pathways, diverse populations including Latinos and military veterans, and cross-cultural studies with non U.S. students. Her research has been sponsored by the National Science Foundation (NSF). Dr. Lord and Dr. Michelle Madsen Camacho are among the first to study Latinos in engineering. In reviewing their 2013 book, *The Borderlands of Education: Latinas in Engineering*, Dr. Riley, Smith College, called it “groundbreaking work...that will challenge your assumptions about women and minorities in engineering”. Dr. Walden, University of Oklahoma said “This book should be high on the must-read list for engineering educators at all levels, from first-year faculty to deans.” Dr. Lord is a Fellow of the IEEE and ASEE and is active in the engineering education community including serving as General Co-Chair of the 2006 Frontiers in Education (FIE) Conference, on the FIE Steering Committee, and as President of the IEEE Education Society for 2009-2010. She is an Associate Editor of the *IEEE Transactions on Education*. She and coauthors received the 2011 Wickenden Award for the best paper in the *Journal of Engineering Education* and the 2011 Best Paper Award for the *IEEE Transactions on Education*. Dr. Lord spent a sabbatical in 2012 at Southeast University in Nanjing, China teaching and doing research. Dr. Lord is currently on the USD team implementing “Developing Changemaking Engineers”, an NSF-sponsored Revolutionizing Engineering Education (RED) project.

IEEE Fellow Award

Mark H. Weichold, Texas A&M University, Qatar

For contributions to international development of engineering education

Dr. Mark H. Weichold is an electrical engineer and has worked for General Dynamics Ft. Worth Division, Motorola in Austin, TX and the U.S. Army Electronic Technology and Devices Laboratory in Ft. Monmouth, NJ. He joined the Electrical Engineering faculty at Texas A&M University in 1982 and now holds the title of Professor. His research interests include electron device fabrication process development, device design and characterization. He has authored more than 80 journal articles, conference papers and scientific reports and holds three US patents. At the University's main campus, he served as the Dean of Undergraduate Programs and Associate Provost for Academic Services. In 2009, he was recognized as a Regents Professor his outstanding work and exemplary contribution to Texas A&M University. In 2013, he was awarded the Abdullah bin Hamad Al Attiyah International Energy Award for 'Lifetime Achievement for the Advancement of Education'.

He is a Fellow of the IEEE, a member of the American Physical Society, and a registered professional engineer in the State of Texas.

In January 2007, Weichold became Dean and CEO of Texas A&M University at Qatar. Since its inception, Texas A&M at Qatar has grown to more than 500 currently enrolled students, including 50 graduate students and over 80 faculty members. Of the more than 500 graduates, nearly half are Qatari nationals and 40% are female. Texas A&M at Qatar is also home to a dynamic research program with more than \$160 million in cumulative funding that supports responsive research projects closely aligned with the goals of Qatar National Vision 2030.

IEEE Fellow Award

Sundaram Ramesh, California State University, Northridge

For contributions to entrepreneurship in engineering education

Dr. Sundaram Ramesh has been serving as the Dean of the College of Engineering and Computer Science at California State University, Northridge since 2006. Prior to joining CSUN he was Professor of Electrical and Electronic Engineering at California State University, Sacramento, where he was the Department Chair from 1994 to 2006. His efforts and leadership have created jobs and enhanced the growth of high technology industries through the Center for Entrepreneurship and Innovation and Energy Research Center at CSU Northridge. Examples include a Satellite Clean Tech Incubator, a Master's Degree in Assistive Technology Engineering – whose graduates help design and create products to serve persons with disabilities; and as the PI of the nationally acclaimed five year AIMS² (www.ecs.csun.edu/aims2) program to graduate underrepresented minorities in engineering and computer science with a \$5.5 Million grant from the US Department of Education.

In 2014 Ramesh was invited by the White House Office of Science and Technology Policy (OSTP) to host one of the four national White House STEM workshops at CSU Northridge to broaden participation of minorities in the STEM disciplines, remove barriers, and improve student graduation rates- especially in engineering and computer science. Ramesh serves on several Boards including IEEE EAB, the IEEE-HKN Board of Governors, and ABET Board of Directors. He has served ABET as a program evaluator representing IEEE. He is the IEEE-HKN President-Elect for 2015-16, and chairs the 2015 IEEE EAB Pre-University Coordinating Committee leading signature programs such as TISP (Teacher in Service program) and EPICS (Engineering Projects in Community Service) in IEEE. Dr. Ramesh's professional interests are in Fiber Optic Communications and he received the BE (Honors) degree from the University of Madras, India, in 1981, and the MSEE and PhD degrees from Southern Illinois University, Carbondale, in 1983 and 1986 respectively. For additional information please visit <http://www.csun.edu/engineering-computer-science/ramesh>.

Reviewers

This year, FIE 2015 had over 700 papers and presentations submitted for consideration. The FIE 2015 Program Committee wishes to thank the following individuals for acting as abstract and paper reviewers. The program committee asked these individuals to help control the quality of the presentations at this year's conference by reviewing the submissions for FIE 2015. Their outstanding effort has helped maintain the high standard that has become the reputation of each FIE conference.

Eric Baumgartner	Ohio Northern University
Kemal Bayrakceken	Turkish Air Force Academy
Mark Bedillion	South Dakota School of Mines and Technology
Luiz Begosso	Fundacao Educacional do Municipio de Assis
Avril Behan	Dublin Institute of Technology
Lluís Belanche Muñoz	Universitat Politècnica de Catalunya
Scott Bell	Kansas State University
José Benlloch-Dualde	Universitat Politècnica de València
Bridget Benson	Cal Poly, San Luis Obispo
Lisa Benson	Clemson University
Edward Berger	Purdue University
Luciana Berreta	Federal University of Goiás
Angela Bielefeldt	University of Colorado Boulder
Anna Bilyatdinova	University ITMO
Roberto Bittencourt	State University of Feira de Santana
Sara Blanc	Universitat Politècnica de València
Manuel Blazquez	Universidad Antonio de Nebrija
Brit-Maren Block	Leuphana University of Lüneburg
Klavdiya Bochenina	University ITMO
Diane Bondehagen	Florida Gulf Coast University
Jennifer Bonniwell	Marquette University
Vanessa Borges	University of São Paulo
Silvia Botelho	Federal University of Rio Grande
Jesus Boticario	Universidad Nacional de Educación a Distancia
Ivica Botički	University of Zagreb
Brian Bowe	Dublin Institute of Technology
Marija Božić	Autonomous University of Barcelona
Jacques Brancher	Universidade Estadual de Londrina
Kalinka Branco	USP - University of São Paulo
Anarosa Brandão	Universidade de São Paulo
Leônidas Brandão	University of São Paulo
Henry Braun	Arizona State University
Rex Bringula	University of the East
Claudio Brito	Science and Education Research Council
Natalia Andrea Bueno Pizarro	Universidad EAFIT
Kevin Burger	Arizona State University
John Burkhardt	US Naval Academy
Jake Byrne	Trinity College Dublin
Elizabeth Cady	National Academy of Engineering

Manuel Caeiro	University of Vigo
Carlos Caicedo Bastidas	Syracuse University
María del Carmen Calatrava Moreno	Vienna University of Technology
Agustin Caminero	The National University of Distance Education
Nathan Canney	Seattle University
Juan-Carlos Cano	Universidad Politecnica de Valencia
Mary Capraro	Texas A&M University
César Cárdenas	Tecnológico de Monterrey - Campus Querétaro
Guilherme Cardim	University of São Paulo State
Dale Carnegie	Victoria University of Wellington
Luís Carriço	University of Lisbon
German Carro Fernandez	UNED - Spanish University for Distance Education
Fabricio Carvalho	Federal University of Paraíba - UFPB
Jose Reginaldo Carvalho	Federal University of Amazonas
Thais Castro	UFAM
Alberto Castro	UFAM - Federal University of Amazonas
Manuel Castro	Spanish University for Distance Education - UNED
James Cawthorne	Purdue University
Ofelia Cervantes Villagomez	Universidad de las Americas Puebla
Mario Chacon	Costa Rica Institute of Technology
Shun-Chih Chang	National Dong Hwa University
Norberto Charczuk	National University of Lanus
Dmitriy Chebanov	LaGuardia Community College of CUNY
Helen Chen	Stan
Wei-Fan Chen	Penn State University
Ye Cheng	MathWorks
R Cheville	Bucknell University
Janneth Chicaiza	Universidad Técnica Particular de Loja
Ken Christensen	University of South Florida
Ivan Claros	Universidad Autónoma de Madrid
José Alberto Cocota	Federal University of Ouro Preto (UFOP)
Maxine Cohen	Nova Southeastern University
Miguel Conde	University of León
Ricardo Cordoba	Speech Technology Group
Evandro Costa	UFAL-Universidade Federal de Alagoas
Lucineia Costa	Universidade Federal do Espírito Santo
Robert Craig	PETROLEUM INSTITUTE
DeLois Crawford	Rochester Institute of Technology
Raquel Crespo	Universidad Carlos III de Madrid
Paul Crilly	United States Coast Guard Academy
Juan Cruz-Benito	University of Salamanca
Jun Cui	Southeast University
Antonette Cummings	Purdue
Davidson Cury	UFES- Universidade Federal do Espírito Santo

I Dabipi	University of Maryland Eastern Shore
Theopisti Dafni	University of Zaragoza
Danilo Dalmon	University of São Paulo
Fábio Damasceno	Universidade Federal do Rio Grande do Sul
Mats Daniels	Uppsala University
Juan Pablo de Castro Fernández	University of Valladolid
Maria De Marsico	Sapienza University di Roma
Rafael de Souza	Federal University of Sao Carlos
Eti de Vries	Hanze UAS
Michael DeAntonio	New Mexico State University
Debzani Deb	Winston-Salem State University
Angel Delgado	University of Alicante
Kimberley DeLong	Massachusetts Institute of Technology
Matt DeMonbrun	University of Michigan
Luis Fernando D'Haro	Technical University of Madrid
Gabriel Díaz	Universidad Nacional de Educación a Distancia - UNED
Leda Digión	National University Investigator and Teacher
Reginaldo do Prado	University of São Paulo
Peggy Doerschuk	Lamar University
Susan Donohue	University of Virginia
Jineet Doshi	IIT Bombay
Anna Douglas	Purdue University
Spyros Doukakis	The American College of Greece – Pierce
Christos Douligeris	University of Piraeus
Adam Doupe	Arizona State University
Alexey Dukhanov	ITMO University
John Dyer	University of Oklahoma
Mauricio Dziedzic	Universidade Positivo
Leovy Echeverria	Universidad Pontificia Bolivariana Montería
Marius Ellingsen	South Dakota School of Mines and Technology
Michael Elmore	Binghamton University
Daniel Epstein	Federal University of Rio Grande do Sul - UFRGS
Elizabeth Eschenbach	Humboldt State University
Alberto Esquinca	University of Texas at El Paso
M. Rosa Estela	Universitat Politècnica de Catalunya
Iria Estevez-Ayres	Universidad Carlos III de Madrid
Odiel Estrada Molina	University of Informatics Science
Jeffrey Evans	Purdue University
Courtney Faber	Clemson University
Ramón Fabregat Gesa	Universitat de Girona
Fabian Fagerholm	University of Helsinki
Francisco Falcone	Universidad Publica de Navarra
Venilton FalvoJr	University of Sao Paulo
K.-Y. Daisy Fan	Cornell University

Tulio Faria	University of São Paulo
Aracele Fassbinder	Federal Institute of Sul de Minas Gerais
Fernando Fernández-Martínez	Dpto. de Teoría de la Señal y Comunicaciones
Carmen Fernandez-Panadero	Universidad Carlos III de Madrid
Deller Ferreira	Federal University of Goias
Maria Joao Ferreira	Universidade Portucalense
Begoña Ferrero	University of the Basque Country
Carla Fidalgo	ISEC/IPC
Eduardo Figueiredo	Federal University of Minas Gerais (UFMG)
Jorge Figueiredo	Universidade Federal de Campina Grande
Pablo Figueroa	Universidad de los Andes
Elena Fitkov-Norris	Kingston University
Shayne Flint	The Australian National University
D. Jake Follmer	The Pennsylvania State University
Paula Fonseca	Queen Mary University of London
David Fonseca	Enginyeria Arquitectura La Salle (Universitat Ramon Llull)
Mark Fontenot	Southern Methodist University
Jordi Fortuny-Santos	Universitat Politècnica de Catalunya
Michael Fosmire	Purdue University
Henrique Freitas	Pontifícia Universidade Católica de Minas Gerais
Eric Freudenthal	University of Texas at El Paso
Stephen Frezza	Gannon University
Wilhelm Friess	University of Maine
Jeff Frolik	University of Vermont
Jeffrey Froyd	Texas A&M University
Mohammad Fuad	Winston-Salem State University
Steven Fulton	US Department of Defense
Bruno Gadelha	Federal University of Amazonas
Eva Garcia	University of Alcalá
Rogério Garcia	São Paulo State University
Vinicius Garcia	Federal University of Pernambuco
Antonio Garcia	University of Alcalá
J. Jesús García Domínguez	University of Alcalá
Felix Garcia Loro	Spanish University for Distance Education (UNED)
Lina García-Cabrera	University of Jaén
Francisco García-Peñalvo	University of Salamanca
Anchal Garg	Amity University
Uma Garimella	Nalla Malla Reddy Engineering College
Cesar Garita	Costa Rica Institute of Technology
Piedad Garrido	University of Zaragoza
Kevin Gary	Arizona State University
Gheorghita Ghinea	Brunel University
Krishnendu Ghosh	Miami University
Koenraad Gieskes	Binghamton University

Inés Gil-Jaurena	Spanish University for Distance Education - UNED
Domingo Gimenez	University of Murcia
Cecilia Gimeno	University of Zaragoza
Kyle Gipson	James Madison University
Anabela Gomes	Polytechnic Institute of Coimbra
Javier Gomez	Universidad Autónoma de Madrid
Andrea Goncher	Queensland University of Technology
Alexandra González	University of Alcala
Juan Carlos Gonzalez de Sande	Universidad Politécnica de Madrid
Gordon Goodman	Rochester Institute of Technology
Wade Goodridge	Utah State University
Aldo Gordillo	Universidad Politécnica de Madrid
Ann Gordon-Ross	University of Florida
Laura Grabowski	University of Texas-Pan American
Ximo Granell	Universitat Jaume I
Antoni Grau	Technical Univ of Catalonia
Olaf Hallan Graven	Buskerud and Vestfold University College
Mary Jo Grdina	Drexel University
Dai Griffiths	Bolton University
Michael Gross	Bucknell University
Mariluz Guenaga	Deusto Institute of Technology - DeustoTech, University of Deusto
Minzhe Guo	University of Cincinnati
Neeraj Gupta	UPTU Lucknow
Shohreh Hadian	Camosun College
Bashar Hammad	The Hashemite University
Laura Hanlan	Worcester Polytechnic Institute
Trevor Harding	California Polytechnic - SLO
David Harding	University of New Haven
Firas Hassan	Ohio Northern University
Pablo Haya	Universidad Autonoma of Madrid
Fredrik Heintz	Linköping University
Jose Ramon Hilera	University of Alcala
Jonathan Hilpert	Georgia Southern University
Margret Hjalmarson	George Mason University
Margaret Hobson	Texas Engineering Experiment Station--Texas A&M System
Kirsten Hochstedt	Penn State University
Archie Holmes	University of Virginia
Melinda Holtzman	Portland State University
Liang Hong	Tennessee State University
Christopher Hovey	The University of Texas at Austin
Shaobo Huang	South Dakota School of Mines and Technology
Shihong Huang	Florida Atlantic University
Yifan Huang	Beijing Institute of Technology
Lisa Huettel	Duke University

Meriel Huggard	Trinity College Dublin
Thorna Humphries	Norfolk State University
Jenefer Husman	ASU
María-Blanca Ibáñez	Universidad Carlos III de Madrid
Hairuzila Idrus	Universiti Teknologi PETRONAS
Vasiliki Ikonomidou	George Mason University
Hudson Jackson	United States Coast Guard Academy
Ashis Jalote-Parmar	Indian Institute of Management, Ahmedabad
Eric James	Huron Consulting Group
Peter Jamieson	Miami University
Daniela Janssen	IMA/ZLW & IfU RWTH Aachen University
Dhammika Jayalath	Queensland University of Technology
Indumathy Jayamani	Michigan State University
Sabina Jeschke	RWTH Aachen University
Brent Jesiek	Purdue University
Isabel Jesus	Institute of Engineering of Porto - ISEP
Elva Jones	Winston-Salem State University
Karl Jones	Liverpool John Moores University
Shawn Jordan	Arizona State University
Anthony Joseph	Pace University
Ann Kaiser	La Salle Academy
Chinami Kaneshiro	Okinawa National College of Technology
Jennifer Karlin	South Dakota School of Mines and Technology
Jamie Kennedy	Drexel University
Megan Kenny Feister	Purdue University
Howard Kimmel	New Jersey Institute of Technology
Adam Kirn	University of Nevada, Reno
Alexander Kist	University of Southern Queensland
Kathleen Kitto	Western Washington University
David Klotzkin	Binghamton University
Vitaly Klyuev	The University of Aizu
Yi Kong	Purdue University
Ari Korhonen	Aalto University School of Science
Daniel Krutz	Rochester Institute Of Technology
Sami Kujala	Aalto University School of Electrical Engineering
Amruth Kumar	Ramapo College of New Jersey
Varun Kumar	Tata Research Development and Design Centre
Viraj Kumar	PES University
Rangith Kuriakose	University of Technology
Gerard Lachiver	Universite de Sherbrooke
Manuel Lama	Universidade de Santiago de Compostela
Micah Lande	Arizona State University
Dieter Landes	Coburg University of Applied Sciences and Arts
Mikel Larrañaga	University of the Basque Country, UPV/EHU

Eric Larson	Seattle University
Claire Lassudrie	Telecom Bretagne
Marcia Laugerman	Iowa State University
Wendy LawrenceFowler	The University of Texas-Pan American
Alistair Lawson	Edinburgh Napier University
Khuan Lee	Universiti Teknologi MARA
Young Lee	Texas A&M University-Kingsville
Kenneth Leitch	West Texas A&M University
Elizabeth Lennon	Manhattan College
Michael Leverington	University of Nevada, Reno
Xiaosong Li	Unitec Institute of Technology
Ying Li	Beijing University of Aeronautics and Astronautics
Xiang Lian	University of Texas Rio Grande Valley
Ying Liang	University of the West of Scotland
Pengtao Lin	Old Dominion University
Euan Lindsay	Charles Sturt University
Julie Linsey	Georgia Institute of Technology
Martín Llamas-Nistal	University of Vigo
Marisa Llorens	Dublin Institute of Technology
Jorge López Benito	CreativITIC Innova SL
Antonio López-Martín	Public University of Navarra
Jorge Lopez-Vargas	UTPL
David Lowe	The University of Sydney
Vicente Lucena	University of Amazonas
Anne Lucietto	Purdue University
Leandro Luque	Sao Paulo State Technological College
José Magalhães	Federal University of Amazonas
Elizabeth Maia	Federal University of Minas Gerais
Joyce Main	Purdue University
Mitsunori Makino	Chuo University
Manish Malik	University of Portsmouth
Natasha Mamaril	University of Illinois
Aleardo Manacero	São Paulo State University - UNESP
Murali Mani	University of Michigan Flint
Theodore Manikas	Southern Methodist University
Vincent Manno	Franklin W. Olin College of Engineering
Rachid Manseur	SUNY Oswego
Mario Manso Vazquez	University of Vigo
Ashutosh Marathe	University of Pune
Maria Marcelino	University of Coimbra
Maria Jesús Marco-Galindo	Universitat Oberta de Catalunya
Bertil Marques	Instituto Superior de Engenharia do Porto
Maíra Marques Samary	Universidad de Chile
Norian Marranghello	São Paulo State University - UNESP

John Marsh	University of Glasgow
Itziar Martija	University of the Basque Country
Carme Martin	Universitat Politecnica de Catalunya - BarcelonaTech
Jose Luis Martin	Instituto de Ciencias de la Educación Universidad Politécnica de Madrid
Sergio Martin	Spanish University for Distance Education - UNED
Francisco Martinez	University of Zaragoza
Pilar Martínez García	Universidad Politécnica de Madrid
Jorge Martin-Gutierrez	Univeridad de La Laguna
Scheila Martins	University of Coimbra
Luis Mata	Lawrence Technological University
Cheryl Matherly	University of Tulsa
John Mativo	University Of Georgia
Holly Matusovich	Virginia Tech
Ciaran Mc Goldrick	Trinity College Dublin
Tom McEwan	Edinburgh Napier University
Jacqueline McNeil	Purdue University
Debbie Meharg	Edinburgh Napier University
Glaucia Mello	Pontifical Catholic University of Minas Gerais
Iratxe Menchaca	University of Deusto
António Mendes	University of Coimbra
Andrea Mendonça	Federal Institute of Education, Science & Technology of Amazonas (IFAM)
John Mendoza-Garcia	Purdue University / Pontificia Universidad Javeriana
Andrew Meneely	Rochester Institute of Technology
Jessica Menold	Penn State University
Rodany Merida	University of the East
Georgette Michko	University of Houston
Arturo Miguel-de-Priego	None
Lee Miller	University of Nebraska-Lincoln
Matthew Miller	Clemson University
Steven Miller	IBM
Mani Mina	Iowa State University
Tsunenori Mine	Kyushu University
Angela Minichiello	Utah State University
Joe Miró	Universitat de les Illes Balears
Sumita Mishra	Rochester Institute of Technology
Elif Miskioglu	The Ohio State University
Crista Mohammed	The University of the West Indies
Thabit Sultan Mohammed	Dhofar University
Maurizio Molinaro	ISMB
Santiago Moll	Universitat Politècnica de València
Margarita Moltó-Aribau	University of Lleida
Carla Montagud	Instituto de Ingeniería Energética, Universitat Politècnica de València
Juan Montero	Universidad Politecnica de Madrid
Young Moon	Syracuse University

Carlos Efrén Mora Luis	Universidad de La Laguna
Jose Antonio Moraño	Universitat Politècnica de València
Fernando Moreira	Portucalense University
Natalia Mosina	The City University of New York
Dulce Mota	FEUP - Faculty of Engineering, University of Porto
Regina Motz	Universidad de la Republica

Xiaohong Yuan	North Carolina A & T State University
Sarah Zappe	Penn State University
Yevgeniya Zastavker	F. W. Olin College of Engineering
Jinghua Zhang	Winston-Salem State University
Xue Zhang	Arizona State University
Ling Zhao	Shanghai University
Carla Zoltowski	Purdue University
Sergio Zorzo	Federal University of Sao Carlos
Danilo Zutin	Carinthia University of Applied Sciences

Session Chairs

The conference committee would like to thank the people that have agreed to act as session chairs at the 2015 Frontiers in Education Conference. Session chairs play an important role in ensuring the conference runs smoothly and that the technical presentations are a valuable experience for both speakers and attendees. Session chairs also have served a critical role in helping with the Ben Dasher Award process.

The primary responsibilities of session chairs are to:

- Read the session's papers in advance and recommend papers for the Ben Dasher Best Paper committee.
- Contact the authors in the session and become familiar with the authors who are presenting.
- Introduce the session and make any FIE announcements that are needed.
- Briefly introduce each speaker and paper.
- Manage audience questions, and ensure that presentations begin and end within their time slots.

The program committee would like to thank the following individuals and those session chairs not listed for their efforts to help make FIE 2015 both informative and successful:

Code	Title	Start time	Room	Chair
T1A	Special Session: Connecting and Expanding the Emerging Engineering Education Research & Innovation (EER&I) Communities	11:00 AM	Kohlberg	Sohum Sohoni (Arizona State University, USA)
T1B	Special Session: Movin' Along: Investigating Motion and Mechanisms Using Engineering Design Activities	11:00 AM	Pancho Villa	Eric Durant (Milwaukee School of Engineering, USA)
T1C	First and Second Year Topics I	11:00 AM	Angus	Jon Sticklen (Michigan Technological University, USA)
T1D	K-12 Education I	11:00 AM	Brahma	David Reeping (Ohio Northern University, USA)
T1E	Social and Cognitive Aspects of Learning	11:00 AM	Charolais	Monique Ross (Engineering Education, USA)
T1F	Innovation and Entrepreneurship I	11:00 AM	Longhorn	Meagan Vaughan (University of Texas at El Paso, USA)
T1G	Learning in Teams	11:00 AM	Hereford	Katherine Goodman (University of Colorado Boulder, USA)
T1H	Learning Analytics I	11:00 AM	Rio Grande	Molly Hathaway Goldstein (Purdue University, USA)
T1I	Software Engineering Education	11:00 AM	Santa Fe	Rose Gamble (University of Tulsa, USA)
T2A	Special Session: Design Metaphors - Rethinking the Vocabulary of Design Education	2:30 PM	Kohlberg	Colin Smith (Edinburgh Napier University, United Kingdom)
T2B	Special Session: Helping Tomorrow's Engineers Ask Productive Questions	2:30 PM	Pancho Villa	Susan Kowalski (Colorado School of Mines, USA)
T2C	Innovative Curriculum & Course Design I	2:30 PM	Angus	Axel Böttcher (Munich University of Applied Sciences, Germany)
T2D	K-12 Education II	2:30 PM	Brahma	Glenda Young (Virginia Tech, USA)
T2E	Blended Learning Approaches	2:30 PM	Charolais	Asad Azemi (Pennsylvania State University, USA)
T2F	Game Based Learning I	2:30 PM	Longhorn	Todd Fernandez (Purdue University, USA)
T2G	Student Engagement I	2:30 PM	Hereford	Andrea M. Ogilvie (Virginia Tech, USA)

T2H	Learning Analytics II	2:30 PM	Rio Grande	Michael Mogessie Ashenafi (University of Trento, Italy)
T2I	Teaching Cryptography & Computer Security	2:30 PM	Santa Fe	Cem Sahin (Drexel University, USA)
T3A	Special Session: Introduction to Systematic Reviews in Engineering Education Research	4:30 PM	Kohlberg	Liping Liu (Lawrence Technological University, USA)
T3B	Special Session: Exploring the Black Box of Dissemination: The Role of Professional and Organizational Development	4:30 PM	Pancho Villa	Walter C. Lee (Virginia Tech, USA)
T3C	Engineering Identity	4:30 PM	Angus	James Huff (Harding University, USA)
T3D	Curriculum Change	4:30 PM	Brahma	Marja Talikka (Lappeenranta University of Technology, Finland)
T3E	Assessment in Computer Science	4:30 PM	Charolais Room	Thomas Staubit (Hasso Plattner Institute for Software Systems Engineering, Germany)
T3F	Game Based Learning II	4:30 PM	Longhorn	Jacques Duílio Brancher (Universidade Estadual de Londrina, Brazil)
T3G	Gender in Engineering and Computing I	4:30 PM	Hereford	Virginia Grande (Uppsala University, Sweden)
T3H	Motivation	4:30 PM	Rio Grande	Sadan Kulturel-Konak (Penn State Berks, USA)
T3I	Teaching and Learning Math	4:30 PM	Santa Fe	Christine F Reilly (University of Texas - Pan American, USA)
F1A	Special Session: Taking Stock: Using a Landscape Inventory to Drive Curriculum and Program Change	9:00 AM	Kohlberg	Yulei Pang (Southern Connecticut State University, USA)
F1B	Special Session: Helping your students learn "Engineering-ese": Using the results of conceptual change research to inform your instruction	9:00 AM	Pancho Villa	Ruth Streveler (Purdue University, USA)
F1C	Innovative Mobile Tools and Applications	9:00 AM	Angus	Amalia Rusu (Fairfield University, USA)
F1D	Game-Based Learning III	9:00 AM	Brahma	Jinghua Zhang (Winston-Salem State University, USA)
F1E	Flipped Classroom	9:00 AM	Charolais	Robert M O'Connell (University of Missouri-Columbia, USA)
F1F	Industry Oriented Teaching and Learning	9:00 AM	Longhorn	Bunmi Bababajide (Purdue University, USA)
F1G	MOOCs and Big Data	9:00 AM	Hereford	Anna Douglas (Purdue University, USA)
F1H	Teaching and Learning Programming I	9:00 AM	Rio Grande	Roberto A Bittencourt (State University of Feira de Santana, Brazil)
F1I	Cyber Security	9:00 AM	Santa Fe	Walter W Schilling, Jr (Milwaukee School of Engineering, USA)
F2A	Special Session: CE2016 Updated Computer Engineering Curriculum Guidelines	11:00 AM	Kohlberg	Xiaosong Li (Unitec Institute of Technology, New Zealand)
F2B	Special Session: What the Heck is That?! Adaptation of Evidence-Based Instructional Practices	11:00 AM	Pancho Villa	Lizabeth Schlemer (Cal Poly, San Luis Obispo, USA)
F2C	Mobile Teaching and Learning	11:00 AM	Angus	Manuel Castro (Spanish University for Distance Education, Spain)
F2D	Game-Based Learning IV	11:00 AM	Brahma	Bhojan Anand (National University of Singapore, Singapore)

F2E	Student Engagement II	11:00 AM	Charolais	Ricardo José Rocha Amorim (State University of Bahia (UNEB), Brazil)
F2F	Gender in Engineering and Computing II	11:00 AM	Longhorn	Amir Zeid (American University of Kuwait, Kuwait)
F2G	Faculty Development I	11:00 AM	Hereford	Jacqueline McNeil (University of Louisville, USA)
F2H	Teaching and Learning Programming II	11:00 AM	Rio Grande	Ivan Mauricio Cabezas (Universidad de San Buenaventura, Colombia)
F2I	Design Methods	11:00 AM	Santa Fe	Susan Donohue (University of Virginia, USA)
F3A	Special Session: Is the Engineer of 2035 a Maker?	2:30 PM	Kohlberg	Neha Choudhary (Purdue University, USA)
F3B	Special Session: Agents for Change in Engineering & Computer Science Education	2:30 PM	Pancho Villa	Kevin Buffardi (California State University - Chico, USA)
F3C	Using Robots in Teaching and Learning	2:30 PM	Angus	Kevin Gary (Arizona State University, USA)
F3D	Retention	2:30 PM	Brahma	Shaobo Huang (South Dakota School of Mines and Technology, United States)
F3E	Design Education II	2:30 PM	Charolais	Jay R Porter (Texas A&M University, USA)
F3F	Social Responsibility and Ethics	2:30 PM	Longhorn	Wilkistar Otieno (University of Wisconsin-Milwaukee, USA)
F3G	Faculty Development II	2:30 PM	Hereford	Jeffrey E Froyd (Texas A&M University, USA)
F3H	Interdisciplinary Education in Programming	2:30 PM	Rio Grande	Laura R. Hanlan (Worcester Polytechnic Institute, United States)
F3I	Embedded Systems Education I	2:30 PM	Santa Fe	Victor F. A. Barros (Science and Education Research Council, Portugal)
F4A	Special Session: Qualitative Research on Psychological Experience: A Starting Point for Using Interpretative Phenomenological Analysis	5:00 PM	Kohlberg	James Huff (Harding University, USA)
F4B	Special Session: Aesthetics and Emotional Engagement: Why it Matters to Our Students, Why it Matters to Our Professions	5:00 PM	Pancho Villa	Nathan Canney (Seattle University, USA)
F4C	Student-Centered Education I	5:00 PM	Angus	Brian Rague (Weber State University, USA)
F4D	K-12 Teacher Education and Computational Thinking	5:00 PM	Brahma	Charles Wallace (Michigan Technological University, United States)
F4E	K-12 Education III	5:00 PM	Charolais	Mary M Capraro (Texas A&M University, USA)
F4F	Design Education III	5:00 PM	Longhorn	Deeksha Seth (Drexel University, USA)
F4G	Philosophy Of Engineering	5:00 PM	Hereford	Geoffrey Herman (University of Illinois at Urbana-Champaign, USA)
F4H	Professional Skills	5:00 PM	Rio Grande	Abe Zeid (Northeastern University, USA)
F4I	Embedded Systems Education II	5:00 PM	Santa Fe	Firas Hassan (Ohio Northern University, USA)
S1A	Panel: International iCampus Forum (IC15) on "Smart Education in Smart Cities"	9:00 AM	Kohlberg	Jason Ng (British Telecom, United Kingdom)
S1B	New Approaches-Student-Center	9:00 AM	Pancho Villa	Rangith Baby Kuriakose (University of Technology, South Africa)

S1C	Student Center Education	9:00 AM	Angus	Brian Skromme (Arizona State University, USA)
S1D	Assessment I	9:00 AM	Brahma	Vladik Kreinovich (University of Texas at El Paso, USA)
S1E	First and Second Year Topics II	9:00 AM	Charolais	Frank Vahid (University of California, Riverside, USA)
S1F	Online Assessment	9:00 AM	Longhorn	Dazhi Yang (Boise State, USA)
S1G	Innovative Curriculum & Course Design I	9:00 AM	Hereford	Venky Shankararaman (Singapore Management University, Singapore)
S1H	Innovative Curriculum & Course Design II	9:00 AM	Rio Grande	Wei-Fan Chen (Penn State University, USA)
S1I	Faculty Development III	9:00 AM	Santa Fe	Megan Tomko (Georgia Institute of Technology, USA)
S2A	Technological Tools I	11:00 AM	Kohlberg	Jean Hertzberg (University of Colorado Boulder, USA)
S2B	Computer Based Learning	11:00 AM	Pancho Villa	Rogério Garcia (São Paulo State University, Brazil)
S2C	Innovative Curriculum & Course Design III	11:00 AM	Angus	Rebecca Reck (University of Illinois at Urbana-Champaign, USA)
S2D	Curriculum Design III	11:00 AM	Brahma	Kari Systä (Tampere University of Technology, Finland)
S2E	Innovative Curriculum & Course Design IV	11:00 AM	Charolais	Brian Faulkner (University of Illinois, USA)
S2F	K-12 Education III	11:00 AM	Longhorn	Noah Salzman (Boise State University, USA)
S2G	Online-Distance Learning	11:00 AM	Hereford	Larry Richards (University of Virginia, USA)
S2H	Assessment	11:00 AM	Rio Grande	Senay Purzer (Purdue University, USA)
S2I	Innovative Curriculum & Course Design V	11:00 AM	Santa Fe	Dan Tappan (Eastern Washington University, USA)
S3A	Innovative Curriculum & Course Design VI	2:30 PM	Kohlberg	Paul B Crilly (United States Coast Guard Academy, USA)
S3B	Global Programs	2:30 PM	Pancho Villa	Joyce B. Main (Purdue University, USA)
S3C	Outreach & University, Community Collaborations	2:30 PM	Angus	Natascha Trellinger (Purdue University, USA)
S3D	First and Second Year Topics III	2:30 PM	Brahma	James Morris (Portland State University, USA)
S3E	Student Interest	2:30 PM	Charolais	Linda P. DuHadway (Utah State University, USA)
S3F	Student-Centered Education IV	2:30 PM	Longhorn	Jose Aguilar (Universidad de Los Andes, Venezuela)
S3G	K-12 Education IV	2:30 PM	Hereford	DeLean Tolbert (Purdue University, USA)
S3H	Innovative Curriculum & Course Design VII	2:30 PM	Rio Grande	Samuel A Malachowsky (Rochester Institute of Technology, USA)
S3I	Project-Based Learning	2:30 PM	Santa Fe	Stephen Frezza (Gannon University, USA)
S4B	Innovative Tools and Approaches	4:30 PM	Pancho Villa	Efraín O'Neill-Carrillo (University of Puerto Rico-Mayaguez, Puerto Rico)
S4C	Non-Traditional Students	4:30 PM	Angus	Maura Borrego (University of Texas at Austin, USA)
S4D	Technological Tools II	4:30 PM	Brahma	Jaspal Subhlok (University of Houston, USA)
S4E	Co-Ops and Early Career Training	4:30 PM	Charolais	Samantha Brunhaver (Arizona State University, USA)

S4F	Communication and Storytelling	4:30 PM	Longhorn	Imelda Smit (North West University, South Africa)
S4G	Computing Education	4:30 PM	Hereford	David R Monismith, Jr. (Northwest Missouri State University, USA)
S4I	Innovative Curriculum & Course Design VIII	4:30 PM	Santa Fe	Chiu Choi (University of North Florida, USA)

Session Grid – Wednesday, October 21st

Time	Brahma Room	Angus Room	Santa Fe Room	Pancho Villa Room	Kohlberg Room
1:00 PM - 4:00 PM	1A: Pre-Conference Workshop: Integrating Service-Learning into Engineering and Computing Education	1B: Pre-Conference Workshop: Teaching and Assessment Strategies that Value Innovative Thinking	1C: Pre-Conference Workshop: Process to Draft the Program Educational Objectives for Undergraduate Engineering Degree Programs	1D: Pre-Conference Workshop: Agile Way of Educating	1E: Pre-Conference Workshop: Ideas at Play: Bring games to your classroom to increase student engagement and deep learning
5:00 PM - 8:00 PM	2A: Pre-Conference Workshop: Encouraging Information Rich Engineering Design		2C: Pre-Conference Workshop: Agile Teaching and Learning	2D: Pre-Conference Workshop: How to Select an Area of Scholarship and Address the Applicable Review Criteria to Publish a Paper in the IEEE Transactions on Education	

Session Grid – Thursday, October 22nd

Time	Kohlberg Room	Pancho Villa Room	Angus Room	Brahma Room	Charolais Room	Longhorn Room	Hereford Room	Rio Grande Room	Santa Fe Room
11:00 AM - 12:30 PM	T1A: SS: Connecting and Expanding the Emerging Engineering Education Research & Innovation (EER&I) Communities	T1B: SS: Movin' Along: Investigating Motion and Mechanisms Using Engineering Design Activities	T1C: First and Second Year Topics I	T1D: K-12 Education I	T1E: Social and Cognitive Aspects of Learning	T1F: Innovation and Entrepreneurship I	T1G: Learning in Teams	T1H: Learning Analytics I	T1I: Software Engineering Education
2:30 PM - 4:00 PM	T2A: SS: Design Metaphors - Rethinking the vocabulary of design education	T2B: SS: Helping Tomorrow's Engineers Ask Productive Questions	T2C: Innovative Curriculum & Course Design I	T2D: K-12 Education II	T2E: Blended Learning Approaches	T2F: Game based learning I	T2G: Student engagement I	T2H: Learning Analytics II	T2I: Teaching Cryptography & Computer Security
4:30 PM - 6:00 PM	T3A: SS: Introduction to Systematic Reviews in Engineering Education Research	T3B: SS: Exploring the Black Box of Dissemination- The Role of Professional and Organizational Development	T3C: Engineering Identity	T3D: Curriculum change	T3E: Assessment in Computer Science	T3F: Game based learning II	T3G: Gender in Engineering and Computing I	T3H: Motivation	T3I: Teaching and Learning Math

Session Grid – Friday, October 23rd

Time	Kohlberg Room	Pancho Villa Room	Angus Room	Brahma Room	Charolais Room	Longhorn Room	Hereford Room	Rio Grande Room	Santa Fe Room
9:00 AM - 10:30 AM	F1A: SS: Taking Stock: Using a Landscape Inventory to Drive Curriculum and Program Change	F1B: SS: Helping your students learn "Engineering-ese": Using the results of conceptual change research to inform your instruction	F1C: Innovative Mobile Tools and Applications	F1D: Game-Based Learning III	F1E: Flipped Classroom	F1F: Industry Oriented Teaching and Learning	F1G: MOOCs and Big Data	F1H: Teaching and Learning Programming I	F1I: Cyber Security
11:00 AM - 12:30 PM	F2A: SS: CE2016 Updated Computer Engineering Curriculum Guidelines	F2B: Special Session: What the Heck is That?! Adaptation of Evidence-Based Instructional Practices	F2C: Mobile Teaching and Learning	F2D: Game-Based Learning IV	F2E: Student Engagement II	F2F: Gender in Engineering and Computing II	F2G: Faculty Development I	F2H: Teaching and Learning Programming II	F2I: Design Methods
2:30 PM - 4:00 PM	F3A: SS: Is the Engineer of 2035 a Maker?	F3B: Special Session: Agents for Change in Engineering & Computer Science Education	F3C: Using Robots in Teaching and Learning	F3D: Retention	F3E: Design Education II	F3F: Social Responsibility and Ethics	F3G: Faculty Development II	F3H: Interdisciplinary Education in Programming	F3I: Embedded Systems Education I
5:00 PM - 6:30 PM	F4A: SS: Qualitative Research on Psychological Experience: A Starting Point for Using Interpretative Phenomenological Analysis	F4B: Special Session: Aesthetics and Emotional Engagement: Why it Matters to Our Students, Why it Matters to Our Professions	F4C: Student-Centered Education I	F4D: K-12 Teacher Education and Computational Thinking	F4E: K-12 Education III	F4F: Design Education III	F4G: Philosophy of Engineering	F4H: Professional Skills	F4I: Embedded Systems Education II

Session Grid – Saturday, October 24th

Time	Kohlberg Room	Pancho Villa Room	Angus Room	Brahma Room	Charolais Room	Longhorn Room	Hereford Room	Rio Grande Room	Santa Fe Room
9:00 AM - 10:30 AM	S1A: Panel: International iCampus Forum (IC15) on "Smart Education in Smart Cities"	S1B: New Approaches- Student- Center	S1C: Student Center Education	S1D: Assessment I	S1E: First and Second Year Topics II	S1F: Online Assessment	S1G: Innovative Curriculum & Course Design I	S1H: Innovative Curriculum & Course Design II	S1I: Faculty Development III
11:00 AM - 12:30 PM	S2A: Technological Tools I	S2B: Computer Based Learning	S2C: Innovative Curriculum & Course Design III	S2D: Curriculum Design III	S2E: Innovative Curriculum & Course Design IV	S2F: K-12 Education III	S2G: Online- distance Learning	S2H: Assessment	S2I: Innovative Curriculum & Course Design V
2:30 PM - 4:00 PM	S3A: Innovative Curriculum & Course Design VI	S3B: Global Programs	S3C: Outreach & University, Community Collaborations	S3D: First and Second Year Topics III	S3E: Student Interest	S3F: Student- Centered Education IV	S3G: K-12 Education IV	S3H: Innovative Curriculum & Course Design VII	S3I: Project- Based Learning
4:30 PM - 6:00 PM		S4B: Innovative Tools and Approaches	S4C: Non- Traditional Students	S4D: Technological Tools II	S4E: Co-Ops and Early Career Training	S4F: Communication and Storytelling	S4G: Computing Education		S4I: Innovative Curriculum & Course Design VIII

Technical Sessions Table of Contents

Wednesday, October 21

IA: Pre-Conference Workshop: Integrating Service-Learning into Engineering and Computing Education

1:00 PM - 4:00 PM

Room: Brahma Room

INTEGRATING SERVICE-LEARNING INTO ENGINEERING AND COMPUTING EDUCATION 1

William C. Oakes (Purdue University, USA)

Carla B. Zoltowski (Purdue University, USA)

IB: Pre-Conference Workshop: Teaching and Assessment Strategies that Value Innovative Thinking

1:00 PM - 4:00 PM

Room: Angus Room

TEACHING AND ASSESSMENT STRATEGIES THAT VALUE INNOVATIVE THINKING..... 4

Şenay Purzer (Purdue University, USA)

Todd Fernandez (Purdue University, USA)

IC: Pre-Conference Workshop: Process to Draft the Program Educational Objectives for Undergraduate Engineering Degree Programs

1:00 PM - 4:00 PM

Room: Santa Fe Room

PROCESS TO DRAFT THE PROGRAM EDUCATIONAL OBJECTIVES FOR UNDERGRADUATE ENGINEERING DEGREE PROGRAMS..... 6

Ramakrishnan Sundaram (Gannon University, USA)

ID: Pre-Conference Workshop: Agile Way of Educating

1:00 PM - 4:00 PM

Room: Pancho Villa Room

AGILE WAY OF EDUCATING 10

Gerald Gannod (Miami University - Oxford, USA)

Douglas Troy (Miami University - Oxford, USA)

Jerome Luczaj (Miami University - Middletown, USA)

Diane Rover (Iowa State University, USA)

2A: Pre-Conference Workshop: Encouraging Information Rich Engineering Design

5:00 PM - 8:00 PM

Room: Brahma Room

WORKSHOP: ENCOURAGING INFORMATION-RICH ENGINEERING DESIGN 13

Michael Fosmire (Purdue University, USA)

Amy Van Epps (Purdue University, USA)

Laura Hanlan (Worcester Polytechnic Institute, USA)

2C: Pre-Conference Workshop: Agile Teaching and Learning

5:00 PM - 8:00 PM

Room: Santa Fe Room

PRE-CONFERENCE WORKSHOP: AGILE TEACHING AND LEARNING..... 15

Kevin Gary (The Ira A. Fulton Schools of Engineering, USA)

Sohum Sohoni (The Ira A. Fulton Schools of Engineering, USA)

Suhas Xavier (The Ira A. Fulton Schools of Engineering, USA)

2D: Pre-Conference Workshop: How to Select an Area of Scholarship and Address the Applicable Review Criteria to Publish a Paper in the IEEE Transactions on Education

5:00 PM - 8:00 PM

Room: Pancho Villa Room

HOW TO SELECT AN AREA OF SCHOLARSHIP AND ADDRESS THE APPLICABLE REVIEW CRITERIA TO PUBLISH A PAPER IN THE IEEE TRANSACTIONS ON EDUCATION 17

Jeffrey E. Froyd (Texas A&M University, USA)

Thursday, October 22

TIA: Special Session: Connecting and Expanding the Emerging Engineering Education Research & Innovation (EER&I) Communities

Chair: Sohum Sohoni (Arizona State University, USA)

11:00 AM - 12:30 PM

Room: Kohlberg Room

CONNECTING AND EXPANDING THE EMERGING ENGINEERING EDUCATION RESEARCH & INNOVATION (EER&I) COMMUNITIES..... 19

Karl Smith (Purdue University & University of Minnesota, USA)

Ruth Streveler (Purdue University, USA)

Rocio C. Chavela Guerra (American Society for Engineering Education, USA)

TIB: Special Session: Movin' Along: Investigating Motion and Mechanisms Using Engineering Design Activities

Chair: Eric Durant (Milwaukee School of Engineering, United States)

11:00 AM - 12:30 PM

Room: Pancho Villa Room

FIE 2015 SPECIAL SESSION - MOVIN' ALONG: INVESTIGATING MOTION AND MECHANISMS USING ENGINEERING DESIGN ACTIVITIES..... 22

Susan Donohue (University of Virginia, USA)

Larry Richards (University of Virginia, USA)

TIC: First and Second Year Topics I

Chair: Jon Sticklen (Michigan Technological University, United States)

11:00 AM - 12:30 PM

Room: Angus Room

ALUMNI AS A RESOURCE TO INCREASE STUDENT RETENTION IN EARLY COMPUTER SCIENCE COURSES..... 27

Linda Ott (Michigan Technological University, USA)

COMPARING COMMON AND DISCIPLINE-SPECIFIC FIRST-YEAR ENGINEERING PROGRAMS: EXAMINING THE NEED AND EXPLAINING THE STUDY..... 36

Mahnas Jean Mohammadi-Aragh (Mississippi State University, USA)

Rachel L. Kajfez (The Ohio State University, USA)

AN "OBJECTS FIRST, TESTS SECOND" APPROACH FOR SOFTWARE ENGINEERING EDUCATION..... 40

Veronika Thurner (Munich University of Applied Sciences, Germany)

Axel Böttcher (Munich University of Applied Sciences, Germany)

THE IMPACTS OF PROJECT BASED LEARNING ON SELF-DIRECTED LEARNING AND PROFESSIONAL SKILL ATTAINMENT: A COMPARISON OF PROJECT BASED LEARNING TO TRADITIONAL ENGINEERING EDUCATION..... 45

Bart Johnson (Itasca Community College, USA)

Ron Ulseth (Iron Range Engineering, USA)

Crystal Smith (Itasca Community College, USA)

Derek Fox (Itasca Community College, USA)

AN EVALUATION OF HOW CHANGES TO THE INTRODUCTORY COMPUTER SCIENCE COURSE SEQUENCE IMPACT STUDENT SUCCESS..... 50

Christine Reilly (University of Texas-Pan American, USA)

Emmett Tomai (University of Texas-Pan American, USA)

Laura Grabowski (University of Texas-Pan American, USA)

TID: K-12 Education I**Chair:** David Reeping (Ohio Northern University, United States)**11:00 AM - 12:30 PM****Room:** Brahma Room

***EMPOWERING TEACHERS TO TEACH CS - EXPLORING A SOCIAL CONSTRUCTIVIST
APPROACH FOR CS CPD, USING THE BRIDGE21 MODEL..... 56***

J. R. Byrne (Centre for Research in IT in Education, Ireland)

L. Fisher (Centre for Research in IT in Education, Ireland)

B. Tangney (Centre for Research in IT in Education, Ireland)

***ENGAGE K-12 STUDENTS IN ENGINEERING: MODEL FOR ENGINEERING PROJECT
ACTIVITIES TO INSPIRE K-12 STUDENTS TO PURSUE CAREERS IN ENGINEERING..... 65***

Ramakrishnan Sundaram (Gannon University, USA)

***VIEWING K-12 MATHEMATICS AND SCIENCE STANDARDS THROUGH THE LENS OF THE
FIRST-YEAR INTRODUCTION TO ENGINEERING COURSE CLASSIFICATION SCHEME..... 69***

David Reeping (Ohio Northern University, USA)

Kenneth Reid (Virginia Tech, USA)

***EFFECTS OF THE BUTTERFLY DIAGRAM EDUCATION IN PRIMARY AND
SECONDARY SCHOOLS ON CONTRADICTION PROBLEM SOLVING ABILITY 75***

Jung Suk Hyun (Jeju National University, Korea)

Chan Jung Park (Jeju National University, Korea)

TIE: Social and Cognitive Aspects of Learning**Chair:** Monique Ross (Engineering Education, USA)**11:00 AM - 12:30 PM****Room:** Charolais Room

***AN ENGINEERING STUDENT LEADERSHIP DEVELOPMENT MODEL FOR 21ST CENTURY
ENGINEERING: USING SOCIOCULTURAL THEORY TO INFORM PRACTICE 83***

Elsa Villa (The University of Texas at El Paso, USA)

Alberto Esquinca (The University of Texas at El Paso, USA)

Erika Mein (The University of Texas at El Paso, USA)

Peter Golding (The University of Texas at El Paso, USA)

Sarah Hug (University of Colorado Boulder, USA)

***DOCUMENTING STUDENTS' FAULTY SCHEMA AND MISCONCEPTIONS ABOUT
COMBINATIONS AND PERMUTATIONS..... 87***

Lance Pittman (University of Illinois at Urbana-Champaign, USA)

Geoffrey Herman (University of Illinois at Urbana-Champaign, USA)

TAXONOMY OF FACULTY ASSUMPTIONS ABOUT STUDENTS 96

Aaron Estrada (California Polytechnic State University, USA)

Lizabeth Thompson Schlemmer (California Polytechnic State University, USA)

***SOCIOCULTURAL APPROACHES TO TEACHING AND LEARNING IN ENGINEERING EDUCATION:
RESEARCH-BASED APPLICATIONS IN A PRE-ENGINEERING COURSE..... 101***

Erika Mein (The University of Texas at El Paso, USA)

Christina Convertino (The University of Texas at El Paso, USA))

Angelica Monarrez (The University of Texas at El Paso, USA)

QUALITATIVE ASSESSMENT OF THE UNIVERSITY OF TEXAS SYSTEM LOUIS STOKES ALLIANCE FOR MINORITY PARTICIPATION SUMMER RESEARCH ACADEMY ABROAD: AN INTERNATIONAL EXPERIENCE IN RESEARCH AND CULTURE 105

Ariana Arciero-Pino (The University of Texas at El Paso, USA)
Benjamin Flores (The University of Texas at El Paso, USA)
Helmut Knaust (The University of Texas at El Paso, USA)
Lynda Gonzales (The University of Texas at Austin, USA)
Maricel Quintana-Baker (MQB-Consulting, USA)

TIF: Innovation and Entrepreneurship I

Chair: Meagan Vaughan (University of Texas at El Paso, United States)

11:00 AM - 12:30 PM

Room: Longhorn Room

LANDSCAPE ANALYSIS AS A TOOL IN THE CURRICULAR CHANGE PROCESS 110

Elizabeth Nilsen (VentureWell, USA)
Victoria Matthew (VentureWell, USA)
Mary Besterfield-Sacre (University of Pittsburgh, USA)
Thema Monroe-White (SageFox Consulting Group, USA)

FOSTERING THE ENTREPRENEURIAL MINDSET IN THE JUNIOR AND SENIOR MECHANICAL ENGINEERING CURRICULUM WITH A MULTI-COURSE PROBLEM-BASED LEARNING EXPERIENCE..... 117

Liping Liu (Lawrence Technological University, USA)
James Mynderse (Lawrence Technological University, USA)
Andrew L. Gerhart (Lawrence Technological University, USA)
Selin Arslan (Lawrence Technological University, USA)

ASSESSING SITUATIONAL CURIOSITY AND MOTIVATION IN OPEN-ENDED DESIGN ELECTIVES 122

Charles Kim (Bucknell University, USA)
Alan Cheville (Bucknell University, USA)
Katharyn Nottis (Bucknell University, USA)
Joseph Tranquillo (Bucknell University, USA)
Erin Jablonski (Bucknell University, USA)
Michael Prince (Bucknell University, USA)
Margot Vigeant (Bucknell University, USA)

"INNOVATIVE OFFICE": BUILDING FUTURE FOR YOUNG ENGINEERS..... 125

Melany M. Ciampi (Safety, Health and Environment Research Organization, Brazil)
Luis Amaral (Computer Graphics Center, Portugal)
Victor F. A. Barros (Science and Education Research Council, Portugal)
Claudio da Rocha Brito (Science and Education Research Council, Brazil)
Rosa Vasconcelos (University of Minho, Portugal)

TIG: Learning in Teams

Chair: Katherine Goodman (University of Colorado Boulder, USA)

11:00 AM - 12:30 PM

Room: Hereford Room

TASK CHOICE, GROUP DYNAMICS, AND LEARNING GOALS: UNDERSTANDING STUDENT ACTIVITIES IN TEAMS 129

Laura Hirshfield (University of Michigan, USA)
Debbie Chachra (Olin College of Engineering, USA)

<i>THE IMPACT OF A PEER LEARNING STRATEGY ON STUDENT ACADEMIC PERFORMANCE IN A FUNDAMENTAL ENGINEERING COURSE.....</i>	<i>134</i>
Shaobo Huang (South Dakota School of Mines and Technology, USA)	
Elizabeth Pierce (South Dakota School of Mines and Technology, USA)	
<hr/>	
<i>T1H: Learning Analytics I</i>	
Chair: Molly Hathaway Goldstein (Purdue University, United States)	
11:00 AM - 12:30 PM	
Room: Rio Grande Room	
<hr/>	
<i>CHECKABLE ANSWERS: UNDERSTANDING STUDENT BEHAVIORS WITH INSTANT FEEDBACK IN A BLENDED LEARNING CLASS</i>	<i>138</i>
Xin Chen (Purdue University, USA)	
Jennifer DeBoer (Purdue University, USA)	
<i>AUTOMATIC RECOGNITION OF MISCONCEPTIONS IN VISUAL ALGORITHM SIMULATION EXERCISES</i>	<i>143</i>
Ari Korhonen (Aalto University, Finland)	
Otto Seppälä (Aalto University, Finland)	
Juha Sorva (Aalto University, Finland)	
<i>FORMULATION OF A PREDICTIVE MODEL FOR ACADEMIC PERFORMANCE BASED ON STUDENTS' ACADEMIC AND DEMOGRAPHIC DATA.....</i>	<i>148</i>
Sandra Milena Merchán Rubiano (Universidad El Bosque, Colombia)	
Jorge Alberto Duarte García (Universidad El Bosque, Colombia)	
<i>ELICITED AND MINED RULES FOR DROPOUT PREVENTION IN ONLINE COURSES</i>	<i>155</i>
Francisco A. de Almeida, Neto (Federal University of Amazonas, Brazil)	
Alberto Castro (Federal University of Amazonas, Brazil)	
<i>XAPI-SRL: USES OF AN APPLICATION PROFILE FOR SELF-REGULATED LEARNING BASED ON THE ANALYSIS OF LEARNING STRATEGIES</i>	<i>162</i>
Mario Manso-Vázquez (University of Vigo, Spain)	
Manuel Caeiro-Rodríguez (University of Vigo, Spain)	
Martín Llamas-Nistal (University of Vigo, Spain)	
<hr/>	
<i>T1I: Software Engineering Education</i>	
Chair: Rose Gamble (University of Tulsa, USA)	
11:00 AM - 12:30 PM	
Room: Santa Fe Room	
<hr/>	
<i>AN APPROACH TO ENHANCE STUDENTS' COMPETENCY IN SOFTWARE VERIFICATION TECHNIQUES.....</i>	<i>170</i>
Omar Ochoa (University of Texas at El Paso, USA)	
Salamah Salamah (University of Texas at El Paso, USA)	
<i>EVALUATION AND ASSESSMENT OF EFFECTS ON EXPLORING MUTATION TESTING IN PROGRAMMING COURSES.....</i>	<i>179</i>
Rafael Oliveira (University of São Paulo, Brazil)	
Lucas Oliveira (University of São Paulo, Brazil)	
Bruno Cafeo (PUC-Rio, Brazil)	
Vinicius Durelli (University of São Paulo, Brazil)	
<i>DIVERSITY AND ANXIETY: A CASE STUDY ON COLLABORATIVE TESTING.....</i>	<i>188</i>
Yulei Pang (Southern Connecticut State University, USA)	
Raymond Mugno (Southern Connecticut State University, USA)	
Xiaozhen Xue (Texas Tech University, USA)	

USABILITY CHALLENGES IN DIGITAL LEARNING SOLUTIONS	192
Veera Kenttälä (University of Jyväskylä, Finland)	
Marja Kankaanranta (University of Jyväskylä, Finland)	
Rebekah Rousi (University of Jyväskylä, Finland)	
Terhi Pänkäläinen (University of Jyväskylä, Finland)	
APPLYING MINDSTORM IN TEACHING AND LEARNING PROCESS AND SOFTWARE PROJECT MANAGEMENT.....	199
José Augusto Fabri (Universidade Tecnológica Federal do Paraná, Brazil)	
Alexandre L'Erario (Universidade Tecnológica Federal do Paraná, Brazil)	
Rodrigo Henrique Cunha Palácios (Universidade Tecnológica Federal do Paraná, Brazil)	
Wagner Godoy (Universidade Tecnológica Federal do Paraná, Brazil)	
<hr/>	
T2A: Special Session: Design Metaphors - Rethinking the vocabulary of design education	
Chair: Colin Smith (Edinburgh Napier University, United Kingdom)	
2:30 PM - 4:00 PM	
Room: Kohlberg Room	
<hr/>	
SPECIAL SESSION ON DESIGN METAPHORS: RETHINKING THE VOCABULARY OF DESIGN EDUCATION.....	207
Stephen Frezza (Gannon University, USA)	
John Krupczak, Jr (Hope College, USA)	
Mani Mina (Iowa State University, USA)	
<hr/>	
T2B: Special Session: Helping Tomorrow's Engineers Ask Productive Questions	
Chair: Susan Kowalski (Colorado School of Mines, United States)	
2:30 PM - 4:00 PM	
Room: Pancho Villa Room	
<hr/>	
HELPING TOMORROW'S ENGINEERS ASK PRODUCTIVE QUESTIONS.....	209
Frank Kowalski (Colorado School of Mines, USA)	
Susan Kowalski (Colorado School of Mines, USA)	
<hr/>	
T2C: Innovative Curriculum & Course Design I	
Chair: Axel Böttcher (Munich University of Applied Sciences, Germany)	
2:30 PM - 4:00 PM	
Room: Angus Room	
<hr/>	
AN EXPLORATION OF BLOOM'S KNOWLEDGE, SKILLS, AND A FFECTIVE-BASED GOALS IN PROMOTING DEVELOPMENT OF FRESHMEN ENGINEERING STUDENTS' PROFESSIONAL IDENTITIES	211
Idalis Villanueva (Utah State University, USA)	
BUILDING INFORMATION MODELING LABORATORY EXERCISES IN A CONSTRUCTION SCIENCE AND MANAGEMENT BUILDING SYSTEMS COURSE	216
Rogelio Palomera-Arias (University of Texas at San Antonio, USA)	
HOW THE WEB WAS WON: KEEPING THE COMPUTER NETWORKING CURRICULUM CURRENT WITH HTTP/2.....	222
Colin Allison (University of St Andrews, United Kingdom)	
Hussein Bakri (University of St Andrews, United Kingdom)	
UNDERSTANDING THE PROTOTYPING STRATEGIES OF EXPERIENCED DESIGNERS	231
Ethan Hilton (Georgia Institute of Technology, USA)	
Julie Linsey (Georgia Institute of Technology, USA)	
Joseph Goodman (Georgia Tech Research Institute, USA)	

T2D: K-12 Education II**Chair:** Glenda Young (Virginia Tech, United States)**2:30 PM - 4:00 PM****Room:** Brahma Room

STEM LITERACY: CHALLENGES IMPLEMENTING 'E' IN LOCAL TEXAS-STEM ACADEMIES 239

Michele C. Williams (University of Texas at El Paso, USA)

MODELING: A COMPUTER SCIENCE CONCEPT FOR GENERAL EDUCATION 244

Barbara Sabitzer (Alpen-Adria-Universität Klagenfurt, Austria)

Stefan Pasterk (Alpen-Adria-Universität Klagenfurt, Austria)

DISSECT: EXPLORING THE RELATIONSHIP BETWEEN COMPUTATIONAL THINKING AND ENGLISH LITERATURE IN K-12 CURRICULA 249

Natasha Nesiba (New Mexico State University, USA)

Enrico Pontelli (New Mexico State University, USA)

Timothy Staley (Las Cruces Public Schools, USA)

USING LIFE COURSE THEORY TO FRAME WOMEN AND GIRLS' TRAJECTORIES TOWARD (OR AWAY) FROM COMPUTING: PRE HIGH-SCHOOL THROUGH COLLEGE YEARS 257

Corey Schimpf (Purdue University, USA)

Kelly Andronicos (Purdue University, USA)

Joyce Main (Purdue University, USA)

MOTIVATIONAL FACTORS PREDICTING STEM AND ENGINEERING CAREER INTENTIONS FOR HIGH SCHOOL STUDENTS 266

Daniel Mangu (Arizona State University, USA)

Andrew Lee (Arizona State University, USA)

James Middleton (Arizona State University, USA)

Jill Nelson (George Mason University, USA)

T2E: Blended Learning Approaches**Chair:** Asad Azemi (Pennsylvania State University, United States)**2:30 PM - 4:00 PM****Room:** Charolais Room

TARGETED BLENDED LEARNING THROUGH COMPETENCY ASSESSMENT IN AN UNDERGRADUATE INFORMATION SYSTEMS PROGRAM 274

Joelle Ducrot (Singapore Management University, Singapore)

Venky Shankararaman (Singapore Management University, Singapore)

INSTRUCTOR AND GRADUATE TEACHING ASSISTANT DEVELOPMENT AND TRAINING FOR A BLENDED LINEAR CIRCUITS AND ELECTRONICS COURSE 281

Bonnie Ferri (Georgia Institute of Technology, USA)

Wendy Newstetter (Georgia Institute of Technology, USA)

David Majerich (Georgia Institute of Technology, USA)

A FEEDBACK-BASED APPROACH FOR EVOLVING A BLENDED CLASS MODEL FOR LARGE ENROLLMENT, MULTIPLE SECTION CIRCUITS COURSES 285

Bonnie Ferri (Georgia Institute of Technology, USA)

Joyelle Harris (Georgia Institute of Technology, USA)

Mary Ann Weitnauer (Georgia Institute of Technology, USA)

David Majerich (Georgia Institute of Technology, USA)

IMPROVING THE LEARNING OF PHYSICS CONCEPTS BY USING HAPTIC DEVICES 293

Luis Neri (Humanidades y Ciencias Sociales Tecnológico de Monterrey, Mexico)
David Escobar-Castillejos (Humanidades y Ciencias Sociales Tecnológico de Monterrey, Mexico)
Julieta Noguez (Humanidades y Ciencias Sociales Tecnológico de Monterrey, Mexico)
Uzma Shaikh (Purdue University, USA)
Alejandra J. Magana (Purdue University, USA)
Bedrich Benes (Purdue University, USA)

EXPRESSION TASKS FOR NOVICE PROGRAMMERS:

TURNING THE ATTENTION TO OBJECTIVITY, RELIABILITY AND VALIDITY 300

Matthias Laengrich (University of Applied Sciences Zittau / Goerlitz, Germany)
Joerg Schulze (University of Applied Sciences Zittau / Goerlitz, Germany)
Amruth N. Kumar (Ramapo College of New Jersey, USA)

T2F: Game based learning I

Chair: Todd Fernandez (Purdue University, USA)

2:30 PM - 4:00 PM

Room: Longhorn Room

THE ISSUES OF ADOPTING SIMULATION GAMES IN SOFTWARE ENGINEERING CLASSES 308

Daniela Peixoto (CEFET-MG, Brazil)
Rodolfo Resende (Federal University of Minas Gerais, Brazil)
Clarindo Pádua (Federal University of Minas Gerais, Brazil)

DIGITAL LOCKDOWN: A 3D ADVENTURE GAME FOR ENGINEERING EDUCATION..... 316

Rasha Morsi (Norfolk State University, USA)

5:00 PM - 6:30 PM

Room: Hereford Room

IMPLICATIONS OF ANONYMOUS ASSESSMENT 1404

Arnold Pears (Uppsala University, Sweden)
Aletta Nylén (Uppsala University, Sweden)

<i>CASE FOR REFLECTION IN ENGINEERING EDUCATION--AND AN ALTERNATIVE</i>	<i>1409</i>
Mani Mina (Iowa State University, USA)	
John Cowan (UK Open University, United Kingdom)	
John Heywood (Trinity College Dublin, Ireland)	
<i>CHALLENGES IN FINDING A CONNECTION BETWEEN IL EDUCATION AND RESEARCH PROBLEM FORMULATION.....</i>	<i>1415</i>
Talikka Marja (Lappeenranta University of Technology, Finland)	
Värri Hanna (Lappeenranta University of Technology, Finland)	
Eskelinen Harri (Lappeenranta University of Technology, Finland)	
Rimppi Heli (Lappeenranta University of Technology, Finland)	
<i>DRAFTING A CODE OF ETHICS FOR ENGINEERING EDUCATION</i>	<i>1420</i>
Alan Cheville (Bucknell University, USA)	
John Heywood (Trinity College, Dublin, Ireland)	
<i>COMPETENCIES FOR PARADIGM SHIFT "SURVIVAL".....</i>	<i>1424</i>
Mats Daniels (Uppsala University, Sweden)	
Åsa Cajander (Uppsala University, Sweden)	
Anna Eckerdal (Uppsala University, Sweden)	
Mats Lind (Uppsala University, Sweden)	
Aletta Nylén (Uppsala University, Sweden)	
Tony Clear (Auckland University of Technology, New Zealand)	
Roger McDermott (Robert Gordon University, United Kingdom)	
<hr/>	
<i>F4H: Professional Skills</i>	
<i>Chair:</i> Abe Zeid (Northeastern University, United States)	
<i>5:00 PM - 6:30 PM</i>	
<i>Room:</i> Rio Grande Room	
<hr/>	
<i>ADDRESSING THE PROBLEM OF MAL-EMPLOYMENT OF LIBERAL ARTS GRADUATES</i>	<i>1430</i>
Abe Zeid (Northeastern University, USA)	
Chitra Javdekar (MassBay Community College, USA)	
Marina Bograd (MassBay Community College, USA)	
Susanne Steiger-Escobar (MassBay Community College, USA)	
Shamsi Moussavi (MassBay Community College, USA)	
Claire Duggan (Northeastern University, USA)	
Daniel Sullivan (Northeastern University, USA)	
Sagar Kamarthi (Northeastern University, USA)	
<i>IMPLIED IDENTITY: A CONCEPTUAL FRAMEWORK FOR EXPLORING ENGINEERING PROFESSIONAL IDENTITY PRACTICES IN HIGHER EDUCATION.....</i>	<i>1434</i>
Maryam Khosronejad (The University of Sydney, Australia)	
Peter Reimann (The University of Sydney, Australia)	
Lina Markauskaite (The University of Sydney, Australia)	
<i>CAMPUS TO CAREER, UNDERSTANDING HOW ENGINEERING STUDENT SKILL PERCEPTIONS LINK TO FUTURE CAREER PATHWAYS</i>	<i>1438</i>
Glenda Young (Virginia Tech, USA)	
David Knight (Virginia Tech, USA)	

F4I: Embedded Systems Education II

Chair: Firas Hassan (Ohio Northern University, USA)

5:00 PM - 6:30 PM

Room: Santa Fe Room

MORE MISSING THE BOAT - ARDUINO, RASPBERRY PI, AND SMALL PROTOTYPING

BOARDS AND ENGINEERING EDUCATION NEEDS THEM 1442

Peter Jamieson (Miami University, USA)

Jeff Herdtner (Miami University, USA)

***DESIGN AND IMPLEMENTATION OF A MICROCONTROLLER BASED WORKSTATION WITH
EDUCATIONAL PURPOSES FOR THE CONTROL SYSTEMS AREA..... 1448***

Juan Felipe Patarroyo (University of Puerto Rico at Mayaguez, Puerto Rico)

Gerson Beauchamp (University of Puerto Rico at Mayaguez, Puerto Rico)

Aidsa Santiago (University of Puerto Rico at Mayaguez, Puerto Rico)

***AUTONOMOUS ROBOT: AN INTELLECTUAL WAY OF INFUSING MICROCONTROLLER
FUNDAMENTALS INTO SOPHOMORE STUDENTS 1456***

Chirag Parikh (Grand Valley State University, USA)

***DEVELOPMENT OF A NOVEL MODULAR INTEGRATED STACKABLE LAYER - ANALOG SYSTEM
ENVIRONMENT (MISL - ASE) PLATFORM FOR EMBEDDED SYSTEMS EDUCATION..... 1460***

Gang Sun (Texas A&M University, USA)

Joseph Morgan (Texas A&M University, USA)

Jay Porter (Texas A&M University, USA)

Hester Yim (Texas A&M University, USA)

VAMONOS: EMBEDDABLE VISUALIZATIONS OF ADVANCED ALGORITHMS 1465

Brent Carmer (Oregon State University, USA)

Mike Rosulek (Oregon State University, USA)

Saturday, October 24

SIA: Panel: International iCampus Forum (IC15) on "Smart Education in Smart Cities"

Chair: Jason Ng (British Telecom, United Kingdom)

9:00 AM - 10:30 AM

Room: Kohlberg Room

INTERNATIONAL ICAMPUS FORUM (IC15) ON "SMART EDUCATION IN SMART CITIES"..... 1473

Jason Ng (United Arab Emirates, UAE)

***AN EXPLORATION INTO THE ATTITUDES OF YOUNG GIRLS TOWARD THE
FIELD OF COMPUTER SCIENCE 1475***

JJ LaBouliere (SDSU, USA)

Amanda Pelloth (SDSU, USA)

Chiao-Ling Lu (SDSU, USA)

Jason Ng (Etisalat British Telecom Innovation Center, UAE)

***INTERACTION DRIVEN COMPOSITION OF STUDENT GROUPS FOR OPTIMAL
GROUPWORK LEARNING PERFORMANCE 1481***

Ling Cen (Khalifa University of Science, Technology and Research, UAE)

Dymitr Ruta (Khalifa University of Science, Technology and Research, UAE)

Leigh Powell (Khalifa University of Science, Technology and Research, UAE)

Jason Ng (Khalifa University of Science, Technology and Research, UAE)

***EXPERIMENTAL DEVELOPMENT AND IMPLEMENTATION OF COMPUTER-BASED
QUIZ GAMES IN GENERAL CHEMISTRY FOR ENGINEERING 1487***

S.S. Ling (Khalifa University of Science, Technology and Research, UAE)

F. Saffre (BT Research and Innovation, United Kingdom)

D.L. Gater (Khalifa University of Science, Technology and Research, UAE)

L. Bt. Halim (National University of Malaysia, Malaysia)

A. F. Isakovic (Khalifa Semiconductor Research Center, UAE)

SMART GROUPING TOOL PORTAL FOR COLLABORATIVE LEARNING..... 1494

David M. Liu (Etisalat BT Innovation Center, UAE)

George Wesley Hitt (Khalifa University of Science, Technology and Research, UAE)

A. F. Isakovic (Khalifa University of Science, Technology and Research, UAE)

Di Wang (Etisalat BT Innovation Center, UAE)

Benjamin Hirsch (Etisalat BT Innovation Center, UAE)

Jason W.P. Ng (Etisalat BT Innovation Center, United Kingdom)

***SMART TEXT-CLASSIFICATION OF USER-GENERATED DATA IN EDUCATIONAL
SOCIAL NETWORKS..... 1499***

Di Wang (Khalifa University, UAE)

Ahmed Al-Rubaie (Khalifa University, UAE)

Ahmed Al Dhanhane (Khalifa University, UAE)

Jason Ng (Khalifa University, United Kingdom)

SIB: New Approaches-Student-Center**Chair:** Rangith Baby Kuriakose (University of Technology, South Africa)**9:00 AM - 10:30 AM****Room:** Pancho Villa Room

A B-LEARNING NEW APPROACH APPLIED TO A PRACTICAL POWER***ELECTRONICS CONVERTERS COURSE 1504***

Alfonso Lago Ferreiro (University of Vigo, Spain)

Andrés A. Nogueiras Meléndez (University of Vigo, Spain)

Ana María Cao-Paz (University of Vigo, Spain)

Jorge Marcos Acevedo (University of Vigo, Spain)

Manuel Castro (Spanish University for Distance Education (UNED), Spain)

INITIAL INVESTIGATION INTO ENGINEERING STUDENTS PROBLEM SOLVING***WITHIN CONTROLS 1512***

Jessica Swenson (Tufts University, USA)

Ethan Danahy (Tufts University, USA)

William Messner (Tufts University, USA)

OPTIMAL CONTROL DESIGN AND IMPLEMENTATION FOR THE DOUBLE***INVERTED PENDULUM SYSTEM IN A GRADUATE CONTROL COURSE..... 1516***

Felix Muñoz-Rodríguez (University of Puerto Rico at Mayagüez, Puerto Rico)

Gerson Beauchamp-Báez (University of Puerto Rico at Mayagüez, Puerto Rico)

Gerardo Cruz-Díaz (University of Puerto Rico at Mayagüez, Puerto Rico)

Juan Carlos Santos-Ferrer (University of Puerto Rico at Mayagüez, Puerto Rico)

A LOW-COST SYSTEM FOR EXPERIMENTS WITH DIGITAL CIRCUITS 1525

Flávio H Toribio Destro (Federal University of Mato Grosso do Sul, Brazil)

Rafael A. Costa (Federal University of Mato Grosso do Sul, Brazil)

Fábio Iaione (Federal University of Mato Grosso do Sul, Brazil)

THE EXPLORATION FOR COMPUTER SYSTEM CAPACITY TRAINING***IN EXPERIMENTAL TEACHING 1531***

Li Shan-shan (Tsinghua University, P.R. China)

Quan Cheng-bin (Tsinghua University, P.R. China)

Chen Yong-qiang (Tsinghua University, P.R. China)

SIC: Student Center Education**Chair:** Brian Skromme (Arizona State University, United States)**9:00 AM - 10:30 AM****Room:** Angus Room

HELPING UNDERGRADUATE ENGINEERING STUDENTS DISCOVER THEIR INTERESTS***(AND REDUCE THEIR FEAR OF RESEARCH) 1537***

Mary Anderson-Rowland (Arizona State University, USA)

Armando Rodriguez (Arizona State University, USA)

Anita Grierson (Arizona State University, USA)

DEVELOPING AN ECOSYSTEM FOR STUDENT SUCCESS IN ENGINEERING***IN RIO SOUTH TEXAS 1545***

Javier A. Kypuros (The University of Texas-Pan American, USA)

Stephen W. Crown (The University of Texas-Pan American, USA)

Arturo A. Fuentes (University of Texas-Pan American, USA)

Horacio Vasquez (The University of Texas-Pan American, USA)

Virgil Pierce (The University of Texas-Pan American, USA)

Jessica Lavariega Monforti (The University of Texas-Pan American, USA)

<i>LEARNING TO LEARN: CREATING ENGINEERING CLASSROOMS FOR DEEP UNDERSTANDING</i>	<i>1549</i>
Sarah Hug (University of Colorado Boulder, USA)	
Elsa Q. Villa (The University of Texas at El Paso, USA)	
Peter Golding (University of Texas at El Paso, USA)	
Gabby Gandara (University of Texas at El Paso, USA)	
<i>AGILE LEARNING THROUGH CONTINUOUS ASSESSMENT</i>	<i>1554</i>
Kevin A. Gary (Arizona State University, USA)	
Suhas Xavier (Arizona State University, USA)	
<i>AMNESIA: A LEARNING OBJECT FOR MEMORY HIERARCHY TEACHING</i>	<i>1558</i>
Fernando Tiosso (University of São Paulo, Brazil)	
Sarita Mazzini Bruschi (University of São Paulo, Brazil)	
Paulo S. Souza (University of São Paulo, Brazil)	
Ellen Barbosa (University of São Paulo, Brazil)	
Carlos Emilio de Andrade Cacho (University of São Paulo, Brazil)	
<hr/>	
<i>SID: Assessment I</i>	
Chair: Vladik Kreinovich (University of Texas at El Paso, United States)	
9:00 AM - 10:30 AM	
Room: Brahma Room	
<hr/>	
<i>HOW SHOULD WE ESTIMATE A MISSING EXAM SCORE?</i>	<i>1565</i>
Michael C. Loui (Purdue University, USA)	
Athena Lin (University of Illinois at Urbana-Champaign, USA)	
<i>HOW TO TAKE INTO ACCOUNT A STUDENT'S DEGREE OF CERTAINTY WHEN EVALUATING THE TEST RESULTS</i>	<i>1568</i>
Joe Lorkowski (University of Texas at El Paso, USA)	
Olga Kosheleva (University of Texas at El Paso, USA)	
Vladik Kreinovich (University of Texas at El Paso, USA)	
<i>THE ACADEMIC PERFORMANCE INDEX: CREATING A MORE ROBUST AND LESS BIASED MEASURE OF STUDENT ACADEMIC PERFORMANCE.....</i>	<i>1573</i>
Allison Godwin (Purdue University, USA)	
Tyler D. Scott (Northwestern College, USA)	
Geoff Potvin (Florida International University, USA)	
Gerhard Sonnert (Harvard University, USA)	
Phillip M. Sadler (Harvard University, USA)	
<i>EVALUATING METRICS FOR AUTOMATIC MIND MAP ASSESSMENT IN VARIOUS CLASSES</i>	<i>1581</i>
Amber Franklin (Miami University, USA)	
Peter Jamieson (Miami University, USA)	
Walter Vanderbush (Miami University, USA)	
Tuo Li (Miami University, USA)	
Julie Semlak (Miami University, USA)	

SIE: First and Second Year Topics II**Chair:** Frank Vahid (University of California, Riverside, USA)**9:00 AM - 10:30 AM****Room:** Charolais Room

STUDENT LED CURRICULUM DEVELOPMENT AND INSTRUCTION OF INTRODUCTION TO ENGINEERING LEADERSHIP COURSE 1589

America Fernandez (The University of Texas at El Paso, USA)

Erwin Delgado (The University of Texas at El Paso, USA)

Yazmin Montoya (The University of Texas at El Paso, USA)

Roger Gonzalez (The University of Texas at El Paso, USA)

Meagan Vaughan (The University of Texas at El Paso, USA)

ENHANCING THE EXPERIENCE OF FIRST-YEAR ENGINEERING STUDENTS WITH AN ENTRY-LEVEL STS COURSE: SCIENCE-TECHNOLOGY-SOCIETY 1597

Jan DeWaters (Clarkson University, USA)

Jessica Halfacre (Clarkson University, USA)

John Moosbrugger (Clarkson University, USA)

Elisabeth Chapman (Clarkson University, USA)

Elisabeth Wultsch (Clarkson University, USA)

ASSESSING STUDENT VIEWS OF TRADITIONAL, FREE, AND INTERACTIVE MODIFICATIONS FOR AN INTRODUCTORY NETWORKING COURSE 1605

Patrick Seeling (Central Michigan University, USA)

A PEDAGOGICAL MODEL FOR INTRODUCING 3D PRINTING TECHNOLOGY IN A FRESHMAN LEVEL COURSE BASED ON A CLASSIC INSTRUCTIONAL DESIGN THEORY..... 1609

Pit Ho Patrio Chiu (City University of Hong Kong, Hong Kong)

King Wai Chiu Lai (City University of Hong Kong, Hong Kong)

Tsz Ki Frankie Fan (City University of Hong Kong, Hong Kong)

Suk Han Cheng (City University of Hong Kong, Hong Kong)

OUTCOMES OF ACCEPTING OR DECLINING ADVANCED PLACEMENT CALCULUS CREDIT 1615

Karen De Urquidi (Purdue University, USA)

Dina Verdin (Purdue University, USA)

Stephen Hoffmann (Purdue University, USA)

Matthew W. Ohland (Purdue University, USA)

SIF: Online Assessment**Chair:** Dazhi Yang (Boise State, United States)**9:00 AM - 10:30 AM****Room:** Longhorn Room

TECEVAL: AN ON-LINE DYNAMIC EVALUATION SYSTEM FOR ENGINEERING COURSES AVAILABLE FOR WEB BROWSERS AND TABLETS 1621

Jesus Jaquez (Tecnologico de Monterrey, Mexico)

Julieta Noguez (Tecnologico de Monterrey, Mexico)

Gerardo Aguilar-Sanchez (Tecnologico de Monterrey, Mexico)

Luis Neri (Tecnologico de Monterrey, Mexico)

Andres Gonzalez-Nucamendi (Tecnologico de Monterrey, Mexico)

SEED-PA. A PRACTICAL INSTRUMENT FOR ASSESSING INDIVIDUAL ETHICS INITIATIVES..... 1629

Trevor S. Harding (California Polytechnic State University, USA)

Donald D. Carpenter (Lawrence Technological University, USA)

Janel A. Sutkus (Carnegie Mellon University, USA)

Cynthia J. Finelli (University of Michigan, USA)

<i>AUTOMATIC FILL-THE-BLANK QUESTION GENERATOR FOR STUDENT SELF-ASSESSMENT</i>	<i>1633</i>
Girish Kumar (Agency for Science, Technology and Research, Singapore)	
Rafael E. Banchs (Institute for Infocomm Research, Singapore)	
Luis Fernando D'Haro (Institute for Infocomm Research, Singapore)	
<i>PLUGGABLE REPUTATION SYSTEMS FOR PEER REVIEW: A WEB-SERVICE APPROACH.....</i>	<i>1636</i>
Yang Song (North Carolina State University, USA)	
Zhewei Hu (North Carolina State University, USA)	
Edward Gehringer (North Carolina State University, USA)	
<i>ARCHITECTURAL SUPPORT FOR NON-EXPERT DEPLOYMENT OF REMOTE LABORATORIES.....</i>	<i>1641</i>
Khanh Nguyen (University of Sydney, Australia)	
David Lowe (University of Sydney, Australia)	
<hr/>	
<i>SIG: Innovative Curriculum & Course Design I</i>	
Chair: Venky Shankararaman (Singapore Management University, Singapore)	
9:00 AM - 10:30 AM	
Room: Hereford Room	
<hr/>	
<i>STUDENT-CONSTRUCTED CONCEPT MAPS FOR ACTIVE LEARNING IN A FOUNDATIONAL UNDERGRADUATE ENGINEERING COURSE.....</i>	<i>1649</i>
Ning Fang (Utah State University, USA)	
<i>O-CHARTS: TOWARDS AN EFFECTIVE TOOLKIT FOR TEACHING TIME COMPLEXITY.....</i>	<i>1654</i>
Scott Barlowe (Western Carolina University, USA)	
Andrew Scott (Western Carolina University, USA)	
<i>ANALYZING EDUCATIONAL COMMENTS FOR TOPICS AND SENTIMENTS: A TEXT ANALYTICS APPROACH.....</i>	<i>1658</i>
Gokarn Ila Nitin (Singapore Management University, Singapore)	
Gottipati Swapna (Singapore Management University, Singapore)	
Venky Shankararaman (Singapore Management University, Singapore)	
<i>PREPARING ECE STUDENTS FOR RESEARCH CAREER IN NANOTECHNOLOGY VIA TRACK PROGRAM</i>	<i>1667</i>
Maher E. Rizkalla (Indiana University-Purdue University Indianapolis, USA)	
Mangilal Agarwal (Indiana University-Purdue University Indianapolis, USA)	
<hr/>	
<i>SIH: Innovative Curriculum & Course Design II</i>	
Chair: Wei-Fan Chen (Penn State University, United States)	
9:00 AM - 10:30 AM	
Room: Rio Grande Room	
<hr/>	
<i>CURRICULUM DRIVEN CLASSROOM DESIGN</i>	<i>1672</i>
Kerry Milligan (Drexel University, USA)	
Adam K. Fontecchio (Drexel University, USA)	
<i>RUBRICS FOR ASSESSMENT ITEM DIFFICULTY IN ENGINEERING COURSES</i>	<i>1676</i>
Shilpi Banerjee (International Institute of Information Technology, India)	
N.J. Rao (International Institute of Information Technology, India)	
Chandrashekar Ramanathan (International Institute of Information Technology, India)	

***INSPIRING UNDERGRADUATE STUDENTS IN ENGINEERING LEARNING,
COMPREHENDING AND PRACTICING BY THE USE OF ANALOG DISCOVERY KITS..... 1684***
 Lei Zhang (University of Maryland Eastern Shore, USA)
 Ibibia Dabipi (University of Maryland Eastern Shore, USA)
 Yuanwei Jin (University of Maryland Eastern Shore, USA)
 Payam Matin (University of Maryland Eastern Shore, USA)

TEACHING PROJECT MANAGEMENT USING A REAL-WORLD GROUP PROJECT..... 1688
 Lawrence Collingbourne (Victoria University of Wellington, New Zealand)
 Winston K.G. Seah (Victoria University of Wellington, New Zealand)

***USING 3-D OPEN SOURCE SOFTWARE TO FACILITATE STUDENTS' SPATIAL
VISUALIZATION SKILLS..... 1696***
 Wei-Fan Chen (The Pennsylvania State University, USA)
 Pao-Nan Chou (National University of Tainan, Taiwan)
 Robert Carey (The Pennsylvania State University, USA)

SII: Faculty Development III
Chair: Megan Tomko (Georgia Institute of Technology, USA)
9:00 AM - 10:30 AM
Room: Santa Fe Room

***LEARNING ABOUT ENGINEERING EDUCATION RESEARCH: WHAT CONCEPTUAL
DIFFICULTIES STILL EXIST FOR A NEW GENERATION OF SCHOLARS? 1699***
 Ruth A. Streveler (Purdue University, USA)
 Nicole P. Pitterson (Purdue University, USA)
 Avneet Hira (Purdue University, USA)
 Héctor Rodríguez-Simmonds (Purdue University, USA)
 Juan Ortega Alvarez (Purdue University, USA)

***APPRENTICESHIP OF OBSERVATION: IMPLICATIONS FOR THE ADOPTION OF
EVIDENCE-BASED INSTRUCTIONAL PRACTICES 1705***
 Kari L. Jordan (Embry-Riddle Aeronautical University, USA)
 James J. Pembridge (Embry-Riddle Aeronautical University, USA)
 Heidi M. Steinhauer (Embry-Riddle Aeronautical University, USA)
 Timothy Wilson (Embry-Riddle Aeronautical University, USA)
 Douglas Holton (Embry-Riddle Aeronautical University, USA)

AMBIGUITY DURING ENGINEERING PROBLEM SOLVING 1712
 Elliot P. Douglas (University of Florida, USA)
 Sevcen Agdas (University of Florida, USA)
 Christine Lee (California State University East Bay, USA)
 Mirka Koro-Ljungberg (Arizona State University, USA)
 David J. Therriault (University of Florida, USA)

***BACKGROUND AND DEMOGRAPHIC FACTORS THAT INFLUENCE GRADUATION:
A COMPARISON OF SIX DIFFERENT TYPES OF MAJORS..... 1716***
 Sara Hahler (Louisiana Tech University, USA)
 Marisa K. Orr (Louisiana Tech University, USA)

S2A: Technological Tools I**Chair:** Jean Hertzberg (University of Colorado Boulder, USA)**11:00 AM - 12:30 PM****Room:** Kohlberg Room

UNDERGRADUATE EXPERIMENTS WITH APERIODIC GRATINGS BASED ON THE FIBONACCI SEQUENCE 1723

J.A. Monsoriu (Universitat Politècnica de València, Spain)

M.H. Giménez (Universitat Politècnica de Valencia, Spain)

E. Ballester (Universitat Politècnica de València, Spain)

L.M. Sanchez-Ruiz (Universitat Politècnica de València, Spain)

AN INTERACTIVE LEARNING ENVIRONMENT FOR ASSISTING STUDENTS IN SOLVING PROBLEMS ON DESIGNING OF LOGIC DIGITAL CIRCUITS BY USING MULTIPLE REPRESENTATIONS..... 1726

Evandro de Barros Costa (University of Alagoas, Brazil)

Hemilis Joyse Barbosa Rocha (Federal Institute of Alagoas, Brazil)

ADAPTIVE VISION STUDIO - EDUCATIONAL TOOL FOR IMAGE PROCESSING LEARNING..... 1732

Krystian Radlak (Silesian University of Technology, Poland)

Mariusz Frackiewicz (Silesian University of Technology, Poland)

Marek Szczepanski (Silesian University of Technology, Poland)

Michał Kawulok (Silesian University of Technology, Poland)

Michał Czardybon (Future Processing, Poland)

ANALYSIS OF OPPORTUNITIES AND CHALLENGES OF THE ELECTRONIC DUAL-BOARD IN INSTRUCTION..... 1740

Li-ping Cai (Central China Normal University, P.R. China)

Rui-hua Shi (Central China Normal University, P.R. China)

Wen-yan Niu (Central China Normal University, P.R. China)

Ming-Wen Tong (Central China Normal University, P.R. China)

AESTHETICS AND EXPANDING PERCEPTION IN FLUID PHYSICS 1747

Katherine Goodman (University of Colorado, USA)

Jean Hertzberg (University of Colorado, USA)

Noah Finkelstein (University of Colorado, USA)

S2B: Computer Based Learning**Chair:** Rogério Garcia (São Paulo State University, Brazil)**11:00 AM - 12:30 PM****Room:** Pancho Villa Room

STEP-BASED TUTORING SYSTEM FOR INTRODUCTORY LINEAR CIRCUIT ANALYSIS..... 1752

B. J. Skromme (Arizona State University, USA)

P. J. Rayes (Arizona State University, USA)

B. E. McNamara (Arizona State University, USA)

V. Seetharam (Arizona State University, USA)

X. Gao (Arizona State University, USA)

T. Thompson (Arizona State University, USA)

X. Wang (Arizona State University, USA)

B. Cheng (Arizona State University, USA)

Y.-F. Huang (University of Notre Dame, USA)

D.H. Robinson (Colorado State University, USA)

IMPLEMENTATION OF AN INTELLIGENT TUTORING SYSTEM USING MOODLE	1761
Vyshnavi Malathi Ramesh (International Institute of Information Technology, India)	
N. J. Rao (International Institute of Information Technology, India)	
Chandrashekar Ramanathan (International Institute of Information Technology, India)	
 A USER PROFILE DEFINITION IN CONTEXT OF RECOMMENDATION OF OPEN EDUCATIONAL RESOURCES. AN APPROACH BASED ON LINKED OPEN VOCABULARIES.....	1770
Janneth Chicaiza (Universidad Técnica Particular de Loja, Ecuador)	
Nelson Piedra (Universidad Técnica Particular de Loja, Ecuador)	
Jorge Lopez-Vargas (Universidad Técnica Particular de Loja, Ecuador)	
Edmundo Tovar-Caro (Universidad Politécnica de Madrid, Spain)	
 SUPPORTIVE ENVIRONMENT FOR TEACHING AND LEARNING DIGITAL IMAGE PROCESSING.....	1777
Lenon Fachiano Silva (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
Celso Olivete Júnior (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
Pedro Henrique Reis (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
Rafael Silva Santos (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
Ronaldo Celso Messias Correia (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
Rogério Eduardo Garcia (Universidade Estadual Paulista "Júlio de Mesquita Filho", Brazil)	
 ADAPTATION RESOURCES IN VIRTUAL LEARNING ENVIRONMENTS UNDER CONSTRUCTIVIST APPROACH: A SYSTEMATIC REVIEW	1784
Vitor Bremgartner (Federal University of Amazonas, Brazil)	
José Magalhães, Netto (Federal University of Amazonas, Brazil)	
Crediné Silva de Menezes (University of Rio Grande do Sul (UFRGS), Brazil)	

S2C: Innovative Curriculum & Course Design III
Chair: Rebecca Reck (University of Illinois at Urbana-Champaign, United States)
11:00 AM - 12:30 PM
Room: Angus Room

BRIDGING THE DIVIDE: STRATEGIES FOR COLLEGE TO CAREER READINESS IN COMPUTER SCIENCE.....	1792
Wendy A Lawrence-Fowler (The University of Texas-Pan American, USA)	
Laura M. Grabowski (University of Texas-Pan American, USA)	
Christine F. Reilly (University of Texas-Pan American, USA)	
 THE INSTITUTIONAL ENVIRONMENT FOR STUDENT VETERANS IN ENGINEERING	1800
Catherine E. Brawner (Research Triangle Educational Consultants, USA)	
Catherine Mobley (Clemson University, USA)	
Joyce Main (Purdue University, USA)	
Susan M. Lord (University of San Diego, USA)	
Michelle M. Camacho (University of San Diego, USA)	
 ASSESSING AN AFFORDABLE AND PORTABLE LABORATORY KIT IN AN UNDERGRADUATE CONTROL SYSTEMS COURSE	1805
Rebecca M. Reck (University of Illinois at Urbana-Champaign, USA)	
Ramavarapu S. Sreenivas (University of Illinois at Urbana-Champaign, USA)	
Michael C. Loui (Purdue University, USA)	
 HANDS ON PROJECT EXPERIENCE IN A CORE CLASS FOCUSED ON SUSTAINABILITY.....	1809
Anoop Desai (Georgia Southern University, USA)	

S2D: Curriculum Design III**Chair:** Rebecca Reck (University of Illinois at Urbana-Champaign, USA)**11:00 AM - 12:30 PM****Room:** Brahma Room

BIOINFORMATICS CURRICULUM DEVELOPMENT**AND SKILL SETS FOR BIOINFORMATICIANS 1813**

Huanmei Wu (School of Informatics and Computing, USA)

Amritha Palani (School of Informatics and Computing, USA)

STUDENTS LEARN MORE WITH LESS TEXT THAT COVERS THE SAME CORE TOPICS 1820

Alex Edgcomb (University of California, Riverside, USA)

Frank Vahid (University of California, Riverside, USA)

Roman Lysecky (University of Arizona, USA)

VIRTUAL LABORATORY PLATFORM FOR COMPUTER SCIENCE CURRICULA..... 1825

Yuanyuan Li (Central South University, P.R. China)

Lei Xiao (Central South University, P.R. China)

Yu Sheng (Central South University, P.R. China)

CLOUD-BASED TEACHING IN AN ENGINEERING-PHYSICS COURSE..... 1832

John M. Long (Deakin University, Australia)

AN AUTOMATION OF THE COURSE DESIGN BASED ON MATHEMATICAL**MODELING AND GENETIC ALGORITHMS 1840**

Alexey Dukhanov (ITMO University, Russia)

Maria Karpova (ITMO University, Russia)

Vadim Shmelev (ITMO University, Russia)

S2E: Innovative Curriculum & Course Design IV**Chair:** Brian Faulkner (University of Illinois, USA)**11:00 AM - 12:30 PM****Room:** Charolais Room

STUDENTS OF ENGINEERING ON BEHALF OF PEOPLE WITH DISABILITIES:**EVALUATING THE IMPACT OF AN INSTITUTION'S FLAGSHIP PROJECT..... 1844**

Orna Muller (ORT Braude College of Engineering, Israel)

Noga Shalit (ORT Braude College of Engineering, Israel)

Orit Braun Benyamin (ORT Braude College of Engineering, Israel)

ENHANCING THE EDUCATIONAL EXPERIENCE FOR DEAF AND HARD OF HEARING**STUDENTS IN SOFTWARE ENGINEERING 1849**

Daniel E. Krutz (Rochester Institute of Technology, USA)

Samuel A Malachowsky (Rochester Institute of Technology, USA)

Scott D. Jones (Rochester Institute of Technology, USA)

Jayme A. Kaplan (St. Mary's School for the Deaf, USA)

GETTING THE ATTENTION OF UNDERREPRESENTED MINORITY COMMUNITY**COLLEGE STUDENTS TO CONSIDER ENGINEERING AS A CAREER..... 1858**

Mary R. Anderson-Rowland (Arizona State University, USA)

Armando A. Rodriguez (Arizona State University, USA)

Anita E. Grierson (Arizona State University, USA)

EFFECT OF ASSERTION HEADINGS AND EXPANDABLE EXAMPLES IN AN ONLINE**ENGINEERING TEXTBOOK..... 1866**

Brian Faulkner (University of Illinois at Urbana-Champaign, USA)

Geoffrey Herman (University of Illinois at Urbana-Champaign, USA)

S2F: K-12 Education III**Chair:** Noah Salzman (Boise State University, United States)**11:00 AM - 12:30 PM****Room:** Longhorn Room

STEM SUMMER CAMP FOLLOW UP STUDY: EFFECTS ON STUDENTS' SAT SCORES AND POSTSECONDARY MATRICULATION..... 1875

Peter Boedeker (Texas A&M University, USA)

Ali Bicer (Texas A&M University, USA)

Robert M. Capraro (Texas A&M University, USA)

Mary Margaret Capraro (Texas A&M University, USA)

Jim Morgan (Texas A&M University, USA)

Luciana Barroso (Texas A&M University, USA)

NANOTECHNOLOGY STEM PROGRAM VIA RESEARCH EXPERIENCE FOR HIGH SCHOOL TEACHERS 1883

Mangilal Agarwal (Indiana University-Purdue University Indianapolis, USA)

Qurat-ul-Ann Mirza (Indiana University-Purdue University Indianapolis, USA)

Joseph Bondi (Indiana University-Purdue University Indianapolis, USA)

Brandon Sorge (Indiana University-Purdue University Indianapolis, USA)

Maher Rizkalla (Indiana University-Purdue University Indianapolis, USA)

Richard Ward (Indiana University-Purdue University Indianapolis, USA)

Corbin Feldhaus (Charlestown High School, USA)

Amy Hinshaw (McKenzie Center for Innovation & Technology, Indianapolis, USA)

Kody Varahramyan (Indiana University-Purdue University Indianapolis, USA)

L.E.A.P.: LOCALIZED ENERGY AWARENESS PROGRAM THROUGH COLLABORATIVE K-UNIVERSITY STEM PROJECTS 1888

Jamie Kennedy (Drexel University, USA)

Brandon Morton (Drexel University, USA)

Adam Fontecchio (Drexel University, USA)

USING COMMON ELEMENTS TO EXPLAIN ELECTROMAGNETISM TO CHILDREN: REMOTE LABORATORY OF ELECTROMAGNETIC CRANE..... 1892

German Carro Fernandez (Spanish University for Distance Education - UNED, Spain)

Ramon Carrasco Borrego (Spanish University for Distance Education - UNED, Spain)

Elio Sancristobal Ruiz (Spanish University for Distance Education - UNED, Spain)

Manuel Castro Gil (Spanish University for Distance Education - UNED, Spain)

Francisco Mur Perez (Spanish University for Distance Education - UNED, Spain)

S2G: Online-distance Learning**Chair:** Larry Richards (University of Virginia, USA)**11:00 AM - 12:30 PM****Room:** Hereford Room

AN AGILE LEARNING DESIGN METHOD FOR OPEN EDUCATIONAL RESOURCES..... 1897

Maurício Massaru Arimoto (University of São Paulo, Brazil)

Ellen Francine Barbosa (University of São Paulo, Brazil)

Leonor Barroca (The Open University, United Kingdom)

STUDENT-PERCEIVED EFFECTIVENESS OF ONLINE CONTENT DELIVERY MODES..... 1906

Julie S. Mullen (Worcester Polytechnic Institute, USA)

John M. Sullivan, Jr (Worcester Polytechnic Institute, USA)

TOPIC BASED SEGMENTATION OF CLASSROOM VIDEOS 1910

Tayfun Tuna (University of Houston, USA)
Mahima Joshi (University of Houston, USA)
Varun Varghese (University of Houston, USA)
Rucha Deshpande (University of Houston, USA)
Jaspal Subhlok (University of Houston, USA)
Rakesh Verma (University of Houston, USA)

**MOTIVATING STUDENTS WITH NEW MECHANISMS OF ON-LINE ASSIGNMENTS
AND EXAMINATION TO MEET THE MOOC CHALLENGES FOR PROGRAMMING..... 1919**

Xiaohong Su (Harbin Institute of Technology, P.R. China)
Tiantian Wang (Harbin Institute of Technology, P.R. China)
Jing Qiu (Harbin Institute of Technology, P.R. China)
Lingling Zhao (Harbin Institute of Technology, P.R. China)

SUPPORTING REAL OPEN EDUCATIONAL RESOURCES IN EDU-AREA 1925

Manuel Caeiro-Rodríguez (Universidade de Vigo, Spain)
Martín Llamas-Nistal (Universidade de Vigo, Spain)
Manuel Fernández-Iglesias (Universidade de Vigo, Spain)
Fernando Mikic-Fonte (Universidade de Vigo, Spain)
Manuel Lama-Peñín (Universidade de Santiago de Compostela, Spain)

S2H: Assessment

Chair: Senay Purzer (Purdue University, USA)

11:00 AM - 12:30 PM

Room: Rio Grande Room

**ON THE EFFECTIVENESS OF USING MIDTERM EXAMINATIONS
STRICTLY FOR FORMATIVE FEEDBACK..... 1933**

Integrating Service-Learning into Engineering and Computing Education

William C. Oakes^{1,2} and Carla B. Zoltowski²

¹Engineering Education, ²EPICS
Purdue University
West Lafayette, IN, USA

Abstract – Community Engagement or Service-learning is a rapidly growing pedagogy in higher education and has come under increased visibility within engineering and computing education. It has been cited as a potential tool for increasing student engagement as well as diversity among our engineering, technology and computing student bodies. It also has opportunities to prepare the next generation of professionals, addressing issues including retention, diversity, learning and professional preparation. This workshop will introduce interested faculty, students, administrators and professionals to service-learning models including EPICS and provide resources for participants to implement such programs at their respective institutions.

Index Terms – Community Engagement, Service-learning, Design Education

GOAL AND OVERVIEW

The goals of the workshop are to

- 1) introduce participants to the pedagogy of community engagement and service-learning and
- 2) explore they it could be integrated into the curriculum at their home institution.

Community engagement or service learning is a growing pedagogy within engineering, and computing globally. It has been widely documented in engineering, computing and many other disciplines [1-26]. It is well-matched with calls for strong technical skills along with a broad set of professional and cultural skills that are beings demanded by industry and accreditation bodies. It provides the kind of curricular efficiency to meet these broad set of attributes without adding times to graduation. Community engagement has been used in many countries to provide service to their communities and enhance learning. The pedagogy is consistent with research in learning sciences and student success [27-32]. There is a growing number of faculty who are using community engagement and service-learning to equip students with the skills needed for leadership in the 21st century's global economy. This workshop will guide

participants through an introduction to the pedagogy and engage them in active discussions about how engagement is perceived and exists within different countries' cultures. Connections to engineering and computing will include models for design education [33-37]. Participants will be guided through the process to integrate the pedagogy into their own classes. Resources, partnerships and potential barriers will be discussed to provide strategies for successful implementation. Participants will be provided additional resources for further support beyond the workshop [38-42]. The workshop will engage participants in discussion about community engagement, student learning, cultural issues and change within the academy. Successful models will be presented and discussed, including the EPICS model [43-61] which was created at Purdue University and is a Signature Program of the IEEE Foundation. The facilitators have conducted more than 70 workshops on six continents and are experienced in working with a diverse community of current and future educators and administrators.

AGENDA TOPICS

- Introduction to the workshop, agenda and format – 10 minutes
- Overview of Service-Learning –20 minutes
 - What are the key characteristics of Service-Learning, Opportunities and Successful models
- Institutional needs assessment – 10 minutes
 - What are the educational needs at one's own institution and how can S-L meet the needs
- Getting started, what are the first steps – 15 minutes
- Course and curriculum issues – 15 minutes
 - How is it managed, What are the course structures, How does it fit EPICS Model and examples
- Break – 10 minutes
- Maximizing Learning with Analysis and Reflection – 15 minutes
- Assessing student learning – 20 minutes
 - EPICS examples
- Developing partnerships - community and corporate – 15 minutes
- Building institutional support – 10 minutes

- Tools and resources – 10 Minutes
- Developing Individual Models and Plans – 20 Minutes
- Questions and discussions – 15 minutes
- Workshop evaluation – 5 minutes

AUDIENCE

Current and future engineering, technology and computing educators or administrators interested in multidisciplinary teams, diversity, retention, innovation or entrepreneurship, design education and service learning or engagement will find this workshop valuable.

AUTHOR INFORMATION

William Oakes, Ph.D., P.E. is the Director of the EPICS Program at Purdue University, one of the founding faculty members of the School of Engineering Education and a professional engineer. He was the first engineer to win the U.S. Campus Compact Thomas Ehrlich Faculty Award for Service-Learning and was a co-recipient of the U.S. National Academy of Engineering's Bernard Gordon Prize for Innovation in Engineering and Technology Education.

Carla Zoltowski, Ph.D., is the Co-Director of EPICS at Purdue University. She has been recognized at Purdue for her leadership in EPICS and community engagement and nationally within the U.S. as the vice-Chair of the Community Engagement in Engineering Education Division of the American Society for Engineering Education (ASEE). She has published extensively on research in design education, ethics in engineering and computing and student experiences in community engagement.

tfernan@purdue.edu

Abstract— Through undergraduate engineering education, we hope to create graduates who have the ability to think creatively and be innovative. Yet, prior studies suggest that students might be losing their creative edge during their undergraduate education. In this workshop, we will review key literature on engineering students' views of innovation and results from a series of studies conducted by the presenters through an NSF CAREER grant. We will then cover strategies to effectively promote and value student innovation. We will focus on planning design activities or projects that are more likely to elicit innovative behavior in students as well as adjustments to assessment practices and grading rubrics that encourage or allow for more innovative work by students.

Keywords—Assessment, creativity, innovation

I. INTRODUCTION AND BACKGROUND

An increasing number of studies indicate that many engineering students are losing their creative edge during their education [1]–[3]. These phenomena are especially troubling in light of the continued push by employers asking for engineers who are more innovative problem solvers [4]. Closing the gap between this employer need and student reality is of fundamental importance to economic competitiveness.

In prior studies, three barriers to innovation experienced by students have been identified: (1) An overwhelming technical identity that values technical problem solving over creativity, (2) a view of innovativeness as an attribute that is attainable by just a few privileged individuals or masterminds, and (3) instructional constraints that demotivate students from taking risks by exploring novel solutions [5].

In addition to understanding the underlying student behaviors, many different approaches have been taken to understand how to measure design creativity and innovativeness [6]. These include evaluations of student sketches [7] to explore the breadth of the design space that students populate in the ideation phase of design.

A mixed bag of assessment methodology is apparent in the entrepreneurship field as well. A literature synthesis by Purzer and colleagues [8] identified a range of instruments used for student assessment in entrepreneurship. However, the literature studied shows little indication of assessment schemes designed to robustly elicit measurable characteristics in a rigorous way.

What is seen in the broad range of assessment in both of these fields is that a large number of instruments and methods exist. However, they often exist without a solid alignment of the assessment methods with course design and pedagogical implementations that collectively form the course.

This workshop is intended to help practitioners bridge the phenomena that constrict innovativeness in student approaches to engineering design. The workshop will focus on strategies for course design and assessment that will value and help elicit more innovativeness during student design projects and build students' long-term ability to think more innovatively.

II. WORKSHOP DESCRIPTION AND TAKEAWAYS:

This workshop will focus on how instructors can teach and assess students in engineering courses that illuminates and values critical, and critically important, innovative thinking for students. Examples of student work from the facilitators' prior teaching and research on the subject will be used to illustrate assessment practices that value creativity and innovative problem solving. The participants will develop rubrics to be used in their own courses or design projects and discuss the merits of these rubrics with other participants.

The workshop is intended to facilitate both theoretical and practical takeaways for participants. The theoretical takeaways are focused on understanding what research literature can tell practitioners about students' conceptions and cognitive implementations of the concepts of innovation and creativity, especially in engineering design. These include expansion upon the phenomena explained in the background section and ways in which assessment strategies can be used to influence manifestation of innovation in students.

The practical takeaways focus on how instructors may orient classroom content, assessment, and pedagogy to elicit innovative behavior through design projects. These will include the development of project scopes and grading rubrics that participants will have the opportunity to take home.

III. WORKSHOP GOALS:

This workshop has two goals: (1) to unpack the implications of key literature on engineering students' views of innovation and the results from a series of studies conducted by the presenters through an NSF CAREER grant, and (2) to develop teaching and assessment strategies that value and promote innovative thinking. These strategies include the development

of grading rubrics that effectively elicit and reward innovative ideas while balancing key learning objects.

IV. WORKSHOP AGENDA

This three-hour workshop includes interactive group learning activities, demonstrations, discussions, and presentations. The first half will focus on prior research and participants' prior experiences. The second half will include interactive group activities that allow workshop attendees to work to put the literature on into practice for their specific needs and courses.

- Introductions and Overview of the Workshop (5min)
- Preview of participants' approaches to teaching and assessing innovation (20min)
- Review of prior research (15min)
- Interactive group activity on rubric development (20 min)
- Break (10 min)
- Presentations of group work by participants (30 min)
- Interactive group activity on design project (20 min)
- Presentations of group work by participants (30 min)
- Connect back to research (15 min)
- Concluding remarks (10 min)
- Feedback/workshop assessment (5 min)

V. QUALIFICATIONS OF THE PRESENTERS:

The first presenter is an engineering education faculty member and researcher who studies innovativeness among engineering students (first-year students to seniors) and teaches a first-year engineering design course. She is the PI of the NSF Career grant whose research grounds the workshop and has authored multiple publications in the research area on which this workshop focuses.

The second presenter is also an engineering education researcher with extensive experience working with high tech start-ups. He has instructed and mentored undergraduate capstone design teams and led the creation of an innovative first year engineering design project using a 'design client' model. Prior to entering the engineering education research field, he worked professionally in the semiconductor industry, as a design and manufacturing consultant with hardware startups, and the director of engineering for a biotechnology startup.

VI. MATERIALS PROVIDED

Workshop materials will be made available to all participants during and after the event. With approval from participants, the group presentations will shared after the workshop's completion. This is intended to help participants collaborate beyond the workshop to continue building shared knowledge.

VII. ACKNOWLEDGMENT:

This material is based upon work supported by the National Science Foundation under Grant No. 1150874. Any opinions, findings, and conclusions or recommendations expressed in

this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

Process to Draft the Program Educational Objectives for Undergraduate Engineering Degree Programs

Ramakrishnan Sundaram
Gannon University, sundaram@gannon.edu

Abstract - This pre-conference workshop will engage the participants in the process to draft Program Educational Objectives (PEOs) appropriate for undergraduate engineering degree programs at ABET-accredited institutions of higher education. The PEOs must reflect the Mission Statement of the institution and serve as a yardstick of student achievement three to five years following graduation. The PEOs must be crafted such that measurable objective evidence can be obtained through appropriate alumni surveys. To be consistent and effective, the entire engineering department must contribute to the discussion, ratification, and eventual adoption of the PEOs. In order to ensure a meaningful contribution from all faculty members involved in defining the PEOs, this workshop presents a framework that facilitates the discussion and the steps which can be taken to define the PEOs that (1) adhere to the Mission of the University (2) achieve consistent and measurable expectations. In addition, the workshop discusses internal and external review procedures to periodically review and revise the language, assessment, and evaluation of the PEOs. The attendees should expect to gain the following from this workshop.

- Understand the step-by-step process to draft and assess PEOs
- Draft PEOs which establish the link between the Undergraduate Engineering Degree program and the Mission of the University
- Work as individuals and on teams to develop the Department-wide consensus on the formulation and assessment language for each PEO
- Learn to clearly distinguish the PEOs from student outcomes

Index Terms – Program Educational Objectives, Accreditation, Assessment, Bloom taxonomy

INTRODUCTION

Program Educational Objectives (PEOs) for undergraduate engineering degree programs constitute the vision of the program for its graduates three to five years after graduation. ABET stipulates in its Self-Study Questionnaire [1] under Criterion 2, Category E that there should be a

process in place to periodically review and revise PEOs. These objectives represent the expectations of the department from its graduates and must be crafted such that measurable objective evidence can be obtained through alumni surveys. In addition, there must be in place internal and external review procedures to periodically review and revise the language, assessment, and evaluation of the PEOs.

The focus of this workshop is to understand and implement the step-by-step process to draft and assess the PEOs. The framework that is proposed is first to provide an assessment language that is similar to the cognitive learning pattern of *Bloom's Taxonomy for Knowledge, Comprehension, Application, Analysis, Evaluation and Synthesis* during the different stages completed by our graduates in their career path.

Faculty members should recognize that the students in the undergraduate degree program are viewed as *learners* who must acquire the intended skills over the duration of the baccalaureate program. These students are then expected to *demonstrate* the application of these skills three years following graduation. They are expected to assume more responsibilities in management or to *lead* in their profession and/or society six years after graduation. Ten or more years after graduation, these students should become *contributors* with significant influence on policy and decision making in their chosen profession and/or society.

The assessment language at these different stages of our graduates' career path is different. Hence, it is important to use the proper set of assessment language intended for the PEOs that focuses only on the immediate or first three years to measure the direct impact of our program on young careers, not the six-year or the ten-year longer term objectives which would measure learning experiences and contributions beyond the direct impact of the engineering degree program. Second, the framework requires faculty to extract key words from the Mission Statement of the institution which emphasize the broad and specific intent of undergraduate education along with a set of key words that the faculty see as attributes to gauge graduates in becoming the individuals the PEOs intended. Third, capture the distinction between educational objectives and student

outcomes, and formulate each objective recognizing the need for measurability.

The undergraduate engineering degree programs at institutions across the country adopt different approaches to create and review PEOs. For instance, the ECE program at one pre-eminent institution [2] develops the PEOs according to three expected outcomes from graduates five years after graduation – *professional expertise, innovativeness, and leadership*. At another institution [3], continuous education program assessment is addressed by bringing together a working team of departments and education specialists using a Web-based assessment process to gather and evaluate the data. There are also institutions that stipulate the PEOs of the program without empowering the faculty to develop, own, and adopt a consistent set of measurable PEOs.

The faculty of the Electrical and Computer Engineering (ECE) department at our institution met on different occasions for discussion and a final work session for almost six hours to complete the steps of the process in order to revise the existing set of PEOs. The PEOs of our fully accredited undergraduate ECE program (accreditation period from 2012 to 2017) were deemed to have language that was very similar to that used in the ABET student outcomes. Therefore, it was imperative to distinguish the PEOs from the ABET student outcomes since the PEOs must quantify the expected attainments of graduates a few years after graduation.

Section 2 describes the framework to formulate the PEOs and outlines the agenda and timetable of the workshop. Section 3 provides a broad overview of the PEO assessment cycle at our institution with internal and external review processes, and the assessment and evaluation process which includes the mapping of these PEOs to the ABET student outcomes. The conclusions appear in Section 4.

SECTION 2: FRAMEWORK TO FORMULATE PEOs

The first step is to recognize that faculty members as *individuals* have independent PEO ideas, which leverage their multi-cultural and multi-discipline resources. Then, the faculty members, objectively as a *team*, have long workout sessions to revise and commit to these new PEOs, thus promoting PEO ownership as individuals and as the entire Department. At the beginning of the workout session, the faculty members identify and agree to the following keywords from the Mission Statement of the institution (e.g. as shown in the following paragraph) such as *holistic development, value-centered, professional, leadership roles, cultural diversity, and lifelong learning*.

This Institution is a Catholic, Diocesan, student-centered University which provides for the holistic development of undergraduate and graduate students in the

Judeo-Christian tradition. As such, it offers each student outstanding teaching and a value-centered education in both liberal arts and professional specializations in order to prepare students for leadership roles in their careers, society, and church. The University faculty and staff are committed to excellence and continuous improvement in teaching, learning, scholarship, research, and service. The University's environment is to be one of inclusiveness and cultural diversity.

In addition, the faculty identified the categories in which objective evidence shall be obtained to measure each key word keeping in mind the proper set of assessment language. Faculty members then formed break-out groups of two to draft the PEO suitable for each key word. Finally, the faculty reconvened as one group to review and revise each objective as well as to arrange the objectives in the order of chronological impact and accomplishment before reaching agreement for adoption.

The framework for the review and revision of the PEOs at the departmental level involving all the faculty members comprises the following broad stages.

1. Provide the assessment language.
2. Use the key words and phrases extracted from the Mission Statement of the institution to identify attributes to gauge graduates.
3. Capture the distinction between the educational objective and the student outcomes.
4. Formulate each objective to be measurable.

The assessment language is based on the *Cognitive domain* of Bloom's taxonomy [4]. Bloom's taxonomy was developed in 1956 as the classification of learning objectives within education to improve communication between educators on the design of curricula and examinations. There are three domains - Cognitive, Affective, and Psychomotor. The Cognitive domain (or *What should I know?*) corresponds to the recall or recognition of specific facts, procedural patterns, and concepts that serve in the development of intellectual abilities and skills.

The six major categories in the Cognitive Domain - *Knowledge, Comprehension, Application, Analysis, Synthesis, and Evaluation* – which range from simple to complex, are covered within every course at all levels (first year to senior year) but the focus of the pattern of learning at each level of course is as shown in Table I.

TABLE I
FOCUS OF LEARNING

Level of Course	Focus of learning
First year	<i>Knowledge</i>
Second year	<i>Comprehension</i>
Third year	<i>Application & Analysis</i>
Fourth year	<i>Evaluation & Synthesis</i>

Table II lists the sequence of activities and the expected duration of each activity planned for this pre-conference workshop. The expected total duration of the workshop is 2 hours (120 minutes).

TABLE II
WORKSHOP SCHEDULE

Activity #	Activity	Duration	Remarks
1	Introduction and Overview	15 minutes	Framework of discussion
2	Review topic: Bloom Taxonomy (BT)	10 minutes	Explain the domains of BT
3	Break-out activity #1(individual)	10 minutes	Keyword extraction
4	Review topic: ABET student outcomes	10 minutes	Discuss link to BT
5	Break-out activity #2 (teams of two to three)	15 minutes	Use BT and ABET student outcomes to formulate PEOs
6	Review topic: Program Educational Objectives (PEOs)	10 minutes	Discuss the language and emphasis of PEOs
7	Break-out activity #3 (teams of two to three)	15 minutes	Revise the sample PEOs; draft the new PEOs
8	Review topic: Assessment of PEOs	10 minutes	Discuss internal and external assessment methods
9	Break-out activity #4 (complete group – all attendees)	20 minutes	Map the new PEOs to the ABET student outcomes
10	Summary and Conclusions	5 minutes	Review the process of PEO; attendees assess the workshop

SECTION 3: PEO ASSESSMENT CYCLE

The program constituents for the PEO assessment process comprise the faculty, staff, students, and the local industry represented by its members on the Engineering Advisory Council (EAC). The PEO assessment cycle is conducted over the 3 to 5 year period and is shown in Figure 1.

FIGURE 1
PEO ASSESSMENT CYCLE

The two primary approaches to PEO assessment are (1) internal review, and (2) external review. The internal review consists of assessing the attainment of student outcomes, through senior exit surveys and embedded course assessment processes, to determine if the skill sets necessary for attainment of PEOs are being provided within each course and across the curriculum.

The external review comprises the assessment of data gathered through the alumni survey to determine how well our graduates are performing in the workforce three to five years following their graduation. This measures the level of attainment of each PEO.

The PEO evaluation process determines the relevancy of each PEO to address and successfully meet the needs of the program constituents. The program constituents are faculty, students, alumni, and industry. The evaluation of the PEOs by both the EAC and the faculty members helps address the needs of program constituents. Action items generated at faculty and EAC review meetings are expected to lead to changes in the PEOs and have significant impact on the shaping of our educational practices.

The mapping of the student outcomes to the PEOs is intended to help us determine if our educational practices within each course and across the curriculum prepare our graduates to meet the intended PEOs. Table III illustrates the mapping of PEOs to ABET student outcomes.

TABLE III
MAPPING OF PEOs TO ABET STUDENT OUTCOMES

ABET Student Learning Outcomes	PEO 1	PEO 2	PEO 3	PEO 4	PEO 5
Ability to apply knowledge of mathematics, science, and engineering	X				X
Ability to design and conduct experiments, as well as to analyze and interpret data					X
Ability to design a system, component, or process to meet desired needs	X				X
Ability to function on multi-disciplinary teams			X	X	
Ability to identify, formulate, and solve engineering problems	X				X
Understanding of professional and ethical responsibility		X	X		
Ability to communicate effectively				X	
Broad education necessary to understand the impact of engineering solutions in a global and societal context	X	X	X	X	
Recognition of the need for, and an ability to engage in life-long learning	X		X		
Knowledge of contemporary issues	X		X	X	
Ability to use the techniques, skills, and modern engineering tools necessary for engineering practice	X				X

The toolsets used in the PEO assessment process are as follows:

- Alumni survey (*external*)
- EAC review (*external*)
- Executive summary report for student outcomes (*internal*)

The alumni survey provides the data for assessment of the PEOs as part of the external review. The survey is administered through secure access on the Web [5] and addresses the following primary question:

How well are our graduates really doing in the workforce?
The survey has quantitative and qualitative sections in the following categories.

- *General information*
- *Employment History*
- *Preparedness of Gannon Education*
- *Soft Skills and Broad Education*
- *Liberal Studies*
- *Intern Experience and Professional Societies*
- *Rate education based on the PEOs*

For instance, Table IV lists the questions asked in the quantitative section of the alumni survey for the category titled *Soft Skills and Broad Education*.

TABLE IV
QUANTITATIVE SECTION

Soft Skills and Broad Education	
Questions	
1	Do you feel your Gannon education helped you to understand the ethical responsibilities of your profession?
2	How well did your Gannon education prepare you to give oral presentations?
3	How well did your Gannon education prepare you to write technical reports and other written communications?
4	Do you feel you have the ability to use the most modern engineering tools and techniques effectively?
5	Do you feel your education at Gannon was broad enough to give you a perspective on how a particular engineering solution might impact society?

SECTION 4: CONCLUSIONS

The following are the primary goals or expected learning outcomes of this workshop.

- Understand the step-by-step process to draft the PEOs
- Use carefully crafted PEOs to establish the link between the Undergraduate Engineering Degree program and the Mission of the University
- Work as individuals and on teams to develop the Department-wide consensus on the formulation and assessment language for each PEO
- Learn to clearly distinguish the PEOs from student outcomes

These goals are aligned with those of FIE because they look to offer attendees ways to nurture their skills, knowledge, and/or materials that they can use in their own teaching practice or scholarship of learning and teaching. The key requirements to guarantee success of this process are as follows:

- Engagement and commitment of the entire engineering department to the discussion, ratification, and eventual adoption of the PEOs
- Active participation by the faculty in defining the PEOs to promote ownership of the goals of the Department and ABET process
- Adherence to the Mission of the University
- Distinguish PEOs from student outcomes
- Draft PEOs with measurable outcomes

Anticipated Audience & Desired Maximum Count

Faculty members, chairpersons and/or those actively engaged in the drafting of program educational objectives in ABET-accredited engineering programs. The desired maximum count would be 30 attendees (10 teams of 2 to 3 per team for the break-out sessions would be manageable).

Author Preparation

The author/facilitator has conducted workshops on the topics related to this proposal [6], [7] and is conversant with the detailed step-by-step process required to train the attendees, having participated in this process as part of the ABET accreditation of an undergraduate engineering degree program.

Abstract— We have investigated whether Agile practices can be applied as a pedagogical approach to derive benefit in the areas of encouraging students to take responsibility for their learning (self managed learning), continuous improvement through reflection, alternative approaches for grading, increased engagement by learners, and more effective data collection and assessment of outcomes. Agile is an umbrella term for values, principles and practices applied to the process of software development. The Agile movement has aimed to develop a new and better culture within the software development community and has seen an increased rate of adoption within corporate settings. The goal of this workshop is to help participants explore how Agile development, a management technique borne out of the software industry, can not only change the way that students engage in project-based and team-based course projects, but also transform the way that we educate our students.

Keywords—Agile; Innovative Pedagogy; Project-based Learning

I. INTRODUCTION

The New Media Consortium NMC creates a yearly publication called the Horizon Report for Higher Education [1]. In the most recent issue, the NMC has identified Agile practices as a trend to be observed for potential long-term adoption for higher education. Agile is an umbrella term for values, principles and practices applied to the process of software development. The Agile movement has aimed to develop a new and better culture within the software development community and has seen an increased rate of adoption within corporate settings [2,3,4,5].

Agile development has transformed the way that many software development and production organizations create knowledge products. Environments where the end product is being discovered and constantly refined are a perfect fit for Agile. Education is by definition based on learning and discovery. As such, as learning becomes more personalized and requires adjustment to changing conditions and requirements while fulfilling stringent accreditation standards, new pedagogical methods are required that can reduce the cost of change.

We have investigated whether Agile practices can be applied as a pedagogical approach to derive benefit in the areas of encouraging students to take responsibility for their learning (self managed learning), continuous improvement through reflection, alternative approaches for grading, increased engagement by learners, and more effective data collection and

assessment of outcomes. The goal of this workshop is to help participants explore how Agile development, a management technique borne out of the software industry, can not only change the way that students engage in project-based and team-based course projects, but also transform the way that we educate our students.

The *Agile Way of Working* (or Agile) is a collection of principles and practices that supports rapid and flexible response to change. It does this by promoting communication, collaboration, continuous improvement, and reflection within teams of problem solvers. The approach also fosters self-managed teams. Agile accomplishes this by embracing changing requirements, delivering products frequently, using human-centric methods, and engaging the customer in regular collaboration. Agile puts heavy emphasis on articulating goals, facilitating interactions, improving team dynamics, supporting collaboration, and encouraging experimentation and innovation. Agile originated and is widely adopted in the software development industry. In a worldwide survey of individuals in the software community, 88% of respondents said their organizations were practicing agile [6]. Other surveys have shown similar usage rates.

II. WHAT IS AGILE?

In 2001, a group of thought leaders in software development created the Agile Manifesto, a set of values to guide how software products are developed (see <http://www.agilemanifesto.org/>). The manifesto stresses a number of specific values including:

- Individuals and interactions over processes and tools
- Working software over comprehensive documentation
- Customer collaboration over contract negotiation
- Responding to change over following a plan

Based on these values the following set of principles were defined to characterize the Agile approach:

- Customer satisfaction by rapid delivery of useful software
- Welcome changing requirements, even late in development
- Working software is delivered frequently
- Working software is the principal measure of progress
- Sustainable development, able to maintain a constant pace

- Close cooperation between business people and developers
- Face-to-face is the best form of communication
- Projects built around motivated (and trusted) individuals
- Continuous attention to technical excellence
- Simplicity is essential
- Self-organizing teams
- Regular adaptation to changing circumstances

These values and principles are translated into action through work practices and tools. The practices are used by teams to realize the benefits of the Agile way of working. Commonly used agile practices include (partial list):

- Whole team: all are accountable for quality of the product
- Time-boxing: fixed time allocation to each planned activity
- Open workspace: face-to-face communication is valued
- Frequent releases: deploying the product in short cycles to create checkpoints
- Sustainable Pace: a constant pace to plan, work, and reflect
- **Story Card Writing**: a short statement about user observable system capability or function
- **Story Wall**: a way to display the status of each story card
- **Retrospectives**: meetings after each iteration designed to help the team improve their process
- **Workshops**: time-boxed meetings with stakeholders to define stories
- Showcases: demonstration of the product to the customer

III. WORKSHOP AGENDA

The workshop length is 3 hours. In addition to overviews and experience reports, a number of Agile exercises and techniques will be demonstrated through active collaboration.

1. Tutorial Overview of Agile (1 hour) - The purpose of the tutorial overview is to provide participants with basic knowledge to understand what Agile is, the techniques used, and resources necessary for a deeper dive into the mindset and practices.
2. Presentations and practical examples on experience using Agile for project and team-based courses (1/2 hour) - These presentations will show how Agile has been applied in the context of the lowest lying fruit - as a way of having students (self) manage their team.
3. Presentations and practical examples on experience using Agile as an educational mindset (1/2 hour) - These presentations will show how Agile principles such as *collaboration*, *transparency*, and *continuous improvement* as well as practices such as *retrospectives* and *Kanban/story walls* can be applied to the educate students.

4. Guided activities to aid participants in generating ideas on using Agile in their courses (1 hour) - In this segment of the session, participants will engage in brainstorming and collaborative activities to identify potential areas within their courses where Agile can be applied. These activities will be used to help build a community for longer-term interaction.

IV. WORKSHOP DETAILS

A. Audience

The topic of this workshop is applicable to any FIE conference attendee. Educators that use project-based or otherwise use team projects in courses will be interested in the workshop for the practical management methods. Others will be interested in the applicability of the Agile Way of Educating as pedagogical methodology.

B. Outcomes

The outcomes for this workshop are the following:

- Basic knowledge of Agile – participants will be exposed to:
 - The history and mindset of Agile
 - Agile practices that facilitate effective communication and Agile values
 - Agile practices that facilitate effective communication in order to control risks and adapt to challenges of working in teams
 - Agile practices that help student teams to prioritize work and consistently deliver high quality content that meets course learning objectives
 - Agile practices that help student team's to plan, monitor, and improve their way of working (especially their way of educating)
- Experience in applying Agile engagement methods for facilitating brainstorming and discussion participants will see a number of methods used within Agile that illustrate benefits for both project work and pedagogical mindset
- Ideas for applying Agile as either a way of working or a way of educating (or both!) - participants will come away with ideas for applying Agile in their courses
- Resources for a deeper dive into Agile - participants will leave the session with resources that will allow them to expand their knowledge and skills with Agile.

C. Logistics

The workshop will use a standard presentation setup including video projector, power strips, and flip charts. We will also need at least one post-it note pad per participant (standard square 3"x3") and Sharpie Fine Point Markers for each participant.

D. Fees

We expect to have a full packet of materials printed and bound for presentations, as well as the aforementioned brainstorming tools (post-it notes, Sharpies, etc.). Fees appropriate to these expenditures are expected.

WORKSHOP ORGANIZERS

Gerald C. Gannod is a Professor of Computer Science and Software Engineering at Miami University and is an ICAgile Certified Professional and Agile Coach. Dr. Gannod is the co-facilitator for the Agile University Faculty Learning Community at Miami. While on sabbatical in AY 13-14, Dr. Gannod was a solution architect on the BT Digital Team with the Suncorp Group in Sydney, Australia, where he gained extensive experience in using Agile.

Jerome Eric Luczaj is an Associate Professor in the Department of Computer & Information Technology. Before entering academia he worked in industry for a decade and a half as a system designer, project leader, and system architect, performing Quality Assurance and Architectural Reviews internationally and domestically.

Diane T. Rover is a Professor in the Department of Electrical and Computer Engineering at Iowa State University. Since beginning her academic career at Michigan State University, she has developed, adapted, and guided effective strategies for student teaming, collaborative learning, and faculty development. Dr. Rover is a Fellow of the ASEE and a

member of the ABET Engineering Accreditation Commission Executive Committee.

Douglas A. Troy is Director of Graduate Programs in Miami University's College of Engineering and Computing, Director of the Agile Launchpad project, an Affiliate of the Myaamia Center focusing on Information Technology strategy, and is Professor emeritus. Dr. Troy joined Miami in 1983 after working in the software development industry at Bell Labs and CompuServe Network.

Worcester Polytechnic University
Worcester, MA
lrob@wpi.edu

Abstract— Students frequently spend too little time understanding the problem in their design projects and jump to solutions without considering alternatives. This leads to inefficient use of time and suboptimal results in the final design. Instead of re-inventing the wheel, students need to explore and understand the work of others applied to similar situations, using strong information gathering, application, and evaluation skills. Ultimately, these reinforce core skills needed for students to be lifelong learners, i.e., determining where they have gaps in knowledge and determining how to fill those gaps efficiently and effectively. This workshop will provide a conceptual model and examples of activities that will help instructors keep students problem-focused, allowing them to generate and weigh alternatives, and ultimately settle on a solution that is most promising to meet their stakeholders' needs. Participants will take away techniques they can apply to their own engineering design courses. This workshop aligns with FIE's focus on turning Research into Practice.

Keywords— engineering design; information literacy; evidence-based decision making;

I. DESCRIPTION

The Information Rich Engineering Design model [1] provides the foundational underpinning for this workshop. The model identifies information activities corresponding to each stage of the engineering design process. In the course of the workshop, attendees will play the role of designers, responding to scenarios and identifying where internal and external information can be obtained to better understand a problem, generate and evaluate solutions, and embody the design. In particular, participants will learn how to determine the needs of stakeholders, better understand the context of the design problem, and make sure they meet professional standards and legal requirements for their designs. In addition to their own brainstorming, they investigate the prior art of others to enlarge the solution space they explore. Evaluating and synthesizing information gathered or generated themselves, they determine the most promising of their proposed solutions.

The format of the workshop is to take each stage sequentially in 30 minute chunks, spending approximately 5 minutes introducing the stage of the engineering design

process and its information components, followed by 15 minutes of hands-on small-group activity illustrating the information gathering and application component, with 10 minutes of reports out to the full group. The workshop will culminate with participants debriefing their experiences, reflecting on which activities seemed to resonate, and how they might adapt some of the activities in their own practice. We anticipate this activity will be synergistic between the facilitators and participants, as a collaborative inquiry approach will uncover experiences and insights that lead to greater understanding of what an informed approach to engineering design means, and the challenges students face incorporating that approach in their own practice.

Fig. 1. Information Rich Engineering Design (IRED) model [1]

II. AGENDA

The workshop will be divided to cover four main topics, corresponding to important, information-rich stages of the engineering design process. After an introduction and orientation to the IRED model (see Figure 1), participants will engage in hands-on activities that illustrate the importance of information gathering, evaluation, and utilization in generating optimal design solutions. The activities provide examples that can be integrated into engineering design courses at any level.

Workshop Time:

0:00-0:10 Introduction and Orientation

0:20-0:40 Overview of the IRED design model

0:40-1:10 Creating a Knowledge Management Strategy

5 minutes: overview of concepts

15 minutes: small-group exercise

10 minutes: debrief

1:10-1:40 Determining Stakeholder Needs

5 minutes: overview of concepts

15 minutes: small-group exercise

10 minutes: debrief

1:40-1:50 Break

1:50-2:20 Evaluating Potential Design Solutions

5 minutes: overview of concepts

15 minutes: small-group exercise

10 minutes: debrief

2:20-2:50 Capturing Lessons Learned, i.e., Reflective Practice

5 minutes: overview of concepts

15 minutes: small-group exercise

10 minutes: debrief

2:50-3:00 Wrap-up

III. TAKE AWAY SKILLS AND AUDIENCE

This workshop is appropriate for engineering design educators in any discipline who are looking for techniques to improve the quality of and innovation in design solutions of their students.

Participants in the workshop will be able to

- Develop strategies for improving student management and communication of information
- Identify the role of information in different stages of the engineering design process
- Create activities to promote the effective use of information in student design projects
- Encourage reflective practice in students to promote lifelong learning skills

IV. FACILITATORS

Professors Fosmire and Van Epps have each taught information literacy in engineering design for over fifteen years. They have published extensively on information literacy instruction, information habits of engineers, and assessment of information literacy skills in an engineering context.

Laura Hanlan is Research and Instruction Librarian at Worcester Polytechnic Institute, where project-based learning is an integral part of the educational process. Hanlan provides instructional support for capstone design projects in mechanical and electrical engineering, using the IRED approach. She has published and presented at ASEE and FIE conferences on the integration of information into engineering design.

ACKNOWLEDGMENT

This project was developed in part through support by the National Science Foundation TUES Grant No. 1245998. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation. The authors also wish to acknowledge the work of David Radcliffe, Megan Sapp Nelson, Jon Jeffryes, Bonnie Osif, Jay Bhatt, Jim Clarke, Senay Purzer, Ruth Wertz, Patrice Buzzanell, Monica Cardella, Jeremy Garritano, and Carla Zoltowski who collaborated on the articulation of the IRED model and its implications for design research.

Pre-Conference Workshop: Agile Teaching and Learning

Kevin A. Gary, Sohum Sohoni, and Suhas Xavier

School of Computer, Informatics, and Decision Systems Engineering (CIDSE)

The Ira A. Fulton Schools of Engineering

Mesa, AZ 85281 USA

kgary@asu.edu*, ssohoni@asu.edu, suhas.xavier@asu.edu

Abstract— Agile methods are the fastest rising software lifecycle process methods in software engineering. Educators are converting traditional and project-base courses to agile in response, but this is a daunting task with few structured teaching resources methods available to reduce the burden on the educator. In professional practice, agile methods have been particularly effective in empowering experienced software engineers through its focus on empirical process control and constant feedback loop. These process traits are difficult to simulate in an academic setting, as student developers are inexperienced, synchronous meeting times are few and far between, and obtaining meaningful constant feedback a laborious undertaking. This workshop will present a comprehensive approach to teaching Agile methods that is itself agile, employing a highly iterative, continuous feedback-driven process. Pedagogical and assessment strategies will be shared, and the presenter will facilitate a best practices interactive discussion to draw out lessons learned from workshop participants. Specific agile practices with supporting labs from the popular Scrum and eXtreme Programming (XP) process models will be presented. The workshop will also encourage interaction amongst participants to share best practices and lessons learned. Research directions related to the application of agile principles to teaching and learning will be discussed.

Keywords—*agile; software engineering; software process; assessment; integration*

I. INTRODUCTION

Agile methods are the fastest rising software lifecycle process methods in software engineering, yet they present unique challenges to educators. Many educators are familiar with agile methods but have not practiced them in an industrialized setting. Further, most textbooks have introduced agile only in later additions with little supporting material, and curricular resources are either scarcely available or geared toward the industry practitioner. This workshop will convey instructional resources to higher ed instructors, and provide the scaffolding to conduct an agile project course. Participants will receive materials including Eclipse-based open source labs, project scripts, and pedagogical scripts to adapt to their classrooms. Additionally, the workshop will include strategies and instructions for setting up Scrum, and supporting XP developer practices including Continuous Integration and Testing using Jenkins, Source Code Control using Git, unit

testing, static analysis, and more. Post-workshop support will be provided through a website hosted by the presenter.

The goals of the workshop are to:

1. Provide participants with ready-to-implement materials and practices for teaching agile methods in the classroom.
2. Identify a community of interest in applying agile methods to project-based learning.
3. Discuss research potential in applying these software engineering principles to teaching and learning.

II. INTENDED AUDIENCE

Post-secondary Computer Science educators who are interested in Agile methods applied to teaching and learning, particularly in a hands-on, project-centered course. Teachers from other disciplines can also benefit through the presentation of Agile principles and considerations for adoption in other disciplines. Engineering education researchers may find the potential research directions of agile and teaching and learning of interest.

III. PRESENTER BIOGRAPHIES

Kevin Gary is an Associate Professor in the School of Computing, Informatics, and Decision Systems Engineering (CIDSE) within the Ira A. Fulton Schools of Engineering at Arizona State University. Kevin is a founding program faculty member for the new B.S. and M.S. degrees in Software Engineering at ASU. He created the Software Enterprise, a highly iterative, agile pedagogy in 2004, which has served as the project spine of 8 courses in the Software Engineering degrees. Contact him at kgary@asu.edu

Sohum Sohoni is an Assistant Professor in the School of Computing, Informatics, and Decision Systems Engineering (CIDSE) within the Ira A. Fulton Schools of Engineering at Arizona State University. Prior to ASU, he was an Assistant Professor at Oklahoma State University. He has published over 25 peer-reviewed papers in journals and conferences including papers in ACM SIGMETRICS, IEEE Transactions on Computers, the International Journal of Engineering Education, and Advances in Engineering Education. His research interests are broadly in the areas of computer architecture and performance analysis, and in engineering and computer science

This work is supported by a grant from the State Farm Foundation.

*contact author

education. He has received many teaching awards including the Regents Distinguished Teaching Award in 2010 at OSU. He has received a best paper award for his work in computer engineering from the IETE Technical Review journal, and two best paper awards for his work in engineering education from the ASEE Midwest Section. He received the B.E. degree in Electrical Engineering from Pune University, India, in 1998 and a PhD in Computer Engineering from the University of Cincinnati, Cincinnati, Ohio, in 2004.

Suhas Xavier is a graduate student in the Master of Science in Software Engineering program at Arizona State University. Suhas' interests are in big data, learning analytics, and software engineering. Prior to enrolling at ASU, Suhas worked in industry as a software engineering for Tech Mahindra Private Limited in India. Suhas holds a Bachelor of Engineering in Information Science (First Class with Distinction) from the Visvesvaraya Technological University

IV. MATERIALS PROVIDED

Each participant will receive printed handouts of slides presented at the workshop. Additionally, a custom Eclipse install with requisite tools will be available for installation during the workshop via USB stick and the Web. The presenter will record and coalesce information gathered from collaborative sessions on the agenda and make the record available to participants on his university website. Instructions for server-based installations and trial accounts will be distributed to participants.

V. AGENDA

1. Topic one: Introduction to Agile Methods, (20 minutes).
 - a. Quick recap of Agile, including Scrum and eXtreme Programming (XP), for those somewhat unfamiliar with these methods.
2. Topic two: Integrating Agile Projects into a semester course (50 minutes)
 - a. Interactive exploration: Challenges teaching agile (table discussions)
 - b. Scheduling Scrum activities during the semester

- c. Setting student expectations
3. Topic three: Establishing an Agile Rhythm (45 minutes)
 - a. What does rhythm mean and why is it important?
 - b. Encouraging continuous project participation using Scrumboards.
 - c. Continuous project assessment
 - d. The role of tools and scaffolding
4. Utilizing Agile development best practices in an Agile project context (45 minutes)
 - a. Agile best practices labs including source code control with Git, continuous integration and testing using Jenkins.
 - b. Immediate synthesis of best practices into agile course project
5. Wrap-up (20 minutes)
 - a. Interactive: Eliciting best practices and lessons learned
 - b. Agile recap

VI. REQUIREMENTS

A. Audio/Visual and Computer Requirements:

It is strongly recommended participants bring a laptop to the workshop, though it is not strictly required. Laptop users will be able to browse/experiment with lab materials and remote server tools. However non-laptop users will still be able to follow along the pedagogical and curricular discussions and participate in the interactive sessions. Wireless Internet is recommended to access remote server tools, though the presenters will also demo these up front. Software will be provided that will be distributed on a website or by USB stick for those without Internet access.

B. Laptop Required:

Laptops are highly recommended. Tablets will be of only limited utility.

C. Space and Enrollment Restrictions:

None. No fee required for materials or expenses.

How to Select an Area of Scholarship and Address the Applicable Review Criteria to Publish a Paper in the IEEE Transactions on Education

Jeffrey E. Froyd

Engineering Academic and Student Affairs

Texas A&M University

College Station, TX, USA

froyd@tamu.edu

Abstract—The Editorial Board for the IEEE Transactions of Education developed and published a new set of review criteria. The review criteria have been built on the foundation of the areas of scholarship offered by Ernest Boyer. The purpose of this workshop is to help authors address the review criteria.

Keywords—Boyer's areas of scholarship; scholarship of discovery; scholarship of application; scholarship of integration; review criteria

I. WORKSHOP GOALS

In an effort to clarify expectations for manuscripts to be published in the IEEE Transactions on Education, the Editorial Board (Editor-in-Chief and Associate Editors) developed and published review criteria for three areas of scholarship proposed by Ernest Boyer. The review criteria were published in July 2013. Since both the FIE Planning Committee and FIE participants are committed to raising the quality of scholarship published in engineering education practice and research, examination of these review criteria could provide valuable input to the engineering education community about expectations for scholarly publication. Workshop participants will be able to:

1. Explain criteria for progress in development of the interdisciplinary field of engineering education
2. Select the appropriate area of scholarship for proposed initiatives in engineering education
3. Explain review criteria for each area of scholarship
4. Evaluate how well sample manuscripts address each of the review criteria.

II. DESCRIPTION

Engineering education publications are expected to make substantive contributions to the field, but there is a need to clarify expectations of substantive contributions across the global community of scholars in this field. For the purposes of the review criteria, contributions will be defined as clear statements of how work described in the manuscript is expected to influence future directions of the field. Many different types of contributions are possible. Review criteria need to be specific to broad areas of potential contributions. Review criteria for the IEEE Transactions on Education are organized based on the three categories of scholarship described by Boyer: discovery, application, and integration.

Workshop participants should expect to learn more about the three areas of scholarship and be able to select the area most appropriate for their manuscript.

A. Maintaining the Integrity of the Specifications

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

III. SCHOLARSHIP OF DISCOVERY

Contributions within this area of scholarship will be primarily in the form of new knowledge. New knowledge in the field of engineering education could take many forms. For example, it might be include a tool or process for assessing student learning in a specific subject area. It might be an explanation of difficulties that students encounter when learning one or more concepts. But these are only examples, and there exist are many more forms that new knowledge might take. Assertions that new knowledge is being contributed require significant understanding of prior contributions. Review criteria will be described in the following areas: relevance, focus, contribution, context, methodology, findings, and conclusions.

IV. SCHOLARSHIP OF APPLICATION

Contributions within this area of scholarship will often be models of how prior research on learning and teaching, in general, or in a specific knowledge domain, e.g., engineering, has been applied to design and evaluate instructional strategies. Strategies may be developed for, but are not limited to, courses, course segments, curricula, laboratory experiments, course projects, capstone courses, and outreach activities. Faculty members across the world design these activities for their students, but published papers should provide models of how prior research on learning and teaching has been applied to one or more areas. Review criteria will be described in the following areas: relevance, intended outcomes, context, application design, findings, and conclusions.

Identify applicable sponsor/s here. If no sponsors, delete this text box (sponsors).

V. SCHOLARSHIP OF INTEGRATION

Contributions within this area of scholarship will often be multidisciplinary, integrative, and/or interpretive syntheses across vast prior research to identify patterns, themes, trends, needs, and opportunities upon which other scholars can build. Review criteria will be described in the following areas: relevance, focus, context, contribution, methodology, findings, and conclusions.

VI. WORKSHOP AGENDA

The agenda for the workshop is shown in Table 1.

TABLE I. WORKSHOP AGENDA

Time	Total Time	Participant Activity
10 minutes	10 minutes	Participant Introductions
10 minutes	20 minutes	Overview
5 minutes	25 minutes	Introduction to Scholarship of Discovery
15 minutes	40 minutes	Small-group Exploration of the Scholarship of Discovery
5 minutes	45 minutes	Introduction to Scholarship of Integration
15 minutes	60 minutes	Small-group Exploration of the Scholarship of Integration
5 minutes	65 minutes	Introduction to Scholarship of Application
15 minutes	80 minutes	Small-group Exploration of the Scholarship of Application
15 minutes	85 minutes	Review Criteria: Scholarship of Application
15 minutes	100 minutes	Small-group Exploration – Review Criteria: Scholarship of Application
15 minutes	115 minutes	Review Criteria: Scholarship of Integration
15 minutes	130 minutes	Small-group Exploration – Review

		Criteria: Scholarship of Integration
15 minutes	145 minutes	Review Criteria: Scholarship of Discovery
15 minutes	160 minutes	Small-group Exploration – Review Criteria: Scholarship of Discovery
20 minutes	180 minutes	Summary, Wrap-up, Next Steps

VII. WORKSHOP FACILITATOR

Jeffrey E. Froyd has served as the Editor-in-Chief of the *IEEE Transactions on Education* since September 2012. Dr. Jeffrey E. Froyd received the B.S. degree in mathematics from Rose-Hulman Institute of Technology and the M.S. and Ph.D. degrees in electrical engineering from the University of Minnesota, Minneapolis. He is a TEES Research Professor in the Office of Engineering Academic and Student Affairs at Texas A&M University, College Station. He has authored over 70 papers and offered over 30 workshops on faculty development, curricular change, curriculum redesign, and assessment. He has served as a program co-chair for three Frontiers in Education Conferences and the general chair for the 2009 conference. Prof. Froyd is a Fellow of the IEEE, a Fellow of the American Society for Engineering Education (ASEE), an ABET Program Evaluator, the Editor-in-Chief for the *IEEE Transactions on Education*, a Senior Associate Editor for the *Journal of Engineering Education*, and an Associate Editor for the *International Journal of STEM Education*.

Connecting and Expanding the Emerging Engineering Education Research & Innovation (EER&I) Communities

Karl A. Smith¹, Ruth Streveler², Rocio C. Chavela Guerra³

¹School of Engineering Education, Purdue University & Civil Engineering, University of Minnesota, ksmith@umn.edu,

²School of Engineering Education, Purdue University, streveler@purdue.edu,

³American Society for Engineering Education, r.chavela@asee.org

Abstract— Currently there is a lot of emphasis on engineering education research (EER) and engineering education innovation (EEI). In the EER domain, several universities have established or are considering establishing engineering education research centers and PhD programs. In the EEI domain, the National Academy of Engineering launched the Frontiers of Engineering Education (FOEE) symposium and NSF recast CCLI as TUES, and more recently IUSE (Improving Undergraduate STEM Education). In 2014 NSF funded a pilot implementation of the NSF Innovation Corps for Learning (I-Corps™ L) and additional cohorts have been conducted and are planned. The growth of interest in the scholarship of teaching and learning (SoTL) has great potential to contribute to EER and EEI as indicated by the response to the ASEE *Virtual Communities of Practice* (VCP) project. Faculty and graduate students interested in engineering education research and innovation (EER&I) are widely distributed and often isolated in their department and institution. Many are eager to meet and interact with colleagues who have similar interests. This session provides the opportunity to for people who have been involved in engineering education research and innovation to reconnect, and to welcome new folks into this emerging community.

Keywords—Engineering Education Research, Capacity Building

I. INTRODUCTION

There are many recent developments in EER&I such as the emergence of new Departments of Engineering Education (e.g., at the University of Texas – El Paso), the NSF *Innovation Corps for Learning* (I-Corps™ L) project [1, 2] that is now in its second year, and the ASEE *Virtual Communities of Practice* project [3, 4] that is focused on the implementation of evidence-based instructional practices. Also, the publication of the National Research Council's Discipline-Based Education Research practitioner guide, *Reaching Students: What Research Says About Effective Instruction in Undergraduate Science and Engineering* [5].

A little over ten years ago, the National Science Foundation (NSF) sponsored three projects to build capacity in engineering education research: Rigorous Research in Engineering Education: Creating a Community of Practice (RREE) [DUE-

0341127], Strengthening HBCU Engineering Education Research Capacity, [HRD-0411994], and the Institute for Scholarship in Engineering Education (ISEE), an element of the Center for the Advancement of Engineering Education [ESI-0227558]. These programs attracted tremendous interest, with participant applications outweighing available slots by a ratio of approximately 3 to 1. The engineering education research communities that RREE and ISEE helped to foster have expanded and now have global reach. Capacity building has also been aided by the creation of PhD-granting departments of Engineering Education at several US and international institutions [e.g., 6, 7].

NSF subsequently funded a new project to continue and expand the work done by RREE and ISEE. Expanding and sustaining research capacity in engineering and technology education. Building on successful programs for faculty and graduate students (which we will call the REEE2) (DUE-0817461) broadens the Community of Practice (COP) model successfully used to develop the RREE and ISEE programs [e.g., 8]. The National Academy of Engineering (NAE) has sponsored the Frontiers of Engineering Education symposium since 2009 and the focus is on engineering education innovation (EEI).

Funded by NSF, the ASEE *Virtual Communities of Practice* (VCP) is a project that enables faculty members to implement evidence-based educational practices in engineering courses [3, 4]. Starting in the fall of 2012, the VCP project provided the infrastructure for faculty members to engage virtually over a sustained period (two academic terms), collaborate, and support each other as they learned and implemented new educational approaches in their classrooms. Spanning two cohorts, the ASEE VCP project involved over 175 faculty members from more than 125 institutions; the project produced a knowledgeable and skilled faculty community of leaders and implementers with a deeper understanding of and experience with evidence-based instructional approaches.

In 2014 NSF funded a pilot implementation of the Innovation Corps for Learning (I-Corps™ L). The eight-week I-Corps™ L program uses a lean approach to scaling teaching and learning innovations into broad practice by using

established strategies for start-ups. Participating teams go through a hypothesis-testing, scientific method of discovery to gather important insights and identify issues associated with their projects [1, 2]. The principal goal of I-Corps™ L is to foster an entrepreneurial mindset within the STEM education community and to impact the way innovations are designed and implemented. A second cohort of 24 teams was conducted on January-February 2015, and two additional cohorts are planned to start in July 2015 and January 2016, respectively.

The Research in Engineering Education Network ([REEN](#)) is an independent, international and inclusive forum in which quality research on engineering education is conducted, discussed and disseminated. REEN has organized symposia about every two years since 2007. The next one will be in Dublin, Ireland, July 2015

These foundation-building efforts have helped build capabilities for engineering education research and innovation; however, continual emphasis is essential to maintain the momentum.

Faculty and graduate students interested in engineering education research and innovation are widely distributed and often isolated in their department and institution. Many are eager to meet and interact with colleagues who have similar interests. This session provides the opportunity for people who have been involved in engineering education research and innovation to reconnect, and to welcome new folks into this emerging community.

II. SESSION DESCRIPTION

A. *Intended Audience*

This session is intended for educators who are interested in strengthening their involvement or exploring becoming more involved with the emerging engineering education research and/or innovation communities. Noting the success of past special sessions and workshops where participants actively engaged in exploring engineering education research, participants interested in engaging in a lively networking and brainstorming session may also enjoy and benefit from attending.

B. *Goals*

The session is designed to provide an informal opportunity for participants to meet and interact with like-minded colleagues, bringing hallway conversations into the meeting room, and to foster the building of community. Participants will meet many people and begin to identify common interests. It is our belief that this combination of interaction, update and reflection will help participants identify the levels of their involvement in engineering education research and innovation. Further, through the shared experience of meeting and interacting with colleagues in a special session, participants will identify a group of peers from whom they can continue interacting in the future.

This session will provide participants with an update on the status, and an opportunity to meet and interact with people

interested in engineering education research and innovation (EER&I) and contribute to future plans by:

- Increasing familiarity with activities and people involved in engineering education research and innovation
- Actively participating in EER&I community building and especially the interaction of the two communities
- Participating in the planning for next steps

C. *Expected Outcomes*

At the completion of this special session, it is anticipated that participants will be able to:

- Articulate the current status of the emerging engineering education research and innovation communities
- Describe key aspects of current efforts at face-to-face and virtual community building
- Identify interested colleagues with whom they will continue the conversation
- Clearly articulate their interest in engineering education research and innovation.

III. SESSION AGENDA

The session is structured as follows:

- **Introduction of session and facilitators** (10 minutes)
- **Brief report on status of EER&I** (25 minutes)
 - Update on Departments, PhD Programs and Centers
 - Update on EER initiatives – NRC DBER, ASEE VCP
 - Update on EEI initiatives – NSF I-Corps™ L, NAE – FOEE
- **Participant Networking** (25 minutes)
 - Rapid introductions around guided questions – Four to five conversations in groups of 3 – as a way to meet many people
 - Identification of “intellectual neighborhoods” around research and innovation questions and opportunities – individual reflection and writing
- **Brainstorming on strategies to connect, expand, and sustain the emerging EER&I communities** (20 minutes)
 - Summary of ideas for (1) local, (2) national and international conferences, etc. and (3) virtual communities
- **Individuals share reflections with the large group, facilitators sum up the session and participants complete feedback forms** (10 minutes)

FIE 2015 Special Session – *Movin' Along*: Investigating Motion and Mechanisms Using Engineering Design Activities

Susan K. Donohue and Larry G. Richards
University of Virginia, susand, lgr@virginia.edu

Abstract – This special session will introduce participants to engineering design activities that use mechanisms, devices that transform one type of motion to another, to support student learning about motion, a topic that recurs throughout K-12 science studies. The activities come from new and revised K-12 Engineering Teaching Kits (ETKs). ETKs are self-contained standards-based and project-based instructional units. Their format and contents reflect an integrated approach to STEAM/d (STEM + Art + design) education. Participants will learn key concepts guiding ETK development and implementation; discuss methods for integrating ETKs and therefore engineering design concepts, practices, and models seamlessly and transparently into their curriculum; discover how engineering design and inductive learning principles help students learn and own key concepts in STEM; and work through selected engineering design activities. This special session is for those interested in exploring a philosophy of engineering education that stresses an integrative, project-based approach to instruction and practice grounded in design, the fundamental process of engineering.

Index Terms – Engineering design process, Engineering Teaching Kits, inductive learning, P-16 engineering education, STEM.

INTRODUCTION

While the intersection of engineering and humanities has long enhanced and reinforced learning in the individual disciplines, the active integration of art, music, and composition activities in STEM studies has been gaining traction in many pre-college (P-12) environments during the past few years. The growing STEAM (STEM + Art) approach emphasizes a hands-on, project-based, interdisciplinary approach to the study of science, technology, engineering, and math (STEM). To emphasize the importance of using engineering design principles to *integrate* learning in science and math and gain technological literacy, this educational movement may also be called STEAM/d. The addition of “d”esign and the integral sign to the STEAM acronym recognizes the kinship between art and engineering as complimentary design-based disciplines and that design is an integrative process. The STEAM/d philosophy is at the heart of Engineering

Teaching Kits (ETKs), our means for delivering integrative, holistic learning. ETKs provide the framework for this session’s activities.

ETKs are self-contained standards-based instructional units grounded in the constructivist philosophy of education [1], [2] and the principles of guided inquiry and active learning [3], [4]. Our primary goal in developing the ETKs is to engage students in a series of age-appropriate engineering design challenges to reinforce targeted concepts in math, science, and technological literacy.

By the end of the session, participants will be introduced to key components of the engineering design process and the STEAM/d movement and be able to identify methods for using engineering design activities to integrate STEAM/d studies seamlessly and transparently in the curriculum as well as strengthening key “21st century skills” like systems thinking, critical thinking, and problem-solving.

MOTIVATION

Years of K-12 outreach activities provide abundant examples of students becoming totally engaged by engineering design activities and project-based learning [5]. However, the majority of outreach initiatives tend to be short-term and episodic, with many leaders conducting activities chosen with little to moderate regards to participant knowledge, culture, experiences, or values. A main goal for our professional learning communities, therefore, is to determine how to ensure consistent exposure to engineering and computer science in ways that truly connect student and learning in context throughout the P-16 – pre-college and undergraduate – experience. Thanks to a growing body of research results, a data-driven design is possible. Realizing that a many-pronged approach is more likely to engage and encourage K-12 students to commit to postsecondary STEM studies – one thing we should have learned by now is that “one size (activity) doesn’t fit all” – we offer our philosophy and curriculum in this session for consideration.

We also recognize that the earlier interventions happen the greater the opportunities to recruit P-12 students into the STEM academic pipeline and, just as importantly, retain them.

While all P-12 students have the ability to benefit from early experience in an integrated STEAM/d educational environment, students from underrepresented populations in

STEM may especially benefit. Many decisions about inclusion in enrichment programs such as gifted and talented courses are made in early elementary grades, and an English Language Learner / English as a Second Language student may be at a disadvantage with respect to entry into these programs if his/her English language skills cannot correctly convey his/her abilities and intelligence [6]. An integrative STEAM educational environment with a design-driven project-based curriculum, with opportunities to connect with all learning styles [7], is one means for engaging students from diverse backgrounds.

OUR CORNERSTONE: ETKs

Since 2002, teams of students and faculty at the University of Virginia have developed, tested, and distributed ETKs for use in science and math classes - initially in middle schools but now throughout K-12 [8], [9]. An ETK is a set of five 50 minute standards-based lesson plans designed to teach targeted math and science concepts in the context of the engineering design process. Lessons are structured to develop understanding of key concepts at both abstract and concrete levels.

The primary goal of ETKs is to promote awareness of and excitement about the nature of engineering. Each ETK emphasizes the engineering design approach to problem solving through a series of design challenges, and includes real-world constraints such as budget, cost, time, risk, reliability, safety, and customer needs and demands. Students develop an appreciation for the tradeoffs involved in the practice of engineering, and how engineering decisions have an impact on society, culture, and the environment. The design/build/test cycle provides opportunities for creativity and exploration. No two designs are ever the same!

Over 50 ETKs are in various stages of development; a dozen are in frequent use in schools in the United States and several other countries in both classroom and professional development workshop settings. The most popular ETKs are *RaPower* (solar cars), *Save the Penguins* (heat transfer), *HoverHoos* (hovercrafts), *Under Pressure* (submersible vehicles), *Brainiacs* (biomedical engineering involvement in the fight against cancer), *Catapults in Action* (projectile motion), *Bridges to Engineering* (bridge design and construction), and *Trash Sliders* (sustainability, vehicle design).

ETKs are also designed to integrate other subjects in the curriculum with the exploration of STEM concepts. For example, an interdisciplinary team of eighth-grade teachers at a Central Virginia middle school uses the *Catapults in Action* ETK as the basis for a week-long series of integrated classes on medieval history, thus folding history, art, and language arts activities into the study of catapults and projectile motion. The potential for similar multidisciplinary activities can be found in all ETKs and thus make them appropriate for use in STEAM programs.

Further, ETKs are designed to be adaptable and flexible. As previously stated, ETKs were initially developed for

students in grades 6 – 8, but have been proven scalable for use by students at all grade levels by varying the amount of scaffolding and support given.

ETK 2.0

We are actively expanding the scope of concepts, material, and activities covered in ETKs. Four of our current initiatives are described in this section.

I. Addressing Misconceptions

A major addition to our initial ETK content is a set of activities and instruments to assess and remediate misconceptions in mathematics and science. We are using adapted and authored concept inventories to assess misconceptions and discrepant events to provide an opportunity for reformulating misconceptions.

Ia. Defining Misconceptions

It is important to understand the process of cognition when developing definitions of concepts and misconceptions. The most basic definition of cognition is the “process of knowing...and the content of those processes.” It is a **fundamental** concept in the science of learning, since learning is dependent on prior knowledge and the nature of changes students can make in both processes and content. (see, for example, [10]; emphasis added) The primary components affecting a person’s level of cognition are declarative knowledge and procedural knowledge. Declarative knowledge can also be defined as “semantic information...(knowledge about ideas)” and procedural knowledge as the “complement” of declarative knowledge; together, they “represent categories for describing knowledge in general” [11, p. 28]. The interplay between the acquisition and application of sets of related declarative and procedural knowledge helps students identify and internalize underlying concepts. However, students may internalize concepts incorrectly for a variety of reasons, and the resulting misconceptions can be a factor in student disengagement and other negative (re)actions.

A concept, therefore, is a mental construct or model that helps a person organize knowledge. It is inductively built from interactions and experiences [2]. Misconceptions, also known as alternative frameworks or invented theory, arise from a flawed development process in which the cognitive process of trying to connect new information to existing knowledge reshapes the new information to fit with the structure of the existing knowledge [12]. They can be remarkably resistant to change [2], [13], [14]. A misconception is distinct from *misunderstanding*, a situation in which a learner does not have sufficient correct information for comprehensive comprehension. The former is a cognitive issue; the latter, a factual issue.

The physics education community has long been involved in the assessment and remediation of misconceptions, especially with respect to Newtonian forces. The concept inventories in this area were pioneered by physicist David Hestenes and his colleagues at Arizona State

University beginning in the 1980s; see, for example, [15], which is one of many articles on the Force Concept Inventory. Other validated methods for evaluating conceptual knowledge are peer instruction [16], direct interview [17], and strategy writing [18].

Ib. Addressing Misconceptions in Movin' Along

Common misconceptions with respect to motion and the concept with which it's typically paired, force, include the following [19], [20]:

- Action-reaction forces act on the same body.
- Friction can't act in the direction of motion.
- The normal force on an object is equal to the weight of the object by the 3rd law.
- The normal force on an object always equals the weight of the object.
- Equilibrium means that all the forces on an object are equal.
- Only animate things (people, animals) exert forces; passive ones (tables, floors) do not exert forces.
- Once an object is moving, heavier objects push more than lighter ones.
- You need force to keep a car moving.
- Friction is an inherent part of an object.
- Going at a steady velocity in a circle around the Earth means there are no accelerations.
- Your weight tells you how much stuff you have.
- Equilibrium is the absence of forces.
- "Energy" and "force" are interchangeable terms.

These misconceptions about force and motion are challenged, in part, by the following "classic" discrepant events that nonetheless should have further distribution:

- The coin, card, and glass exercise, which addresses misconceptions regarding friction and inertia [20]
- The Coke / Diet Coke exercise, which addresses misconceptions regarding buoyancy and density [21]
- The hollow egg and book exercise, which addresses misconceptions about material strength, shapes, and forces [22]
- The glass full of water and card exercise, which addresses misconceptions about gravity [23]

These discrepant events were researched and adapted for inclusion in the *HoverHoos/Save the Glades*, *Under Pressure/Save the Whales*, *Bridges to Engineering*, and *Imagineer Your Ride* ETKs. We are developing a set of new discrepant events for *Movin' Along*.

II. Grounding the ETKs in Society's Problems

ETKs are also being updated to address the need to connect STEM to student context and experience by grounding an ETK's theme in real world issues. In *Save the Penguins*, for example, student learning about materials science and heat transfer and supporting design activities occur within the context of an environmental issue that affects them - climate change - using an appealing subject population: penguins [24]. Similarly, *HoverHoos* was restructured as *Save the Glades* and *Under Pressure* was restructured as *Save the*

Whales in order to have students connect the practice of engineering to the solution of large scale societal problems. This restructuring is prompted by the noted phenomenon of attracting students from underrepresented populations in STEM by offering socially relevant projects and the chance to solve society's needs via engineering design projects (see, most recently, [25]).

III. Parent-Teacher Guides

Another addition to the ETK library are detailed guides for parents and teachers, in part to promote the family engineering movement [26] so that student learning is supported in both formal and informal learning environments, and in part to provide additional support to activity leaders who may not necessarily have a background in the topic(s) covered by a given ETK. These guides provide background on the engineering design, science, and math concepts addressed in the targeted ETK as well as information to use in guiding students and other participants through the design challenges. This support is especially important for the growing number of parents searching for engineering education opportunities for summer enrichment or to supplement a homeschool curriculum.

IV. Scaling ETKs to Fit Time Constraints

We have also successfully tailored ETKs to fit time and interest constraints. For example, we have successfully adapted *RaPower* and *Save the Penguins* to 3 hour versions for summer camp activities [27] and to 90 minute versions for professional development sessions [28]. Similarly, we have created a 90 minute version of *Wind-E* for outreach and enrichment programs [29], [30] and professional development [28]. Ninety minute versions of *HoverHoos* (*Save the Glades*) and *Under Pressure* (*Save the Whales*) were piloted at the Village School's Take Your Daughter to Work Day [31].

THE BASICS OF MOVIN' ALONG

The main subjects covered in the *Movin' Along* ETK are from the discipline of kinematics, or the study of motion. We focus on types of motion and the mechanisms used to transform and redirect motion. There are four types of motion in mechanical systems: linear, or motion in a straight line; oscillating, or repetitive motion about a central point or between different states; reciprocating, or motion (sometimes called "strokes") back and forth or up and down in a straight line; and rotational or rotary motion, motion that is circular. In constructing mechanisms to redirect motion or transform one type of motion to another, gears and/or linkages are used. The resulting mechanisms include the cam, slide, and follower, which transforms rotary and reciprocating motion; the chain and sprocket, which translates rotary and linear motion; the crank, link, and slider, which transforms oscillating and rotary motion; the peg and slot, which transforms oscillating to rotary motion; the rack and pinion, which transforms rotary motion to linear or reciprocating; and the rope and pulley and wheel and axle,

which transform rotary motion to linear [32], [33].

Mechanical systems abound in our world, but students may not be aware about how many are involved in their lives. For the opening exercise, students are asked to brainstorm about the systems they encounter on a regular basis and why we would need to transform one type of motion to another. Vehicles provide good examples due to the high probability of student familiarity with commonly available/used ones. To make the discussion concrete, students work through how bicycles transform rotary motion to linear motion.

The larger societal context includes discussions about the need for alternatives to the internal combustion engine and other methods of mechanical propulsion, which lead to the major issues of depletion of non-renewable sources of energy and climate change. For example, marine propulsion methods are, at best, 70% efficient. Increasing this efficiency by 10% would result in annual saving of millions of gallons of fuel and the related monetary and environmental costs. As it happens, many marine species achieve up to 87% efficiency; a number of researchers are involved in designing propulsion systems inspired by sea turtles, manta rays, dolphins, penguins, and whales [34], [35]. This problem formulation adds the opportunities to discuss how engineers can help preserve endangered species and bio-inspired design practices.

Design challenge activities include the assembly of automata, a mechanical system (typically, a toy like a Jack in the Box) that's constructed to look as though it's moving on its own; designing and building kinetic sculptures and Rube Goldberg systems (an overdesigned mechanical system built to accomplish a very simple goal) out of various types of mechanisms; and spirographs, in which students choose the type of gears and linkages they want to use in tandem to make drawings. The last one can involve the designing of gears, for example, in a CAD program for construction on a 3D printer, thus including other activities that may be in the curriculum and giving students to construct linkages among seemingly disparate learning activities.

SESSION AGENDA

The session is structured as follows:

- **Welcome, Introductions, and Agenda Review** (10 minutes)
- **Initial Exercises** (20 minutes)
Participants will construct a set of physical models that illustrate different types of motion – linear, rotary, reciprocating, and oscillating – and mechanisms for translating one type of motion to another. They will be encouraged to explore how their models could be joined with others to form a functioning mechanism or system of systems. The final product may be an automaton, a kinetic sculpture, or a Rube Goldberg system; participant interest will drive this decision.
- **Regroup, Reflect on Lessons Learned, and Review of Important Concepts** (15 minutes)

- **Follow-on Activities** (40 minutes)
Participants will work in groups with the facilitators to elaborate on their designs. We will also discuss scaling the activities to various grade levels. This discussion will include a review of expectations as to cognitive development and skill levels for students in those grades, necessary to the proper scaling and scaffolding of the activities.
- **Concluding Activities and Discussions** (5 minutes)

ACKNOWLEDGMENT

We are grateful to the Payne Family Foundation and the National Science Foundation for the initial financial support required to launch the VMSEEI and develop and implement ETKs; to current and former ETK development teams for their contributions to the ETK library; to the members of the ETK community; and to the reviewers for their feedback and recommendations.

Susan K. Donohue, Lecturer and ENGR 1620 Co-ordinator, Department of Engineering and Society, School of Engineering and Applied Science, University of Virginia, Charlottesville, VA, 434.953.5190, susand@virginia.edu. Her research interests include P-16 engineering education with an emphasis on design; development of skills important to success in the engineering profession, such as systems thinking, spatial skills, and creativity; and identification and remediation of misconceptions.

Larry G. Richards, Professor, Department of Mechanical and Aerospace Engineering, University of Virginia, Charlottesville, VA, 434.924.3191, lgr@virginia.edu. His research interests include P-16 engineering education, engineering design and manufacturing, innovation, and entrepreneurship. He also leads the Virginia Middle School Engineering Education Initiative (VMSEEI).

Alumni as a Resource to Increase Student Retention in Early Computer Science Courses

Linda Ott

Department of Computer Science
Michigan Technological University
Houghton, MI 49931
linda@mtu.edu

Abstract—Student persistence in computing majors is one of the keys to providing the talent needed to fill the projected job openings in the computing professions. A range of factors can affect a student's decision to remain in a computing major or change to another major. In this paper we describe an assignment that we use in a course for first semester computing majors. The assignment is based on students interacting with alumni on an individual basis. The nature of the assignment addresses a number of the factors that have been shown to influence students' persistence and may result in an individual student getting the specific intervention that he or she needs.

Keywords—computer science education; student persistence; first year courses

I. INTRODUCTION

Retention of students in computer science programs is key to increasing the number of students graduating with computing degrees and ultimately being available to fill the numerous projected job openings in the computing occupations. Some of the reasons that students choose not to persist in a computer science major include uncertainty that the jobs available after graduation will be of interest to them long-term, limited or misinformation about career opportunities, and a lack of confidence in their ability to succeed in more advanced computing courses. A range of tactics have been recommended to encourage students to persist in the early computing courses. These include breadth-first courses, separate courses for students with no programming experience from those for students with programming experience, appropriate problem selection, and pair programming.

We have been utilizing an assignment that pairs first year students with alumni as a means of introducing the students to some of the many careers available to them after graduation for approximately fifteen years. Feedback from students indicates that the assignment gives them a much broader perspective on computing careers than they had prior to the assignment. Because of the one-on-one nature of the assignment, the alumni often provide information and encouragement about other issues that first-year students may be encountering. As an example, students sometimes confide in emails to their alumni

that they are finding college coursework much more difficult than they had anticipated. Hearing back from an individual, who is now successfully employed in the field and who may also have had similar problems early in college, can give a student the needed reassurance that perhaps what is needed is a bit of hard work, better study habits, or better time management. In this paper we describe our implementation of the assignment, along with a description of how and why the assignment has evolved over the years. Our goal is to provide sufficient detail to allow others to use a similar assignment in their courses. Since multiple retention related interventions occur in our course, it is difficult to independently assess the effectiveness of this specific assignment. Hence, we rely on more anecdotal evidence that we do have that demonstrates the value of this specific assignment as it relates to factors identified to impact student persistence in a computing major.

II. BACKGROUND

A. The Need

The need for computing graduates is well-documented as the job projections through 2022 continue to show strong growth in computing occupations [1]. Although enrollments in undergraduate computing degree programs are increasing [2], student persistence in the major can still be an issue. Various studies have examined factors that influence a student's decision to persist in computer science.

One significant issue appears to be the limited knowledge that students have regarding the actual breadth of the computing field. During a study that examined how students choose courses, Hewner interviewed an academic advisor who estimated that about a third of incoming students had "a very off-base view of what CS is about" [3].

Another significant issue is students' lack of awareness of potential careers available to them if they graduate with a computing degree. Hewner and Guzdial reported that students were not aware of career options "beyond working at Google" and had a difficult time envisioning possible career options that did not involve programming [4]. These results are not dissimilar to what Carter found when studying why high school

students chose not to major in computer science [5]. Carter found that many students believed that a computer scientist sits in front of a computer and programs all day. Others simply had no idea what a computer scientist might do.

A study by Uzoka et al. demonstrated that students lack a solid understanding of the differences among computing fields [6]. In their study, students were asked to indicate how well certain tasks fit in with different computing disciplines. Students did best identifying the tasks that are most closely associated with computer engineering, i.e., tasks that involve hardware or integrate hardware and software. Students were least able to identify the tasks typically associated with software engineering. Some of the tasks that students had the greatest difficulty with are less directly focused on technology, e.g., “Manages large scale technological projects” and “Evaluates and improves the usability (user experience) of computing systems.” In addition, the amount of uncertainty indicated by students showed that the students had significant gaps in their understanding of the various computing disciplines.

An interesting study by Biggers, Brauer, and Yilmaz examined differences between students at Georgia Tech who graduated with a degree in computer science and those who left the major [7]. Those who remained in a computer science degree and graduated tended to describe computer science using an active voice with expressions such as “creating the applications, processes, and tools that allow computers to solve real world problems”. Students who had changed majors used more passive expressions, e.g., “learning how to manipulate code”. In addition many of the students who had left the major focused on perceived negative aspects of the job environment such as “Sitting at the computer with minimal human interaction.” Perhaps most telling that computing students are aware of widespread misperceptions of their chosen field is the observation that many of the computer science graduates replied in a negative fashion when describing what computer science is. That is, they tended to state, for example, that CS is not about fixing hardware or being a code monkey. According to Biggers et al., these specific terms were exactly the terms used by students who had changed majors from computer science. They conclude with an indication of several areas in which changes can be made to improve the retention of students in computing majors. These include students’ belief that CS is coding and the students’ lack of awareness of the bigger picture, the students’ perception that what they are learning is not relevant to the real-world and that computing is asocial. Finally, Biggers et al. suggest their findings show that students who leave the major “lack vision and understanding of opportunities a career in computing affords them and they leave within a limited time” and thus their recommendations include a need to “create vision and excitement around the major and network them with positive role models so they can have an early vision of a broader dream, and can ‘keep their eyes on the prize’ as they go through the major.”

Another group of studies examine aspects related to a student’s sense of self or identity and how that relates to persistence in a computer science major. A study by Veilleux et al. [8] indicated that a student’s sense of belonging is closely related to a student’s perception of his or her ability to do

computer science and that a student may discount his or her actual performance when determining self-efficacy. Lewis et al. [9] identified five factors that impacted students’ decisions to major in CS. These were: ability in CS, enjoyment of CS, their fit in CS (“the extent to which their own values and identity align with the values and cultural expectations they associate with CS”), utility of CS, and the opportunity cost. Students measured their CS-related ability based on their previous experiences, their speed in completing CS-related tasks, and grades. Student interpretations of these factors were influenced by whether they believed ability was fixed or malleable. Kinnunen and Simon [10] also studied students’ sense of self-efficacy and their success in programming. They found that computer science majors tended to develop their sense of self-efficacy based on a comparison of themselves with their classmates. These findings are consistent with some focused more broadly on STEM education [11, 12].

A recent study by Dempsey et al. looked at gender differences in student perceptions and their intent to study computer science [13]. Based on a survey they measured student perceptions of CS, attitudes about science and CS, self-efficacy in science and CS, self-concept and intention to continue in CS. The subjects of their study were students in an introductory computer science class that is taken predominately by CS, mathematics, and engineering majors. Examining their results by gender they found no statistically significant differences in the scores of men and women for perceptions of CS, attitudes of science, attitudes of CS, or science self-efficacy. They did find statistically significant differences in the scores for CS self-efficacy, CS identity, and CS intention. In all three cases the women’s scores were lower than the men’s scores. This seems to indicate that the women are less likely to see themselves as succeeding in CS and less likely to see themselves as computer scientists. Their concluding recommendation is that focusing on changing women’s perception of themselves in a computer field may increase the effectiveness of efforts to encourage more women to go into computing.

In summary, we see multiple factors that may potentially lead computing students to change their major early in their college career. These include the misperception that computer science is just programming and consistent with that misperception a lack of awareness of the breadth of the computing field, the belief that the computing field is asocial, a sense that their coursework is not relevant to the real world, a limited awareness of career opportunities, a belief that intelligence is fixed rather than malleable, and particularly for women a lack of self-efficacy and the inability to see oneself as a computer scientist.

It is our experience that the alumni assignment that we use in the orientation course for our majors helps to ameliorate these issues at least for some of the students. The nature of the assignment allows the students to some extent to tailor it to address their individual questions and perceptions. The next section will provide the context in which we give the assignment, followed by a section that discusses the assignment in detail.

III. THE CONTEXT

A. Our Environment

Michigan Technological University enrolls approximately 7,000 students primarily in STEM-related degree programs, with about two-thirds of the undergraduate students enrolled in programs in the College of Engineering. The Department of Computer Science is the largest department in terms of undergraduate enrollments in the College of Sciences and Arts and offers undergraduate degree programs in computer science and software engineering, as well as MS and PhD programs in computer science. We have approximately 375 undergraduate majors total in the undergraduate degree programs with a typical first year class of around 100 students

The Department currently offers three introductory programming courses. CS1121, Introduction to Programming I, is the expected starting point for students majoring in our Department. This is a typical CS1 course with no previous programming experience required. Majors make up less than half of the students enrolled in CS1121. CS1131, Accelerated Introduction to Programming, is aimed at students with previous programming experience. This course covers in one semester the material normally covered in typical CS1 and CS2 courses. Students can begin in this course instead of CS 1121 if they have had sufficient programming experience, regardless of the programming language they know. Typically, computer engineering and computer science majors enroll in CS1131. CS1111, Introduction to Programming in C/C++, is for students in electrical engineering and certain technology degree programs. It does not serve as a pre-requisite for advanced courses in the Department.

B. Explorations in Computing Course

The Department first introduced a majors-only one-credit course around 1990 to augment the introductory programming course during a student's first semester. The original course focused on an introduction to the department, e.g., the faculty and various departmental procedures; advising matters, e.g., degree requirements and co-op opportunities; and computing skills, e.g., e-mail, word processing, and useful Unix commands. It evolved over the years as the students' backgrounds and the degree programs changed. From 2004 to 2011 the course was also taken by computer engineering majors who were uncertain whether their interests were in computer engineering or computer science. During those years the emphasis was placed on covering a breadth of material across the two disciplines to help students better understand the differences between the degree programs. Early lectures in the course focused on topics closer to the hardware such as computer logic, followed by core CS topics such as operating systems and ultimately covered areas such as artificial intelligence and graphics.

With the focus of the course once again solely on majors within our Department since Fall 2012, it was possible to reevaluate the goals for the course. A major issue within our Department, like many computer science departments, has been retention of our majors. For example, of the students who started in Fall 2008, only 42% had either graduated from or were still working toward completing a degree in our

Department four years later. In fact after just one semester, the Fall 2008 class was down to 80% of the original members. By Spring 2010 the class was down to 49%. Clearly the majority of the retention problem is within the first semesters.

In a recent paper [14] we discussed retention issues in our computing degree programs and how changes in CS1000 appear to be having a positive impact. In this paper we focus on an assignment regularly given in CS1000 that we believe is contributing to student success and retention in the major.

C. An overview of CS1000

In Fall 2014 the course consisted of 14 class sessions.

- The first class session highlighted computing history.
- Half of the class sessions were lectures by computer science faculty members introducing their research area. Topics covered included data mining, virtual reality, computer vision, machine learning, human computer interaction, and software engineering. The goal of these lectures is to give the students a sense of the breadth of the field including a taste of some of the opportunities available to them later in their academic careers.
- During the second class session, an industry representative explained how to write a professional resume. Students were required to prepare a resume after this session and prior to our Fall Career Fair.
- In two sessions representatives from various industries discussed the range of opportunities for computing professionals in their companies.
- Other sessions included presentations on Study Abroad opportunities, student organizations, and computing in the news.
- Students were given opportunities to earn extra credit by attending specified events on campus. Examples of such events included the career fair, industry informational sessions, and an informal session with a visiting computer science alumna.

Class attendance is required. Some weeks the students have a small homework assignment, usually related to the lecture topic of the week. The major assignment involves corresponding with an assigned alumnus/a. This assignment is described in detail in the next section.

IV. THE ALUMNI ASSIGNMENT

The alumni assignment is built around an email correspondence between each student and that student's assigned alumnus/a. The initial intent of the assignment was to give the students a better sense of possible careers and career paths for graduates with computing degrees. Over the years we have come to see that the assignment plays a broader role, at least for some of the students. This section will describe the assignment in detail. The following section will discuss comments and feedback from students and alumni that demonstrate the different impacts the assignment has on individual students.

A. Description of the assignment

The assignment consists of three parts:

1. Email correspondence with an alumnus/a.
2. A one page report describing what the student learned from the email correspondence.
3. A second one page report discussing three other alumni of their choice based on the other students' reports.

The following subsections provide greater detail on each aspect of the assignment.

1) *Introducing the assignment.* Students are told that the primary goal of the assignment is for them to learn about career opportunities, but that most of the alumni are comfortable giving advice about school-related concerns as well as talking about a broad range of topics from their experiences as a student to "life after college". A bit of time is devoted to talking about the appropriate level of professionalism to be demonstrated in the email correspondence. The intent is not to make the assignment into a formal business correspondence but to expose the students to the reality that the professional world can be "small" at times. In addition to letting the students know that some of the alumni attend the career fairs and recruit for their companies, I rely on several anecdotes to convey the message. One of the stories involves a CS1000 student who was offered a part-time job by his alumnus which upon the student's graduation became the student's full-time position. A second anecdote perhaps shows more clearly how small the professional world can be. After taking an initial job upon graduation, a former CS1000 student decided to pursue other options on the West coast. It turned out that one of the people he interviewed with was his CS1000 match. Students are also introduced to LinkedIn and we suggest that they look up their alumni match on LinkedIn.

2) *Email correspondence logistics.* Initially each student is emailed the name and email address of the assigned alumnus/a. The student alumni matches are random with the exception that female students are matched with alumnae. (Some male students are also assigned to alumnae in hopes of helping to dispel the possible misperception that the field is only populated by males.) The alumnus/a is also emailed the name and email address of the student. Students are told to use their Michigan Tech email address and to use a specified subject (e.g., Michigan Tech CS 1000) to facilitate the alumni recognizing the email from an unfamiliar person. Students are typically given three to four weeks to correspond with their alumni. This is usually ample time for several exchanges between the student and alumnus/a even if one or the other is really busy or will be away from email for a few days. Students are given a set time by which they must send an initial email to their alumni, usually about 5 days after the assignment is given. Since many of our students are

introverts, we quickly learned that many students needed the deadline to get over their hesitation/fear/procastination and send that first email. We require they copy the initial email to a grader email account. This allows us to verify that they emailed by the stated deadline. Additionally, it provides a way to examine an email that was sent and identify possible problems if the email didn't reach the alumnus/a. Subsequent emails may be private between the student and the alumnus/a.

3) *Thank you email.* At the end of their correspondence with the alumni, we require students to send a brief thank you email expressing their appreciation for their alumni's time and insights. Again this email is to be copied to the special email account. Besides encouraging good manners, this also serves as a mechanism for the alumni to know when the obligatory correspondence has ended. In some cases the alumni and students continue their correspondence on their "own time".

4) *Initial report.* Students are expected to write a one-page, single-spaced report summarizing what they learned from their alumni and any reactions they had to the correspondence. In addition, each student submits a short (approximately five words) description of his or her alumnus/a. The reports are then posted in our course management system using the short description as the label of a link to the given report.

5) *Final report.* After the reports are posted, students then read the posted reports and choose three alumni not including their original match on which to write a second report. They are told they can pick these alumni for any reason, but they should indicate why they chose the alumni. Examples of reasons include interesting career paths, similar interests either in terms of work or hobbies, or geographic location of interest.

B. Rationale for the current structure of the assignment

The assignment had originally only consisted of the correspondence with an alumnus/a and the initial report. The obvious weakness was that each student was only exposed to one career path. Depending on the career path of that particular alumnus/a, this may not have broadened the student's perspective much. Thus, we wanted a second component to the assignment that would expose the students to other alumni reports. Requiring students to read all the other reports isn't realistic considering there are typically 100 students in the class. Since most of the alumni have had fairly different career paths by requiring that students look at a minimum of at least three reports, they tend to get at least some sense that there are a variety of career options available to them.

Posting the reports in a table and using the student-generated descriptive phrases as links to the reports is a relatively recent addition. Initially we had posted the reports by some non-descriptive identifier. With no information to help them choose which reports to read, most students read the first three reports. We have found that students are reporting

on a more diverse set of reports now that they have some way of identifying reports that may be of interest to them. And an additional benefit of the descriptive phrases is that as they scan the list, they are exposed to bits of information about the alumni. In some cases, it's a bit of a job description or a company that they work at or even a hobby. Here is a sampling of the student descriptions of their alumni matches from last fall include:

- Cellular software developer, master architect, and other management
- Director of product management
- Working at his own start-up
- Entrepreneur, innovator and developer
- Writing drive system software for giant mining trucks
- Medical programming and system testing
- Eased my mind about classes and grades
- Working on systems for aircraft
- Successful, experienced, flexible, skilled, happy
- Advantages of a large company

As can be seen from this sample, just skimming the list can broadened one's awareness of career opportunities and career paths. It might even subtly attack one's biases about types of individuals who succeed in the field. And it may even ease a student's concern that he or she is struggling a bit with coursework. By not prescribing precisely how the students should describe their match, the students are free to pick what they see as most important.

C. Grading

The alumni assignment is worth 35% of a student's grade. I give 10% of the points for the initial email and another 10% for the thank you email. The remaining 80% of the grade is divided between the two reports. The reports are primarily graded on effort – did the student produce a report that meets the length requirement and has relevant material.

D. Soliciting Alumni

Over the years we have built a list of alumni who are willing, and even eager, to correspond with the first year students. The initial list came from a broad solicitation to alumni in a departmental newsletter article that explained the assignment. Many of those original alumni have been consistent volunteers year after year. Occasionally an alumnus/a will indicate a need to take a year off due to a timing conflict, such as an extended business trip or a new baby. But most alumni indicate that they look forward to interacting with a new student each fall. Most of our alumni live out of the area, so this is one way for them to stay in touch with what is happening on campus. To make up for the inadvertent lost contact due to a changed email address, I typically add a few students from the recent graduating class to the list. This also ensures that the list includes new, as well as well-established

professionals. A few times when the incoming class was particularly large, I have needed to put out another broad call.

I am frequently reminded that many of the alumni truly enjoy the experience. One small example occurred this spring. I received an email from an alumnus who had realized that he hadn't gotten his regular fall request from me. His division was sold to another company and the transition occurred in fall. Since his email had changed, he hadn't gotten my request and the work transition had distracted him. He had contacted me as soon as he remembered to be sure I had his new email for the round next fall.

E. The alumni

Since a goal of the project is to expose students to the range of career possibilities with a computing degree, we have gathered a diverse set of alumni volunteers. A wide range of industries are represented including automotive, medical, chemical, computer, gaming, aerospace, transportation, entertainment, and finance. Alumni are in a wide range of positions such as web and mobile applications developer, software engineer, test engineer, research scientist, project manager, consultant, various types of executives, and entrepreneurs. Companies range from the major well-known corporations to small start-ups. The most recent graduates are from 2014 with the other extreme being 1976. A few of the alumni are retired.

V. THE IMPACT

A. Career Awareness

The stated purpose of the assignment is to provide students with some insight into the range of possibilities for careers in the computing field. Based on the student writings, it is clear that at least for some of the students the assignment did increase the students' knowledge of computing careers. Here are some quotes from student reports to support this statement:

...it has helped me gain some insight into the professional field of computer science.

Perhaps the biggest thing I took away from my correspondence with [alumnus] was the fact that with a computer science degree, you can literally do whatever you would like, the possibilities are endless.

I told her what I was interested in doing with my education and she suggested some really cool, high demand, jobs.

I definitely feel like I have a better idea of what jobs are available to me in my future.

A few comments in the survey given at the end of the course also indicate that students learned substantial information about computing careers. For instance,

... from the Alum assignment I got to hear a lot of different possible careers, including some that are really specific so aren't the kind you would see on a list

of "Possible Computer Science Careers" so I found the diversity really interesting

... this course showed me many different things software engineers can do and lots of different employment opportunities I have once I graduate.

I think this is worth noting, as it shows that for computer science majors [who] have an understanding of computer science but don't necessarily want to do actual programming when it comes to a long-term job that there is certainly a place for computer science people in managerial positions.

Before seeing her response I hadn't thought much of the idea of traveling as a consulting firm to assist people with their software development, and just find it to be an interesting idea for a potential job for CS/SE majors in the future.

A few students were particularly enthusiastic about having learned about careers. For example,

Getting to see all the opportunities available to a CS major is awesome.

B. Dispelling negative stereotypes

A few of the student comments show that the assignment went beyond simply given students information about possible careers, but also helped to dispel the negative stereotypes associated with computing jobs. For example,

This correspondence has shown me that the Computer Science field has a wide variety of applications. When I used to picture a job involving Computer Science, I used to think of someone working in cubicles, or an office, and I imagined that the programs that they were working on had to do with computers, software, or video games. My alum has worked on many diverse things.

And from the final survey,

... it has opened my eyes to so many opportunities in my major. Knowing that I can do other things in this specific major alone instead of just sticking to computers all day I can branch off and do so many other things.

A large part of [alumna]'s day-to-day work also involves communicating with others about her progress, mostly through email. Although it may not appear to be so on the surface, human interaction does play a significant role in the computing field.

As discussed earlier, Biggers et al. found that students who left a computing major held stereotypical, negative beliefs about computing careers [7]. Helping to dispel those

stereotypes early may support the student persisting in the major.

Some of the descriptive phrases that the students used to describe their match may also help to dispel the image that everyone in the computing field is an asocial, nerdy, male computer geek. Here are a few examples:

A cheerfully, intelligent, programming mother.

Google, funny, nice, interesting.

[Alumnus] can be surprisingly cool.

She is an awesome person who works for a government agency ...

C. Breadth of Computer Science

Student reactions to the assignment also demonstrate that they learned more about the breadth of the field.

After corresponding with my assigned alum, I feel my knowledge of the work involved with Computer Science has increased. I used to think the field of computer science was much more narrow [sic] before I talked to my alum.

D. Relevance of course work

Multiple student reports included comments related to the relevance of course work. Some, for example, related to general education courses.

The fact that he said "It is interesting that some of the classes like chemistry that I thought I would never use once I finished my prerequisites have proven very useful when working in several of my different roles" makes me much happier that a lot of the general education courses will actually come in handy and not just something I will forget about and never use again gave me some much needed confidence that yes these classes do matter.

... he said that taking a wide diversity of classes gave him a wide perspective in life and in his career and is a good idea for students.

Of course, computer science students were curious about programming languages and whether they were learning the "right" ones and enough different languages. Here are some examples of what they learned from their alumni:

One should always learn the fundamentals of computer science, instead of just focusing on one small aspect or language. What this means is that you should learn how the languages themselves work at the core, the theory behind the languages, and the practice behind what they allow to be expressed. Doing this will give you the most flexible future, as you will know a much broader range of information and have a much better time when learning something new.

I also asked him how many programming languages I should learn to feel comfortable in a workplace. I don't want to get a job and not know what I'm doing there or feel inferior to my peers. He said that "I think of programming languages like driving a car. Once you know how to drive one car really well, you can almost drive any other car in the world with little effort."

Besides programming languages, first year students are often concerned that they should be acquiring certifications since many of them were exposed to certifications in high school. Here's one example of a student report describing what he learned from his alumnus:

I asked my alumni, [alumnus], if getting a Cisco Certification would be helpful for finding jobs in my career path. I asked because at a tech center I went to in high school, we were pushed to start the Cisco curriculum. Since I already had the majority of it finished, I was curious if it would be worth my time to finish it. [Alumnus] said that they were not very useful for finding a job for companies other than Cisco. I also asked about getting a Microsoft Certification. [Alumnus] works for Microsoft ... [Alumnus] did not get Microsoft Certified until after joining Microsoft. He said, "I think if you just focus on school work, you'll be fine."

E. Self-efficacy

One of the short descriptive phrases used to describe alumni presented in the previous section (*Eased my mind about classes and grades*) demonstrates that for at least one student getting reassurance about his class performance was important enough that it was how he described his match. Other students also commented about getting support and encouragement by hearing advice and or similar stories from their alumni match. Some examples are:

I also brought some of the issues I was having in CS1131 and he told me that programming can be extremely stressful, and you'll even want to quit, but the challenges are the fun part. Doing something you already know how to do over and over can just become extremely tedious.

[Alumnus] had a rough time adjusting at first, and that makes me feel better because I'm having the same problem.

... a bit of advice: Even if you have never taken any Java classes and have no experience, if you like it, keep working at it because in the end all of the hard work that you put into it will pay off.

It's nice to know that [alumnus] struggled and survived Tech. At my high school I was considered one of the "smart people", then I came here and I'm just like everybody else. The word smart is taken to a whole new level, the kids I grew up thinking were smart are

only average by Michigan Tech standards. In a way, this is a really good thing because it pushes people like me to work harder than ever.

F. Fixed versus malleable mind-set

Although alumni did not use terminology related to fixed or malleable mindsets, students often reported that their alumni stressed the need to work hard.

If you're looking for words of wisdom, I would say that you can come back up from anything if you're willing to put the work in piece by piece. Everyone does bad on a homework or a class, or a work thing every now and then, but being able to recognize mistakes and slowly recover from them is what it's all about. I remember doing badly in one of my first computer science classes at MTU. My problem was not starting assignments in time and expecting to be able to finish them. I recovered enough to get a B in that class, and do the same or better in subsequent more challenging classes.

I have taken from this that if I work hard I can have a life where I travel the world, experience a bevy of impactful careers, and make lifelong friends and companions. [Alumnus] himself said he was not the greatest student but he still was able to make an incredibly successful career, meet his wife on campus, and still have time to spend on hobbies. That sounds like a life after Tech that I would like to make as well.

G. Identity

Identifying with a computing professional can be one way of helping an individual to see him or herself as a computing professional in the future. Here are some examples of how students identified with their alumni and or the field after their alumni correspondence.

I'm excited to be in a major that is in such high demand. It makes working hard to get my degree that much more meaningful.

I hope that one day I have as many opportunities as she did with her CS degree from Tech.

... starting a business is something that is very appealing to me. As I reach a point in my life where my path will no longer be set in stone and I'm free to do whatever I want, that is the path that seems most appealing to me. Hearing that to this day, your friend is still managing to get by perusing [sic] his business ventures is inspiring.

In reference to her alumna's discussion of her family,

I would also like to have a family when I'm older. It's really important to me. I don't want a career that will overtake my life.

The following statement from an upper level student when asked about her CS1000 experience with the alumni assignment also expressed a stronger sense of confidence in pursuing computer science after being able to identify with someone in the field who had managed a family and a career.

Talking to my CS alum made me more confident that I could have a career and be married and have kids, and I really appreciated that.

H. Words of Wisdom

Several students shared words of wisdom from their alumni. It's likely that the students could have gotten similar wise tidbits from numerous people on campus, but perhaps it has greater impact coming from an alumnus/a rather than a faculty member. Here are some examples:

[Alumnus] had some words of wisdom for me, he said that if you take anything away from this story, it should be you never know who you will run into during your college career, and how much of an impact it will have on your life.

I had the opportunity to learn from [alumna], whose daughter I know and is also attending Michigan Tech, demonstrating how small our world truly is.

... he provided a large amount of incredibly useful information that is applicable to nearly everyone. The first thing he mentioned was that getting to know the faculty (such as professors) is an important step. The next thing [alumnus] mentioned was the natural beauty of Houghton. Another piece of advice was the importance of getting involved in groups on campus. [Alumnus] made the point that going to the career fair is an amazing opportunity.

First, she recommends to make time for internships and co-ops even if you take more than four years to graduate in the process. ... She also believes studying abroad to be a great opportunity that one should pursue.

Her end message was to peruse whatever you find interesting in your college career, because that will deliver you to the job you'll like the most.

VI. DISCUSSION AND CONCLUSION

As discussed in the background section, a variety of factors have been shown to relate to student decisions to persist in computer science or to switch majors. These include the misperception that computer science is just programming and consistent with that misperception a lack of awareness of the breadth of the computing field, the belief that the computing field is asocial, a sense that their coursework is not relevant to the real world, a limited awareness of career opportunities, a belief that intelligence is fixed rather than malleable, and,

particularly for women, a lack of self-efficacy and the inability to see oneself as a computer scientist.

The extent that any given factor influences a given student is likely a function of that particular student's experiences and abilities. Thus, a student who did not have to study much in high school might feel uncertain about his or her choice of major when encountering academic challenges for the first time in a university-level computer science course. Meanwhile a student who learned that success in high school depended on hard work and good study habits would be less likely to have such doubts when faced with a challenging assignment. Similarly, a student with parents in computing professions likely has a greater awareness of computing careers than one with no role models. The nature of this assignment allows the individual student to focus on the factors that may be most relevant to him or her and thus get an appropriate intervention through the assignment. We have not verified systematically how frequently this is what is occurring, but based on the student reactions to the assignment it occurs fairly frequently.

It was quite interesting when reviewing the student papers and surveys that the factors discussed in the literature as being related to persistence accounted for much of what was discussed between students and their matches. This may be considered additional support that indeed these issues are on the minds of first semester students and are likely influencing their next steps.

In summary, we find that this alumni assignment provides the students with an opportunity to network with a role model, broaden their vision of the field of computing and careers in computing, demythify the asocial nature of computing, and learn about the relevance of the field to the real world. The nature of the assignment is such that it could be used in a number of different types of courses taken by first year computing majors. Assuming enrollments in computing programs continue to increase, more departments may find it increasingly challenging to address individual student needs as the students struggle with deciding whether to continue in a computing major. Relying on alumni to provide individual communication through a structured assignment such as this one, may mean that more first year computing students are actually retained in the major and ultimately help meet the demand for computing talent in the workforce.

To conclude, here are some student expressions of the value of the assignment to them.

I plan on staying in contact with him because knowing somebody who has real world experience and is willing to help guide me along could possibly be a life savor [sic] in the future

I may have just got lucky, but I definitely feel like emailing alumni makes your first year a lot better.

This assignment was actually a very neat thing to do, and I wish that more majors would have something like this in place so the majority of students could begin networking their freshman year.

ACKNOWLEDGMENT

I am grateful to the more than one hundred Michigan Tech Department of Computer Science alumni that have participated in this activity for many years and the hundreds of first year students who have made my fall semesters so interesting year after year.

Abstract—Work in Progress: Although there exists a variety of first-year engineering (FYE) course structures and content areas, there is little understanding supported by research of which structures or content may be more or less appropriate for novice engineering students compared to others. This Work in Progress addresses the clear need for comparing different FYE programs through a research study. We begin our comparison through the lens of community of practice because community and identity have been linked to current and important engineering issues such as retention. We employ a semi-longitudinal exploratory mixed methods design to investigate two popular FYE program structures. One of the data collection sites utilizes a common first-year and the other site utilizes discipline specific courses for each of separate engineering disciplines. Our research will result in tools that can be used to gather information about engineering community and identity development in different FYE landscapes. This research is relevant to anyone who works with FYE students and those interested in improving FYE through research.

Keywords—*first-year engineering, introduction to engineering, identity, community*

I. MOTIVATION FOR COMPARING FYE PROGRAMS

Despite numerous and repeated calls for change in engineering education (e.g., [1-3]), new practices have not been widely adopted [4, 5]. One commonly noted exception lies with first-year engineering (FYE) courses. Nationally, nearly three-fifths of engineering programs have established a FYE course [6]. Based on discussions at the First-Year Engineering Education (FYEE) conference, engineering programs without a first-year course are looking to adopt one and other programs may modify existing first-year courses to ensure continual improvement. FYE education, while arguably established, is changing within a field that is also changing. This flux is exciting as there are opportunities for impactful change; however, change as a singularity does not automatically produce positive or desired results.

In her Journal of Engineering Education guest editorial, Watson [7] states the importance of research for changing and improving engineering education commenting that change

must be consciously designed based on what is known from research. While in many cases, the structure and content of FYE education programs is heavily dependent on the history, design, and political structure of the host institution, that fact does not negate the need for using research to inform the creation and alteration of first-year courses for improvement. A common question of many engineering faculty that has not been addressed by engineering education researchers is: Is common-year or discipline specific better in the first-year? While it is likely that the answer is that neither is better or worse, there are differences, and it is important to tease out the differences so faculty and administrators can make informed decisions regarding FYE change and improvement. Equally, these differences may not result in major changes to a first-year program, but instead the awareness of differences in student development may result in different approaches of educating engineers in subsequent years. To contextualize Watson's [7] concerns, changes in first-year programs, uninformed by research, will lead to mistakes, wasted resources, and inadequate foundations for future efforts. It is our goal that changes be rigorously designed and informed by research so that programs have intended and desired positive impacts.

Institutional history, design, and political structure have combined to produce multiple different approaches to the first-year (e.g., discipline specific, common first-year). Recently, research projects have been conducted to better understand the differences between these structures considering admission into major processes [6, 8] and course content [9, 10]. While these research projects provide useful information that help us better understand the FYE landscape, they tell us little about the student experience, which is critical for understanding how students develop within these structures and for making informed changes. Our work-in-progress aims to fill this gap through an exploratory case study of two different FYE structures at two different yet similar institutions. The overarching research question guiding this proposed investigation is:

How do different first-year engineering structures and their corresponding content impact engineering student development?

In this work, examine student experiences through the lens of a community of practice. Specifically, we are interested in understanding the similarities and differences between student experiences in these structures and what effect, if any, they and their content have on engineering community and identity development. We recognize that other structures, programs, and people may affect a student's community and identity (e.g., living learning communities, women and minority in engineering programs, specific courses); however, through our semi-longitudinal exploratory mixed methods research design, we will be able to determine if FYE structure has an impact or if other mechanisms are more impactful. This research study, in conjunction with future research studies addressing our overarching research question, will provide concrete evidence for engineering colleges looking to make FYE change.

II. THEORETICAL FRAMEWORK: COMMUNITY OF PRACTICE

Through our research, we focus on engineering community and identity development. Wenger defines a social theory of learning as including practice, community, meaning, and identity [11]. This theory or approach to understanding learning begins with the concept of a community of practice that includes and affects the elements identified above. Our research uses this perspective as our framework where practice, community, meaning, and identity will be explored in relation to FYE and its effects beyond the first-year. Specifically in a community of practice, legitimate peripheral participants learn new skills and take on responsibilities over time to become central members of their group [11]. For our work, this process includes becoming an engineer and belonging to an engineering community, which could be the field in general or a specific discipline. Other researchers in engineering education have embraced communities of practice as a theoretical lens, but they have not employed it to study FYE (e.g., [12-14]). Our research builds on past community of practice research by applying the framework to FYE and specifically focusing on the impacts regarding identity.

Community and identity are appropriate constructs to investigate since both have been previously tied to recruitment and retention in engineering (e.g., [15-19]), topics which has the potential to have a real impact on engineering. While previous studies provide information related to the identity development of engineering students, they do not consider the impact that different FYE structures or content have on student experiences. Our work adds a direct investigation into the impact FYE structures and content may have on community and identity development.

III. METHODS

Our research design is a case study of two different FYE programs with different structures and content. Our design employs a semi-longitudinal exploratory mixed methods approach to ensure we generate both a depth and breadth of understanding related to student experiences. Our design is consistent with Creswell and Plano Clark's design recommendations [20]. Our study is separated into three phases, each designed to answer one of the following research questions:

- RQ1 How do students experience engineering communities in different FYE structures with varying content areas?*
- RQ2 To what extent do various factors impact students' engineering identity and community?*
- RQ3 Based on the results of Phase 2, how can student accounts of their experiences further our understanding of the quantitative findings?*

A. Research Sites

Our data collection sites include two separate engineering colleges strategically selected for their similarities (i.e., both are large research focused land grant institutions) but different approaches to FYE education. One site has a FYE enrollment of 2300 students and utilizes a common first-year. The second site has a FYE enrollment of 850 students utilizes discipline specific courses for each of its disciplines. According to Chen et al. [6], these two sites represent the most common engineering matriculation taxonomy classifications: pre-major matriculation with a FYE structure (FYE), and direct matriculation with introduction courses required by all majors (DMa). Interestingly, within the overall FYE taxonomy for each data collection site, there exist a variety of courses based on content areas based on Reid et al.'s FYE course classification scheme [9] (e.g., one engineering skill focused, one professional skills focused, etc.), which provides multiple subcases that will be examined in this research. Table 1 outlines the differences and subcases for our two research sites. Reid and his coauthors provide a description of course content for each classification listed in Table 1.

TABLE I. SUMMARY OF RESEARCH SITES AND SUBCASES

Site	Matriculation Taxonomy Classification [6, 8]	Number of FYE Students	Number of Engineering Disciplines	Primary Course Content Classification [9-10]
1	Pre-major with FYE structure (FYE)	2300	14	DESN/ESTT
				ACAD
2	Direct matriculation with departmental introduction courses (DMa)	850	11	DESN/ESTT
				ENPR/ACAD
				ENPR/DESN
				ENPR/ESTT

B. Phase 1 Methods and Analysis

In Phase 1, we will interview both men and women at the sophomore and senior levels at our two research sites to gather semi-longitudinal data to understand community development over time. We plan to conduct at least 28 interviews to cover the various courses at the two institutions. These interviews will be semi-structured in nature where we will have a list of pre-determined questions, but we will follow up on interesting and important portions of each interview as needed. By interviewing sophomore students, we will be able to examine community and identity immediately after the conclusion of

FYE courses. By interviewing senior engineering students, we will be able to examine lasting effects and changes after FYE courses. The questions used in the interviews will be developed based on the theoretical framework and past studies designed to measure similar constructs in FYE.

All of the interviews will be recorded and transcribed verbatim for analysis. Additionally, summaries of the interviews will be provided to participants as a form of member checking to ensure trustworthiness in the findings. Analysis will include open coding, axial coding, and theme generation. The notion of a community of practice will serve as a lens to view the data, but the analysis will not be confined to the framework. Due to the exploratory nature of this project, we want to ensure we allow themes to develop directly from the data. Once the themes have been generated, they will be used to guide the development of a survey based on community in FYE and identity.

TABLE II. SUMMARY OF PHASE 1

<i>RQ1: How do students experience engineering communities in different FYE structures with varying content areas?</i>		
Measurement Tool	Analysis Method	Outcomes
Interviews with sophomores and seniors	Open coding and thematic analysis of interviews	Understanding of the FYE experience and carryover effects
		A set of best practices for establishing community

C. Phase 2 Methods and Analysis

In Phase 2, our effort is focused on using the qualitative findings from the participants in Phase 1 to inform survey instrument design and then test the instrument with a broader population. The Phase 2 survey will measure student perceptions of community and identity with Likert-type scales and will include demographic questions so we can investigate differences between groups (e.g., men and women). We will create contingency tables highlighting the influence of FYE structure and content areas on identity and community. We will also perform Analysis of Variance (ANOVA) tests (or Kruskal-Wallis tests, the non-parametric ANOVA equivalent) to examine differences between the mean (median) for various groups. Phase 2 participants include all undergraduate engineering students at the two research sites (site 1 ~ 3200 students, site 2 ~ 4500 students).

TABLE III. SUMMARY OF PHASE 2

<i>RQ2: To what extent do various factors impact students' engineering identity and community?</i>		
Measurement Tool	Analysis Method	Outcomes
Survey of freshman, sophomores, junior, and seniors	ANOVAs between student groups and between different FYE structures, courses, content areas, majors, gender, etc.	Tool to measure students' engineering identity and community
		A comparison of identity and community between key factors

D. Phase 3 Methods and Analysis

In Phase 3, the mixing phase, we plan to use focus groups to follow-up with student participants from each research site. We will also hold focus groups with TAs and faculty to provide a more complete picture of the FYE courses. Since Phase 3 directly depends on the results of Phase 2, it is difficult to fully define what the focus groups will entail; however, we do have a preliminary idea how these groups will function. For example, if we do find gender differences related to community and identity, we will hold focus groups separated by gender. We will hold at least 2 focus groups for each identified area so we can ensure we are finding trends in our analysis opposed to anecdotes.

As with the interviews in Phase 1, the focus groups will be semi-structured in nature and will be recorded and transcribed verbatim for analysis. The analysis of the focus groups will take an *a priori* approach where the items observed in the survey will serve as the initial coding scheme for the focus groups. After the *a priori* coding, open coding will be conducted to reveal any new findings related the impact of the first-year on community and identity.

TABLE IV. SUMMARY OF PHASE 3

<i>RQ3: Based on the results of Phase 2, how can student accounts of their experiences further our understanding of the quantitative findings?</i>		
Measurement Tool	Analysis Method	Outcomes
Focus groups with students, TAs, and faculty	Targeted <i>a priori</i> analysis to better understand survey results	Further understanding of the FYE experience through triangulated data points

IV. CLOSING

The three phases of this work are each distinct, but they will build a better understanding of the impacts of FYE structure and content through the research study described herein. The three study phases will provide avenues for future investigations into other types of FYE approaches and additional comparisons of FYE approaches using alternate theoretical frameworks and lenses.

This research will produce tools that can be used to gather information about community and identity development in different FYE landscapes. The results from this study and from our future work will allow for informed decision making when creating new or redesigning FYE programs, particularly at large land grant institutions such as the two case study sites. This Work In Progress paper outlines our research study through an overview of our theoretical framework and methods. Results of this research including applications and implementations for practice will be presented in future articles and publications.

This research is relevant to anyone who works with FYE students and those interested in improving FYE through research. These individuals will include faculty assigned to teach FYE courses and administrators that are in charge of determining the structure and content of FYE. Since

differences in student development identified through this investigation will provide explanatory power to other studies, our results will also be relevant to engineering education researchers conducting research in FYE programs. Additionally, our findings, while situated in engineering, will be of interest to other STEM disciplines as there are similarities across the domains. For example, in physics in the United States from 2008 to 2010 females accounted for 21% of bachelor degrees awarded [21]. Similarly in engineering, females accounted for 18.9% of bachelor degrees awarded in 2012 [22]. These similarities in retention and diversity make transferability possible.

An “Objects First, Tests Second” Approach for Software Engineering Education

Veronika Thurner, Axel Böttcher

Munich University of Applied Sciences

Faculty of Computer Science and Mathematics, Lothstr. 64, D-80335 München

E-Mail: veronika.thurner@hm.edu, axel.boettcher@hm.edu

Abstract—Since unit testing is a skill required of professional software developers, lecturers have to develop this skill in their software engineering students. Therefore, we introduce the approach of “objects first, tests second”, which incorporates unit testing into introductory programming classes. We discuss requirements that teaching materials must meet to effectively support this approach, and present a concept for assessing the quality of student written tests. An analysis of students’ results illustrates the effectiveness of this teaching approach.

Keywords — *Computer science education; Software engineering; Design for testability*

I. BACKGROUND AND MOTIVATION

Introducing objects early on in courses on object-oriented software development is a widely used and well accepted teaching approach, known as “objects first” [4], [12]. It ensures that objects and classes are established in the students’ minds as the crucial concepts, on which object-oriented software systems are based nowadays.

Another indispensable technique in modern professional software development is unit testing [14]. As a consequence, students holding a degree in software related study programs ought to be well educated in this area. However, a detailed analysis of both textbooks on software development and current curricula has shown that unit testing often is addressed only in later stages of the education process, if at all.

In this paper, we investigate into how unit testing can be taught effectively right from the beginning of first term programming classes, in order to equip students with an amount of expertise and experience that meets the requirements of their later jobs in this area. As well, we analyse how the success of this teaching approach can be measured, by assessing the testing skills that students acquired. We call our approach “*objects firsts, tests second*”, reflecting the fact that we introduce unit testing right after the concept of objects in our two-term course on software development in Java [2].

II. GOALS

To appropriately prepare our students for their later professional lives, we attempt to equip them with at least solid foundations in relevant software engineering practices and techniques at an early stage of their studies. Among others, this includes proper unit testing.

In this work, we tackle the question of how to effectively teach unit testing to students. More precisely, our teaching goals are that, firstly, students write unit tests as a matter of

course in any given programming task. Secondly, these unit tests should reach a high code coverage. Thirdly, students’ unit tests are required to be of high quality, i.e. they should be likely to detect defects within the program’s logic.

As our goal is to teach these issues *effectively*, we need to define criteria which measure to what extent we achieved these goals. Our first issue of students writing unit tests as a matter of course can be measured by simple observation – either they do or they don’t. To assess our second issue of test coverage, we employ the tool emma [5] to formally measure code coverage. Finally, to evaluate whether our students write high quality tests, we develop a tool that measures the quality of our students’ tests by running them iteratively against our sample solution, into which specific errors were patched in each iteration. Thus, we can formally assess to which extent students’ tests detect defects within the programming logic.

III. RELATED WORK

To investigate the state of the art of teaching unit testing to students, we analysed curricula of several software engineering courses (e.g. from within Germany, UK and USA) as well as existing literature. Although nowadays, unit testing is considered to be a fundamental, essential skill for any developer in the software work force, most of the analysed curricula cover it explicitly only at a rather late stage, if at all. Nonetheless, literature provides several proposals for approaches to adopt testing early in fundamental programming courses, e.g. [4], [6], [7], [10], [15], [16].

Very fundamental and useful work has been performed by Edwards [3], [4]. He reflects on the concept of objects-first, and states that students must provide test cases to demonstrate the correctness of their own code right from the beginning. In addition, he offers advice on how to implement this concept.

Patterson et al. [16] describe how JUnit can be integrated into BlueJ [12], a Java development environment especially designed for programming novices. Janzen and Saiedian [10] report positive effects early testing has on the students’ performance, but mention also that students are reluctant to adopt a test-first approach. Furthermore, they describe tools that were developed in order to support beginners in their writing of tests, as well as tools that facilitate automated grading.

Also, several approaches have been undertaken to evaluate the quality of students’ tests. An overview of work in this area was recently provided by Edwards [5]. Despite all these efforts, introductory textbooks that focus testing right from the

beginning are thin on the ground. Of the 40 English and 20 German text books we consulted, only two (see [8] and [13]) introduced testing at an early stage.

IV. OVERALL COURSE DESIGN

Note that as our class addresses freshmen students, there are no pre-requisites regarding computer science knowledge.

Our approach of teaching unit testing to freshmen students requires some changes to the traditional teaching of object-oriented programming. One major difference concerns the order in which the different topics are introduced. We start out with object-orientation. As soon as students have this down their belt, we follow up with unit testing. Thus, we call our approach “objects first, tests second”. As a consequence, students learn about unit testing almost immediately at the beginning of their first term of studying computer science.

In fact, students have their very first contact with unit testing even before we officially introduce them in class as a technical concept, as they have to implement their very first assignment on object-orientation against some unit tests that we lecturers provide via the automatic grading system that we employ.

As a next step, we present some theoretical background information on unit testing in our lecture, rounded off with introductory sample code. Based on that, students work on a lab session assignment focussing unit testing. Here, they actively implement their first unit tests, which have to be handed in to be graded.

From then on, all assignments comprise both productive code and the corresponding unit tests. More precisely, we establish the general rule that every assignment automatically includes the development of appropriate tests, even if tests are not explicitly mentioned. Thus students have to actively implement tests right from the beginning of the course.

In addition, for each assignment we provide tests in our automatic grading system, to evaluate the students’ productive code. However, these tests usually are not visible to the students before they hand in their assignments.

V. REQUIREMENTS ON TEACHING MATERIALS

To effectively incorporate testing right from the start, teaching materials must meet certain requirements, which in our case required some major adjustments of existing material.

A. Samples and sample code must be testable

First of all and quite obviously, to set an appropriate example all our sample code must be testable. This implies two major consequences: For one thing, we must refrain from writing code into the `main()`-method. For another thing, all methods must return a proper result value, rather than writing information to the console via `System.out.println()` (as is frequently done in many textbooks, to visualize changes in the program’s state).

1) *The trouble with `main()`*: Execution of any code must have an entry point. Using public static void `main(String... args)` introduces a lot of voodoo and – even worse – is not an object-oriented concept. Furthermore, entry points seen by programmers in today’s software projects are tests or callback methods in component-based or in web frameworks (“Don’t call us – we call you”) – and not a `main()`-method. Thus, entering crucial parts of the productive code into the `main()`-method opposes best practices of modern software development. So obviously, we should not teach this to our students.

2) *The trouble with `System.out.println()`*: To make students aware of what they have really implemented, it is important to visualise the effects of their running software. The traditional way to give insight into the state of objects is the creation of some output on the console, using `System.out.println()`. “Hello World” is probably the most commonly used introductory example for programming.

However, there are some drawbacks to this approach. *Hello World* is normally not presented in an object-oriented way – and if so, it can become quite complicated and thus is not suitable for beginners, as carried to its extreme by Kerievsky [11].

Furthermore, output to the console is hard to test: replacing the JVM’s standard output stream with a `PrintStream` printing to a `ByteArrayOutputStream` whose bytes can then be compared to the expected output, is definitely a concept that is far too abstract to be suitable for beginners. Finally, printing to the console is not useful for the majority of today’s software. For the creation of output, logging is introduced into today’s software projects [17]. Here again, logging is not a concept that is suitable for beginners.

Note that avoiding `System.out.println()` in our examples implies that we cannot rely on console output to inspect the program state. Therefore, an alternative way to visualize the program state is needed, which helps students to haptically explore their software, in addition to running tests.

B. Provide GUIs to allow inspection of program state

As unit tests are a quite abstract means to get feedback on their code, our students requested a more tangible way to follow the change of their programs’ state. Since we banned printing to the console, we decided to use graphical user interfaces (GUIs) instead. Thus, as a second major amendment to our teaching materials, we develop GUIs for the examples we use, which we provide with our assignments. These GUIs use the classes implemented by our students, and give visual feedback on the program state.

As an example, consider an exercise to implement classes representing points and rectangles in the plane. The class `Rectangle` is required to provide a method that returns `true` if and only if a rectangle intersects another one, which is passed as parameter. The GUI allows dragging rectangles around and color codes them, depending on whether that method returns `true` or `false` (see Fig. 1).

This GUI provides a very immediate, easy to understand feedback to the students. Therefore, it can be used right from

Fig. 1. Simple GUI that lets students drag and drop rectangles. Colors are changed when the student-written `intersects()`-method returns `false` or `true`, respectively (cases a) and b)). In case c), we observe a bug in the student's implementation: as they visually intersect, rectangles should be depicted in the same colour. However, the student's implementation of `intersects()` returns `false`.

the beginning of the course.

Overall, our approach is based on similar pedagogical ideas as presented by Kölling et al. for their BlueJ approach [12].

VI. PROVIDING FEEDBACK TO STUDENTS

For keeping students' motivation up throughout the whole semester, it is helpful to provide them with feedback on their learning achievements on a regular basis. As well, we as lecturers need information on our students' learning progress, to get a notion of whether our teaching reaches our students successfully or not. Therefore, to support our goal of teaching unit testing, we need an effective means for assessing the testing skills of our students.

There are several strategies for giving feedback to the students based on their code. An overview is given by [5]. Among others, for our own approach we were inspired by the idea of *mutation analysis* [1], but adapted the concept of mutations to meet our specific needs for assessing test quality.

To equip our students with a high level of practical expertise in the area of software development and unit testing, classes are backed up with lab sessions, during which students actively apply the newly acquired knowledge. In addition to individual feedback provided by the lecturer during lab sessions, we employ three tool based approaches for offering feedback to our students.

1) *Run tests against students' code*: Students hand in the results of their lab session assignments via an automated grading platform. For each assignment, this is backed up with a set of given test classes provided by the lecturer, which are run against the students' solutions. Thus, we generate feedback on the quality of the students' *productive* code.

2) *Measure the achieved code coverage*: A rather straight forward quality criterion for unit tests is the achieved code coverage. To measure this, we employ the tool *emma* [5], integrated into our automatic coding platform.

3) *Test the students' test quality*: Last but not least, we attempt to provide feedback on the *quality* of the tests our students write. To assess this automatically, we designed and developed a new infrastructure. This not only enables us to run the students' productive code against the tests provided by the lecturer. Rather, it allows us to apply individual sets of "patches" (which introduce selected sets of errors on purpose) into a reference sample solution. Then, it automatically checks whether the students' tests detect these errors, thus measuring the quality of the tests that our students developed. On this

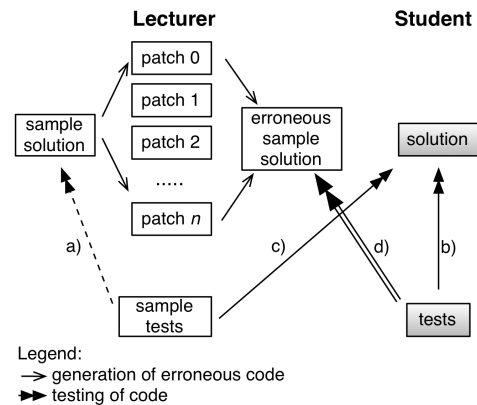

Fig. 2. Evaluation of productive code and corresponding tests: a) Lecturer's sample tests against sample solution. b) Student's tests against their own solution. c) Lecturer's tests against students' solution. d) Student's tests against intentionally buggy sample solutions.

basis, we are able to provide detailed feedback on the quality both of the students' tests and of their productive code.

Fig. 2 visualizes all four combinations of code and tests that can be considered in this tool setting:

- The lecturer provides both a sample solution and a comprehensive set of sample tests. Run against this sample solution, all tests are required to pass.
- Students hand in the productive code of their own solution, accompanied by corresponding self-written tests. When run against their own solution, the student's tests are required to pass, indicating consistency of the implemented logic and the requirements documented as test cases.
- Running the lecturer's sample tests against the productive code of the students' solution is part of many automatic assessment systems [9]. In this case, passing tests indicate the quality of the students' productive code.
- Finally, as an innovative feature in our solution, we run the students' test cases successively against a set of modified erroneous sample solutions. Here, tests are supposed to fail in every iteration, indicating that students identified and implemented sufficient and well chosen test cases, so that they reliably detect errors in the productive code.

VII. RESULTS AND FINDINGS

We applied our approach to bachelor students of computer science related study programs of the Faculty of Computer Science and Mathematics, Munich University of Applied

Fig. 3. Measured code coverage using emma [5] for 45 students' solutions (teams of max. 2) before concept of code coverage was introduced in class.

Sciences. The following data reflects the experience gathered with freshmen students from Scientific Computing and from Geotelematics. Both include a compulsory software engineering learning path, starting with software development in Java.

In our approach, from an early point of the class, students had to write unit tests on their own to ensure the quality of their productive code. After introducing the theoretical background on unit testing in a lecture, the corresponding assignment that explicitly focused on unit testing provided a rather detailed description of what to test. After that, we established the general rule that appropriate unit tests must be turned in as part of every assignment, even if they are not requested explicitly. *All* of our students adhered to this rule and provided unit tests. Thus, we achieved that students internalized *always* to implement test classes along with their productive code.

In the second semester (and thus rather late), we explicitly required our students to use the tool emma [5] to evaluate their code coverage themselves. Even before that, and right from the start of first term, we lecturers employed emma to assess the students' code coverage, as one quality indicator we used in the grading process.

Fig. 3 shows the coverage measured for the turned-in solutions of an exercise, just before code coverage was introduced explicitly in class. It indicates that students reached a good coverage even without having heard about this concept before. This supports our observation that students accepted the habit of thorough unit testing as a matter of course.

Finally, we evaluated the students' test quality, using our patch-and-test tool to introduce selected errors on purpose into the sample solution, and then running the students' tests against this erroneous solution. Fig. 4 visualizes the quality of the unit tests written by 64 students, against a total of eight errors that were introduced into the sample solution on purpose. The corresponding assignment was set in the middle of the first semester, where students only had very limited experience in unit testing yet.

Of these 64 student written tests, 9 indicated errors when run against the *correct* sample solution. Nevertheless, 35 students (more than 50%) detected *all* the errors that were patched into the solution. Another 16 students (25%) detected 7 errors out

Fig. 4. Quality of students' unit tests (from 64 students), trying to detect a total of eight errors introduced on purpose.

of 8, and 9 students (14%) still detected 6 errors out of 8. None of the students detected only 3 or less errors.

This confirms that our teaching approach helped students to learn writing high quality unit tests as a matter of course.

VIII. CONCLUSIONS AND FUTURE WORK

Nowadays, appropriate unit testing is a skill that is required from any professional software developer. Therefore, we as lecturers need to foster this skill in our students as software-developers-to-be.

To achieve this, we introduced our approach of "objects first, tests second" and described our overall course design. Then, we discussed the specific requirements that the teaching materials must meet to effectively support our approach. Based on this, we presented our concept for assessing the quality of student written tests, which directly reflects on the success of our teaching.

In our teaching experience, this approach has proven to be successful. Students internalized the development of tests along with their productive code and achieved high test coverage. In addition, the vast majority of students learned to write meaningful tests that help detect critical errors within the program's logic.

However, introducing testing in the first semester rises some fundamental questions, some of which still remain to be clarified.

The first set of questions addresses didactic aspects. Generally, as time is limited, there is only a certain amount of knowledge and skill that can be developed during a single term. As a consequence, when introducing testing as an additional topic in a beginners' course on software development, previous content necessarily will be curtailed to a certain extent. This leads to two related questions, namely: Where do we cut previous content?, and: When, and to what extent, do we cover the theory of software testing in our teaching?

Another, more content related question is: How do I know that I've written the right tests, and enough of them? Answering this question appropriately involves both a significant amount of test theory and practical experience. How this can be taught effectively is subject of further research.

Abstract— Based upon a successful implementation of an upper-division project based learning (PBL) curriculum, an integrated first/second year PBL experience was designed and implemented. The integrated courses were physics 1, statics, design, and professionalism. The curriculum has been delivered from 2012 to 2015. This work in progress paper describes the design process, the trajectory of the program as it continuously improved, data collection methods, and initial results. Two of the members of this research team were members of the team that adapted the Aalborg (Denmark) model of PBL to an upper division 100% PBL curriculum. The model evolved into an ABET accredited program that is based on the solution of complex industry problems for the last four semesters of a bachelors degree. The results were used as the basis for the design of this lower division PBL program. The lower division program evolved from 2012 to 2015. Upon conclusion of the lower division experience, survey instruments were administered to students. Tools specific to self-directed learning and professional development were employed. The instruments are the Motivated Strategies for Learning Questionnaire (MSLQ) and professional development and professional expectations instruments designed by the authors of this paper.

Keywords— *Self-Directed Learning, Evaluation, Project Based Learning, Professional Skills and Abilities*

I. INTRODUCTION

In recent years Project Based Learning (PBL) has continued to emerge as a pedagogical model in engineering education [1]. PBL implementations exist on a continuum from one course in a traditional engineering program to fully integrated PBL curricula [2]. One of the motivations to implement PBL is an increased development of professional outcomes by student participants [3].

For over a decade, there have been numerous calls for a transformation in engineering education [4,5,6,7,8]. In response to these calls, a Midwestern community college and a Midwestern university collaborated to develop a two-year, upper-division, completely integrated PBL model of engineering education [9]. The program has 75 graduates to date and has earned ABET-EAC accreditation. The

community college developers of this upper-division program adapted the curricular model used in the 3rd/4th year PBL curriculum into a portion of the 1st/2nd year engineering education at the community college. This paper analyzes the adaptation/implementation and provides initial results of the impact this PBL engineering program has had on the student attainment of professional outcomes in comparison to students in traditional engineering programs.

II. BACKGROUND

In 2009, a new upper-division only undergraduate project based learning (PBL) engineering program was developed and implemented as an adaptation of the Aalborg model [10]. The developers of this PBL model sought to address the alignment gap between the outcomes desired for engineering graduates and those attained by graduates of traditional engineering programs [9]. It was designed to address the three interrelated domains of professional, technical, and design competence [11]. Design projects became the central theme upon which design learning, technical learning, and professional learning took place [12].

Each semester, these upper-division students select engineering projects from industry clients. Working on teams, with a faculty mentor as a guide, students complete the design process from an initial scoping to final deliverable. They acquire skills in engineering design, practice ideation, manage resources, and produce products. Integral to the design is the acquisition of technical knowledge required to complete the design. Faculty members scaffold the self-directed learning skills students will need upon graduation to independently acquire the technical competence they will need as practicing engineers [11]. The third domain of professionalism is highly integrated into the design work. Specifically targeted are written communication, verbal communication, project management, entrepreneurialism, lifelong learning, professional responsibility, personal marketing, and inclusivity [12]. Students, working with faculty, characterize

their initial competence level in each area on a scale from deficient to exemplary [12].

In 1967, Carl Rogers, a highly regarded psychologist, wrote “The only man who is educated is the man who has learned how to learn” [13]. Acquiring this skill is an outcome of an engineering education, arguably one of the most important. The recruiter for the PBL bachelors program previously described often engages potential students with this commentary:

“I’d like you to visualize your first day of work after graduation. Let me tell you two things that are not going to happen on that day... two things your new boss isn’t going to say. First, he won’t say *“Greetings John, welcome to ABC Engineering, we are glad you are here. I would like to introduce you to Dr. Jill, we have hired her to be your professor. When you need to learn something new, Dr. Jill will be here to teach it to you.”* The second thing he is not going to say is *“Here are some text books. Each week, your job is to do the problems at the end of each chapter. If you get them correct, we will issue you a paycheck. At the end of each month we will give you some written exams. Your performance on the written exams will determine the amount of your bonus.”*”

This story resonates with the students. To this point in their engineering education, nearly all of their learning has been one-directional from an instructor and nearly all of their performance has been through the completion of closed-ended chapter problems and written exams. They know this is what they neither expect nor want as the duties in their profession and they struggle with this misalignment of activities during college with expectations after college.

Lifelong learning, self-directed learning, continuous professional learning, self-regulated learning, and being metacognitive are all terms used, often interchangeably, to address the outcome expected of new graduates. A summary is that new engineering graduates are expected to be able to acquire new knowledge efficiently and effectively and be able to use it to solve complex, ill-defined, problems quite different than those at the end of a chapter in a textbook.

Originally developed in the 1990’s by a team led by Pintrich [14] the Motivated Strategies for Learning Questionnaire (MSLQ) is an 81 item survey that addresses both motivation (intrinsic & extrinsic goal orientation, task value, control of learning beliefs, self-efficacy for learning & performance, and test anxiety) and learning strategies (rehearsal, elaboration, organization, critical thinking, metacognitive self-regulation, time/study environmental management, effort regulation, peer learning, and help seeking). Pintrich’s group completed reliability and validation testing at the time of the MSLQ’s development. The MSLQ was originally developed for addressing course specific motivations and learning strategies [14]. It was modified by removing course specific questions and reducing it down to 44 questions. Rotgans and Schmidt showed the modified MSLQ to be reliable and validated for general curricular use [15]. The MSLQ has four relevant subscales. They are self-efficacy, intrinsic motivation, cognitive strategy use, and self-regulation.

A pair of 2005 studies by Shuman [16] and Loui [17] focused on the ineffectiveness of the traditional lecture format for teaching the ABET professional skills and argued that a modern engineering education should focus on active and cooperative learning approaches. The Loui study identified that students primarily learn about professionalism from relatives and co-workers who are engineers and rarely from their technical courses and proposed that engineering education should have a focus of “socializing students to become professional engineers”.

A promising approach for developing the professional competencies is a curricular focus on professional identity formation. Ibarra and Barbulescu [18] identified professional identity as an important factor in the student adaption to the workplace. Sheppard, et. al. [5] describes professional identity in terms of standards of the professional community, “to serve the public with specialized knowledge and skills through commitment to the field’s public purposes and ethical standards”. Eliot and Turns [19] define it as the “personal identification with the duties, responsibilities, and knowledge associated with a professional role”; developed through a social process where students are connecting expectations with their own needs, wants, and attitude.

Thorton and Nardi [20] proposed that professional role identification is a four-stage developmental process where individuals go from having idealized perceptions of the professional role to a more personalized role aligned with their own values and goals: 1) Anticipatory Stage: Individuals start with a highly idealized understanding of the role of the professional, which is often incomplete; 2) Formal Stage: Individuals undergo a formal learning experience with the purpose of learning the duties, responsibilities, and knowledge for a professional role; 3) Informal Stage: Individual encounters the unofficial or informal expectations associated with the professional role which that may align or contradict the formal expectations; and 4) Personal Stage: Individual begins internalizing the professional role expectation and attempts to align or adapt it with their values and goals.

The development of the PBL model in this study focused on creating for students their professional identify as engineers with the purpose for their acquiring professional competencies. In the development process, three core curricular foci emerged: 1) the recognition of the social nature of engineering education and the importance of students developing their professional identity as an engineer; 2) the importance for the learning to be embedded in professional practice [21]; 3) the potential a PBL curriculum has to support the first two foci [1]. This model is reflected in Figure 1.

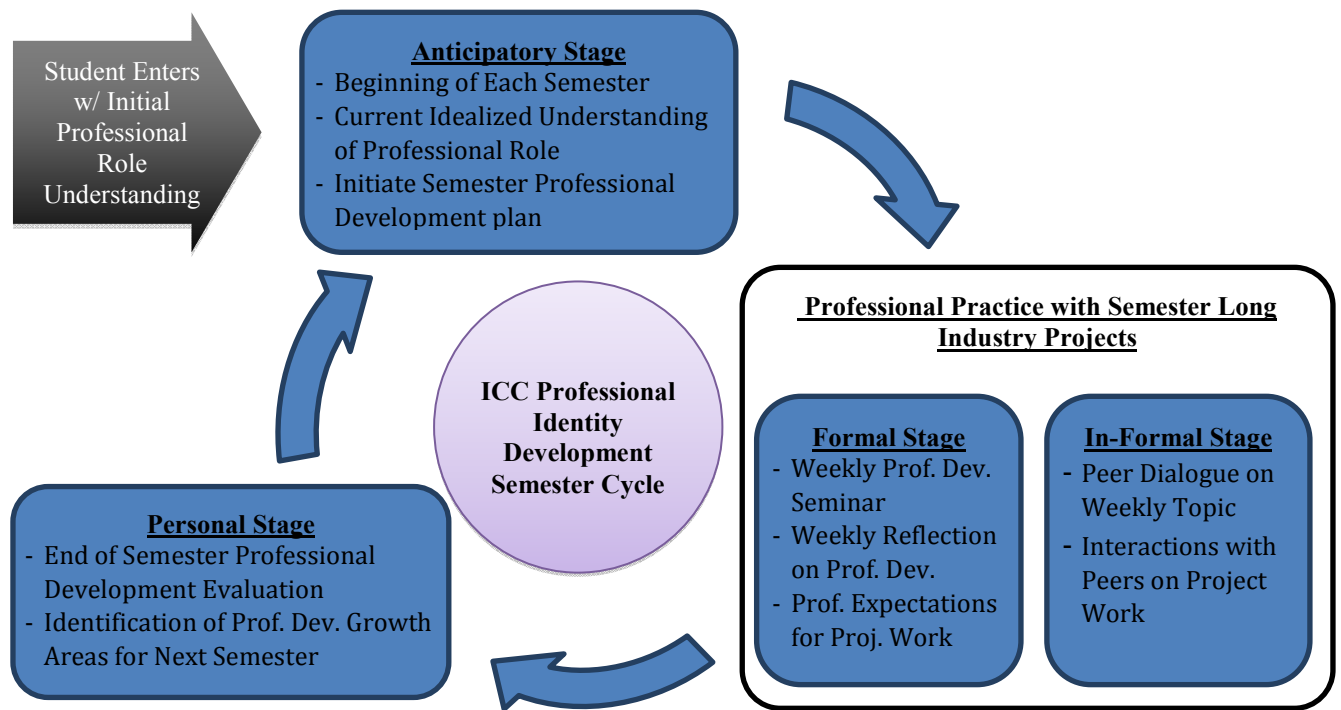

Figure 1. PBL Professional Identity Development Semester Cycle

Currently there are limited well-established resources for assessing student attainment of professional skills [16]. As part of the quantitative study, two instruments were developed to evaluate the professional growth of students in the PBL model as compared to students studying in a more traditional model.

The first, **Individual Professional Development Instrument**, focuses on the professional abilities of the individual. It is 1-5 Likert-scale survey tool, based on the ABET student outcomes [22], that evaluates a set of 19 professional expectations. Students self-identify the importance they place on a professional development topic and their current level of performance.

The second, **Team Professional Development Instrument**, identifies students' beliefs on the importance of professional development and their current performance level within the context of functioning as a member of a team. It is a 1-5 Likert-scale survey tool based upon the TIDEE professional development work of Denny Davis and Steve Beyerlien [23]. Results for both instruments are discussed in section V.

III. DEVELOPMENT OF THE PROJECT BASED LEARNING (PBL) ENGINEERING EDUCATION MODEL

As the successes of the upper division PBL program began to emerge, so did the belief that many of the successes could also be achieved in lower division. The first adaptation came from the perspective that engineering education flows through the integration of the three domains of design learning, technical learning, and professional learning. For nearly ten years, the community college program had focused on these three domains. It was done through the separate instruction of

technical knowledge in traditional courses and in a combined engineering professionalism and design course for each of the 4 semesters of lower division. This separation however, did not promote the use of technical knowledge in design, nor the integration of all three as being the *act of engineering*. Further, there was a sense across all instructors that students lacked the ability to transfer technical knowledge from any one learning experience into another.

PBL as a pedagogy provided the opportunity to gain this integration and transfer, while the successes in the upper-division program were indicating these outcomes were possible.

The model implementation built off of the existing 4-semester design sequence [21]. Students start the fall in a cohort with a six-credit design focused introduction to engineering and engineering graphics course pairing. In the first year of implementation, spring 2012, a group of ~30 students selected in the spring of their freshman year to participate in a nine-credit PBL pairing of engineering physics 1, static mechanics, and a second engineering and professional development course. This "PBL Cohort" met daily to develop the course outcomes for students in engineering physics 1 and static mechanics. This learning took place in the context of students developing these outcomes to support their projects. Professional development was an integral component of the experience. Each week a professional development topic was introduced with the expectation for students to reflect and internalize the skill associated with the topic. The experience followed the model displayed in figure 1. At the core of this experience was the creation of the professional identity of each student. These students moved on in their sophomore year to have an engineering and professional development

course each semester. The difference being that students took engineering courses related to their intended engineering discipline and there was not the intentional integrating of the student technical learning with their design and professional learning.

In the second year of development, the spring sophomore semester PBL model was expanded to include all students who met the math prerequisites to be in engineering physics 1. In the second year, there was an increased emphasis of the weekly cycle of professional development dialogue described in figure 1. Since then, the program has adopted this model for all students in the spring of their sophomore year and continues to further develop each semester.

IV. METHODS

This in-progress study looks specifically at how students in the lower division project based learning environment develop compared to students in a more traditional program. There are two student groups in this comparative study:

1. **PBL Completers:** Community college students just having completed their second year of engineering including one semester of the PBL program described in this paper as part of the four-semester course sequence. All students who completed the PBL program were asked to complete the instruments. There are three subgroups in the PBL completers, those who participated in the semester PBL program in the springs of 2012, 2013, and 2014. The 2015 group will be evaluated at the end of their sophomore year in the spring of 2016.
2. **Traditional University Student:** University students just having completed their second year of engineering without any PBL experience. A group of students at a Midwestern university were contacted through their professors and asked to complete the instruments.

MSLQ data and the professional development instruments results were analyzed using a two-tailed t-test with $p < 0.05$.

V. RESULTS

The greater research question for the implementation of this PBL curriculum is "How do PBL students experience the development of these professional and learning skills?" By comparing PBL students to traditional students, the differences of the experiences can be highlighted. Further qualitative studies can then be designed and implemented to characterize the PBL development experience.

The MSLQ areas studied in this research are self-efficacy, intrinsic value, cognitive strategies, and self-regulation. Students answer on Likert 7-point scale from 1-not at all true of me to 7-very true of me. Table 1 details the results of this comparison study.

TABLE I. MSLQ RESULTS

	PBL (n=73)	Comparison (n=80)	t-test ($p < 0.05$)
Self-Efficacy	5.63	4.93	4.53
Intrinsic Value	6.05	5.75	2.34
Cognitive Strategy Use	4.97	4.81	1.26
Self-Regulation	4.79	4.69	0.84

The self-efficacy score relates to both the students' perceptions that they can master a task and their confidence in doing so [14]. The higher the score, the higher the self-efficacy. Intrinsic value relates to the level to which the student is participating in the learning for personal mastery, challenge, and curiosity. Cognitive strategy use scores the levels students use rehearsal, elaboration, and organization. Self-regulation refers to the levels to which students continually monitor and refine their learning strategies [14].

The results would indicate that the PBL experience significantly increases the self-efficacy of engineering students, as well as the intrinsic goal orientation of their learning. While cognitive strategy use and self-regulation are less impacted. Further qualitative study will be designed to determine which aspects of the student experiences led to the marked differences in self-efficacy and intrinsic value and to further investigate impacts on cognitive strategy and self-regulation.

Given these results, it would be expected to see a higher reported professional importance and performance of professional skills for the students who experienced the PBL experience versus the control group. However, there are no areas in the 31 items of the two instruments where the PBL students combined from all subgroups self-reported higher than the control group. An evaluation of each sub group itself compared to the control group shows similar results with no items of higher reporting for the 2012 and 2014 groups.

An evaluation of the 2013 subgroup shows six items of higher self-reporting than the control group. Five items of higher importance for the individual professional development are:

1. Speak professionally, free of vulgarities and with appropriate grammar
2. Meet the needs of your team by completing work on time and of high-quality
3. Give proactive feedback to others
4. Continually seek to improve yourself
5. Act safely while completing all tasks

One item of higher performance for the team professional development:

Developing shared vision & plans; empowering to achieve individual & mutual goals

Further qualitative study will be designed to determine why the 2013 group only has the items of higher self-reported results.

Abstract—Our university, as with many others throughout the world, has a relatively low pass rate in the introductory computer science courses. Over the course of more than fifteen years, various changes have been made to the introductory course sequence with the hope of improving student success. We describe these changes and perform an initial analysis of student course performance that finds little change in pass rates. We propose new changes to the course sequence and to individual courses within this sequence. These new changes are focused on increasing student engagement and developing the problem solving skills that are necessary for being a successful computer science major. We propose pilot projects that implement these changes and outline evaluation strategies for these pilot projects.

I. INTRODUCTION

Over the span of more than fifteen years, our Computer Science department has made a number of changes to the sequence and content of the introductory courses. Many of these changes have been motivated by the faculty's desire to improve student success and learning outcomes, while other changes have been motivated by institutional factors. Our department is fairly typical in the fact that our courses change over time and with the motivating factors for these changes [1]–[5]. Various studies have found that computer science faculty tend to use intuition and anecdotal evidence as the motivation for their course changes. We acknowledge that many of our changes have been based on these non-scientific motivations, but now aim to evaluate the changes that have been made and to use research to drive future changes.

We begin this paper by describing the evolution of the introductory course sequence in our department over the past fifteen years. Next, we evaluate the effects of these changes on student success. We then discuss how other factors may impact the success of our students. Finally, we present changes that are in progress and outline our plans for evaluating the effects of these changes.

II. OVERVIEW OF OUR COMPUTING PROGRAMS

Our university is a primarily undergraduate, state-supported institution with an enrollment of more than 20,000 students. We are a Hispanic Serving Institution with over 90% of these students being Hispanic. The majority of our students are first generation college students. The university primarily

serves the local region, and the demographics of the university are similar to those of the region.

The Computer Science Department at our university offers an ABET accredited bachelor's degree in Computer Science, and master's degrees in Computer Science and Information Technology. The department also offers an ABET accredited bachelor's degree in Computer Engineering, in cooperation with the Electrical Engineering Department. In Fall 2014, we had 343 undergraduate Computer Science majors, 282 Computer Engineering majors, and 124 master's students.

As is typical at many universities throughout the world [6], our sequence of introductory computer science courses have a high fail rate. Over a four and a half year period, we found that on average both our CS1 and CS2 courses had a 60% pass rate [7]. The instructors who teach these courses are frequently examining methods for improving the pass rates. In addition to making changes to the individual courses, we also consider these courses as a sequence. In this paper, we focus on the pipeline of introductory computer science courses as a sequence and examine how changes in this sequence impacts student performance. We begin this discussion with a presentation of the recent history of our introductory computer science course sequence.

A. History of Computer Science Introductory Courses

When the department was formed in the mid-1990's we initially offered a three-hour CS1 course that focused on introducing programming concepts and a three-hour CS2 course that provided an introduction to data structures. The core objectives of our CS1 and CS2 course remain largely the same today as they were almost 20 years ago. One change is that now CS1 is a four credit-hour course (three hours of lecture, and one credit-hour for a 3 hour seat time lab). The major changes during the past 20 years have been to the course sequence, as described in detail below. These changes included the introduction of a course in-between CS1 and CS2, then the removal of this course along with the introduction of a CS0 course.

In 1998, a three-hour course called "Foundations of Computer Science" (course number CSCI 1381 at our university) was introduced and was placed in between CS1 and CS2 in

the course sequence. One of the goals of this course was to include the breadth of computer science early in the sequence of courses for Computer Science majors, while another goal was to help students better transition to the level of abstraction required for CS2. The impacts of CSCI 1381 on student learning outcomes and success in CS2 were analyzed after CSCI 1381 had been offered for three years. It was found that students reported that they achieved the learning outcomes, but there was not a clear improvement in performance in CS2 [8]. Some of the lack of improvement in CS2 performance was attributed to students not taking the courses in the proper sequence. Additionally, the impacts of CSCI 1381 likely changed over time because the number of programming assignments in CSCI 1381 were increased following the first few semesters that the course was offered.

In the late 2000's, the Computer Engineering program began offering a Bachelor's degree in Computer Engineering. This program is jointly administered by the Computer Science and Electrical Engineering departments. Most of the Computer Engineering courses are cross-listed with either Computer Science or Electrical Engineering courses. The Computer Engineering majors take the same CS1 and CS2 courses as Computer Science majors. However, CSCI 1381 was not included in the Computer Engineering degree program. Therefore, upon reaching CS2, the Computer Science and Computer Engineering majors had different levels of programming experience.

In Spring 2011, a one-hour "Introduction to Computer Engineering" (course number CMPE 1101) was introduced as a requirement for the Computer Engineering major and was set as a pre-requisite for CS1. The goals and content of CMPE 1101 are discussed below. One of the reasons for introducing CMPE 1101 was to more closely align the Computer Engineering major to the other engineering majors within our college that already had a one-hour introductory course.

The final change to the introductory course sequence came in Fall 2011 when CSCI 1381 was phased out and a one-hour "Introduction to Computer Science" (course number CSCI 1101) was introduced. This change was made to more closely align the beginning of the Computer Science major courses with the Computer Engineering major courses.

We also note that some of our Computer Science and Computer Engineering students have transferred into our university from the local community college. The community college offers a three-hour version of CS1 and continues to offer an equivalent course to CSCI 1381. However, the community college does not offer a course that is equivalent to CSCI 1101 or CMPE 1101. For this study, we focus on the students who began the introductory computer science course sequence at our university, but we acknowledge that some of the students in our CS2 course took CS1 and CSCI 1381 at the local community college.

B. Description of Our CS0 Courses

Currently, the first class in the sequence of introductory computer science courses for students who major in Computer Science is "Introduction to Computer Science" (CSCI 1101). The first class in the sequence of introductory computer science courses for students who major in Computer Engineering is

TABLE I. TOPICS COVERED IN CSCI AND CMPE 1101

Number representation
<ul style="list-style-type: none"> • Unsigned binary numbers • Hexadecimal representation • Signed binary numbers • Binary floating point representation

<ul style="list-style-type: none"> • Operating systems • The Internet and the World Wide Web

"Introduction to Computer Engineering" (CMPE 1101). CMPE 1101 was first offered in Spring 2011, and CSCI 1101 was first offered in Fall 2011. Initially, the courses were very similar and they remain mostly similar to this day.

The prerequisite for CS1 is either CSCI 1101 or CMPE 1101, along with a co-requisite of college algebra. Both CSCI 1101 and CMPE 1101 are one credit-hour laboratory courses that have two and one half hours of seat time per week. They are typically offered on a two-day per week schedule for one hour and fifteen minutes per day.

CSCI 1101 and CMPE 1101 were started following a similar pilot course [9]. Much of the computer science breadth material from CSCI 1381 was carried over to CSCI 1101 and CMPE 1101. These courses also include programming assignments using the LEGO Mindstorms robots. The LEGO Mindstorms programming environment has an intuitive drag and drop block programming interface. This environment allows students to gain experience with basic programming concepts and control structures without the frustration of syntax errors. The goal of the programming component of CSCI 1101 and CMPE 1101 is to provide an introduction to programming concepts so that students already have some familiarity with these concepts when they reach CS1.

Table I shows an outline of the topics that are covered in both CSCI 1101 and CMPE 1101. The Computer Science course tends to spend a bit more time on algorithms and programming, while the Computer Engineering course tends to spend a bit more time on number representation.

The class time for both CSCI 1101 and CMPE 1101 is approximately evenly split between traditional lecture and time that students spend working on the lab assignments. Because these are scheduled as laboratory classes, the goal is for students to be able to complete the bulk of the coursework during class time.

A typical section of CSCI 1101 or CMPE 1101 has between twenty and forty students. Because the class is held in a computer lab, enrollment is absolutely capped at a maximum of 45 students. In addition to the full-time faculty instructor,

TABLE II. PASS RATE IN CS1 BASED ON WHEN 1101 IS TAKEN

When Took CMPE or CSCI 1101	Number of Students	Percent Passing CS1
Never took 1101	397	60%
Prior to CS1	155	54%
Concurrently with CS1	163	63%
After CS1	87	55%

CMPE 1101 typically has one or two graduate student teaching assistants assigned to each section in order to assist during the lab. Typically, CSCI 1101 has a full-time faculty instructor plus an undergraduate student assistant.

III. IMPACT OF CHANGES TO COURSE SEQUENCE

We have performed an initial data analysis in order to evaluate whether or not taking CSCI 1101 or CMPE 1101 helps students perform better in CS1. This analysis is summarized in Table II. The data set includes all students who took CS1 at our university between Fall 2009 and Fall 2014, a total of 802 students.

The column titled “When Took CMPE or CSCI 1101” indicates when the student took the 1101 course in relation to when they took CS1. The first row, “Never took 1101” is likely to mostly contain students who took CS1 prior to the introduction of 1101. Students in the row labeled “Prior to CS1” are those who took 1101 in some semester prior to the semester when they took CS1. The students labeled “Concurrently with CS1” are those who took 1101 and CS1 in the same semester. The last row, labeled “After CS1” are students who took 1101 in a later semester than they took CS1.

The results shown in Table II are somewhat counterintuitive and we hypothesize that the results are indicating the impact of factors other than the 1101 course on student performance in CS1. These initial results show that students who take the 1101 course during the same semester as they take CS1 have a higher pass rate in CS1 than the students who take 1101 prior to taking CS1. The Computer Science department and Computer Engineering program are typically willing to give permission for students to take 1101 and CS1 concurrently for those students who have prior programming experience or have other indicators that they are well prepared for CS1. Therefore, the students who are taking 1101 and CS1 concurrently are likely to be higher performing students in general.

Another observation of the data presented in Table II is that the pass rate in CS1 for students who never took 1101 is not remarkably different from the pass rate of students who did take 1101. One of the goals of having a CS0-type course is to better prepare students for CS1. It does not appear that our 1101 course is currently meeting that goal.

At this point, we could dive deeper into the data that we have on grades in these courses. We could also analyze whether removing CSCI 1381 (the course that was once taken between CS1 and CS2) has had any impact on student performance in CS2. However, our intuition is that there are other factors that are having a greater impact on the success of students in the pipeline of introductory computer science courses than a simple analysis of performance from one course to the next can reveal. Also, we think it is unlikely that we could reintroduce a course in-between CS1 and CS2. Therefore, we have decided

to focus the remainder of this paper on taking a closer look at some of the other factors that may influence the success of students in our courses, as well as considering how we could better leverage our current courses to better meet the educational needs of our students.

IV. IMPACT OF OTHER STUDENT SUCCESS FACTORS

As was presented in Section II, the majority of students at our university are first generation college students who attended high school in the Rio Grande Valley region of South Texas. This region has one of the highest poverty rates in the United States, and is also one of the most rapidly growing regions of the country. Students enter our university with a wide range of levels of college readiness.

The faculty in our department have informally noted that many of the students who do not pass our courses are not fully engaged in the course. These students typically have poor class attendance and do not complete all of the required work for the course. Of course, if a student does not turn in the required course work, they will not earn the points necessary for passing the course.

In this section, we present a snapshot of the amount of coursework that is completed by students who fail CMPE 1101 and CS1. We also reflect on various issues that affect student engagement. In Section V we will discuss ideas for changes that may increase student engagement.

We compiled data on the percent of assigned coursework that was completed by the students who failed CMPE 1101 and CS1 over a number of semesters. In CMPE 1101, this assigned coursework is the lab assignments that are worth 50% of the course grade. Figure 1 shows the fraction of the students who failed CMPE 1101 (on the y-axis) that completed various amounts of the required work (on the x-axis). CS1 has two types of assignments. The lab assignments, which are intended to be completed during the weekly lab period, are worth 30% of the course grade. There are also larger programming assignments that are completed throughout the course of the semester and are worth 20% of the course grade. Figure 2 shows the fraction of the students who failed CS1 (on the y-axis) that completed various amounts of the labs and programming assignments (on the x-axis). We see in Figures 1 and 2 that a few of the students who fail do complete all or almost all of the required work. However, the majority of students who fail these courses are completing a small amount of the required coursework.

We understand that there are many factors that may impact an individual student’s decision of whether or not to complete required coursework. Because most of the students in these courses are lower-division students, they may have not yet developed good time management skills. From conversations with our students, we have learned that some of them are balancing other demands on their time in addition to school. Some students work more than 20 hours per week, or have family responsibilities that require a good amount of their time. The combination of work and family commitments with poor time management skills can make it difficult for a student to complete the coursework. Another factor that may affect many of our students is that first-generation college students are sometimes hesitant to ask for help, may not recognize when

Fig. 1. Completion of Assigned Work by Students who Failed CMPE 1101

Fig. 2. Completion of Assigned Work by Students who Failed CS1

they need to ask for help, or may not be aware of the various sources of help that are available.

Therefore, we propose that the most effective approach for improving performance in our introductory computer science courses is to focus on developing and encouraging a collaborative atmosphere that provides many opportunities for students to become engaged in the learning process. We also propose the need to focus on the overall concepts and skills that are required for computer science and computer engineering, as opposed to focusing on small details.

V. IDEAS FOR MOVING FORWARD

Over the past several years, the Computer Science faculty have often discussed how we could redesign the courses in the introductory sequence to improve student success. Suggested changes involve revisions to the course sequence as a whole and to individual courses. The various ideas for changes demonstrate how the Computer Science faculty continue to struggle with identifying the core issues that affect student success in Computer Science and Computer Engineering courses.

During many informal discussions, our Computer Science faculty have identified common issues among students that appear to lead to diminished student success in computer science, both at the introductory level and downstream. These issues include a general lack of problem solving skills, low engagement and motivation, lack of participation in class and in completing assignments out of class, and difficulty with varying levels of abstraction. These issues are certainly not unique to our department, university, or program. Many university faculty members express concerns about student engagement [1], and the growing emphasis on active learning reinforces the importance of drawing students into an active learning process.

In this section, we first describe ideas for changes to the sequence of introductory computer science courses. Then we discuss specific changes to the CS0 and CS1 courses that are currently being piloted or will be piloted in an upcoming semester.

A. Changes to the Pipeline

Several of our faculty members advocate reviewing the entire introductory course sequence (CSCI or CMPE 1101, CS1, CS2) by first identifying what the *sequence* should accomplish, as opposed to thinking about the courses in isolation. This type of revision is far more sweeping than the incremental changes that have been made over time by individual faculty members. Consequently, such alterations to the introductory sequence have not yet been implemented.

One suggested approach to these far-reaching revisions to our introductory sequence focuses on improving engagement and problem solving skills. With this approach, CS0 (*i.e.*, CSCI and CMPE 1101) will focus on problem solving and broad ideas, providing a better foundation for programming in CS1 and CS2. Some details of proposed changes to the content of CS0 are provided below. In this redesign, the CS1 course will concentrate on enhancing problem solving skills and introducing core programming concepts. Even though the existing CS1 course content includes all the core programming concepts, some faculty members feel that the students struggle with the details of syntax in C++. It is also challenging for faculty to devise interesting and engaging assignments for CS1 using C++. In light of these two notions, we are considering changing the language used in CS1 to Python, with a switch to C++ in CS2. This approach has been tested successfully at other institutions, with no significant difference in performance between students who switched languages after CS1 and those who used C++ in both CS1 and CS2 [10]. Our reasons for considering using Python for CS1 include the relative ease of use and reduced syntactic complexity of Python as compared to C++, and the fact that the many libraries available in Python enable students to execute more interesting and engaging programming projects much sooner than students writing in C++. In this revised course sequence, CS2 will begin with a brief review of the CS1 content to introduce C++ to the students, and then continue with much of the current CS2 content (*e.g.*, dynamic memory allocation, data structures), retaining a focus on modular programming, with nearly all considerations of object-oriented programming and design addressed in an additional course. We have not yet fully addressed how to deal with the impact of the proposed redesign

on downstream computer science courses, but a number of possible solutions to these issues have been suggested and we are confident that this is not a major stumbling block to pursuing the revision of the introductory sequence.

B. Changes to CS0

Although the Computer Science department faculty have not yet determined how extensively the introductory course sequence should be modified, two faculty members who teach CS0 are working on revisions to that course that can set the stage for the larger revisions discussed above. The two faculty members will collaborate on developing a new course structure and course materials for CS0 in Summer 2015, and will use the revised course in two pilot sections in Fall 2015. We hope to leverage existing collaborations with colleagues in social sciences and education to design tools to measure the impact of the revised course on student problem solving skills and student engagement.

The modified course will revolve around three “big” ideas: algorithms, the stored program concept, and social impacts of computing. These three ideas provide a conceptual framework for organizing the course content, and allow exploring ideas that students will revisit time and time again in their future course of study. The updated course will use a strong active learning approach that encourages and rewards student involvement. While these approaches and activities are not novel, introducing more active learning in our CS0 course will set the stage for increased use of such approaches throughout courses in the Computer Science department.

Algorithms is, without a doubt, a core concept in computer science and engineering. Beginning the CS0 course with algorithms allows us to address topics such as problem solving processes and paradigms, algorithm design and description, and the notion of “one algorithm, many implementations, many languages.” These ideas will be supported with hands-on class activities. Problem solving approaches will be investigated through games and puzzles. Creating and communicating an algorithm clearly can be explored in engaging activities such as building with Legos. The concept that one algorithm can be executed many ways and with many programs will be addressed by exercises such as implementing the same simple algorithm using different tools (*e.g.*, Scratch and Lego Mindstorm robots). Placing algorithms at the start of the course introduces important concepts, but also may promote student interest and increase engagement in the course. With this topic, we have the opportunity to have students do many game-like activities early on and have them working with robots right away in the course.

The stored program concept is critical to both programming and the design of computing machinery. This core idea allows us to address issues such as data representation, the instruction cycle, and computer hardware components. Although this topic appears much “drier” than the previous topic at first glance, there are many activities available that deal with the information in appealing ways.

CS0 provides an ideal context for introducing the idea of social impacts of computing. Although our students will all take professional ethics courses as part of their degree requirements, addressing the societal and cultural dimensions

of computing in the very first major course introduces a discipline-centered perspective on those questions and underscores the importance of considering these issues. This topic will allow us to address issues related to privacy, security, and professional ethics in computer science and engineering. We will also be able to explore sustainability as it relates to computing. This topic is a particularly good opportunity to provide content that is tailored for computer science or computer engineering students. For example, the computer engineering students may look at considerations in chip design that impact power consumption, while computer science students may explore a variety of software applications that support community sustainability and green technology.

C. Changes to CS1

In academic year 2014 – 2015, we began a pilot study in some sections of our CS1 course with the goal of identifying more effective interventions for student success. These interventions are part of a large-scale collaboration between the College of Engineering and Computer Science and the College of Science and Math at our university. The first initiative is the development of a pre-test for CS1 that could identify students who are at risk of failing. The second initiative is the use of the pre-test data to inform intentional intervention with peer mentors. An overview of these initiatives is provided below. We plan to publish a separate paper that details the results of these interventions following the conclusion of the current study.

While the pre-test data is only preliminary, we have already found interesting results that are driving the continued development of the pre-test. Through two semesters, pre-test questions on basic algebra and logic puzzles have had virtually no correlation (correlation coefficient < 0.1) with exam scores or final course scores. Samples of these questions are shown in Table III. This was quite surprising, as the connection between these questions and CS1 material seems intuitively obvious. One question that does have a correlation with exam scores or final course grades is a multi-equation word problem, which had a correlation coefficient of 0.28 in the first semester ($n = 31$) and 0.173 in the second semester ($n = 41$). This problem is shown in Table IV.

In the second semester, we tried pre-test questions on simple automation, showing a robot on a grid with pseudo-code to move it up, down, left, or right with conditional checks for blocked squares. We also included a question requiring students to post a simple note on the course blog later that day, in order to examine organizational skills. Those questions showed more promise, with an overall correlation coefficient of 0.30 ($n = 41$).

The second intervention we are piloting in some CS1 sections is peer mentoring. An often overlooked element of engaged learning is having effective life skills, including a good social support network. A student can be interested and have every intention of learning, but fail to manage the process and fall short in their learning goals. This is particularly true for lower-division students who are adjusting to college life. For this reason, the mentoring initiative in this course is focused on relationships, goals, plans, and progress rather than traditional tutoring. Students met, in groups, with a peer

TABLE III. CS1 PRE-TEST QUESTIONS THAT DO NOT CORRELATE WITH COURSE PERFORMANCE

1)	Given the equation: $x = 8 \times (y + 3)$ Let $y = 2$, then the value of x is ____
2)	Given the equation: $y = 8 \times 2(x - 1)$ Let $y = 6$, then the value of x is ____
3)	<p>Five cities got more rain than usual this year. The five cities are: Last Stand, Mile City, New Town, Olliopolis, and Polberg. The cities are located in five different areas of the country: the mountains, the forest, the coast, the desert, and in a valley. The rainfall amounts were 12 inches, 27 inches, 32 inches, 44 inches, and 65 inches.</p> <ul style="list-style-type: none"> • The city in the desert got the least rain; the city in the forest got the most rain. • New Town is in the mountains. • Last Stand got more rain than Olliopolis. • Mile City got more rain than Polberg, but less rain than New Town. • Olliopolis got 44 inches of rain. • The city in the mountains got 32 inches of rain; the city on the coast got 27 inches of rain. <p>Which city got the least amount of rain? Where is Mile City located?</p>

TABLE IV. CS1 PRE-TEST QUESTIONS THAT DO CORRELATE WITH COURSE PERFORMANCE

<p>John is three times as old as Greg, and Greg is half the age of Bob. Steve is two times the age of John and Bob combined. If Steve's age is 60, how old is Greg's older cousin Jane, who is 2 years older than Greg?</p> <p>Jane's age: ____</p>

mentor to discuss their expectations, methods of preparation, and results from the first 2-week exam in the course. Each student was required to create a plan of study to go over with the group indicating their expectations and actual experiences with time spent in different course activities. While this is initiative is in its early stages, we have some evidence that students connected with each other for support networks and followed up with the mentor for tutoring at a higher rate. Going forward with this activity, we are developing an online web-based tool for students to do simple weekly progress check-ins, so that they can see how their expectations and effort correlate to performance in class activities. The peer mentors in academic year 2015 – 2016 will be working to roll out that system with the students and evaluate its effectiveness in keeping them engaged and actively planning for success.

VI. CONCLUSIONS

This paper marks a shift in the focus we are taking when making changes to our introductory computer science courses.

Instead of focusing on small performance metrics, we are now looking at the bigger picture of student success. The changes that we are piloting in select sections of our CS0 and CS1 courses aim to increase student engagement and confidence.

We expect that our introductory computer science courses and course sequence will continue to evolve over time. Our goal is to make changes that are motivated by well-known best practices in engineering education and to scientifically evaluate the changes that we make. We are currently working to achieve this goal by using pilot sections to test changes and using initial results from these pilot projects to guide future changes.

Empowering Teachers to Teach CS – Exploring A Social Constructivist Approach for CS CPD, using the Bridge21 Model

J. R. Byrne, L. Fisher, B. Tangney

Centre for Research in IT in Education

School of Education and School of Computer Science & Statistics, Trinity College Dublin

Dublin, IRELAND

jake@bridge21.ie

Abstract— This paper describes current research exploring the adaption of the Bridge21 pedagogical model for the provision of a Computer Science (CS) Continuing Professional Development (CPD) Programme for post-primary/high school teachers in the Republic of Ireland. This paper outlines the design of the programme and explores the delivery of two, week long CS CPD interventions delivered in the authors' home institution over the summer of 2014. The interventions were designed to help teachers develop expertise in areas such as computational thinking, programming and game design, text based programming and hardware configuration. The Bridge21 Learning and Activity Models were used throughout each workshop delivery and teachers were invited to use the same models in their own delivery of CS classroom activities. An Exploratory Case Study approach, using Evaluation Theory, informed data collection, coding and analysis procedures. Teacher reactions towards the Bridge21 CS CPD programme were investigated. Analysis indicate that teacher reaction towards the programme was positive and that teachers intended to use elements of the Bridge21 Learning and Activity model for CS delivery in the classroom.

Keywords—*Computing and Programming; 21st Century Teaching and Learning; Social Constructivist Pedagogy; CPD.*

I. INTRODUCTION

There is an international trend, within a number of education systems, exploring the inclusion of CS at both primary and post-primary/high school levels. In the Republic of Ireland, a number of “short courses” in Digital Media [1] and Coding [2] are available for the first time in post-primary/high schools across the first three years of the Junior Cycle (ages 12 – 15 approx.) curricula. These courses are being introduced as part of an overall reform of the Junior Cycle the aim of which is to move away from more traditional teacher-centred delivery approaches to flexible approaches that foster creativity, problem solving and help students develop a wide range of 21st Century key skills [3].

Teaching computing using flexible delivery methods results in courses that broadly encourage project work using a wide range of digital media, including coding. Their aim is to help learners develop expertise in the design, construction and implementation of computer generated artefacts. Despite the

introduction of these flexible learning models, there is limited CPD available to teachers that targets the creation of digital content and fewer still that combine it with a 21st Century approach to learning that is also promoted in these “short courses”.

II. LITERATURE

Policy makers and industry both agree that the economic and social trends in the 21st Century are shifting work practices, particularly in the Computer Science domain, from one of simply creating goods and offering services to one of knowledge, information and innovation [4-6]. This shift requires education systems to update pedagogical approaches in order to help students develop skills needed to work in this knowledge intensive world. Recent pedagogical approaches suggest developing the whole learner through the development of problem-solving, meta-cognitive skills [7]. With these approaches, students are not viewed as simply passive “Knowers” who reproduce received information, but “Learners” who develop transferable learning dispositions [4].

Social constructivist learning models emphasis learning through doing and encourage knowledge acquisition through problem solving and self-directed learning [8]. A self-directed approach to teaching and learning, with an emphasis on helping the learner construct new meanings from prior knowledge [9], offer teachers one possible route towards helping their students play a more active role in their own learning. The need to help students become more active, and autonomous learners, comes from educational reform concerned with helping students push deeper into curricula content knowledge. There is also a need to guide student development in a range of social and technical skills designed to help them engage with content in ways which shape understandings, while also providing students with the confidence to express and share their learning with their peers [10].

Refocusing post-primary (high school) curricula to nurture the development of these skills also coincides with renewed emphasis on Computer Science delivery as a 21st Century (21C) subject option for post-primary students [11].

Computing and programming are increasingly perceived as essential skills for 21st century learners [12].

Supporting this transition to new 21st Century work practices in Computer Science and ICT across both social and economic sectors, requires students' who are both capable of learning to use a wide range of technical tools whilst also developing a wide range of transferable 21st Century skills needed to effectively work as part of a team. The challenge here is to create a safe environment within which students, with the guidance of their teachers, can develop and hone both these technical and transferable 21st Century skills.

A. Computing is not easy

Teaching computing, and programming in particular, is inherently difficult due to what is perceived as the abstract concepts and technical nature of constructing programs [13]. Lathinen et. al [14] suggest that novice programmers should have experiences that are problem-solving in nature rather than explicitly focusing on abstract concepts. This emphasis on problem-solving resonates with the 21C approach to learning, as described above.

B. Approaches to Continual Professional Development

Given that computing is perceived as a difficult subject for students to learn, and for educators themselves to learn and subsequently teach [15-18], this raises questions as to how best to support teachers with appropriate professional development [19]. Social constructivist learning models, may offer one solution to this problem. Peer collaboration, a core tenant of CPD [20] enables teachers to share existing knowledge and experience, while also providing a forum that teachers can use to explore ideas and engage in practical work in a collegial environment. CS CPD programmes, using 21st century learning models in their delivery, are positioned to help CS teachers both experience and practice techniques designed to encourage students to become more active learners. These programmes also provide teachers with first-hand computing and programming experiences in an attempt to scaffold expertise and build confidence with delivering CS in schools.

III. PROGRAMME DESIGN

A. The Bridge21 Learning Model

Bridge21 is a practical model of 21st century teaching and learning which is being used by teachers across a number of Irish secondary schools, in subjects ranging from history [21] to mathematics [22]. The core elements of the Bridge21 learning model are: (1) structured team-based pedagogy, (2) project based activities, (3) technology-mediated learning, (4) recognition of the social context of learning and (5) facilitation, guiding and mentoring [23, 24].

B. Bridge21 Activity Model

Although the Bridge21 pedagogical model describes the structural and contextual elements necessary to orchestrate and deliver an effective 21C learning experience; it does not provide a detailed guide around which activities can be

designed. The Bridge21 Activity Model (Figure 1) consists of seven steps around which a learning activity can be designed. The activity model builds on ideas from design thinking [25] where teams move through phases of inspiration, ideation, and implementation. As with design thinking the activity model allows for a non-linear approach where the teams can go back and revise previous phases if required.

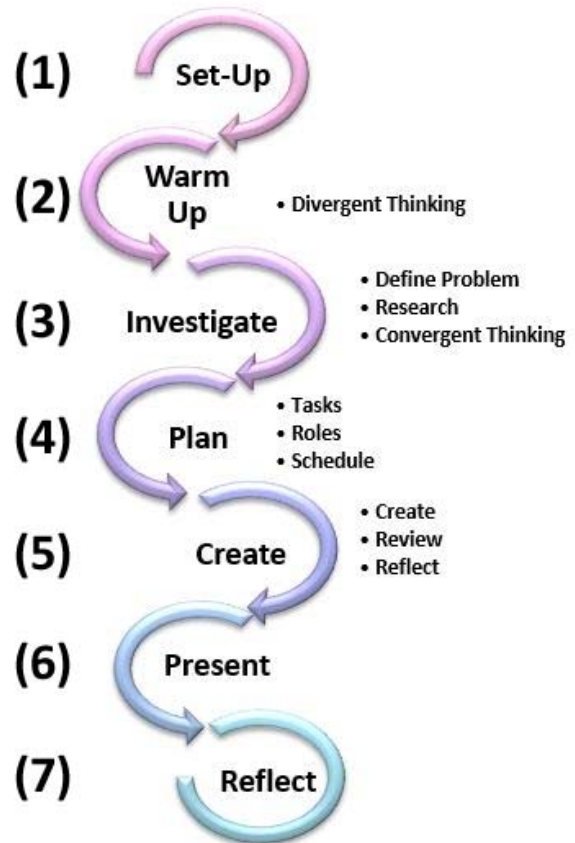

Fig. 1. Bridge21 Activity Model

1) Set-Up

A typical activity will start with an optional (1) “set-up” activity that is usually employed when the group is new to team work or does not know each other. It also provides an opportunity for team formation. There is usually some sort of “ice-breaker” activity to help the members of the group get to know each other and establish intra-group communication. Team formation follows the ice-breaker, is facilitator orchestrated and is an essential element of the Bridge21 model. It is important for the facilitator to make sure that there is a spread of ability in each team so that they can support each other as they progress through the activity.

2) Warm Up

The (2) “warm up” activity is designed to promote divergent thinking and get the teams working together and thinking in a creative manner. Initial brainstorming can either

be topic specific or be deliberately unrelated. It is desirable to get the teams practicing and modelling creative practices before tackling the central topic of the main activity.

3) Investigate

The (3) “investigate” phase involves convergent thinking and sets the context of the workshop. Teams investigate, ideate, research and define the problem context, which is set or scoped by the facilitators. It is here that the activity model can explore the design thinking elements of “inspiration” and “ideation”. Here, teams are encouraged to use lateral thinking to explore ideas, and formulate areas of interest to investigate further. The context is refined and focused when the facilitators give the teams a task where they have to create some digital artefact that addresses a number of requirements or targets. Teams are encouraged to identify and then explain problems that need to be addressed in order to fulfil the defined task targets. This can require further research into the problem context in preparation for planning and the creation of some digital artefact. This phase can also be used by the facilitator to deliver some technical content knowledge that may be needed in order to tackle the task, this may be delivered in a traditional didactic approach but it is recommended that these periods are kept short and interspersed with practical “hands-on” experience to help contextualise the materials being presented.

4) Plan

In the (4) “planning phase” team members negotiate the assignment of tasks, roles and agree a schedule for the delivery of work to be completed. A comprehensive task list should be developed based on the refined problem context that arose from the investigate phase. The facilitator may provide a template that helps scaffold the activity and implementation (e.g. using a story boarding and crew roles templates for video production). The goal here is to get the teams taking responsibility for completing the activity and thinking practically about how they are going to achieve their goals.

5) Create

The creation phase is a cyclical process in which the teams (5) “create/implement” their plan. This phase is where the teams’ task list/outlines are put into action. In line with design thinking there is opportunity to revise the plan in the short cycles of execute-review-reflect. This is time/context dependant and the facilitator can liaise with team leaders as to gauge how they are progressing and provide an opportunity for the teams to review and reflect on their progress. Utilising team leaders in such a fashion can help to reduce disruption to the whole group by limiting the number of individuals whom need to stop working on the main activity, while also promoting intra-team communication when the team leader reports back to their team.

6) Present

Once the deadline has been reached and the teams have completed the task they are invited to (6) “present” their digital artefacts to their peers and share what they have learned.

7) Reflection

A final (7) “reflection” phase is used to consolidate the learning. Here both teams and individuals reflect on their experiences using the provided templates. This provides an opportunity for the team members to reflect on how they worked together and what they personally learnt during the activity. Emphasis should be put on using the outputs from this step to improve future learning scenarios.

The activity model is used to design Bridge21 workshops, the “set up” phase (1) is optional if the teams are already formed or the group is familiar with each other. Additionally the “reflection” phase (7) is generic/not content specific and follows each workshop. Content specific material is therefore generally present in phases 2-6. Workshop design will generally follow this formula unless noted otherwise.

C. CS CPD Workshop Design

In order to help teachers to up-skill in Computer Science and gain expertise in 21C teaching and learning strategies, a series of 6 workshops were designed and then delivered on campus during weekends and school holidays. The programme consists of 1 “Digital Media and 21C Teaching and Learning” workshop followed by 5 computer science and programming related workshops. Each was delivered using the Bridge21 learning and activity models.

1) Digital Media Literacy and 2C Teaching and Learning

The Digital Media Literacy workshop is a primer that introduces the Bridge21 Learning and Activity Models without too much technical content. This allows teachers to focus on the pedagogical model rather than worrying about keeping up with any highly-technical content. This workshop provides an opportunity to use the Bridge21 Model to produce a number of artefacts relating to Digital Media issues using digital media editing software and skills.

The workshop starts with a (1) “set up phase” in which there is an introduction to the Bridge21 Model followed by a “Low Tech Social Network” ice-breaker. This activity requires teachers to complete a one page profile, which then then exchange with others in order to obtain the most number of ‘matches’ or shared items. This offline activity was designed to replicate the concept of “following”, used on social media applications. This ice-breaker has everyone individually fill out a paper profile, then they have to find those that have the same “favourite” things on their profile. The person with “the most friends” is the first to get all items matched with others in the room. The rules are then changed so that they have to find another person with a matching item and then swap profiles and repeat. The profile should move away from the original creator and the first with 8 swaps is the one that has gone “viral”. Once the ice-breaker is complete teams are formed and introductions are made.

This is followed by a (2) “warm up” activity which is designed to encourage divergent thinking and get the teams working together and thinking creatively. A typical activity is to ask teams to brainstorm “*different ways of communicating.*”

Next the (3) “investigate” phase promotes convergent thinking and sets the context of the workshop and makes up the majority of the time. Here the group works to define what is within the scope of “Digital Media Literacy” and brainstorm what they consider are the key issues which need to be addressed with students, e.g. On-line Safety, Piracy, Privacy, Cyber Warfare, etc.. The teams then select one of these issues and use the internet to research the topic, using guiding questions. Teams are then set a task to create a 1 minute information video and 30 second radio advert as part of an awareness campaign on the Digital Media issue they choose.

The teams then (4) “plan” what sub-tasks need to be completed, how much time do they have them and to whom tasks should be delegated.

Teams then (5) “create” their digital artefacts. Once the deadline is reached the teams are encouraged to (6) “present” their work to their peers as well as what they learned and what they might like to try in the classroom. A final (7) “reflection” phase is used to consolidate the learning and gain feedback to inform the workshop design.

2) Problem Solving for the 21st Century

This workshop differs from a general Bridge21 activity in that the majority of the workshop resides in the “investigate” phase as it is largely composed of lots of small problem solving activities which are inspired by CS Unplugged [26] in which algorithmic thinking is exercised without the use of a computer.

For example, in the initial (1) “set-up”, the ice-breaker gets the group to pair up and guess each other’s name, or middle name, using a set of predefined questions. After working out the other’s name, they have to describe their approach and add two more questions that they think will make for a more efficient strategy.

The “warm up” (2) phase asks teams to brainstorm “*what computers are good at.*”

The (3) “investigate” phase is comprised of lots of short problem solving activities including those from CS Unplugged. The only time a computer is used is when the teams have to write short programs using the Blockly tool [27]. After a number of these activities the teams are provided with a sheet developed by the CSTA and ISTE [28] that explore “*computational capabilities*” across the curriculum. The teams are then set the task to design learning experience that includes a number of these capabilities.

Teams then (5) “create” a brief presentation of their learning experience. Once the deadline is reached the teams are encouraged to (6) “present” their work. The final (7) “reflection” phase is used to consolidate the learning and gain feedback.

3) Introduction to Programming Through Animation

This workshop uses the Scratch programming environment to introduce basic programming concepts, such as operators.

As with all workshops, this starts with a (1) “set up” and (2) “warm up” phases, consisting of an ice-breaker, team formation and divergent thinking activity.

Next the (3) “investigate” phase introduces the scratch programming environment using two short Youtube videos. This is followed by a brief team free play with Scratch to familiarise the teams with the interface. The group is brought back together and a discussion follows about what algorithms are. Each team is given an image and asked to write a set of verbal instructions that would enable another team to duplicate the image without seeing it. This emphasises the importance of using common and clear language in designing the steps in an algorithm. Once completed the teams are then asked to interpret what a given Scratch¹ program does but without actually executing it. Once completed the teams are set the task to create a 2 scene animation that must include an audio component.

The teams (4) “plan” by deciding what sub-tasks, such as story-boards, need to be completed.

Teams then (5) “create” the animations using Scratch. Once completed the teams (6) “present” their work to their peers as well as what they learned. Finally the (7) “reflection” phase helps consolidate the learning and gain feedback to inform the workshop design.

4) Intermediate Programming Through Game Design

This workshop again utilizes Scratch to explore advanced concepts, such as variables, events and concurrency.

Again the workshop starts with a (1) “set up” and (2) “warm up” phases, consisting of an ice-breaker, team formation and divergent thinking activity. Here they brainstorm “*Types of computer games*”.

Next the (3) “investigate” phase introduces a number of advanced scratch features such as operators, events, broadcasts and variables. A brief group discussion explores what makes a good game, highlighting that they need to be challenging, fun and look good. The teams are set the task of creating a 2 level game.

The teams (4) “plan” deciding what sub-tasks such as controls, mechanics and game aesthetics that need to be delivered

Teams then (5) “create” their games using Scratch. Once completed the teams (6) “present” their work to their peers as well as what they learned. Finally the (7) “reflection” phase is used to explore their learning in more depth and provide feedback to inform the workshop design.

5) Exploring Computer Systems

This workshop is centred around the Raspberry Pi computer and the Python programming language and introduces embedded systems and inputs and outputs.

Again in the (1) “set up” phase groups are formed and introductions are made. This is followed by a (2) “warm up” where the teams are asked to brainstorm examples of

¹ <http://scratch.mit.edu/>

computers in everyday life, with an emphasis on inputs and outputs. Examples usually include applications such as house alarms, ATMs and smartphones.

Next the (3) “investigate” stage has teams investigate how the Raspberry Pi is setup and explore how to alter a pre-existing code base to interface with a gaming controller using the General Purpose Input Output (GPIO) pins. This is followed by a Python exercise that interfaces with an LED and switch, again using the GPIO pins.

Fig. 2. Team Working at Raspberry Pi workshop

The teams are scaffolded in the set-up of the hardware and installation of the default ‘Raspbian Operating System’ as recommended by the Raspberry Pi foundation². Once the Pi is powered up they launch the OS, open the Scratch programming interface and create a very simple program that moves the character around using the arrow keys on the keyboard (Figure 2). A Makey-Makey, a hardware controller device that enables users to create control inputs by attaching any household object that can conduct electricity, can be used to briefly show an alternative control mechanism for controlling the on screen character or sprite. After completing the set-up tasks, a tutorial available from Adafruit Industries³ is followed in order to setup a retro gaming controller to control the character in Scratch using the on-board General Purpose Input Output pins. Teams are also asked to tweak the accompanying code to alter the output actions. On completion of this task the Python GPIO library is introduced and they are tasked with wiring up an LED and switch and using a Python program to turn on the LED when the switch is pressed.

The (4) “planning phase” involves teams exploring what projects they might do with their students in school, and exploring various options online. Participants are then invited to (5) “create” a presentation. Teams are encouraged to (6) “present” to their peers, - what they learned and what they might like to try in the classroom. Finally (7) “reflection”

phase is used to consolidate the learning and gain feedback to inform the workshop design.

6) Advanced programming

The Advanced Programming workshop introduces Python, a first text-based programming language, and uses it to solve a number of mathematical tasks.

As with each workshop it starts with a (1) “set up phase” in which groups are formed and introductions are made. This is followed by the (2) “warm up” where the teams are asked to brainstorm examples of “things that are programmed”. In this conversation, there is an emphasis on how Python can be used for many of these applications in order to highlight the relevancy of the language.

In the (3) “investigate” phase teams are set a “Python from Scratch” task. The teams are handed out a sheet with a list of Python commands on it and they are tasked with coming up with the Scratch code equivalents. These commands vary from printing text, entering variables to conditional statements and loops.

Once the teams have completed the first task they can progress onto a number of progressively harder tasks in which they must create Python programs. The tasks are stated as problems, beginning with “create a program that prints out ‘hello world’”. The teams can use their sheet from the “Python from Scratch” task as a cheat sheet to figure out what to write. These activities progress to problems which calculate speed, distance and time based on user input (conditionals) or iterated over a certain distance (loops). For more advanced students the task is to download an existing piece of code that uses Python on the Raspberry Pi to return a distance using an ultrasonic rangefinder and the GPIO pins. This code is a practical example of the mathematics used for calculating distance, speed and time as the returned distance is calculated using these equations. The final task is to turn the existing code into an ultrasonic speedometer that alerts the user is an object is travelling over a certain speed.

As this workshop deals with technical content, a large proportion of the workshop is spent in the “investigate” phase. After completion of the above tasks the teams are asked to put together a very quick presentation. The (4) “planning” phase involves teams exploring what they learnt during the workshop, what might do with their students in school and one thing they wished the workshop had covered. Participants are then invited to (5) “create” a presentation. Teams are encouraged to (6) “present” to their peers including what they learnt and what they might like to try in the classroom. Finally (7) “reflection” phase is used to consolidate the learning and gain feedback to inform the workshop design.

IV. DELIVERY

The contents of each week session were delivered in the order described above, with the exception of the Problem Solving workshop. Elements of the Problem solving workshop were used as warm up activities at the start of each day rather than delivered as a workshop in itself. The first of the two week sessions ran from Monday 9th June until Friday 13th

² <https://www.raspberrypi.org/downloads/>

³ <https://learn.adafruit.com/retro-gaming-with-raspberry-pi/>

June, with N = 91 attendances. The second week ran from Monday 9th July until Friday 11th July 2014, with N = 73 attendances, resulting in a combined total of N = 164 attendances. Each week ran concurrently for 5 days and each day commenced at 10 am and concluded at 3.30 pm. Participants attended the Bridge21 CS CPD workshop interventions of their own accord, and thus samples were self-selecting. Some participants had prior CS delivery experience, with others new to the domain of CS.

V. RESEARCH QUESTIONS AND METHODS

This paper explores teacher reactions towards the use of the Bridge21 model for CS CPD delivery, during the two weeklong pilot workshops.

A. Methods

The authors used an exploratory case study design to define the research context, the case and units of analysis [29]. The context relates to teaching Computer Science (CS); the case refers to use of the Bridge21 model for post primary/high school teacher CS CPD delivery and each CS workshop is defined as an individual unit of analysis. The authors then combined evaluation theory [30] with an exploratory case study approach to examine teacher reactions to the CPD programme.

1) Evaluation Framework

The evaluation framework used to organise data collection was that of Kirkpatrick [31]. This evaluation framework operates over four levels. Level 1 explores participant reactions to the training and Level 2 explores participant learning in the context of the training environment. Level 3 examines perceived changes in behaviour as a result of the training, while Level 4 examines results, in terms of changes to wider organisational workplace practices as a result of the training. This paper presents results gained from the administration of a Kirkpatrick Level 1 – Reaction instrument which explores participant reactions towards CS CPD programme delivery. The authors are also engaged in designing Level 2, 3 and 4 instruments, to explore learning as a result of the CPD, and use of the CPD on return to teaching.

The authors’ adapted an existing Kirkpatrick mixed methods reaction instrument [32]. The instrument contained 12 closed numeric (Likert) questions and 4 open text questions to capture reactions across each of the six programme topics.

B. Reaction Instrument Question Design

The 12 Likert questions were organised into four question categories, each of which explored participant reactions towards the CPD. Category 1 contained 4 questions which focused upon Workshop Design. Category 2 contained 4 questions, which explored the use of Facilitation as a delivery method. Category 3 contained 3 questions which examined usefulness of learning Activities and Case Studies. Finally, Category 4, contained 1 question prompting for an overall workshop satisfaction rating. All questions were scaled left to right, with 1 = Strongly Agree, allocated a 100% rating, to 7 = Strongly Disagree, allocated 0%.

The instrument also contained four open, text questions. Question 1 asked participants to identify workshop topics they would like to spend more or less time on. Question 2 asked participants to list key learnings. Question 3 asked participants to comment on perceived changes to their delivery as a result of the CS CPD, where they intended to teach CS and Question 4 asked participants to comment on the perceived usefulness of the CPD.

C. Data Collection Procedures

Data collection occurred as follows. The authors distributed a hard copy ethics and consent form to all participants on the first day of each week. Participants whom opted into the research process provided a signature (a total of N = 33 unique signatures were obtained from a total of N = 36 individuals over the two week period); while others opted out by leaving forms blank. As each workshop ended, participants were invited to complete the Kirkpatrick Level 1 Reaction form. A total of N = 157 forms were collected over the two week period. Instrument completion was optional and this paper includes data from participants with a corresponding ethics signature.

VI. ANALYSIS

The section describes coding processes used to analyse quantitative and qualitative data sets.

TABLE I. PERCENTAGE RESPONSE PER QUESTION CATEGORY

Question Category	Percentage Response
Design	82%
Facilitator	93%
Other Aspects	92%
Overall Rating	93%

TABLE II. TEXT RESPONSE CODE REDUCTION

Coding Stage	Codes
Inductive Coding Cycle 1	215
Deductive Coding Cycle 1	123
Deductive Coding Cycle 2	28
Sub-Themes	2
Theme	1

A. Quantatative Data

Likert responses were processed using SPSS statistical software. SPSS summed the total number of responses per workshop question category, and then generated an average of means. The average or mean score was then converted into a percentage, as detailed in Table I.

Text responses were manually and then electronically transcribed, open coded and stored in a searchable database.

Three iterations of manual re-coding were performed against the transcribed text responses. This process resulted in the generation of 215 text codes from a total number of 383 database records. Comparative coding was used to reduce the qualitative data set [33] to a total of 28 codes. These codes (Table II) were further reduced into 2 sub-themes, which were then linked to the central theme of teacher 'empowerment.'

B. Sub Themes and Themes

The theme 'empowerment' emerged from qualitative data analysis. The sub themes of 'delivery model' and 'self-directed learning' emerged as sub themes related to empowerment.

VII. FINDINGS AND DISCUSSION

This section is structured as follows. Section A explores teacher reactions towards the use of the Bridge21 model for CS CPD delivery using a combination of statistical results and participant text responses. Section B then explores empowerment and related sub themes with text examples.

A. Reactions to the Workshops

As detailed in Table I, teacher reactions across all quantitative question categories were positive, indicating a high level of satisfaction with the delivery of the workshops. The following discussion explores these reactions in detail.

1) Design

Participants reacted positively to the week long programme giving an overall satisfaction rating total of 82%. The qualitative data revealed that the programme helped participants think about how they might teach CS. One participant stated that workshops had demonstrated *the importance of introducing new topics slowly.* This approach prompted another participant think about giving *'more time in classes to harder topics not just rush,*' and had helped another *'with my timing and planning of difficult concepts.'*

2) Facilitation

Participants also reacted positively to the use of facilitation for CPD delivery, registering a satisfaction rating of 93%.

The qualitative data revealed that the experience had encouraged one participant to want to *'act more as facilitator in class,*' while another now wanted to *'re-think completely how group work is facilitated and organized,*' having experienced group based CPD. Group work exposure encouraged participants to think about adjusting their own delivery. One participant reflected *'because I have been forced to work in groups and problem-solve myself I have enjoyed it. I will feel more comfortable about using this model in the classroom.* Another reflected that they had also gained a better *'understanding of student difficulties with basics so as to assist them in a full understanding of the use of technology.'*

3) Other Aspects

The 'other aspects' workshop question category asked participants to comment on the use of case study materials and activities used during the workshops. Participants gave an overall satisfaction rating of 92%. One participant enjoyed

using practical approach to CPD *'as opposed to following book or showing end product.'* Other participants also enjoyed the practical exercises and could visualizing using them - *'basic (programming) worksheet exercises are good class fillers,*' also the activities provided *'good material and structure for class,*' with *'good templates / demo of how things can be done.'* The range of practical exercises provided *'a good alternative for differentiated delivery,*' and had exposed participants to a *'new model to play with,*' and a structure with which to introduce *'new ideas for class.'*

4) Overall Rating

Participants again, registered a positive overall satisfaction rating of 93% towards the week long Bridge21 CS CPD sessions. At the end of the first week, one participant reflected, *'I learned a bucket load so thanks very much. I admit that I did struggle at times but a higher competence in math's would have helped so it is my ability rather than the course itself. That said, I will certainly peruse these skills in the future as I believe they have a place in Secondary Schools.'* At the end of the second week, another participant commented that that they would *'certainly be able to advise students on computers / programming and getting involved in computer clubs. (The workshop topics are) also relevant to our chemistry club. Also languages - encouraging girls (in computing) as many girls good at languages but see computers as something completely different.'*

B. Teacher Reactions to the Bridge21 CS CPD Programme

This section sets out to explore the theme of empowerment, and sub themes of delivery model and self-directed learning.

1) Empowerment

Empowerment is defined as developing processes or programmes which seek to 'help people, help themselves' [34]. Following this definition, the theme of empowerment is discussed with the aim of exploring the extent to which the CS CPD programme helped participants again in confidence to adjust delivery methods to enhance teaching and learning according to a 21st century approach, and gain in confidence to teach CS in their schools.

The activity and hands on approach to CS CPD delivery offered by Bridge21 was not expected by one participant whom was surprised that the programme was *'was not a math's course - I came today with a calculator and lots of tables!'* Instead, participants gained a *'working with variables and lists in Scratch,*' and were encouraged to *'spend time experimenting with Scratch'* and other digital tools. One participant commented that they had learned how to *'work around for issues; don't over complicate the code on scratch.'* Visual programming had also helped another participant *'think more about approaches to scratch with the class and for coding short course.'* The completion of group based coding projects had also helped contribute to a positive learning experience, where learning *'scratch can be fun - the harder you make it the better fun it can be!'* Participants felt energized and confident to apply their learning in the classroom - *'I feel confident that I could use scratch in class,'*

while another participant shared that they *'felt I could introduce this to students through I think they could pass me out technically very quickly! And teach me!'* In relation to the delivery of the more advanced computing workshops (Raspberry Pi and Python), participants liked bridging activities *'I liked matching Scratch codes -> Python Codes'* and other hands on activities which helped to demonstrate the *'importance of correct codes and one mistake can affect everything.'* One participant reflected that they had learned *'how important language is to coding,'* while another commented they now understood how to combine codes, and the *'the impact one code has on another.'* The group based approach to coding and programming also generated conversation on the role team and group projects played on learning computing concepts - *'group work is great for complex project.'* Introducing and using team based, facilitated activities for exploring computing systems had helped to *'motivate, stimulate and brighten up student learning'* in ways which had enabled participants to think about how they might *'integrate more coding and computational exercises in classes.'*

a) Delivery Model

The CS CPD programme had introduced participants to an delivery model which encouraged them to reflect on their own teaching style, and think about how they might adjust their own delivery in light of experiencing a 21st century approach to teaching, and learning. One participant reflected that *'you primarily teach the way you were taught,'* indicating that it is difficult to change or switch between delivery methods. Another participant reflected that they intended to change their delivery methods so that *'students and myself should discover how to do something as opposed to being led.'* The CPD experience had also helped one participant *'realize how others think and learn differently,'* and the practical approach had provided another participant with a range of techniques and activities with which to *'complement the things I already do in my teaching.'* For those new to computing, the facilitated nature of the delivery, *enabled* one participant to explore *'coding and its processes,'* and the delivery process was perceived by another participant as potentially *'great for students understanding of the process that goes into making a game and logical thinking.'* The delivery process also helped one participant become *'more familiar and confident using this (the Bridge21 model) in class and the process is important - not having perfected the task!'* One participant continued that *'this process will help me raising awareness on responsibility re: digital media,'* while another participant expressed the view that the Bridge21 CS CPD approach to delivery was a *'good tight format, practical workshop, good pace, I will seek to emulate.'* The workshop design helped participants explore computing concepts, but within a structure, they could see themselves using in the classroom with their students. As summarised by one participant, *'I think its brilliant, it really energizes and interests me, I'm really looking forward to using it in after school activities'.*

2) Delivering a Self-Directed Approach to Learning

The theme of self-directed learning indicated intent towards adopting a self-directed learning approach when they

returned to the classroom. One participant commented that they intended to use *'less teacher directed learning and more self-directed learning.'*

The workshops had also prompted consideration of a number of other delivery changes. One participant intended using more *'problem-based learning in the classroom,'* while another participant aimed to use *'problem solving in my classes'* as the activities undertaken in the workshops had helped expose participants to a *'logical structure to problem solving,'* which some aimed to use with the computing students. The Bridge21 approach to CS delivery had helped participants explore the *'importance of learning from other members of your team,'* and develop some *'techniques for software and team dynamics,'* resulting in the use of *'use more group work in the classroom.'* Using team work in a classroom setting was prosed as a key delivery change on return to teaching. One participant commented that *'team work (creates a learning experience where) all can learn from each other.'* Team work also helps students with their time management where groups are working towards *'deadline pressures'.* The Bridge21 experience had encouraged one participant to *'use more experiential learning in classroom'* but had also provided others with a mechanism by which to help their *'students can help each other,'* as *'student lead learning is the way forward!'* One key learning participant had taken from the Bridge21 CS CPD experience was the knowledge and practice to implement a self-director approach to teaching and learning in the classroom, either for use in helping students explore some of the complexity surrounding learning to use computing tools and write computing programmes, or as a mechanism for changing general subject delivery to help engage students.

VIII. CONCLUSIONS

This paper set out to investigate teacher reactions towards the Bridge21 CS CPD programme. The previous analysis and subsequent discussion indicate that teachers' reactions towards the programme were positive (see Table I). Teachers also expressed how they intended to use aspects of the Bridge21 Activity Model for CS delivery and move their teaching practice, and student learning towards a more self-directed, 21C approach.

Not only has our approach introduced teachers to CS topics but has opened some teachers' minds *'to new content and methodologies'.* This suggests that there is a move towards *'more learning by discovery / more peer learning'.* A combination of the Activity Model and using problem solving and visual programming languages such as Scratch as a starting point has helped address a number of the difficulties associated with teaching novice programming.

This CPD programme, using the Bridge21 Models helped CS teachers both experience and practice using techniques designed to combine self-directed learning, computing and programming activities and gain the experience, expertise and confidence needed to empower teacher in their own delivery of CS in their schools.

ACKNOWLEDGMENTS

First, the authors would like to thank all the post primary school teachers involved in this research whom generously gave their consent to include written contributions which appear in this paper. Second, the authors would like to thank all the staff at Bridge21 (www.Bridge21.ie), Trinity College Dublin, Trinity Access Programme (TAP), and Centre for Research into IT in Education (CRITE) for their continued support and guidance, and finally to Google Inc. for funding this research paper under the Trinity Access 21 initiative.

Engage K-12 Students in Engineering: Model for Engineering Project Activities to Inspire K-12 Students to Pursue Careers in Engineering

Ramakrishnan Sundaram
Gannon University, sundaram@gannon.edu

Abstract - This paper discusses the model to create and implement the exploratory “Engage K-12 students in engineering” program to inspire K-12 students to pursue careers in engineering disciplines. Through this program, the K-12 students will participate in engineering project activities with science, technology, engineering, and mathematics (STEM) components. Engage K-12 students in engineering will (a) raise the level of awareness among K-12 students of the promising careers in the engineering disciplines upon graduation with baccalaureate and/or advanced degrees (b) establish and sustain the dialog between the K-12 schools and the University to encourage the K-12 school students to pursue and excel in subjects with STEM components (c) promote the interaction between the engineering faculty at the University and the K-12 school students through activities which deliver critical STEM components. “Engage K-12 students in engineering” will be identified at all levels of K-12 STEM education and will be delivered to a widespread audience of K-12 students through (a) direct outreach activities such as on-campus visits, (b) extended outreach activities through cyber-learning networks, and (c) University partnership with the K-12 schools.

Keywords – STEM-based engineering projects, Outreach

INTRODUCTION

The factors that contribute to the high drop-out rates of students from the STEM school systems and the low enrollment of school graduates in the STEM colleges and universities across the U.S. include (a) lack of awareness of the promising careers after the successful completion of STEM-based school and college education (b) STEM curricula in K-12 schools which fail to inspire the students to develop a life-long passion for STEM learning (c) inadequate preparation and the lack of technological resources available to the K-12 STEM teachers to effectively deliver STEM teaching. The partnership between the engineering departments at Universities which offer the ABET-accredited baccalaureate degrees and K-12 schools with STEM curricula is viewed as a means to exploit the synergy between the two environments and can address the critical issues facing STEM learning and teaching in the following areas.

(1) *Introduce revisions to K-12 STEM courses and curriculum*

The K-12 curriculum must include new and revised STEM courses which introduce the engineering design process and teach students how to use engineering technology to solve engineering problems with design and cost constraints. These courses will incorporate project-based and goal-oriented STEM learning experiences to supplement the traditional STEM curriculum.

(2) *Raise student motivation and desire to learn STEM concepts*

The proliferation of the internet technologies with multimedia make it possible to deliver the hands-on STEM-based project activities as a virtual educational experience to a geographically widespread audience of K-12 students and teachers. The easy access to STEM education materials will (a) encourage the students to advance their understanding of basic and advanced STEM concepts (b) equip the K-12 STEM teachers with the knowledge and skills required to sustain the STEM learning experience for their students.

(3) *Improve the retention of STEM concepts by the students*

The students participating in the outreach and cyber-learning environment will reinforce the learning of STEM components through activities and interaction that is structured, consistent, and constantly motivating. The students will improve their retention of STEM concepts learned in the classroom through hands-on project activities.

This paper documents the work-in-progress to create and implement the “Engage K-12 students in engineering” program. The program will consist of hands-on STEM learning activities delivered through forms of outreach [1]-[5] and collaborative partnerships between the University and K-12 schools. The outreach from the University to the K-12 schools is broadly classified as direct and indirect.

The direct outreach will include the following.

- (1) K through pre-middle school students participate in day-long introductory STEM-related activities
- (2) middle school students participate in day-long STEM-based engineering project activities
- (3) high school students participate in day-long STEM-based engineering project activities.

The extended outreach will take place through cyber-learning networks. The cyber-learning networks will create the internet-based environment for presentation of and access to STEM learning materials. The networks would create the environment to enable widespread and remote K-12 schools and school districts to participate in the activities and thus have a *virtual* STEM education experience. In addition, the K-12 teachers can adopt new and/or revised instructional practices to raise the STEM learning standards of the students.

Section 2 provides details of past and on-going direct STEM outreach initiatives launched by the University in general as well as by the Electrical and Computer Engineering (ECE) department in particular. Section 3 identifies one of the cyber-learning infrastructures to deliver the proposed extended STEM outreach initiative. Section 4 addresses the evaluation and dissemination of the proposed outreach project. Section 5 summarizes the conclusions and work planned for the future of the “Engage K-12 students in engineering” program.

SECTION 2: DIRECT OUTREACH

The ABET-accredited undergraduate engineering programs at our University can establish and sustain “Engage K-12 students in engineering.” The engineering laboratories are equipped with state-of-the-art equipment to deliver STEM-related project activities to enhance the STEM learning by K-12 students. The direct outreach programs are identified in the following categories.

- (1) Discipline-specific
- (2) Broad engineering
- (3) Engineering summer camp
- (4) Engineering explorer program

(1) Discipline-specific

The ECE department at our University hosts *ECE day* [5] during its spring session (typically, the month of April). ECE day features project activities for high school students in electronic circuits, wireless communication, wind-based electricity generation, and embedded system design through hands-on laboratory activities related to project design, test and validation. The students work on the project under the guidance and supervision of the ECE faculty member and undergraduate students assigned to coordinate the project activity. The project activity lasts for about one hour and is intended to stimulate the student interest in practical, real-world STEM-based applications of engineering principles. The ECE projects are summarized as follows:

Project title: *Renewable energy mini project -- wind power*
Project summary:

The students worked with a small-scale windmill, 5” generator, wire, and LED to convert the wind power into electricity and power the LED.

Project title: *Traffic signal control circuit*

Project summary:

The students operated the three-light traffic signal set up on the printed circuit board (PCB) with timer and counter chips.

Project title: *ZigBee for Wireless Communication*

Project summary:

The students configure communication devices to create a wireless network and demonstrate “*instant messaging*” over the network.

Project title: *Logic circuit and FPGA design*

Project summary:

The students perform logic circuit design through the capture of schematics and execute their design on the FPGA board.

Figure 1 illustrates the flow of project components in one of the ECE laboratories during the ECE day event. The students engage in a similar sequence of activities in each of the four ECE labs over an interval of four hours.

Figure 1. Project (a) overview (b) activity (c) test and (d) validation.

(2) Broad engineering

The engineering departments at our University have hosted Engineering Day (E-day) events for high school students to participate in pre-engineering STEM-related project activities in the following engineering programs - electrical and computer engineering, environmental engineering, and mechanical engineering.

Electrical and Computer Engineering (ECE):

Project title: *Traffic signal control*

Project summary:

The students assembled the circuit to control the operation of red, yellow, and green lights of a three-light traffic signal. Environmental Engineering (ENV):

Project title: *Water Filtration Hydraulics*

Project summary:

The students operated lab-scale versions of sand filters to purify drinking water based on the counter flow model. The “head loss” is measured and the results are compared to the head loss predicted by theoretical equations.

Mechanical Engineering (ME):

Project title: *Watercraft*

Project summary:

In this activity, the students build a platform to float on water for a specified duration while supporting a weight. The students are scored based on efficiency of material used and the design objectives met.

(3) Engineering summer camp

The Engineering summer camp is designed for students who are entering their junior or senior year of high school with the interest and aptitude to pursue careers in engineering. This week-long camp introduces the students to principles of engineering, the engineering design process, methods for scientific computation and issues related to the environment. Students gain hands-on experience with design projects in mechanical engineering, electrical and computer engineering, and environmental engineering. The students work in teams of two to three members and compete in contests to determine the design with the best features.

(4) Engineering explorer program

This program introduced local area high school students to the undergraduate electrical and mechanical engineering degree programs at our University. The students participating in this program would visit the campus for two hours, one day each week during the first seven weeks of the spring semester (January through May). The activities would take place after the students concluded their school activities for the day. During each meeting, there would be (a) laboratory demonstrations by engineering faculty and undergraduate engineering students and, (b) Engineering design projects which can be completed in at most a couple of hours.

The proposed initiative comprises (a) identification of STEM-based engineering project activities for K-12 students (b) set up of the schedule for direct outreach (c) creation and delivery of the STEM educational materials through cyber-learning networks.

Figure 2 illustrates the direct outreach activities and schedule for all grades of the K-12 students. The students in each grade category will participate in STEM-based engineering project activities tailored to their level of understanding of STEM concepts. These project activities will range from introductory to advanced across the K-12 grade structure and offer the students the opportunity to relate engineering concepts to engineering design and practice.

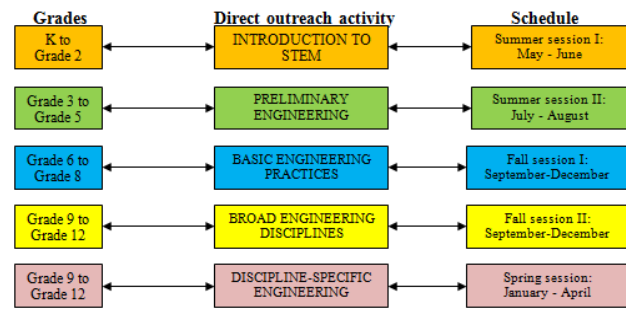

Figure 2. Direct outreach across STEM K-12.

Summer session - I: *E-Day for K to grade 2*

Occurrence: Two per month (May – June)

Theme: *Introduction to STEM*

The direct outreach activity for students from K to grade 2 consists of simple and introductory STEM projects to motivate the students toward STEM learning. The emphasis is on the demonstration of the use of engineering to solve problems in daily life.

Summer session - II: *E-Day for grades 3 to 5*

Occurrence: Two per month (July – August)

Theme: *Preliminary engineering in STEM*

The direct outreach activity for grade 3 to grade 5 identifies STEM projects to explore creative approaches to solving engineering problems using mathematics, science, and technology.

Fall session - I: *E-Day for grades 6 to 8*

Occurrence: One per month (September – December)

Theme: *Broad engineering*

The middle school students from K-12 programs with STEM components participate in engineering project activities which engage the students in problem solving with constraints on design and cost at their level of STEM education.

Fall session - II: *E-Day for grades 9 to 12*

Occurrence: One per month (September – December)

Theme: *Broad engineering*

The high school students from K-12 programs with STEM components participate in engineering project activities which challenge the STEM learning of the student in the process of engineering design, test, and validation.

Spring sessions: *ECE, ENV, ME Day*

Occurrence: Each discipline assigned to one day in the specified month (January – April)

Theme: *Discipline specific*

The high school students engage in laboratory-based sessions in each discipline. For instance, the ECE project activities take place in four different ECE laboratories. The

duration of each activity is 55 minutes during which the students are assigned the engineering design problem, given the required background material and step-wise instructions. The students must then build and test their engineering solutions.

Table I illustrates the schedule for the set up of E-day activities in the fall session in three categories of items to be addressed i.e. pre-activity, activity, and post activity.

TABLE 1
SET UP SCHEDULE OF E-DAY

Pre-activity items	Activity	Post-activity items
Admissions contacts schools; schedules date for E- Day	Mail invitations	Create the roster of participants and their contact information
Engineering departments prepare for E-Day	E-Day	Departments follow through with the participants (coordinate with admissions)
Admissions contacts schools; determines the students with interest; offers incentives to enroll in one of the engineering programs at the University	Invite these students to the discipline-specific Spring sessions	Continue the dialog with these students; set-up the mentoring process for students who confirm enrollment
Assessment setup for identifying "intend" to major in engineering or another subject	Matrix tracking of student's development to apply to other schools in engineering fields	Track students enrollment in engineering at other universities/colleges

The schedule for set up of the discipline-specific outreach day would be similar to Table 1 but the E-day would be discipline specific for instance, ECE day or ENV day.

SECTION 3: EXTENDED OUTREACH

The proposed initiative will lead to the creation of new instructional material, laboratory experiments, and design projects. The cyber-learning network shown in Figure 3 will be created to disseminate the content through secure internet sites. The K-12 students as well as their teachers will access these sites to obtain instructional material or engage in interactive sessions with the engineering faculty responsible for the course content. The cyber-learning network will benefit the schools and school districts as follows:

- (1) enhance the laboratory experience of the student
- (2) interact with the engineering faculty to motivate and broaden the learning process
- (3) overcome the inability of the students and teachers to commute to Gannon University due to the weather or other unforeseeable reasons
- (4) engage remote school districts with no means to bus the students to the Gannon campus
- (5) possibly reduce/eliminate scheduling conflicts within the regular day by organizing the laboratory session after school hours

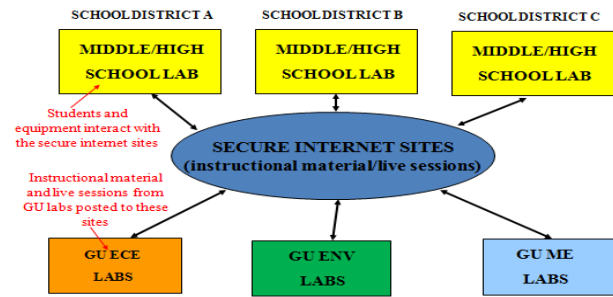

Figure 3. Cyber-learning network.

SECTION 4: PROGRAM EVALUATION & DISSEMINATION

The program evaluation comprises *external* and *internal* evaluation. The external evaluation will be conducted by a qualified STEM program evaluator. The internal evaluation will consist of *formative* and *summative* evaluation plans based on surveys created for each activity in the direct and extended outreach components of the initiative. The *summative evaluation for direct outreach* will consist of short-term and long-term survey analysis. The surveys will be administered as part of each project activity. The program will be disseminated through (a) laboratory manuals (b) the cyber-learning network (c) conference presentations and journal publications (d) community news.

SECTION 5: CONCLUSIONS & FUTURE WORK

The "Engage K-12 students in engineering" program promotes outreach and partnership between the undergraduate engineering institution and K-12 schools through engineering project activities for the K-12 students. The outreach comprises the implementation of direct and extended outreach aimed at year-round engagement with the K-12 STEM schools in order to inspire and guide the K-12 students toward undergraduate engineering education and careers in engineering disciplines. Future work includes completion of the set up of the cyber-learning network.

Abstract— While there have been efforts to integrate engineering into K-12 through the planned development of standards, only recently have these plans come to fruition, albeit with seemingly little progress to appropriate integration. While the Common Core State Standards and the Next Generation Science Standards (among others) have provided a preliminary attempt to bring engineering into K-12, the research within this paper invites a different perspective on evaluating the preparation students are receiving for the first year of engineering. The hypothesis surrounding this review suggests that there exists a mapping of topics found in a first year engineering course, the classification scheme, into the Common Core State Standards for Mathematics and Next Generation Science Standards. Such a mapping would be multifaceted, enabling the construction of lessons tied to not only to Common Core, but also to the topics in the Classification Scheme. This paper will present the argument for the flexibility between the documents. Discussion on applications to advance K-12 Engineering Education will also be included with particular attention to the use of the Classification Scheme for First Year Engineering Courses as a foundation for the STEM pathway curriculum.

Keywords—K-12; curriculum; taxonomy; standards

I. INTRODUCTION

The Common Core State Standards for Mathematics and Next Generation Science Standards are recent attempts to standardize the knowledge expected of a high school graduate in the United States [1, 2]. These educational standards have been adopted or modeled after in multiple states and define the learning objectives for students in K-12 [3]. Separate standards for Engineering within K-12 have been considered, but have been deemed unsustainable given the current pool of teachers with the sufficient qualifications to integrate the subject into their classrooms [4]. Teachers who have attempted to incorporate engineering into their courses have often struggled due to the time constraint of covering the required standards by which students are formally assessed. In spite of a teaching force largely unprepared to teach engineering [5], there is considerable interest in creating pathways to success in a STEM degree program through the existing curriculum [6].

We will begin by examining the educational standards themselves and the current status of engineering in K-12. Then, methods of STEM integration will be discussed along with best practices associated with the idea of integration.

A. Educational Standards

The prevailing educational standards in use are the Common Core State Standards for Mathematics and the Next Generation Science Standards. From an organizational standpoint, the structure of Common Core and the Next Generation Science Standards are fundamentally similar, but differ in areas. For instance, the Common Core State Standards for Mathematics document is divided into two distinct sections, namely the Standards for Mathematical Practice and Mathematical Content Standards [1]. The Standards for Mathematical Practice (SMP) define eight skills that are expected to be developed throughout the student's mathematical career (which were inspired by the *Principles and Standards for School Mathematics*) [7]. All eight of the standards are listed below:

- SMP.1) Make sense of problems and persevere in solving them.
- SMP.2) Reason abstractly and quantitatively.
- SMP.3) Construct viable arguments and critique the reasoning of others.
- SMP.4) Model with mathematics.
- SMP.5) Use appropriate tools strategically.
- SMP.6) Attend to precision.
- SMP.7) Look for and make use of structure.
- SMP.8) Look for and express regularity in repeated reasoning.

The Mathematical Content Standards contain specific statements of skills that students must master. The skills are specified by grade level for grades K-8. Beyond these grades, the High School section of the content standards elect to split into six categories of topics: Number and Quantity, Algebra, Functions, Modeling, Geometry, and Statistics & Probability [1]. In order to compensate for varying curricula and student ability, the separated topics tend to be much easier to apply rather than topics grouped by grade level. To illustrate, the

following excerpt from CCSS.MATH.CONTENT.HSN.TF.C.9 (this is a code identifying where the standard is placed by section, grade level, domain, and specific standard) in the context of the Common Core State Standards:

“Prove the addition and subtraction formulas for sine, cosine, and tangent and use them to solve problems.” [1]

and another example from the Number and Quantity section:

“Explain why the sum or product of two rational numbers is rational; that the sum of a rational number and an irrational number is irrational; and that the product of a nonzero rational number and an irrational number is irrational.” [1]

It should be made clear that these individual statements of proficiency are more complex and expect a particular performance from students on the associated standardized assessments unlike simplistic bulleted topics of the past. This is highlighted in the action verbs used to identify the level of competency expected from the student: prove, explain, and so on (reminiscent of *Bloom’s Taxonomy*).

The Next Generation Science Standards are structured in a slightly different fashion and the topics themselves are primarily inspired by the National Research Council’s *A Framework for K-12 Science Education* [2, 8]. A topic begins with the performance objectives, as one would see if reading through the Common Core State Standards for Mathematics. A reader would then see what are called “Foundation Boxes” with the following headings: Disciplinary Core Ideas (DCIs), Science and Engineering Practices, and Crosscutting Concepts [2]. Figure 1 provides a general layout of how the boxes appear in the Next Generation Science Standards.

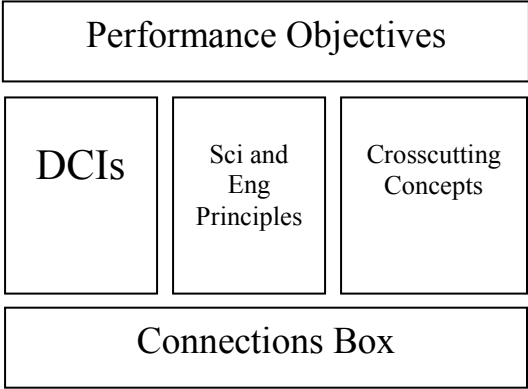

Fig 1: Layout of the Next Generation Science Standards

The Disciplinary Core Ideas are fundamentally the same as the performance objectives, albeit some additional clarification provided by the writing team after “unpacking” main ideas from the science disciplines. Any performance objectives that could be used to construct the Disciplinary Core Ideas are listed in the Science and Engineering Practices category. Finally, Crosscutting Concepts contains relevant performance objectives that highlight the dependence that science has on engineering and vice versa.

Moreover, the last section associated with each broad topic is the “Connection Box” which is also separated into three boxes: connections to other DCIs in this grade level, articulation of DCIs across different grade levels, and connections to the Common Core State Standards [2]. “Connections to other DCIs in this grade level” is self-explanatory; a list of related performance objectives are given. “Articulation of DCIs across grade levels” lists the DCIs related to other DCIs which provide either a foundation for the given topic or build on DCIs for later grades. The “Connections to the Common Core State Standards” contains standards from Common Core English Language Arts & Literacy and Mathematics that are directly related to the performance objectives. This particular section will be revisited later in the paper.

Beyond Common Core and the Next Generation Science Standards, separate standards for Engineering within K-12 have been considered and implemented such as the Massachusetts State Standards for Engineering and Technology [9], but others have been typically unsustainable on a larger scale [4].

B. Engineering in K-12

Often existing outside of the standard curriculum, particular portions of STEM do not reach a large population of students. A few notable engineering, or pre-engineering, programs do exist and have been successful over the past few years since their creation.

Project Lead the Way (PLTW) is likely the most visible program that is prepackaged with existing professional development opportunities [11]. Another advantage is the common assessment associated with the Project Lead the Way curriculum. The Tufts Center for Engineering Education and Outreach with LEGO Education offer the LEGO Engineering program to be integrated into the curriculum at any feasible age group [12]. Unlike Project Lead the Way, this particular attempt at integration is done through a familiar medium which is naturally hands-on. The familiarity can be exploited particularly in lower grades due to the average age of students, but this can certainly be effective in higher grades [13]. While LEGOs can be flexible in some respect, there are a few limitations – mostly in design freedom.

Another leader in engineering curricula, the Boston Museum of Science, developed what is currently known as Engineering is Elementary. This outreach rivals the Project Lead the Way program by also offering professional development opportunities in addition to rich methods of assessment for student learning [14]. Also, as a program built from the ground up, the Engineering is Elementary curriculum is aligned to the set of standards native to the Boston Museum of Science, namely the Massachusetts State Standards.

Schools created outside of the traditional K-12 systems often focus on project based learning; for example, MC2STEM High School in Cleveland is one such school [15]. Other than project based learning, other methods of integrating engineering include problem based learning and model eliciting activities. These three different, but related, types of activities and pedagogies are all applicable for instilling a

STEM state of mind. A brief summary of these three topics are as follows:

1) *Project Based Learning*

Within the context of project based learning, students react to a real-world, authentic scenario. The teacher guides the students through a plan beginning with preliminary research, followed by analysis, and concluding with performing the design process. The key to project based learning is requiring the students to present to an authentic audience once the project is complete [16].

2) *Problem Based Learning*

Students begin with the presentation of a problem, which is the primary motivation. Problem based learning is similar to project based learning in the sense that the problem is wholly dependent on an authentic real life scenario. Another similarity that can be drawn from project based learning is the ill structured nature of the problem, where not all of the information is given. Students are required to research and use appropriate resources at their disposal in order to solve the problem [17].

3) *Model Eliciting Activities (MEAs)*

This type of activity is far more involved than both problem and project based learning. Similarities to the previous two pedagogies are obvious, such as using an authentic scenario - preferably an appropriate application in STEM. Students are required to develop a model, either physical or purely mathematical, in order to solve a real world problem. The set-up of MEAs are purposely designed to be as realistic as possible, even to the point of having memos from their "customer" delivered to the students at the appropriate times. The rigor is the distinction with an MEA, both in creating and implementing them. Plenty of MEAs already exist, but finding adequate classroom time is the issue [18].

Through these three different avenues to incorporate STEM, particularly engineering, into the curriculum, we turn to the guiding principles for K-12 Engineering Education [19]:

Engineering design should be emphasized – As a centerpiece of engineering, design needs to be the focus of modeling and analysis when dealing with what we would call an "engineering problem."

Appropriate STEM knowledge and skills should be incorporated – Without a strong basis of skills in the context of STEM, we cannot expect students to succeed in the higher level tasks within science, math, engineering, or technology careers.

Engineering habits of mind should be promoted – The "habits of mind" refer to the necessary skills for the 21st century citizen: systems thinking, creativity, optimism, collaboration, communication, and ethics.

C. *Integration of Engineering in K-12*

The report by the National Academy of Engineering, *Standards for K-12 Engineering Education?*, defines *infusion* as incorporating learning objectives of one discipline in standards for another discipline [10]. In this case, it is simple

to bring the guiding principles for K-12 engineering education into the mix of the current curriculum. Another approach, called *mapping* in the report, involves drawing attention to how and where main ideas from a discipline naturally relate to the standards of another discipline [4].

By combining these two methods, the principle of infusion can be successfully used in order to allow engineering content to be more prominent in STEM standards, better communicate the relationship between engineering and other disciplines, and – as a result – engineering would be included in the standards for assessment. After a successful mapping, different connections that the developers of the standards did not see can be revealed, and the likelihood of engineering being used as a motivation tool can be increased.

In *STEM Integration in K-12 Education: Status, Prospects, and an Agenda for Research*, the Committee on Integrated STEM Education summarizes three key implications for STEM integration initiatives: (1) integration should be made explicit, (2) knowledge of individual disciplines should still be supported, and (3) more integration is not necessarily an improvement [20]. Issues primarily begin in the urge to string various concepts together in the name of making connections between subjects. We now turn to a tool which can facilitate making connections to engineering while following the guiding principles for K-12 engineering education and the Committee on Integrated STEM Education's recommendations.

II. A DIFFERENT LENS FROM FIRST-YEAR ENGINEERING

While *not* a set of standards by nature, The *Classification Scheme for First Year Engineering Courses* is a taxonomy that outlines the possible topics that can be found in a first year engineering course [21]. Created with support from a National Science Foundation grant, the scheme allows instructors to classify the content of their courses using a common tool [21]. In addition, students transferring to one university from another can be awarded accurate credit for an introductory course based on the classification results.

For organizational purposes, the taxonomy is divided into eight primary aspects, or main topics: Communication (COMM), Engineering Profession (ENPR), Math Skills and Applications (MATH), Design (DESN), Global Interest (GLIN), Professional Skills / Latent Curriculum (PROF), Academic Success (ACAD), and Engineering Specific Technology/Tools (ESTT) [22]. These main topics are each given by a four letter code, as shown. A topic that is listed under a main topic is given a Roman numeral and sub-topics related to the one level above are given letters. Any topics under a sub-topic are given numbers.

To illustrate the ID assignment, *Empirical Functions*, which is under Math Skills, is given the following way:

Main Topic MATH, Topic IX, Sub-Topic A, Specific Topic 1.

Using the organizational methodology, this piece's ID would be MATH IX.A.1. Notice that the structure is reminiscent of Common Core and the Next Generation Science

Standards. Thus, a convenient mapping between the taxonomy and the other educational standards is feasible. In fact, a fair amount of work has been done to map between various sets of standards already.

A. Mapping Standards

Plenty of efforts have attempted to make explicit connections between standards. One such attempt was presented by Palincsar in her argument for meeting objectives of Common Core State Standards for Science and Next Generation Science Standards simultaneously. This is primarily achieved by using principles of literacy and oral language to facilitate the learning of concepts [23]. Another exploratory study by Mayes and Koballa provides an alignment between the Standards for Mathematical Practice (SMP) and Scientific and Engineering Practices (SEP) as defined in the Next Generation Science Standards [24]. The eight Scientific and Engineering Practices are taken from *A Framework for K-12 Science Education* [8] and are listed below:

- SEP.1) Asking questions (for science) and defining problems (for engineering).
- SEP.2) Developing and using models.
- SEP.3) Planning and carrying out investigations.
- SEP.4) Analyzing and interpreting data.
- SEP.5) Using mathematics and computational thinking.
- SEP.6) Constructing explanations (for science) and designing solutions (for engineering).
- SEP.7) Engaging in argument from evidence.
- SEP.8) Obtaining, evaluating, and communicating information.

The connections drawn by Mayes and Koballa are shown in Figure 2.

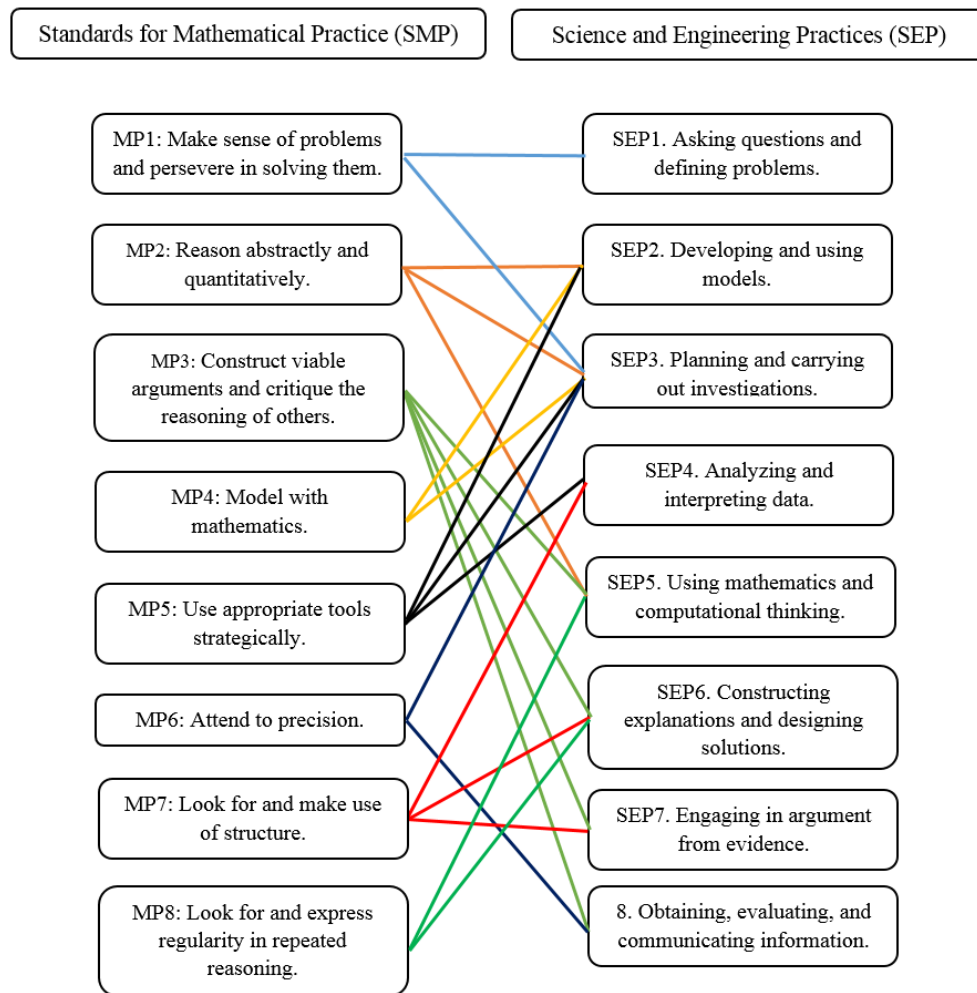

Fig 2: Mapping of Alignment between the SMP and SEP [24]

Another model is offered by Stage et al. which connects Common Core State Standards for English & Language Arts, Mathematics, and the Next Generation Science Standards [25]. To some respect, the model can be considered an expansion of Mayes and Koballa with the distinction being that the Science and Engineering Practices are not directly mapped to the Standards for Mathematical Practice. However, due to the lack of a direct mapping, Stage et al. claims that the intersection of math and science is merely the use of models and mathematical/computational thinking while Mayes and Koballa assert that the relationship is much tighter [24,25]. In addition to the external studies, the authors of the Next Generation Science Standards provided a mapping of their own into the Common Core State Standards.

In Appendix L of the Next Generation Science Standards, the authors noted more obvious connections to the Common Core State Standards for Mathematics [2]. The authors claim that three particular standards for mathematical practice are related to science: “Reason abstractly and quantitatively” (MP.2), “Model with Mathematics” (MP.4), and “Use appropriate tools strategically” (MP.5). The authors then proceed to define connections that are more explicit.

III. UTILIZING THE CLASSIFICATION SCHEME FROM A CURRICULUM EVALUATION PERSPECTIVE

First-year programs across the nation typically feature an introductory curriculum featuring a semester or yearlong “Introduction to Engineering” course or course sequence [21]. Upon examination of these courses, variation in content is prevalent [26]. For instance, a course from one institution could focus on MATLAB programming while a course at a different university could emphasize technical communication. Through the development of the taxonomy, the composition of first year engineering was distilled into predictable topics that could appear within an introductory course. The process of filtering through the taxonomy is referred to as “classifying a course,” naturally. Most applications of the classification scheme have been with the intention of program evaluation [21], but data has been collected in an attempt to define a *typical* first year engineering course [26].

Statistically, the summary described in [26] is limited to the sample from which the courses were taken; however, there is some insight that can be culled from the preliminary results in the context of preparing a STEM pipeline. In the previously reported study, a sample of 28 classified courses from 24 different institutions were used from an NSF sponsored workshop at the First Year Engineering Experience Conference in Pittsburgh in 2013 [26]. In the analysis, the total number of times each topic was marked as covered in the course was recorded on a separate document; the five number summary (minimum, first quartile, median, third quartile, and maximum) was calculated for each of the eight main topics.

For the sample, communication and professional skills were emphasized, but mathematical skills were surprisingly absent – likely due to the fact that courses such as Calculus are taken at the same time.

As a reflective piece, we invite K-12 educators and administrators to examine their definition of engineering and

how well they believe their students are being prepared for the first year of engineering. As evidenced in the literature, the perception of engineering is generally not on mark, which serves to spread myths about the profession. Moreover, the development of students as proficient communicators is of considerable interest when considering the sample since emphasis appears to be placed on team-based and professional communication. Finally, preparation in mathematics is of concern. Thus, the following guiding questions are offered for those interested in using the *First Year Engineering Classification Scheme* as a tool for curriculum evaluation:

- 1) *How well does the curriculum address the subject of engineering?*
- 2) *How well does the curriculum develop effective communicators?*
- 3) *How well does the curriculum develop students that are proficient in mathematics?*

The taxonomy provides a convenient bridge to these questions using *keywords*. Recall that the Common Core State Standards and the Next Generation Science Standards are phrased in such a way that keywords can be pulled and tied.

The topics outlined in the taxonomy are deliberately lumped to simplify the classification of courses and reduce statistical variables, which creates a useful correspondence to the domains found in the Common Core State Standards. For instance, CCSS.MATH.CONTENT.HSF.TF, the domain on Trigonometric Functions perfectly maps to MATH I.0.0 (Trig Review) in the classification scheme. In the Next Generation Science Standards, the most relevant section would be HS-ETS1, “Engineering Design.” Indexed under this is the first performance expectation HS-ETS1-1, “Analyze a major global challenge to specify qualitative and quantitative criteria and constraints for solutions that account for societal needs and wants.” [2] Plenty of topics from the taxonomy will map to this such as GLIN I.0.0 “Grand Challenges,” GLIN II.0.0 “Concerns for Society,” and DESN IV.0.0 “Criteria and Constraints.”

IV. IMPLICATIONS

Simply using the taxonomy as a guide to integrate engineering while simultaneously covering standards should be a welcome tool for the K-12 environment. To reiterate, the report, *STEM Integration in K-12 Education: Status, Prospects, and an Agenda for Research*, the Committee on Integrated STEM Education provides three key implications for STEM integration initiatives, one of which is that integration should be made explicit [20]. Much of what K-12 currently does can be reframed as engineering; this is the concept of “mapping” discussed earlier.

One distinct benefit of the mapping is bringing awareness to the community of K-12 educators and demystifying the profession. Knowing what can be found in the context of first year engineering can aid in the reforming of curricula in order to feed competent students into the STEM pipeline.

In addition, much of engineering lends itself to the Standards for Mathematical Practice – especially modeling. Making sense of problems and reasoning abstractly and quantitatively are naturally engrained in the process of creating design solutions. The students need to “construct viable arguments and critique the reasoning of others” to decide on the most feasible design to realize, and so on. Engineering is hidden in the K-12 curriculum, it is hoped that this mapping will aid in solving the subject’s identity crisis.

Possible actions for first year engineering programs could include using the classification scheme in order to determine what is covered in their courses in terms of the topics and codes. Becoming more familiar with the K-12 standards can also be advantageous by adjusting expectations for incoming first year students in terms of their math and science skills. Both schools and universities can use the scheme for curriculum development and evaluation, but with the realization that covering all of the topics listed in the taxonomy is not feasible in a single course.

V. CONCLUSION

The *First-Year Introduction to Engineering Course Classification Scheme* is a tool that was developed and validated through testing with multiple institutions. The taxonomy has been a useful tool for departments assessing the content of their introductory curricula.

This literature review suggests that there exists a clear mapping of topics found in an arbitrary first year engineering course, the classification scheme, into the Common Core State Standards for Mathematics and Next Generation Science Standards. This mapping would be flexible in order for the construction of lessons tied to all three documents naturally.

It is hoped that K-12 finds the taxonomy to be a useful tool for the examination of curricula and tying appropriate standards to lessons.

Abstract—In the history of science and technology, many creative and innovative cases were found in contradiction problem solving. However, most research about creativity has rarely paid attention to contradiction solving so far. This paper introduces the way how adolescent solves contradiction problems with the Butterfly diagram, and shows the effects of the Butterfly diagram education in primary and secondary schools on contradiction problem solving ability. The Butterfly diagram uses symbolic notation and systematic representation for solving contradiction problem. It shows the structure of a given contradiction problem visually. Drawing a Butterfly diagram for solving a contradiction problem can reduce the problem space because it helps to figure out the problem structure and the problem type of the given problem. In the three experiments of this paper, we analyzed the effects of the Butterfly diagram education on contradiction solving ability. The students who learned the Butterfly diagram have awarded for 9 years (2007~2015) in a row when they participated in invention festivals. Three primary school students, 12 secondary school students, and 46 college students have awarded in invention festivals so far. Among them, 5 middle school students, 4 high school students, and 15 college students, and one graduate school students have registered 18 patents.

Keywords—creative problem solving; The Butterfly diagram; contradiction problem solving; TRIZ

I. INTRODUCTION

In the history of science and technology, many creative and innovative cases have solved contradiction problems. For example, James Watt made a break-through in Newcomen steam engine by solving the contradiction that the cylinder of the engine should be hot and cold at the same time [1]. The second example can be found in the public key infrastructure. When two parties communicate with each other trustworthily on the internet, the two parties should share a private key to construct a secure channel. However, the private key should not be opened to others due to security. Thus a contradiction occurs in this problem. The private key should be opened and not be opened for secure communication. In 1976, Diffie and Hellman proposed the innovative public key concept. E-Commerce became possible due to their idea by separating

key roles into two: one is locking with a public key and the other is unlocking with a private key [2].

Duncker's radiation problem has been a well-known problem in the area of problem solving psychology. It is described as follows [3]:

“Suppose you are a doctor faced with a patient who has a malignant tumor in his stomach. It is impossible to operate on the patient, but unless the tumor is destroyed the patient will die. There is a kind of ray that can be used to destroy the tumor. If the rays reach the tumor all at once at a sufficiently high intensity, the tumor will be destroyed. Unfortunately, at this intensity the healthy tissue that the rays pass through on the way to the tumor will also be destroyed. At lower intensities the rays are harmless to healthy tissue, but they will not affect the tumor either. What type of procedure might be used to destroy the tumor with the rays, and at the same time avoid destroying the healthy tissue?”

Duncker's solution was dividing the intensity level of the ray into high and low. In other words, for destroying the tumor, the ray at the high intensity level was used, whereas for avoiding harmful effect to the healthy tissue, the ray at the low intensity level was used. Duncker's radiation problem has a contradiction that the intensity level of the ray should be high and low at the same time to solve the two conflicting problems. However, many research works on Duncker's radiation problem did not examine the problem from the contradiction resolution point of view [4][5][6].

Most research about creativity has rarely paid attention to contradiction problems so far because the western science since Aristotle has regarded contradictions as false, wrong thing, and empty set [7]. Due to this tradition, problem solving psychology in the west has classified problems into well-defined problems and ill-defined problems, or analytic problems and insight problems [8]. Many western researchers did not examine the problem from the contradiction resolution point of view [1]. Simonton, who had performed a lot of research on scientific discovery, explained that logic plays a secondary role in the generation of highly creative ideas. He argued that serendipity is important in truly original ideas and scientific discovery than logic [9]. He considered that creative

Chan Jung Park is the corresponding author of this paper.

idea cannot be solved by an algorithm consisted of a set of pre-determined steps.

Simon proposed that in order to solve complex problems, it is important to grasp problem types and to represent them appropriate [10][11]. The appropriate symbols and systematic representation enhance the problem solving ability of a problem solver [12][13]. So far, most of the research and the models for creative problem solving were descriptive [14]. However, the Butterfly diagram of this research proposes a systematic representation about contradiction problem using symbolic notation. The Butterfly diagram was motivated from TRIZ [14][15][16][17] originally. However, it overcame TRIZ's limitations, and the logical proofs about the Butterfly model was given in [1]. The Butterfly diagram helps to decide the right solution strategy for contradiction types by showing trade-off and contradiction relations of the given problem. The diagram contains the trade-off relation between the functions of a given problem and the contradiction relation between the system states generated for performing the functions. It shows the structure of a given contradiction problem visually [1]. The Butterfly diagram for contradiction problem solving can reduce the problem space by figuring out the problem structure and the problem type of a given problem [11][13].

This paper describes the way how adolescent applies the Butterfly diagram to contradiction problem solving, and shows the effects of the Butterfly diagram education in primary and secondary schools on contradiction problem solving abilities. In order to achieve these objectives, we performed three experiments to examine if the Butterfly diagram education affects the students' problem solving ability.

The first experiment is as follows: we selected the contradiction problems of the cannon ball and the installation art for measuring the students' contradiction problem solving abilities. The number of the students was 129. They solved one problem before they learned the Butterfly diagram. And then, they solved the other problem after they had learned the Butterfly diagram. Next, we analyzed the effects of the Butterfly diagram education on contradiction solving ability. The second experiment is as follows: we chose Duncker's radiation problem [3]. We analyzed the difference in the ratio of solving the radiation problem between the students who learned the Butterfly diagram and the students who did not. The third experiment checked if learning how to solve contradiction problems with the Butterfly diagram affected the students' growth mindset positively [18][19]. In Dweck's self-theory, people's mindset types are divided into 2: the fixed mindset and the growth mindset. According to the theory, people who have the growth mindset usually have a tendency to embrace challenges and to learn from failure [18].

The rest of our paper is organized as follows. In section 2, we review the drawbacks of TRIZ [14][15] and the mindset theory proposed by Dweck [18][19]. In section 3, we define a steps of our experiment. In section 4, we describe the results of the experiment. Finally, we conclude our paper in section 5. We discussed the reason and the practices about the students' increased contradiction problem solving ability in section 5.

II. BACKGROUND

A. TRIZ

TRIZ is the Russian acronym for the "Theory of Inventive Problem Solving". It was developed by Altshuller and his colleagues [14]. They found out that innovative inventions had something in common. The common thing was that the inventors had resolved contradictions without compromises [15].

We can find an example contradiction from a home bar link of a refrigerator produced by Samsung [20]. Recently, in many refrigerators have home bars (small doors) to take something out of the refrigerator easily without open the big door of the fridge. After opening the home bar, in order to prevent the home bar open fully and to close the door easily, GE invented home bar links and attached the links to the both edge sides of the home bar as shown in Fig. 1 (a). The links are expensive, but they are needed to open and fold the home bar door. In fact, there was a trade-off relation between function efficiency and manufacturing cost of the home bar link. Since Samsung had paid a lot of loyalty to GE for home bar links [20], Samsung started to develop a new method to open the home bar safely and to improve its aesthetic appearance with TRIZ researchers. Samsung Electronics eliminated the home bar link as shown in Fig. 1 (b) [21]. Samsung modified the home bar so that it performed the link's function by itself (Self-service principle of TRIZ 40 principles [22]). Samsung solved the contradiction by extending the latch of the home bar door behind the joint. There was no need to install links any more.

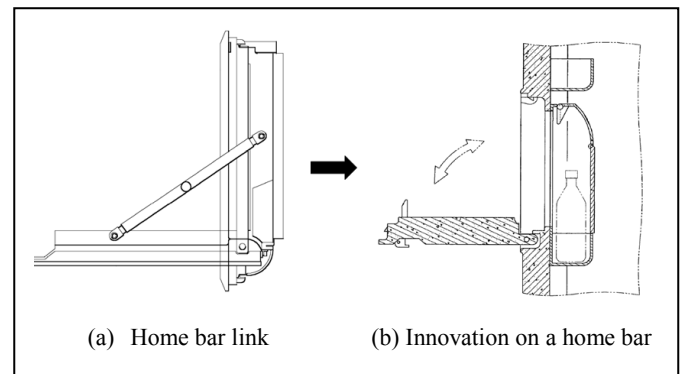

Fig. 1. A home bar innovation of refrigerator [21].

Even though TRIZ has contributed to problem solving area, it has a few limitations. Firstly, Altshuller and his colleagues established TRIZ having a set of rules found by inductive patents analysis not deduction [14]. Secondly, since they did not define TRIZ terminologies exactly, many researchers have defined the terms arbitrarily. Thirdly, TRIZ experts have insisted that TRIZ can avoid trial-and-errors such as Brainstorming, but this is not true. ARIZ-85c, the algorithm of inventive problem solving, has many steps [15]. Among them, the step 6.3 specifies "Go to step 1.4 and analyze another alternative if the chosen method cannot solve the problem correctly". This step tells us that TRIZ still has many trial-and-errors (a brute-force method) like other creative problem solving algorithms [23]. Fourthly, Altshuller

recommended that learners study more than 80 hours in order to apply TRIZ to the real problem in the preface of ARIZ-85c. It seems a long time for teenagers to learn TRIZ at schools. If we have a tool for teaching TRIZ easily to teenagers, then the teenagers will enhance their creative problem solving ability.

B. The Butterfly Diagram and the Butterfly Model

Every proof in mathematics consists of a chain of deduction. Deductive reasoning reaches a new true fact based on the already identified premises. The certainty of mathematics came from deductive proofs. Euclid published 'Elements' about 2,300 years ago. Euclid's Elements is innovative because it followed the proof systems that if an premise is true, then the conclusion is also true by using the deductive reasoning [24].

As Euclidean geometry derived 465 theorems based on 23 definitions, 5 postulates, and 5 axioms, the Butterfly model defined the components of the model firstly based on classifying contradiction problems into 9, and then performed a logical proofs about the optimal solutions of the 9 types of contradiction problems [1]. This approach is to adopt the method which divides a complex problem into a set of small problems, and then solve from the simplest problems to the most complex one like Descartes method.

The Butterfly diagram is a component of the Butterfly model described in [1]. The Butterfly diagram assumes the interconnectivity of a system that when some part of a system gets better, other part of the system gets worse, and vice versa [16][17]. It represents the interconnectivity with the relations caused by required functions required by a given problem. Fig. 2 shows a net. In the net, when a person pulls the area w , the area u shrinks on the contrary. In addition, there are a trade-off relation and a contradiction relation for a given problem in a Butterfly diagram[1]. The trade-off relation in a diagram can be depicted in rectangles containing two functions, w (wanted function) and $\sim u$ (not unwanted function), whereas the contradicting relations between two system states, s and $\sim s$. We explain the trade-off relation with a seesaw as shown in Fig. 3. Fig. 3 represents the importance of the fulcrum of the seesaw. In order to perform a specific function between the two functions of a system, it is important where to set the fulcrum. If the fulcrum is located closer to w (wanted function) than u (unwanted function), then the function w will be improved, and vice versa. Thus, the definite cause for generating a trade-off relationship depends on the location of the fulcrum (s or $\sim s$), where s and $\sim s$ have a contradiction relation [1]. The Butterfly diagram helps to select the right solution strategy for contradiction types by showing trade-off and contradiction relations of the given problem visually [16][17].

Next, the Butterfly diagram uses symbolic notation and systematic representation for solving contradiction problem [7]. Let us explain the necessity of symbolic notation and the systematic representation. Symbolic logic has advantages that eliminate the ambiguity of natural language and simplify the logical structure of a given problem. As a result, symbolic notations and systematic representations enhance the problem solving ability. If we know the structure and the type of a

given contradiction problem, we can solve the problem easier by using the representation [13][25].

Fig. 2. Interconnectivity between two areas of a net.

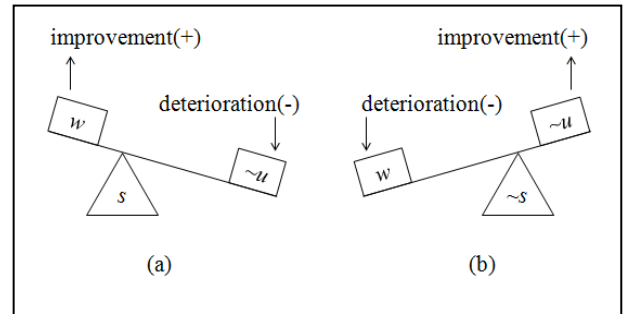

Fig. 3. The importance of the location of the fulcrum.

The conditional proposition ($w \rightarrow s$) in logic is equivalent to ($\sim s \rightarrow \sim w$) by the contraposition law. Therefore, for the relationship among conditional propositions with w , s , and u , we have a logical equivalence such that ($w \rightarrow s$) \equiv ($\sim s \rightarrow \sim w$), ($s \rightarrow u$) \equiv ($\sim u \rightarrow \sim s$). Base on these equivalences, we can draw a Butterfly diagram for the relationship among w , u , and s as shown in Fig. 4. In Fig. 4, let w be the wanted function to solve a given problem and s be the state caused by performing w . We describe it as $w \rightarrow s$. Next, let u be the unwanted function cause by the state s and $\sim u$ be the contradictory function of u . At this point $\sim u$ should make a trade-off relation with w . Then, $\sim u$ causes the state $\sim s$ by the contraposition law, and s and $\sim s$ have a contradiction relation by nature. The examples about Butterfly diagrams will be presented in the following section.

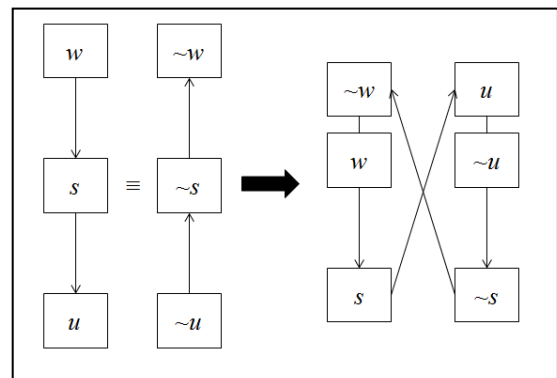

Fig. 4. Components of a Butterfly diagram.

The Butterfly model defines a problem, P , as a system, S , which is composed of 6 components, w , $\sim w$, u , $\sim u$, s , and $\sim s$ [26]. In the model, w is a wanted function of S , $\sim w$ is the contradictory function of w and u is the harmful function caused by satisfying s and the contradictory function of $\sim u$. $\sim u$ is the function that have a trade-off relation with w , s is a condition for supporting w , and $\sim s$ is a condition for supporting $\sim u$. At this moment, system state s and $\sim s$ have a contradiction relation. In summary,

$$P = S(w, \sim w, u, \sim u, s, \sim s).$$

In the Butterfly model, a contradiction relation is more concrete, and thus it has narrower problem space than trade-off relation. And then, the Butterfly can find out the solution strategy for the given problem easily by combining its trade-off relation and contradiction relation. After finding out its solution strategy, according to the type of the problems, the appropriate system states are applied to derive the problem solutions more precisely. The process of the Butterfly model as shown in Fig. 5.

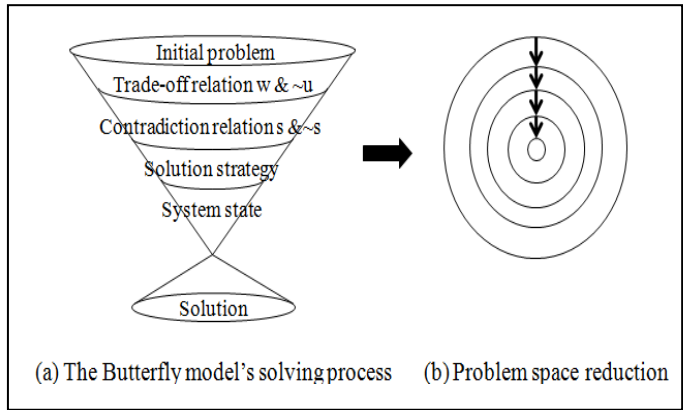

Fig. 5. The Butterfly model's solving process and its problem space reduction

III. EXPERIMENTS

In this paper, we examined if our students' contradiction problem solving ability and their growth mindsets were affected positively by learning the Butterfly diagram. In order to achieve the research objective, we surveyed three times and describe in detail in the following. The respondents of each experiments are different each other. In experiment 1, the average age of the primary school students was 12, whereas the one of the middle school students was 14. In experiment 2 and experiment 3, both of the average age of the middle school students were 14. Our learning process is as shown in Fig. 6.

A. Experiment 1

In the first experiment, there were 59 primary school students (37 males and 22 females) and 70 middle school student (45 males and 25 females). They were all gifted students attending a university's science gifted education center. The student selection standards do not discriminate gender and residential district, and the selection methods are recommendation and interview. Or, the students who are

included in the top 10 percent in schools have a chance to apply.

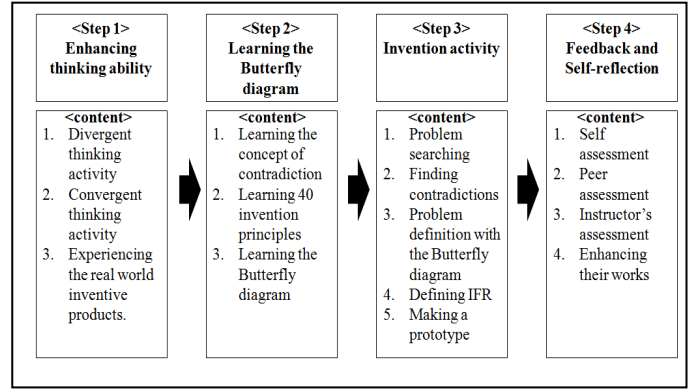

Fig. 6. The learning process.

To the students, we gave two problems. One was Armour-piercing fin-stabilized discarding-sabot (APFSDS) and the other was Bill Culbert's Bulb Box Reflection 2. The APFSDS problem is as following: if the size of a cannon is big, then the destructiveness of a shell will increase due to the explosive force of gunpowder in the cannon. However, since the size of the shell increases due to the size of the big cannon, the shell cannot fly further due to the heavy weight of the shell. In order for the shell to fly away, the size of the shell should be small. Thus, there exists a contradiction in this problem, i.e., the size of the shell should be big and small. The APFSDS solved the contradiction by changing the size of the shell shown in Fig. 7. and Fig. 8.

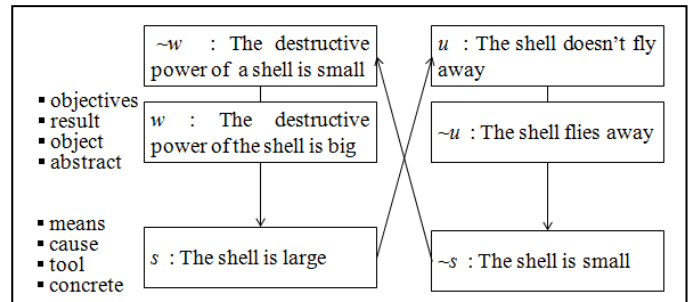

Fig. 7. The Butterfly diagram of the APFSDS problem.

Fig. 8. The solution of the APFSDS problem. The small shell is put on the top of the big shell. The big shell contains huge amount of gunpowder.

The other contradiction problem was Bill Culbert's Bulb Box Reflection 2. In the Bill Culbert's Bulb Box Reflection 2, the bulb's reflection in a mirror is alight while the actual bulb

itself is not. The mirror reflects the opposite side except the light bulb (See also Fig. 9) [27].

Fig. 9. Bill Culbert’s Bulb Box Reflection 2.

In 1975, Culbert installed two light bulbs and one-way mirror between the two light bulbs. If the light bulb in the box is turned on and the light bulb outside the box is turned off, then the one-way mirror reflects not only the light bulb outside the box in the mirror, but also projects the light from the box at the same time. Culbert displayed this work successfully by using the one-way mirror’s contradiction feature. Fig. 10 represents the Butterfly diagram for Bill Culbert’s Bulb Box Reflection 2.

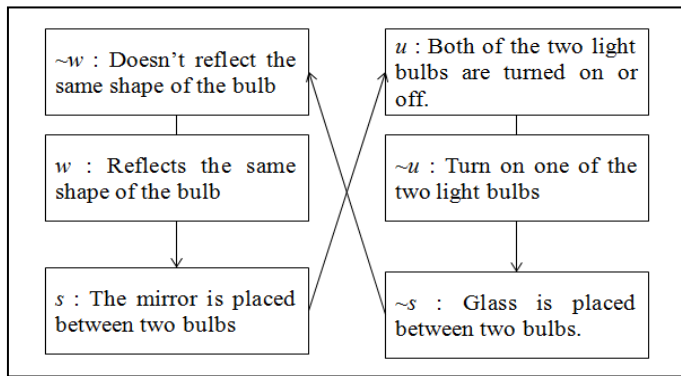

Fig. 10. The Butterfly diagram for Bill Culbert’s Bulb Box Reflection 2.

Before the students learned about the Butterfly diagram and the principles, the students solved one problem. And then, the students learned the theory for 4 hours, and then solve the other problem. The experiment design model is as follows (See also Table I) :

TABLE I. THE EXPERIMENT DESIGN MODEL

Primary school student	O ₁	X	O ₂
Middle school student	O ₂	X	O ₁

O₁ : To solve Bill Culbert’s Bulb Box Reflection 2 problem
O₂ : To solve APFSDS problem
X : To learn the Butterfly diagram

B. Experiment 2

In the second experiment, we provided Duncker’s radiation problem to see how many students solved the problem correctly after the students learned the Butterfly diagram. Duncker’s radiation problem has a contradiction between ‘to destroy the tumor’ (w) and ‘not to destroy healthy tissue’ (~u). We draw the problem with a Butterfly diagram as shown in Fig. 11. In the diagram, in order to destroy the tumor (w), the intensity level should be high (s). However, if the intensity level is high, then the healthy tissue can be destroyed (u). Not to destroy the healthy tissue(~u), the intensity level should be low (~s) [1]. ‘To destroy the tumor’ and ‘Not to destroy the healthy tissue’ have a trade-off relation, whereas ‘the intensity level of the rays is high’ and ‘the intensity level of the rays is low’ have a contradiction relation. The solution for Duncker’s problem is to use the weaker beams from each side so that it doesn’t harm the tissue, but the total power of the beams will meet at the tumor, enough so that it will destroy it.

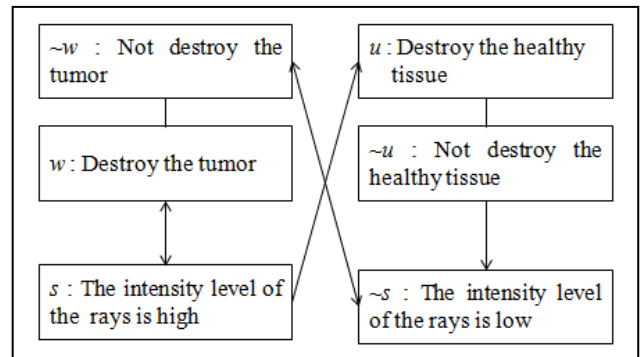

Fig. 11. The Butterfly diagram for Duncker’s radiation problem [1].

In the second experiment, there were 41 middle school students in total, and they were all the gifted students in the same university’s science gifted education center mentioned in the experiment 1. We divided the students into two groups: one was consisted of 15 7th grade students who are in the computer science class and learned the Butterfly diagram for 15 hours. The other was consisted of 13 physics class students and 13 biology class students. They did not learn the Butterfly diagram.

C. Experiment 3

In the third experiment, there were 44 middle school students. We taught the students with the same learning content. However, the 33 students did not learn the Butterfly diagram (24 mathematics class students, 9 physics class students), where as 11 students (computer science class) learned the Butterfly diagram for 17 hours. They were all the gifted students in the same university’s science gifted education center mentioned in the Experiment 1. After the education, we measured the growth mindset level of the students if there exists any difference between the experimental group and the control group.

IV. EXPERIMENTS' RESULTS

A. Experiment 1

We firstly performed an two-way ANOVA to check if there existed a mean difference between two student groups (primary and middle) for APFSDS problem and Bill Culbert's Bulb Box Reflection 2 problem (the bulb problem). If a student's answer was absolutely wrong or no answer, then the answer was scored as 0 point. If the answer was perfectly correct, then the answer was scored as 3 points. And, if the answer was slightly better than the zero-point answer, the answer was scored as 1 point. Similarly, if the answer was slightly worse than the 3-point answer, the answer was scored as 2 points.

For the primary school students, the mean value of the bulb problem was 1.03 ($SD = 0.72$) (before education), while the mean value of the APFSDS problem was 1.54 ($SD = 0.80$) (after education). On the other hand, for the middle school students, the mean value of the APFSDS problem was 0.57 ($SD = 0.79$) (before education), while the mean value of the bulb problem was 1.39 ($SD = 0.87$) (after education).

According to the result of the two-way ANOVA for solving the contradiction problem solving, the main effect of the Butterfly diagram learning presence was significant ($F(1, 254) = 43.83, p < 0.001$). The main effect of the difference between the bulb problem and the cannon ball problem was not appeared ($F(1, 254) = 2.34, p = 0.127$). The interaction effect between the learning presence and the problem type was also significant ($F(1, 254) = 9.60, p = 0.002$) as shown in Fig. 12. Table II shows the results of the two-way ANOVA with the interaction effect between the learning presence and the problem types.

Fig. 12. The result of the two-way ANOVA.

Next, we performed a paired t-test to examine if there was the enhancement of program solving ability for each student. For the primary school students, the result of the paired t-test was statistically significant ($t(58) = -4.26, p < 0.001$). For the

middle school students, the result of the paired-t test was also significant ($t(69) = 5.20, p < 0.001$). It means that there existed the enhancement of the problem solving ability after the students learned the Butterfly diagram.

TABLE II. THE RESULT OF TWO-WAY ANOVA

Source	Sum of square	df	Mean square	F	p
Education (A)	28.01	1	28.01	43.83	< 0.001
Problem Type (B)	1.50	1	1.50	2.34	0.127
A * B	6.14	1	6.14	9.60	0.002
Error	162.31	254	0.64		
Total	197.96	257			

B. Experiment 2

In Duncker's research, the number of people who solved his radiation problem was 2. It was only possible after Duncker gave them hints. When a person is facing a given problem, getting a hint from somebody is not a realistic situation [28]. In the previous research of analogical problem solving with Duncker's radiation problem, when the researchers gave no hint, they got the solving ratios as follow: (1) In Gick and Holyoak's first experiment 0%, their second experiment 8%, their fourth experiment 7%, their fifth experiment 10% [5], (2) In Spencer and Weisberg's first experiment 7%, their second experiment 4% [29], (3) In the Pedone, Hummel, and Holyoak's first experiment 13%, their second experiment 11% [30]. In summary, the average problem solving ratio was 7.50% ($SD = 4.11$).

This research examined if there existed the difference in contradiction problem solving ability between the students who learned the Butterfly diagram and the students who did not. In experiment 2, the number of male students who did not learn the Butterfly diagram was 20 (76.9%) and the number of male students who learned the diagram was 11 (73.3%). Firstly, for Duncker's radiation problem, the problem solving ratio for the students who did not learn was 8%, whereas the ratio for the students who learned the diagram was 33%. It was the higher value than the previous experiments. In the Gick and Holyoak's 4th experiment, they gave a hint to the participants. As a result, they got the 20% problem solving ratio [5]. Also, Catrambone and Holyoak's first experiment showed 16% problem solving ratio with a hint to the participants [31]. Our ratio is much higher than them. As a result, we verified the educational effect of contradiction problem solving on the Butterfly diagram.

C. Experiment 3

In experiment 3, the number of male students who did not learn the Butterfly diagram was 28 (84.8%) and the number of male students who learned the diagram was 8 (72.7%). In order to avoid the respondents' answers that were desirable to the authors of this paper, a graduate student helped us by saying that she wanted their answers for her paperwork. The respondents firstly answered the questionnaires to measure their time perspectives for about 5 minutes. And then, they answered three questions that are developed by Dweck

[18][19] as follows: (1) Your intelligence is something about you that you can't change very much (reverse coded). (2) As much as I hate to admit it, you can't teach an old dog new tricks. People can't really change their intelligence (reverse coded). (3) No matter who you are, you can significantly change your intelligence level.

The first 2 questions are about the fixed mindset, whereas the third one is about the growth mindset. By using the 3 answers of the questions, we obtained the mean value of the growth mindset. And then, we defined this value as the growth mindset value. The Cronbach's alpha (α) was 0.83. It means that the 3 questions had an internal consistency, and were reliable as a measurement. Next, we performed a t -test between the student group learned the Butterfly diagram and the student group not learned the diagram with the growth mindset value as a dependent variable. Fig. 13 shows the result.

The growth mindset value of the students who did not learn the Butterfly diagram was 4.65 ($SD = 1.28$), whereas the growth mindset value of the students who learned the Butterfly diagram was 5.55 ($SD = 0.69$). The result of the t -test was statistically significant (Levene test $F = 4.14$; $p = 0.048$, $t = 2.95$, $p = 0.006$) (See also Fig. 13).

Fig. 13. The result of the t -test for the growth mindset mean value

V. CONCLUSIONS

In order to solve problem well it is important to represent the problem appropriately. If the type of a problem is determined, then the type of its solution can also be found easily [11][12][13]. So far, contradiction problems have been classified as difficult puzzles. A lot of problem solving psychologists dealt with Duncker's radiation problem for a long time, however almost everyone didn't examine the problem from the contradiction solving point of view [4][5][6]. In addition, there has rarely existed the research that classified contradiction problems and derived the solution

strategy for the contradiction problems. Unlike the existing research that treated Duncker's radiation problem as an ill-defined one, the Butterfly diagram of this research analyzed the radiation problem, and then converted it to a well-defined problem. This research introduced the Butterfly diagram that represents contradiction problems as symbolic logic, and then verify if the Butterfly diagram education affected students' problem solving ability.

If we figure out the structure and the types of contradiction problems, then we can solve the problems easily due to the reduced problem space [13]. In addition, when students are confronted with difficult contradiction problems, they are inclined to try to solve the problems. And, when they solve the problem finally, their mindsets become growth mindsets with their experience [18][19]. In this research, we conducted three experiments that analyzed the differences in the growth mindset and the problem solving ability between the students who learned the Butterfly diagram and the students who did not learn. The first experiment examined the problem solving ability about the Culbert's bulb problem and the APFSDS problem. The result of the first experiment was that the students solved better when they had learned the Butterfly diagram. The second experiment was about Duncker's radiation problem. In the previous studies, the average problem solving ratio about Duncker's problem was 7.5% ($SD = 4.11$). However, in this study, we got 33% by the Butterfly diagram education. Finally, the third experiment surveyed the students' growth mindset level after the Butterfly diagram learning. In other words, the growth mindset of the students who learned the Butterfly diagram was higher.

The reasons for enhancing students' contradiction problem solving ability with the Butterfly diagram are as follows:

Firstly, Gocłowska et al. found in their experiment that when people met the word thinking outside of the box such as 'female mechanic', their creative levels became higher [32]. When we determine a solution strategy for a given problem as satisfying two conflicting functions at the same time, the gap between the given solution strategy and the common and ordinary solution strategy becomes bigger. It leads us to increase counterfactual thinking ability [33]. As a result, problem solvers can overcome their psychological inertia. In other words, contradiction solving can reduce the problem solvers' fixed idea and increase the opportunities about creative problem solving [34].

Secondly, when the direction of a problem solving is given by others, the problem solvers think more creatively. When the direction of the problem solving is defined by themselves, it is difficult to overcome their fixed ideas [35]. The students who learned the Butterfly diagram had opportunities to think differently from their fixed ideas. The unfamiliar solution strategy given by the Butterfly diagram made the students more creatively. Thinking in the opposite direction increases the possibility of innovation [36].

Thirdly, the contradiction relation found by the Butterfly diagram is more concrete than the trade-off relation of the Butterfly diagram. During learning the Butterfly diagram, the students' thought about the solution of a problem changed from abstract to concrete. As a result, the students could have

a reduced solution space, and then they could find out the solution more quickly.

On the other hand, in the learning process, the students felt stressed and frustrated while defining problems and classifying the problem types with the Butterfly diagram by themselves. However, their iterative challenges and accomplishments to solve the problems enhanced their increased growth mindset.

The students who learned the Butterfly diagram awarded for 9 years (2007~2015) in a row when our students participated in invention festivals. During this period, 3 primary, 12 secondary, and 46 college students were awarded in invention festivals. And then, 5 middle school students, 4 high school students, and 15 college students, and one graduate school students registered 18 patents. In the 2014 Invention Idea Competition Festival, two primary school students who learned the Butterfly diagram were awarded one of 578 ideas in total. Furthermore, the college students who taught the two primary school students were also awarded one of 3,961 teams with 7,990 ideas. The students were also awarded in the Korean Science Creativity Festival. It showed the validity of the Butterfly model as a contradiction resolving model and the effectiveness of the educational content the students had learned.

An Engineering Student Leadership Development Model for 21st Century Engineering

Using Sociocultural Theory to Inform Practice

Abstract— To meet the demand for increased engagement of diverse engineers who possess 21st century skills, a leadership program was established in 2011 at a majority Hispanic four-year institution with an aim to develop engineers who work effectively with others in both public and private sectors through ideating, innovating, and thinking holistically through a systems approach to engineering problem solving. Designers of the program drew on leadership theory combined with situated learning theory to design and develop the program. Two theories of leadership informed our blended design: the relational model of leadership and the distributive actions theory of leadership. Situated learning theory, a sociocultural theory of learning, informed the programmatic implementation emphasizing learners' participation in authentic activities and the social relations in which they are embedded. Integral to the development of the leadership program model was a mixed methods research design to investigate its efficacy in relation to student development, which was structured in part to emphasize awareness and self-realization of various leadership skills. Qualitative research findings show that students associate their participation in situated learning activities of the leadership program with greater initiative and efficacy in their engineering classes. These findings corroborated the findings of the quantitative study.

Keywords—*leadership theory, sociocultural theory of learning, engineering education research*

I. INTRODUCTION

With funding from the U.S. Department of Education, the College of Engineering at the University of Texas at El Paso [UTEP] established its first leadership institute—Hispanic Engineering Leadership Institute [HELI]—in 2011 to support leadership skills development of engineering and computer science (hereafter referred to as engineering) undergraduates as a mechanism for persistence and ultimately success in preparing the 21st century workforce. HELI's emphasis on leadership was in response to the 2004 report of the National Academy of Engineering *The*

Engineer of 2020: Visions of Engineering in the New Century, which recommended a new paradigm for educating engineers to meet the nation's competitiveness and improve the quality of life from a global perspective [1]. To meet the demand for increased ingenuity and innovation of engineers, it is imperative to expand the engagement of diverse individuals who can contribute across disciplines and ensure continuous advancement in engineering. With the rapid growth of the Hispanic population [2] the need to tap into this underrepresented segment of the U.S. population is vital. [3] further emphasized the need to retain engineering students in the pipeline and to systematically address gender and ethnic equity. Following the recommendation from [4], we responded to developing a new paradigm for educating engineering leaders of the 21st century. The research reported here is part of that effort.

II. CONTEXT

A. About UTEP Engineering

UTEP is a minority institution located on the U.S./Mexico border serving a largely Hispanic population in a region of Texas with the lowest median income in the state [5]. Residing in the bicultural and bilingual community of El Paso on the U.S./Mexico border, UTEP is one of the largest binational universities in the world and, given its demographics, is unique among research institutions. UTEP enrolls over 23,000 students, of which approximately 78% are Hispanic, and 55% are the first in their families to attend college. Since its beginnings as a small mining school in 1914, UTEP has been committed to providing access and excellence in higher education. Today, the University offers 81 bachelor's, 81 master's and 17 doctoral degrees, with others in development. With over \$60 million in annual research spending, UTEP is classified as a Doctoral/Research-Intensive institution.

The UTEP College of Engineering offers undergraduate degrees in computer science and in civil, industrial, mechanical, electrical and computer, and metallurgical and

materials engineering. Its undergraduate enrollment of engineering majors is almost 2,000, of which 19% are female and 79% are Hispanic. The UTEP mission is to provide access and excellence to a non-traditional community of learners in the University region. This mission is coupled with a commitment to excellence in preparing students to make significant contributions to their professions, communities, and the world. Furthermore, a core belief of the UTEP College of Engineering is "diversity drives innovation." The nation's future depends on its ability to be a global leader in innovation, and advancing diversity is a key to innovation.

B. About HELI

The *Hispanic Engineering Leadership Institute* (HELI) is an integrated research and programmatic initiative with an aim of increasing the number of underrepresented groups, particularly Hispanic women and bilingual students, who persist in and graduate from UTEP's undergraduate engineering program possessing a competitive advantage through purposeful development of leadership skills. Two major components of HELI are (1) leadership curriculum designed for students to develop 21st century professional skills, and (2) field-based professional opportunities for students to practice and refine developing skills.

III. THEORETICAL FRAMEWORK

In designing the Hispanic Engineering Leadership program, the literature indicated a paucity of research in this particular area. Thus, we drew on leadership theory combined with situated learning theory to design and develop the program. Two theories of leadership informed our blended design: the relational model of leadership [6] and the distributive actions theory of leadership [7]. The relational model of leadership emphasizes the importance of developing (1) strong interpersonal skills; and (2) an inclusive, empowering, and ethical stance. In a similar manner, the distributive actions theory posits a cooperative framework to enable team members to work together effectively in order to establish and maintain effective working relationships and interdependence in meeting individual and team goals. Likewise, we drew on situated approaches to teaching and learning, which emphasize learning through practice and social interaction [8] to construct program activities that encouraged meaningful interactions among students as well as hands-on practice with leadership skills.

Together these informed our design in purposefully and intentionally targeting skills development with an expectation that engineering students would further seek and participate in internships, study abroad, cooperative education experiences, undergraduate research, and other co-curricular experiences to use their skills in authentic and meaningful interactions with others.

[These theories of leadership] emphasize the mutual goals and motivations of both followers and leaders, and elevate the importance and role of followers in the leadership process. In other words,

these theories posit, leadership is not just something that a leader does to followers; rather, leadership is a process that meaningfully engages leaders and participants, values the contributions of participants, shares power and authority between leaders and participants, and establishes leadership as an inclusive activity among independent people [6, p. 53].

Thus, we specifically encouraged English Language Learners and females to join our institute; we were successful in maintaining a higher percentage of females in our leadership than UTEP engineering enrollment. The skills we identified and targeted were managing conflict, oral and written communication, building trust and trustworthiness, understanding personality traits, being proactive, and actively listening.

IV. RESEARCH DESIGN, FINDINGS, AND CONTRIBUTION

Integral to the development of the leadership program model was a mixed methods research design to investigate its efficacy in relation to student development, which was structured in part to emphasize awareness and self-realization of various leadership skills. The driving questions informing the data collection were: (1) What challenges do Hispanic women and English Learners (ELs) face in undergraduate engineering programs? What are the most suitable mechanisms of support for academic success? (2) What components of HELI are most conducive for academic support? What aspects can be improved? (3) Does participating in HELI have better outcomes compared to other groups?

A. Participants

Overall, 59 HELI members (33 males, 26 females) were active in the program over three years with 92.3% self-identified as Hispanic or Latino/a. With respect to language background, 50% of students reported that Spanish was their native language, and 32.69% of students reported both Spanish and English as their native languages. Only 13.46% of students reported English as their native language.

B. Method

We drew on mixed methods, though primarily qualitative methods, to understand and assess the experiences of participants, especially women and ELs, in HELI. The focus of this paper is on the research design and findings of the qualitative study.

Five primary sources of data were collected: (1) a demographic survey soliciting background information related to language, gender, and academic supports; (2) focus groups with all HELI participants; (3) more than 54 hours of observations of HELI workshops; (4) a final evaluation survey of participants' experiences in HELI; and (5) in-depth interviews with participants in the language of their choice. For some participants, initial and follow-up interviews were conducted. In addition, we also conducted a phone survey with seven participants who discontinued participation in HELI.

Most participants agreed to be interviewed (36 of the 59 active members), and 17 were interviewed a second time. All of the interviews were uploaded and analyzed in NVivo10 qualitative data analysis software. The interviews were analyzed with an “open coding” and a “focused coding” approach [9] in NVivo10. Particular instances (codes) were identified in which the participants talked about HELI, HELI expectations, HELI and leadership engineering, and HELI and engineering.

C. Key Findings from Focus Groups and Interviews

This section outlines key findings from the systematic analysis of the qualitative data collected during the program. In analyzing the participant feedback provided in focus groups and individual interviews, several important themes emerged, each of which will be explored in detail in this section.

1) Impact of HELI on Engineering Leadership Skills

a) Communication

Improving communication skills was an important theme that emerged from female participants' interviews. For example, Adela expressed how HELI helped her with her confidence, saying “Well, finally, HELI with Dr. Elsa (HELI facilitator) and the group has helped a lot like in my confidence like in my leadership positions...During class like I feel more comfortable like taking the initiative, so I feel like I've learned a lot not only how to express myself and how to communicate with others.” Another female participant, Carolina, mentioned how HELI has helped her gained confidence to speak in English, “Well, I would say that I've learned many things. Before I was very nervous to speak to someone in English.” A third female participant, Adriana, highlighted the importance of communication skills in engineering leadership, saying that “an engineering leader [should] be able to talk to people because they have this stereotype that engineers are not like social persons they try to avoid people; and, if you do want to be an engineer, you have to break through that stereotype.”

b) Teamwork

Being able to work in teams was another important theme that emerged from the interviews. Both females and males expressed the need to work in teams. For example, Graciela mentioned that she learned in HELI the importance of listening to other peoples' ideas and trust. Adriana talked about how the workshops showed her how to work with different types of people and accomplish goals when working in teams. Similarly, Cristian and Andres mentioned the importance of trusting others when working in teams.

2) Application of engineering leadership knowledge in other contexts

Several female participants expressed how they have applied what they learned in HELI in their courses and

work. One participant, Monica, specifically pointed out using what she learned from the workshop on conflict management in other contexts. Another participant, Donna, revealed how she noticed that she had started to take initiative and become the leader in group projects associated with courses, which she attributed to her participation in HELI. Several male participants also expressed how they have applied the knowledge in their summer internships and classes. Leonardo said, “everything I applied from HELI in the summer definitely got me noticed the primary reason I was asked to come back but getting introduced to the petroleum industry and NASA.” Similarly, Luis talked about reaching out to younger students in his internship, “it was an engineering/internship so I had to put an example to high school students and talk to them about college and future plans”. Javier emphasized that he has used his knowledge in courses as well, saying “in class, I mean if I'm working in teams if I don't see that somebody has the capacity, or just by [my own] nature I take the lead of the team”.

3) Unique conceptions of engineering leadership

Two participants had conceptions of leadership engineering that differed from the other participants. For example, Carolina had a view of engineering leadership as a way of having a balanced life. In her interview she said, “I say that leadership is power, enjoy what you are doing in college, to have, to have I don't know the time for your homework, your projects, your classes, without neglecting other priorities that we may have.” Likewise, Leonardo saw engineering leadership as both knowledge of the business aspect and the technical aspect: “I would consider a leader engineer to be like the middle point of everything um how to get a technical aspect and how to relate it in business terms and to make sure that's the right thing so that it succeeds”.

4) Impact of HELI on Students' Engineering Identities and Professional Preparation

a) Professional preparation

Another theme that emerged from the interviews was the perceived benefit that being part of an organization had on their professional trajectories. For instance, Carolina compared herself to students who were not part of an organization, saying that she was prepared for career fairs and had her resume ready while her friends were not ready. Another participant, Andres, highlighted his professional trajectory as a key reason for deciding to be a part of HELI: “That's why I joined this student group, because I think that being part of this leadership group is going to help me in my future.” Cristian also compared himself with other students who were not part of an organization, saying that participating in HELI put him at an advantage in the job market.

b) Research opportunities

A common theme among males and females was how they benefited from HELI with respect to research opportunities. Some participants mentioned the chance to work in the summer because of HELI (Adriana, Graciela, Karina, Andres, Javier, Roger, Roberto, Cristian). Graciela and Javier said that they heard about the COURI program in HELI. Roger said during an interview, "I really like HELI and I got to do a research project over the summer because I was in HELI." Cristian also said during an interview "This program actually it has helped me a lot, I consider it a valuable opportunity that I got to be part of this group because I think that being part of this group opened the door for me to get a job in the summer."

c) Developing professional networks

Meeting faculty and other contacts was a theme that emerged from the interviews. Several females reported meeting engineering faculty as one of the key benefits of HELI. One female participant said that she felt that meeting HELI director and workshop facilitator Dr. Villa opened many doors for her, such as the opportunity to go to London (Karina); another mentioned getting a recommendation letter through HELI (Adela). A third participant mentioned how she was able to meet people with different interests (Monica). Finally, another participant, Adriana, said that being part of HELI helped her develop friendships with other members. This theme was not mentioned by any of the male participants.

IV. SUMMARY OF FINDINGS

Students found the skills of communication and teamwork to be significant; and were able to identify the application of engineering leadership knowledge to other spaces. Thus, students associated their participation in situated learning activities of the leadership program with greater initiative and efficacy in their engineering classes. Findings also strongly suggest how HELI was influential in further development of their engineering identities through the opportunity it provided in their professional preparation, in undergraduate research, and developing their professional networks; these are opportunities suggested by [10].

V. SIGNIFICANCE AND RELEVANCE

The recent shift emphasizing professional skills development of engineering students is evidenced by the release of a call for proposals under the National Science Foundation Directorate for Engineering, Engineering Education and Centers *Professional Formation of Engineers: Research Initiation in Engineering Formation* [NSF 15-539]. This program recognizes both the technical and professional skills development of engineers are critical for the future workforce, particularly with its inclusion of an ethical perspective.

Thus, HELI is one model for developing professional skills intentionally and purposefully using sociocultural approaches that emphasize social interaction and participation in meaningful leadership engineering

activities; participating students recognize and value professional skills development.

VI. ACKNOWLEDGMENT

The HELI project is supported by a grant from the U.S. Department of Education under the Minority Science and Engineering Improvement Program (MSEIP), Award #P120A110086-12.

Abstract— STEM educators have devoted increasing attention to discrete mathematics in recent years due, in part, to its strong connections with subjects like computer science, probability and statistics, and business management. Combinatorics problems, in particular, while useful for modeling concrete situations, are often considered to be tricky for students. To develop a better understanding of students' conceptions regarding problems involving permutations and combinations, a secondary data analysis using a grounded theory approach was performed on transcripts of student interviews obtained during an earlier study. Participants had recently completed a college-level discrete mathematics course with a passing grade. Analysis focused on answering two research questions: 1) What patterns of responses do students generate while producing solutions to combinatorics word problems? 2) What underlying conceptual ideas lead to these patterns?

Keywords—combinatorics, permutations, combinations, student conceptions/misconceptions

I. INTRODUCTION

Education researchers in STEM fields have devoted increasing attention to discrete mathematics in recent years due, in part, to its strong connections with subjects like computer science, probability and statistics, and business management. The National Council of Teachers of Mathematics (NCTM) devoted their 1991 yearbook to the topic [1]. The importance of combinatorics, in particular, has been increasingly emphasized in the mathematics education literature [2-5] as well as K-12 standards documents [6]. However, while combinatorics problems are known for modeling concrete problems, they are often considered to be tricky for students. In the next section we present a brief review of the literature on college students' difficulties with introductory combinatorics. Subsequent sections are devoted to our research questions, study methods, and results/discussion.

II. LITERATURE REVIEW

We restrict our focus to the post-secondary literature. See [7] and [8] for detailed reviews of the K-12 literature. There are only a handful of peer-reviewed papers published at the post-secondary level examining students' understanding of combinatorics. Several of these articles focus on more

advanced topics than we will be addressing here [9-11] or use combinatorics problems as a context in which to study other issues such as cooperative problem solving [12], metacognition [13, 14], and semiotics [15].

Recently, four unpublished thesis dissertations have examined the learning of combinatorics at the undergraduate level. In the first of these [16], Smith employed a multiple case study approach to study how students, with varying levels of experience, approached solving basic counting problems of the four basic types appearing in Table 1. Note that a *permutation* is a particular ordering of k objects selected from among n distinguishable objects ($k \leq n$) whereas a *combination* is a selection of a particular subset of k of those n objects without regard to their order.

TABLE I. FOUR BASIC TYPES OF COUNTING PROBLEMS

	Permutations (ordered)	Combinations (unordered)
No repetition allowed	$\frac{n!}{(n-k)!}$	$\binom{n}{k} = \frac{n!}{k!(n-k)!}$
Repetition allowed	n^k	$\binom{n+k-1}{k}$

Smith found that the permutation problems (both with and without repetition) were easy for students, whereas combination problems were difficult. Furthermore, students approached the permutation problems from a more conceptual perspective based on the use of the multiplication rule, whereas formula recall was the strategy of choice for combination problems. Smith warned, however, that students' conceptions of permutations were rigid and resistant to generalizability beyond the simplest of counting problems. Additionally, Smith found that students' understanding of the notion of ordered/unordered sets was tenuous. Students had no problem connecting ordered sets with permutations and unordered sets with combinations. However, when asked during interviews to elaborate on the distinction, most participants appeared to

believe that the distinction had to do with whether the problem allowed repetition.

In the second dissertation [17], Kavousian presented college-level discrete-mathematics students with an unfamiliar (and somewhat complicated) definition and a corresponding set of tasks chosen to help reveal their concept image of the new mathematical object. The study revealed that, when attempting to understand the new concept, most students did not generate their own examples (rather, they expected examples to be provided for them by the teacher), and, while many students could eventually find a formula for counting these new objects after being exposed to related tasks, they did not make many of the anticipated connections to prior knowledge (e.g., knowledge of combinations and of the binomial theorem). Furthermore, students that generated pictorial representations of their new understanding did not consider these significant in their understanding. On the contrary, an algebraic representation was considered by students to be a necessary (and often sufficient) form of understanding.

In the third dissertation [18], Lockwood conducted *think aloud* interviews with advanced undergraduate and graduate students who were asked to solve difficult counting problems. The interview data was used to develop a model of combinatorial thinking in which students tend to relate algebraic *formulas/expressions* (like those contained in Table I) to *sets of outcomes* (the collection of objects being counted) via *counting processes* (the active mental and/or physical processes of enumeration). Lockwood also noted, however, that students frequently ignore the set of outcomes in counting problems, unless specifically prompted to address it. She later used the model as an analytical tool for interpreting her data as well as other researchers' data [19]. In a separate study [20], Lockwood also examined some of the spontaneous connections that students make between different combinatorics problems. Lockwood's is (to our knowledge) the only of the four dissertations to have resulted in peer-reviewed publications.

In the final dissertation [21], Halani studied the ways in which four Arizona State students, who had no prior experience with counting problems, conceived of the sets of outcomes in combinatorics problems. Halani identified three broad categories of ways that students think about solution sets which she labeled *subsets*, *odometer*, and *problem posing*. The subsets category involves envisioning the solution set as a union of subsets, while the odometer category involves holding an item (such as a digit in a number or character in a string) constant and varying the other items systematically. The problem posing category involves the spontaneous generation of a new problem whose solution set is somehow related to the solution set of the original problem.

III. RESEARCH QUESTIONS

Evidently, there are many gaps in the post-secondary literature on combinatorics education. In particular, among the studies we reviewed, several do not focus specifically on combinatorial concepts [12-15]. And those that do tend to focus on difficult problems [9, 10, 17] or examine populations of students with a great amount of mathematical experience

[11, 18-20]. The exceptions are the studies by Smith [16] and Halani [21]. However, Smith focused only on the most basic counting problems (those of the form listed in Table I), and Halani's study involved students who had had no prior instruction in combinatorics.

As a result, little has been done at the college level with problems that are just a bit more difficult than those represented in Table I. For example, little is known about how students in possession of basic knowledge of permutations and combinations (but not much more than that) approach a problem that naturally lends itself to the use of both a permutation and a combination or a problem requiring a simple combination but with an added restraint. Such problems would not lend themselves to the "order matters implies permutations" and "order does not matter implies combinations" schemas. In light of Smith's [16] claim that the notion of ordered/unordered sets is problematic for students as well as his claim that students' models of permutations are inflexible and resistant to generalizability, one would expect these intermediate level problems to be a rich site for study. With these considerations in mind, we pose the following questions:

- 1) What patterns of responses do students generate while producing solutions to combinatorics word problems that are slightly more complex than those in Table 1?
- 2) What underlying conceptual ideas lead to these patterns?

IV. METHOD

In this study, we performed a secondary data analysis of data originally gathered by different researchers in the University of Illinois at Urbana-Champaign's Computer Science Department. The data was part of a larger project to construct assessment tools to measure students' understanding of discrete mathematics concepts used in theoretical computing. The only portion of the project that will be discussed here is the part directly relevant to the current research on students' conceptions regarding combinatorics problems. The first subsection below will describe the data collection process that was carried out by a team that did not include any of the individual researchers involved in the present study. The second subsection will describe the data analysis process that was carried out by the researchers involved in the present study.

A. Data collection

Here we detail the data collection process, including details about the participants, the interview process, and the interview questions (by which we mean the combinatorics problems to be solved during the interviews).

1) Participants

In the spring of 2009, eighteen undergraduate volunteers from the University of Illinois at Urbana-Champaign enrolled in the study by responding to an email sent to recent "CS173: Discrete Mathematical Structures" students whose course performance merited a grade of B or C. Of these, there were

five women and thirteen men, all but two of whom were majoring in the mathematical sciences or engineering. The other two were undeclared. Fourteen were domestic students. Ten of the eighteen were computer science or computer engineering majors who are required to take a course on discrete mathematics. Students were paid \$15 for their participation. Students with grades B or C were targeted as they were more likely to generate error-prone solutions. It should be noted, however, that Illinois has a highly competitive engineering program, and the average ACT score of the students who participated was 32.6 (the 99th percentile). Of the eighteen participants, only eleven of them attempted to solve one or more of the interview questions specifically involving combinatorics, and, therefore, the present study included only those eleven students. Since the data had been anonymized prior to having been given to the current research team, there is no way to know which of the original eighteen students are included in the present study.

2) Interview process

Prior to being interviewed, students were briefed about the goal of the study, which was to understand how they think through various topics in discrete mathematics. They were warned that they would frequently be asked to expand on what they were writing or saying as they solved problems and were told not to expect feedback about the correctness of solutions. Participants were then interviewed for one hour about their understanding of a variety of discrete mathematics problems. They were instructed to “think aloud,” vocalizing their thoughts as they solved problems and answered questions [22]. Students’ work was recorded using a document camera. Audio was recorded with a microphone. The interviewer was an advanced-undergraduate computer science major. Participants were provided with a “cheat sheet” that contained basic notation and definitions that participants were free to consult during the interview. The portion of the “cheat sheet” relevant to the counting problems contained reminders of the notation for permutations and combinations as well as the formula for combinations with repetitions (the bottom-right formula from Table 1), though none of the problems actually required the use of this formula. All interviews were transcribed verbatim, and notes regarding what students wrote and when were included in the transcripts. All student work was scanned and stored electronically for future analysis.

3) Interview questions

The interview questions were a collection of fifteen discrete mathematics problems, four of which were basic counting problems involving permutations and combinations that will be discussed in the present study. These problems resembled those that the participants were likely to have previously encountered in CS173. Not all students answered all of the questions due to time constraints. Students were allowed to pick and choose which problems to attempt. The four counting problems are listed in Table II along with possible solutions. They are labelled Problem 3 through Problem 6 since these were the original labels of the combinatorics problems among the complete set of 18 discrete math problems.

Notice that, while Problem 3 and Problem 4 each have a potential “permutation only” solution (represented by the expression on the right of the equality sign in the solution), the contexts of these two word problems lend themselves strongly to a mixed approach that involves using a combination and a permutation (represented by the expression on the left of the equality). Also notice that, while the form of the solution is the same for both problems, the questions being asked appear quite different. In Problem 3 there are eight crayons being arranged in a box, some of which happen to have the same color. Problem 4, by contrast, involves a total of twelve crayons, none of which have the same color and from which only eight are being selected for later arrangement into the box. So, while a mathematician would tend to view these two problems as isomorphic, a novice might not.

Smith’s (2007) study suggests that combinations alone are difficult for students, so Problem 5 is a simple combinations without replacement problem (as in Table I) in a context in which it is clear that order does not matter. Problem 6, on the other hand, is a combinations without replacement with an additional constraint—the three red crayons cannot all be next to one another. Furthermore, the context of Problem 6 is a situation in which the order of the crayons in the final arrangement clearly matters even though the most natural solutions involve the use of only combinations. This apparent contradiction is resolved by noting that the unordered selection of several slots in which to place crayons of one color can be done in exactly the same number of ways as there are to arrange the eight crayons. It is worth noting that this problem is most easily solved indirectly by counting *all* arrangements of the crayons, then counting the six “disallowed” arrangements, and, finally, subtracting to find the number of “allowable” arrangements. It is possible to solve this problem by focusing only on the allowable arrangements (see the expression on the right side of the equality in Table II), but this approach makes the solution process much trickier, and we would expect a lower rate of success for students who choose this approach.

TABLE II. INTERVIEW QUESTIONS AND SOLUTIONS

Problem Statement	Solution
Problem 3: Suppose we have 8 crayons, three of which are the exact same color of red, and the others of which are different. Now how many ways are there of arranging the crayons in the box?	$\binom{8}{3} 5! = \frac{8!}{3!}$
Problem 4: Now suppose we have 12 different colored crayons, and a box that holds only 8. How many different arrangements of 8 crayons, selected from the 12, can be put in the box?	$\binom{12}{8} 8! = \frac{12!}{4!}$
Problem 5: A bundle of crayons is a collection of colors in no particular order. How many different bundles of 5 crayons can be made from a set of 8 uniquely colored crayons?	$\binom{8}{5} = \frac{8!}{3! \cdot 5!}$
Problem 6: Suppose you have a box of eight crayons, three of which are red, and five of which are blue. How many ways are there to arrange the crayons in the box so that the three red crayons are not all next to each other?	$\binom{8}{3} - 6 = 2 \binom{6}{2} + \binom{6}{3}$

B. Data analysis

Three researchers at the University of Illinois participated in the data analysis: a graduate student studying math education (the author), a professor, Geoffrey, specializing in engineering education, and an advanced undergraduate, Tom, majoring in computer science. A grounded theory approach [23] was used to analyze the interview transcripts and students' written work (hereafter referred to simply as "interviews"). First, each researcher individually coded the interviews, line by line, without any predetermined coding scheme. "Codes" were essentially annotated comments that referred to a specific line (or lines) or piece of written work. This approach allows theory to arise from the data, rather than force-fitting data to a predetermined theory. Second, the researchers met to discuss one another's coding, negotiate potential differences or disagreements, and eventually produce a single document containing all agreed upon codes. (Agreement on the application of the codes was essentially universal.) Next, Tom and the author reexamined all of the coded interviews to identify and come to agreement on any themes that were appearing in the data. A list of these themes were produced and then later discussed with Geoffrey present to ensure agreement. Finally, the author reexamined the interviews in an attempt to synthesize the thematic elements and develop theories that might help explain what contributes to students' difficulties in solving counting problems.

V. RESULTS AND DISCUSSION

One issue that became apparent while studying the transcripts was that the interviewer allowed his teaching instincts to interfere with the interview protocol (especially in earlier interviews). During uncomfortable moments when a student was struggling, the interviewer frequently asked leading questions, confirmed (or disconfirmed) students' work, or simply had the student move on to the next problem. At other moments, when students indicated that they were finished with a problem, they were allowed to move on without their solution being challenged or more deeply explored. This interference complicated the analysis of the transcripts as it was no longer possible to determine what the student would have done "naturally" (without the interference). As a result, we report only on findings that we believe hold up to scrutiny *in spite of* the interviewer interference.

Each subsection below, with the exception of the first, will focus on a theme that was identified in the data and was considered noteworthy of discussion. Segments of interview transcripts are used to provide vignettes that demonstrate each theme. Participants are referred to as Student 1 through Student 11. The five themes are summarized in Table III while the results are summarized in Table IV (located the end of this section) which indicates the presence (or lack thereof) of each theme for each student/problem pair.

A. A note on overall success rates

Problems 3, 4, 5, and 6 were attempted by 11, 9, 6, and 8 of the students, respectively, for a total of 34 attempts. Of

these attempts, 15 (or 44%) were found to be successful. By problem, there were 5, 4, 3, and 3 successful attempts, respectively, giving success rates between 37.5% and 50%. These rates are likely upper bounds as students were allowed to skip problems and likely skipped problems that they felt they would be unable to solve. It is also worth noting that 11 of the 15 successful attempts were made by just three of the students (Students 1, 7, and 8) who succeeded on every attempt they made. These numbers indicate (in agreement with the literature) that counting problems involving combinations are quite difficult for many students.

TABLE III. LIST OF THEMES

Problem assumptions: Student questions inherent problem assumptions. Four types of assumptions that were questioned included: the shape/capacity of the crayon box, the distinguishability of crayons, the importance of order, and the number of different crayon colors were implicated in a problem statement.
Dichotomous solutions: In the context of Problems 3 and 4, the student indicates that the solution should involve a permutation or a combination only, but not both.
Allowable arrangements: For Problem 6, the student employs a solution strategy that involves focusing on the enumeration of the allowable arrangements of crayons, rather than the simpler approach of counting all possible arrangements and then subtracting the number of disallowed arrangements.
Related constraints: For Problem 6, the student fails to notice that the arrangement of the crayons of one color within the box will necessarily constrain the number of possible arrangements of the crayons of the other color.
Use of diagrams: Simply indicates whether a student used a diagram in their solution attempt. Note that a string of characters indicating a particular arrangement of crayons (e.g., RBBRRBBB) as well as any visual representation of "slots" to be filled (e.g., use of underscores to represent slots) were all counted as diagrams.

B. Understanding the problem assumptions

One of the most common patterns we noticed was that novice counters tended to question problem assumptions more than "experts" (students who were most successful at solving the interview problems¹). Four types of assumptions were questioned: the shape/capacity of the crayon box, the indistinguishability of crayons of the same color, the importance of order, and the number of different colors of crayon contained in a problem. The first and last will not be elaborated upon any further as they seemed to reflect ambiguities in the wording of the interview problems more than conceptual difficulties regarding counting.

1) Distinguishability of crayons

Several students questioned whether crayons of the same color were distinguishable from one another as demonstrated by the following exchange that occurred during an attempt to solve Problem 3:

Student 4: [...] you have two ways of deciding whether or not the, whether or not the crayon's arrangements are different. For example, if you have

¹ We are careful to note, therefore, that "expert" behavior used in our sense is not necessarily meant to refer to behaviors characteristic of an instructor or professor.

a box of eight, um, if these three are the exact same shade of red, you could count them as essentially the same crayon, and then not care where those are placed in the box. And that would lead you to one answer. If you count them as distinct crayons, then it would be pretty simple. [...]

Interviewer: Well we give you that they're the exact same color. So...

Student 4: Yeah, but they're *different* crayons.

Student 4 is caught up on the distinguishability of the three red crayons and notes that, while they are all red, they are still "different" crayons. In the "real world" different red crayons are, ultimately, distinguishable, but the more expert problem solvers in this study tended to more readily "buy into" the intended problem assumption that the red crayons are indistinguishable.

2) Importance of order

The most common assumption that students' questioned or clearly misunderstood based upon their given solution was whether "order matters." Technically, this condition refers to the order in which distinguishable objects are arranged. However, students often ask, rather vaguely, "whether order matters" without any real indication of precisely what set of objects has its "orderability" being called into question. In a particular problem it may be the case that order both matters and does not matter depending upon what you are referring to. For example, in Problem 3 and Problem 6 the order of the overall arrangement of crayons matters while the order of the reds or blues alone does not matter.

Issues with order came up for each of the four problems. In the following example, Student 3, having just finished reading the statement of Problem 3, vaguely questions the issue of order using non-normative language:

Student 3: Would this be um, according to sequence, or just combinations?

Student 9, solving the same problem, seems to have a conflict between "order mattering" and "distinguishability":

Student 9: And the order matters, so I don't see why it points out that there are three [crayons] of the same color, well kind of.

In contrast, Student 6, while solving Problem 5, and in direct violation of the problem statement, counts the number of "bundles" as though order mattered:

Student 6: This is the same as the last one, isn't it? [Writes down 8 choose 5 times 5!] I mean it's the same idea from the last one, you're choosing 5 crayons from a set of 8, and then put that set of 5 crayons in a specific order.

More examples of order issues will be apparent in the discussion of the closely related "dichotomous solutions" theme to be discussed below.

Consideration of these implicit problem assumptions allows us to begin to grasp the cognitive complexity that combinatorics problems require of a novice. We found that most instances of questioned assumptions occurred during a failed solution attempt. If, for each student, we count each questioned assumption only once per problem, then there were 16 such instances. Of these 16 instances, 13 occurred during a

failed solution attempt by one of six different students. In particular, all but one of the seven instances in which the "order matters" assumption was questioned occurred during a failed attempt.

Students with incomplete conceptions regarding distinguishability and order were prone to developing unstable interpretations of problems that impeded progress toward a solution. This observation suggests that students may need more time than is typically devoted to discussion of the meanings of various assumptions about properties like order and distinguishability and how they relate to various problems. In the author's experience, students are typically presented with a table of basic counting formulas like the one in Table I very early on in combinatorics instruction and focus quickly moves on to more "interesting" problems in which these formulas are taken as "given" knowledge. More time is likely needed for students to develop mental models for the various counting processes represented by these formulas and how these processes are related to various types of problem assumptions regarding order and distinguishability.

C. Dichotomous solutions

We previously alluded to a schema that students often employ that dictates that permutations are to be used when "order matters" while combinations are to be used when order "does not matter." By *dichotomous solutions* we refer to an extension of this schema which further dictates that the solution to a counting problem must use either a permutation or a combination, but not both. Or, said differently, for a given counting problem either order matters or order does not matter (in some vague overall sense), but not both. We found evidence for the existence of this schema in solution attempts for Problem 3 and Problem 4—the two problems most likely to solicit solutions that involve both a permutation and a combination.

Four of the eleven students (Students 4, 6, 9, and 10) demonstrated this schema, and one demonstrated it on both problems (Student 10), giving a total of five instances. Note that none of these students were any of the three highly successful students (Students 1, 7, and 8). Consider first the following which occurred after Student 4 had abandoned a first solution attempt of Problem 3 and was starting on a fresh solution:

Student 4: OK. [Reading from the cheat sheet.] Number of ways to choose elements from a set of size N ... ok. So yeah, there's...yeah. The three that are the same and five that are distinct. Um...so I guess for each, each individual slot, you are choosing, for eight slots you're choosing on of...six possibilities it seems like, because these [referring to the 3 red crayons] are all counted as one possibility, um, so it might be eight choose six...umm, we have to choose R elements, oh nevermind, that doesn't take into account order. So it would be, because you care about order, it would be a permutation of...out of eight, six. [Writes " $P(8,6)$ "] Yeah. Cause there's six distinct elements. And you want to choose all the possible ways of arranging them.

Notice that this student begins by fixating on the notation for combinations contained on the cheat sheet and continues by using choosing language ("you are *choosing*, for eight slots

you're *choosing* one of..." and "so it might be eight *choose* six...umm, we have to *choose* R elements"). But the student abruptly abandons the use of combinations because they do not "take into account order" and decides to go with a permutation, which is this student's final answer.

As another example, here is Student 6 struggling with Problem 4:

Interviewer: [Student writes 12 choose 8.] And that counts what?

Student 6: How many ways to choose 8 from the 12. And then, that's pretty much it, isn't it?

Interviewer: Well, what do you think?

Student 6: [Repeats problem statement aloud.] Well this will count how many ways you can pick 8. Then, how many different arrangements of eight crayons is 8 factorial. So would it be times 8 factorial? No. No, that's right, because you're still counting... This is gonna count all the arrangements you can get from 12, how many different ways you can get 8 from the 12, That should be fine, shouldn't it? Just 12 choose 8?

Interviewer: Ok, that's it for you?

Student 6: Well, I guess, we have 12 different colored crayons, wait, no no no. 12 different colored crayons in a box that holds only eight. Do I still use 12 choose 8? Cause it's different crayons. So if its 12 choose 8, that means, that wouldn't, that's unordered. And then we have to choose 8 that *are* ordered. Which is 8 factorial.

Interviewer: Do you mean that there are two different "choosing processes" happening?

Student 6: I'm, I think so. Kind of, because it's first we're choosing 8 random crayons from the 12, and then, which is kind of, unordered I guess, because you don't care which 8 you choose. Well, do you? No, yeah. I can't use 12 choose 8, because that means, ah damn. I'm confusing myself. So, they're all different colored crayons, so if you have 8 crayons, they're different colors, so there's gotta be 8 factorial in there. Errg.

The interesting thing about this attempt is that Student 6's instincts are ultimately leading to a correct solution, namely, $C(12,8) \cdot 8!$. However, the dichotomous solutions schema is preventing the student from accepting it as it mixes permutations with combinations. The student is sure at first that $C(12,8)$ must be part of the solution, but later the student realizes that $8!$ must be part of the solution since order matters and reneges on the combination. This student goes on to offer $C(12,8) \cdot 8!$ as a final answer but does so with reluctance and admits that he or she is unsure if it gives the correct number or not. (Unfortunately, the interviewer immediately confirmed the answer rather than probing further.)

As illustrated by Student 6, the dichotomous solution schema tends to result in unstable interpretation of the problem assumptions. As students seesaw back and forth between wanting to use permutations and wanting to use combinations, they must also toggle between the assumptions that order matters and that order does not matter. This toggling, in turn, creates dissonance with students' intuitions (rooted in the physical context of the problem) that *both* assumptions appear to be true.

We speculate that the dichotomous solution schema is likely induced (at least partially) by instruction. Language

including statements like "use permutations when order matters and use combinations when order does not matter" is probably common in instruction. It is also implicit in tables like Table I that are contained in most introductory combinatorics and discrete math textbooks. Consequently, it may be a good idea to encourage students to think of Table 1 as a collection of counting *techniques* rather than a collection of solutions to counting problems (though they are that too). Perhaps there would then be less of a tendency for students to believe that they are mutually exclusive in the solutions to counting problems. Also, as students build more robust notions regarding the concept of "order mattering"—in particular as they develop the understanding that it is not a global feature of a counting problem but, rather, a local feature that can differ for various aspects of the problem—they probably become more likely to discard the dichotomous solution schema.

D. Focus on allowable arrangements

Recall that Problem 6 has a solution (the one on the right side of the equality in Table II) that is obtained by focusing on the enumeration of "allowable" arrangements of the crayons, rather than enumerating all possible arrangements and then subtracting the number of "disallowed" arrangements (the six in which all three red crayons are adjacent to one another). The former strategy leads to a more difficult solution process as it is easier to describe and count the disallowed arrangements than it is to describe and count the allowed ones. Nevertheless, this strategy was tempting for students. Perhaps this result is not surprising as the strategy involves inspecting the actual solution set (that is, the set of different arrangements whose cardinality is the answer to the counting problem) as opposed to two sets which are not the solution set but that happen to be closely related to it. Four students (Students 2, 4, 6, and 7, making up half of the students who attempted Problem 6) tried to enumerate allowable arrangements directly. Only Student 7, who solved all problems correctly, was successful in using this approach.

The following vignette is notable in that Student 4 continues to focus on an allowable arrangements strategy, even *after* having computed the number of disallowed arrangements and after stating that the strategy is not "very slick" (emphasis ours):

Student 4: So, um, there's one two three four five six, six total possibilities, where it's not allowed, essentially. And there's a total of, the permutations of, oh no, that's not right. Let's see. Can't do a simple permutation cause they're not distinct elements. The six is, the six was where there's not...for each, for each place it...for the first place you have two choices, red or blue, and if it's red...that's not a very slick way of doing it. And I'm not...once again, lazy, so I don't wanna go and draw out all possible combinations and just count them. Uhhh...but. *How many ways are there...so that the three crayons are not all next to each other?* Alright. Now I just have the impulse to talk, so that I am not leaving a big space on the transcript, but, nothing is actually coming into my mind at the moment, so...

Having computed that there are six disallowed arrangements, Student 4 attempts to connect this information back to the original question. But, in doing so, has reverted to a

permutation-centric approach that draws the student's attention back to the allowable arrangements of red crayons. This approach leads to a rather convoluted analysis that leaves the student wondering whether his/her focus should instead be placed on the blue crayons—at which point the interviewer intervenes in an attempt to refocus the discussion on the disallowed arrangements (emphasis ours):

Student 4: How would I count that...I would put down the well I'd put down the red one's first. Um, so, I'm starting with one there's, you know there's eight choices on the first one. And then there's seven choices on the second one. So the first one, put down here [first spot], second one, just go ahead and go straight across. The third one, there's not this choice [red], but there's all the rest of the choices, so there are five choices for the remainder. And I think that's going to always be true. It's gonna be eight choices for the first one, if you're putting in red first, seven for the second one, and then five, well I guess if you put a red one in the middle...red one in the middle, one two three four, five six seven eight, and then there, a red here [to the right of the middle red crayon], and then there's, if that's in the middle then those two are both invalid [the spaces to the side of the two middle crayons], so it's possible that it could be eight, seven, and then four. *So I guess the other way to say that the three red crayons are not all next to each other is that, there is, um, there is some gap in the blue ones. That not all five blue ones are continuous.* So it could be blue, blue, I guess, yeah.

Interviewer: OK, so what did you count before? When you were doing, you know, the written count of the...

Student 4: *The original count was the, was all the possible illegal placements of red.*

Interviewer: OK. So you counted that. So what are you currently trying to count?

Student 4: I'm trying to count the total number of placements², using three and, five separate elements [...]

Thus, some students more readily focus attention upon the set of arrangements evident in the problem statement at the expense of the other closely related sets (e.g., the set of all arrangements and the set of disallowed arrangements) that simplify the counting process. While this finding is not particularly surprising, it does suggest that the technique of examining related sets that are not explicitly mentioned in the statement of a counting problem should be focused on as an explicit goal of instruction rather than simply being an implicit aspect of the solution process of particular problems.

E. Related constraints

Another theme that was highlighted in the context of Problem 6 was students' failure to recognize "related constraints" on the arrangements of crayons. In the vignette above Student 4 recognized the constraint on the red crayons would result in a related constraint on the blue crayons (but mischaracterized it). Student 2, in contrast, never perceives this related constraint. Frustrated with examining allowable arrangements of red crayons, this student shifts focus to the blue ones in the following excerpt (emphasis ours):

Student 2: Yeah, um, well I don't think this is a good strategy, cause I can't really, cause these are different...I could split these up into containers, red red red red...ok. Little stuck here. So I can have, this [Draws new arrangement of red crayons], I can have like...this, [Draws another arrangement], I can have...[Draws another arrangement]...ok, well, I'm gonna think about it a different way now, *let's just ignore the reds for now*, and I know that I have five other spaces that I can choose. Blues. *So I have no restriction on where I put the blues in.* Or anyway, I can say, for the blues...order doesn't matter, so I could just do, so there's five places [Student spends some time doing calculations.] alright no, I'm stuck. *I'm trying to figure out how I can arrange just the blues in, and not worry about the reds, so...*

In the next vignette, Student 3 does not seem to realize that, once the reds have been placed, the placement of the blues is determined and continues counting the number of ways to arrange the blues (and, further, counts permutations of the eight crayons as though they were all distinguishable):

Interviewer: So, what were you just counting there?

Student 4: I was just counting um, how many positions it is possible for three of them to be together, and it's six. So I know to eliminate that. In the...

Interviewer: Eliminate it from what?

Student 4: From the thing I'm trying to calculate. So from that...it's...just...eight...[Writes, "8C3*8C5"... then tacks on, "8C3*8C5*8! - 6"]

Interviewer: So, where did you get the eight choose three times eight choose five times eight factorial?

Student 4: So eight choose three would be basically choosing three of the crayons, the three reds, and multiplying it with the five...

Interviewer: So it's, so the eight choose three counts the number of ways to place the three red crayons?

Student 4: Right right. And...

Interviewer: And, and what is the, the eight choose five counts the ways to place the blue crayons?

Student 4: Right. Um, and then this factorial is for the arrangement of all of those. And minus six is to...

Interviewer: To, yeah, take away the invalid cases.

Student 4: Right.

F. Use of diagrams

An unexpected finding was that the use of diagrams was associated with unsuccessful solution attempts. A diagram was produced during 19 solution attempts (representing all four problems), only four of which were successful attempts. Almost all diagrams were some sort of a representation of the slots in the crayon box (e.g. a string of horizontal dashes or squares or tick marks) or a representation of an arrangement of crayons (e.g., a string of R's and B's). So one reason for this association could be that students who are unsure of what to do may be more likely to draw specific arrangements of crayons/colors. It may also be the case that students with more counting experience develop a gestalt-like connection between the counting process and the algebraic formulas and, therefore, no longer need to use diagrams. Future research that examines

² Here the student is referring to the total number of arrangements allowed subject to the given restriction on the reds.

the use of diagrams in a more nuanced fashion³ could potentially provide valuable insight into the problem solving process for counting problems.

TABLE IV. SUMMARY OF RESULTS

Understanding Assumptions / Other Themes				
	Problem 3	Problem 4	Problem 5	Problem 6
Student 1	B/-	-/-		-/D
Student 2	O/D	C/D	-/D	-/DER
Student 3	O/D	-/D		OI*/DR
Student 4	BI/D2		-/-	B/DE
Student 5	B/DE			
Student 6	IO/-	-/2	O/-	-/DE
Student 7	-/-	C/-	-/-	-/DE
Student 8	-/-	O/-	-/-	-/-
Student 9	-/D	-/2		
Student 10	-/2	-/D2	O/D	-/D
Student 11	-/D	-/D		

Table IV Key: Understanding Assumptions - **B**: questioned shape of box, **I**: questioned indistinguishability of crayons (**I*** - though not explicitly mentioned out loud, this student's solution implicitly implied distinguishable, same-colored crayons), **O**: questioned importance of order, **C**: questioned the number of crayon colors. Other Themes - **2**: dichotomous solution schema present, **E**: enumeration of allowable arrangements, **R**: failure to perceive related constraints, **D**: drew a diagram. Note: '-' indicates absence of questioned assumptions/other themes. Green/Red indicates successful/unsuccessful solution attempts. White indicates the problem was not attempted.

VI. CONCLUSION

The five themes discussed above (understanding problem assumptions, dichotomous solutions, focus on allowable arrangements, perception of related constraints, and use of diagrams) highlight various difficulties that students experience when solving basic combinatorics problems involving permutations and combinations. Many of these difficulties are attributable to overlooked subtleties regarding the problem assumptions in combinatorics problems. We have tried to highlight some of these thorny issues via the vignettes presented in the previous section and, in some cases, have offered suggestions about how some of the difficulties might be mitigated (or at least not encouraged) by instruction. We have specifically called attention to students' difficulties with understanding problem assumptions and dichotomous solutions because instructors are more likely to be blind to these difficulties as their expertise blinds them to what assumptions they are making during their own problem solving [24].

³ More nuanced than just a binary code for whether a diagram was used or not as was done for this study. Different types of diagrams, for example, could be distinguished and details regarding how they are produced and used during the problem solving process could be studied.

Abstract—If you are part of a faculty meeting, a committee, or a learning community of instructors, you will sooner or later hear the same conversation - the conversation that begins with complaints about students. The attributions about lack of engagement, focus on grades, or the entitlement of this generation are common, and though typically unexamined such complaints are not completely ungrounded. This narrative creates a community around a shared “problem.” This camaraderie is natural, but what are the consequences? Beyond whether such statements are “true,” we believe these assumptions about students are affecting student learning. There is a phenomenon in education known as “self-fulfilling prophecy” where what we believe about students becomes manifest in part because instructors behave in ways that bring about what the instructor initially expects. As a first step in exploring these assumptions, 150 participants in a Teaching Professor Conference in May 2014, generated a list of assumptions they held about students. These assumptions were categorized into four dimensions: Motivation, Behavior, Preparation, and Systems with each dimension having a continuum. This paper describes the taxonomy and references theories to support the organization. The paper will give examples of the assumptions and discuss the next steps to validate the ideas.

Keywords—Faculty assumptions, teaching, psychology

I. INTRODUCTION AND BACKGROUND

Organizational theorists have long recognized that the assumptions held by the humans in the system determine the systemic outcomes [1] [2]. It is no different in engineering education. The connections between our assumptions and actions is made clear by Ambrose [3] where she explicitly states “Because assumptions influence the way we interact with our students, which in turn impacts their learning, we need to uncover and at times questions those assumptions.” (p 181). In the 1950’s Carl Rogers introduced some radical views on education [4]. Rogers articulated the assumptions on which the educational system was based and in so doing was able to illustrate the conflict. For instance, from page 171:

- The student cannot be trusted to pursue his [or her] own ... learning
- The ability to pass examinations is the best criterion for student selection and thus judging professional promise
- Presentation equals learning: what is presented in the lecture is what the student learns
- Creative scientist develop from passive learners

As a contrast to these assumptions, Rogers, Maslow [5], and others [6] used a constructivist approach [7] [8] and an emphasis on the innate drive and ability of people to learn. Rogers argues that individuals can and will grow when there is a safe environment present. This developed into his philosophy of “unconditional positive regard” which he extended to education [9]. In this model, the role of an instructor is to provide structure, inquiry, and space to explore while holding positive assumptions about the individuals ability to grow and change. Many others have also endorsed the importance of this disposition [3] [10] [11] [12] [13] [14]. Some of these ideas made their way into schools in experiments on “self-directed learning” in the 1970’s and 1980’s. Bellanca, et al [15] provide a vivid glimpse of a high school program in the 1980’s that embraced benevolent assumptions.

When reviewing literature on instructor assumptions we quickly become aware of a concept referred to as “self-fulfilling prophecy.” Most of the research on this particularly named phenomenon has been done in elementary schools [23]. In 1968, Rosenthal and Jacobson [24] performed an often quoted experiment and wrote about it in “Pygmalion in the Classroom.” They identified randomly chosen students and told their teachers that these students had been tested as “spurters,” an imaginary label, and could be expected to make great gains in school. After a year, they tested these students and found that indeed the “spurters” had made significant higher gains in ability when compared to the gains made by the control group. Later this was referred to as the “self-fulfilling prophecy” [16] [25]. Others have called it “teacher expectation bias” or “perception bias” [26].

Although people have been thinking about the role of assumptions in personal change, and to some extent in the K12 classroom, those that explicitly look at higher education are fewer. An exception is a study by Scheurman [16] using King and Strohm-Kitchner’s [17] framework for critical thinking through reflective judgment to study both faculty and students’ espoused and practiced thinking patterns. Interestingly they found that faculty assume both that students have a less mature reflective judgment than students actually have, and faculty themselves believe faculty have a more mature reflective judgment than faculty actually practiced in the classroom. The authors argue that the assumptions about student’s lower maturity lead to easier assignments and less engagement by students, which actually reinforces the

faculty's belief that the students are unable. This faulty feedback serves to amplify a lower level of learning in the students, the self-fulfilling prophecy.

Another study done in higher education in Physics classes looked at six instructors [18] to produce a very detailed mental model of the instruction process. The study highlights the importance of the initial classification of students in the instructors mind (assumptions) into two groups: "students who can improve" and "typical students." This initial classification leads to dramatically different instructional techniques and interactions, and presumably learning.

Carol Dweck's [19] [20] and other researchers' earlier work [21] [16] on Mindset concepts also have the same premise of self-reinforcement. These researchers assert that there is a role for the instructor to help change mindset from a fixed one to a malleable one, but the mindset held by a particular instructor influences the effectiveness of this instruction. This is consistent with the dynamics of self-fulfilling prophecy. As another example Rattan, Good and Dweck [22] argue that instructors who comfort struggling students in math might be reinforcing a fixed mindset and thus limiting potential achievement.

Some of these concepts have been extended to biases for under-represented groups such as women in engineering amplifying stereotype threat [27] [3]. Many studies validate that the expectations of significant others including parents and teachers does impact student performance [22] [28] [29].

One particularly interesting study on college classroom "incivilities" by Boice [30] connected negative classroom activities to poor learning for students and discouragement for teachers. He used observational studies, surveys, and interviews over a five-year period. He was able to observe incivilities of both students and faculty and found these had a direct impact on learning. The vicious cycle of misunderstanding is illustrated in his quote: "Faculty who struggle with CI [classroom incivilities] in their classrooms mistakenly believe that the students can only be won over with pandering - easy assignments, tests, and entertainment in place of serious classroom material. In the usual vicious cycle that follows, faculty often find ways to confirm the misbelief when they alternate distant, demanding styles with periodic bouts of lower standards, students quiet, but only temporarily" (p. 480).

The arguments we make here about the need to understand instructor's assumptions, certainly apply to all of education, but we believe engineering education probably suffers more from a pervasive negative bias. The roots of engineering are set in the military and in the orientation toward progress [31]. Although this has produced great results, there is some evidence that the persistence of a culture based on these assumptions is one not at all hospitable to under-represented groups like women, Latinos, or African Americans [32]. Studying engineering faculty's assumptions with the potential to intervene in the system may have great impact on STEM education.

It is clear to us that the assumptions we hold about students could impact the methods used in the classroom, which could in turn impact learning. As a first step to investigate this we are asking: "What are the types and range of assumptions that we hold as instructors?"

II. METHODS

In order to gain insight into the various assumptions held by faculty, one of the authors facilitated a workshop at the Teaching Professor Conference in Boston in May of 2014. 150 participants collaborated in small groups and generated a list of nearly 100 assumptions that we as faculty hold about students. These were collected on a "Sticky Wall." During the conference the assumptions were sorted into *negative* and *benevolent* assumptions. The conference participants debriefed the assumptions and many commented on how easy it was to think of negative assumptions while it was hard to come up with the more benevolent beliefs. The whole of the assumptions were later sorted into categories to create the taxonomy.

Figure 1 shows this taxonomy of faculty assumptions. It is important to remember these are assumptions that faculty hold about students, and not the traits of the students. The assumptions do map onto exiting psychological theories (explained below) indicating these assumptions probably do have a correlation to actual students traits, but our interests in this work in progress paper is in laying foundational work around the range of assumptions that faculty hold.

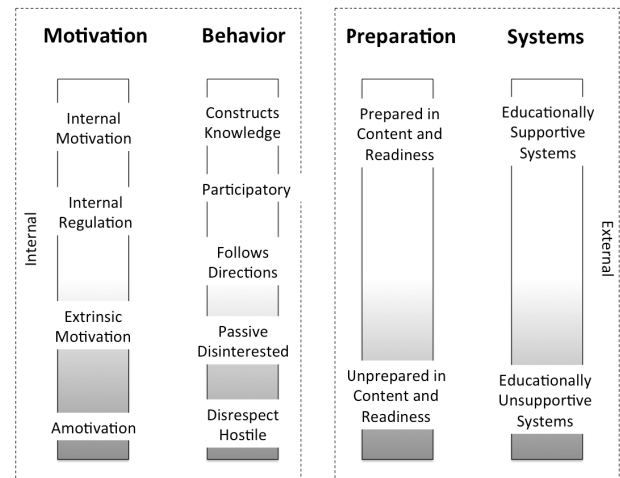

FIGURE 1: TAXONOMY OF ASSUMPTIONS

There are two general categories of assumptions: *Internal* influences and *External* influences. Within Internal we have identified *Motivation* and *Behavior*, and within External, there is *Preparation* and *Systems*. Below we explore each of these categories within the context of psychological theory.

III. PSYCHOLOGICAL THEORIES

To set a framework for exploring the assumption categories, we wish to be clear that although the taxonomy is presented as isolated, discrete groupings, in actuality they are mutually influential. Although each of the four categories are presented in order, across the domains there is interaction,

interdependence, and sway upon one another that yields a more complex process than the presentation might suggest.

A. Motivation

In their work on self-determination theory, Deci and Ryan [33] articulate a system ranging from motivated (defined as “energized or activated toward an end”) to unmotivated (defined by “no impetus or inspiration to act”). The authors further suggest that motivation can be distinguished in terms of *level* (quantity) and *orientation* (type), where the latter distinction relates to goals and attitudes.

Motivation is guided by attitudes and expectations about tasks, which are in turn directly related to goals and achievement behavior. Students’ motivation can vary in terms of whether they are striving to achieve due to a desire for positive outcomes (e.g. getting an A grade), which is an *approach* orientation, or because they are trying to *avoid* negative outcomes (e.g. not getting “bad” grade). Elliot and McGregor [34] further this distinction in describing what many have discussed as *mastery* and *performance goals*. Ryan and Deci [35], suggested this differentiation might be based on personal interest and curiosity versus seeking approval and recognition, respectively.

Intrinsic motivation relates to personal investment and leads to proactive behavior, depth of learning, retention of information, creativity, and is oriented to the mastery of a domain. Extrinsic Motivation conversely is derived from outside forces. In a learning context, this form of motivation relates to compliance and, worse yet, coercion where students engage in learning processes and assignments because they have to, not because of personal interest. Extrinsic motivation can lead to the same level of achievement as intrinsic, but the former form typically results in compromised retention of information because goals tend to be short-term. To clarify, the orientation of motivation as presented here suggests a dichotomous ordering, whereas in actuality the types are not mutually exclusive and may operate in combination or proportion.

Exploring how motivation ultimately translates into action adds complexity. We might consider motivation as related to potentials, whereas behavior is the actualization of motivational energy. For example, in taking the *Disrespect/Hostile* pole of the Behavior continuum, we understand it to be a predictable behavioral outcome as explained in Ryan and Deci’s [35] work. The authors assert that, “Students can perform extrinsically motivated actions with resentment, resistance, and disinterest... [which is] the classic case of extrinsic motivation” (pp. 55).

B. Behavior

Observable behavior can be considered as selection from a virtually infinite array of options. In theorizing about the influence perceptions of personal control have on behavior, Julian Rotter [36] posited the notion of *behavioral potential* to account for the litany of options for action available to each of us in any given situation. Rotter explained that *expectancy* of reward or punishment and *reinforcement value* decide our

actions. Regarding expectancy, students’ learning behavior depends upon their expectations of success or failure on exams and projects. Reinforcement value on the other hand relates to whether or not good grades and/or mastery of information are important to students. If neither of these outcomes matters to a student, or if more desirable alternatives are available, learning behavior will be undermined.

In providing a more balanced account, Kurt Lewin [37] challenged such one-sided notions in asserting that behavior (B) is a function (*f*) of both the person (P) and the environment (E): $B = f(P, E)$. More specifically, P symbolizes that which is internal to the individual (motivations, thoughts, and feelings), and E symbolizes the influential factors in the environment (setting, cultural factors, physical and social climate, interpersonal and sociopolitical histories). Lewin held that the person and the environment influence one another such that neither are passive recipients and that each responds to and influences the other. Dewey and Bentley [38] suggest, “A behavior is always to be taken transactionally: i.e., never as if the [student] alone, any more than of the environment alone, but always as of the [student]-environmental situation, with [students] and environmental objects taken as equally its aspects (pp. 290).”

All this is to stress the point that we have a role in students’ academic behavior. Our attitudes, interpersonal styles, and beliefs about teaching, learning, and students influence the environmental facets of the behavioral equation. As instructors, we must ask ourselves, “What is the environment of my classroom?... my campus?... and what is my role in that?” Learning, as well as teaching, is a social and relational event. If we do not endorse and embrace the fact that our behavior impacts the behavior of our students we miss the opportunity to reflect upon how our teaching assumptions and practices either facilitate or compromise students’ potential and learning.

C. Preparation

Student preparation can be divided into two broad categories; 1) that of information and skills derived from completion and retention of prerequisite course work (content knowledge), and 2) that of a broader level of readiness for college in general terms of cognitive strategies, transition knowledge and skills, and learning skills and techniques [39]. In reaching back across the previous two categories of the taxonomy, Gaertner and McClarty [40] assert that college readiness, related to content, is most notably impacted by students’ behavior and motivation. Conversely, the more general learning and transition skills relate more to readiness in terms of being able to navigate the college experience as a whole.

Preparation is increasingly discussed in terms of “non-cognitive” factors [39]. The ever expanding literature on First Generation College Students helps to highlight the specific challenges some students face in navigating the transition to college and the difficulty of engaging and thriving in a foreign environment. Often, the skills that got them to college are not

sufficient for subsequent success in and through degree completion. First generation students are simultaneously tasked with learning both discipline specific content as well as general college success skills, whereas second generation college students and beyond, the unwritten rules of college life and success are typically passed on from parents to children. In terms of utilizing resources, the example of instructor office hours comes to mind. There is a change that occurs in the shift from high school to college, wherein the former context “going to the office” typically holds a negative connotation, whereas in college utilizing office hours is viewed as a proactive behavior and often interpreted by instructors as a sign of engagement and motivation. Conversely, when instructors observe by way of performance that a student is struggling and reflect that the student has not sought help during the allotted office time, instructors may errantly interpret the lack of seeking out help as disengagement or laziness.

D. Systems

The systems dimension in the taxonomy reflects the external factors impacting students in their learning. Bronfenbrenner’s [41] widely applied ecological model accounts for the various systemic levels and their interactions in describing the educational contexts of students. At the center of the systems model, the *microsystem* addresses immediate interpersonal relations between a student and those she encounters in various academic or social settings which might include family, friends, classmates, and instructors. Next, the *mesosystem* refers to the interrelations and interactions between these specific groups. It is still rather immediate but occurs “around” the student more than always at the immediate transactional level where the student is central to the interaction. *Exosystems* are yet another step removed from personal engagement and denote major social structures that influence the individual broadly, yet not directly. They influence the other systems the individual is more intimately involved in. Finally, the *macrosystem* occurs at an overarching cultural level and is more abstract in housing the values learning that shape behaviors.

Beyond these broad categorizations, we must also address that many students face competing agendas for their resources of time, energy, and attention. From a diversity standpoint in terms of socioeconomic status, the funded, full-time, student-only lifestyle appears to be on the way out. Many students come from families who cannot afford to fund their education and as such must work part- or full-time jobs on top of being full-time students. In accord, we must be cautious in interpreting student grades as pure and equal markers for all students because not all students have the luxury of what may be assumed “typical” college reality in that academics are the primary focus of students’ lives. Finally, there are systems-based issues related to the climate of individual disciplines, such as engineering, as well as for the university at large. Research on college students’ sense of belonging [42] has been positively correlated to their identification with university and college life in a broad sense, as well as for

engagement and performance in coursework specifically. A systems perspective is broad yet necessary in understanding the range of both academic and nonacademic factors that impact students.

Given the list of assumptions and the above psychological theories we hypothesize that the assumptions we hold will map onto these categories. Figure 2 shows some of the actual assumptions collected at the Teaching Professor conference in May 2014 mapped onto the categories.

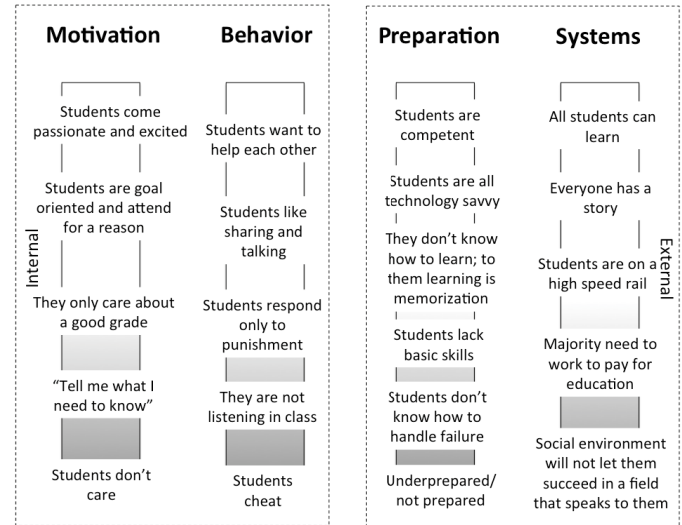

FIGURE 2: ACTUAL ASSUMPTIONS MAPPED ONTO TAXONOMY

IV. CONCLUSIONS AND NEXT STEPS

We are convinced that the assumptions faculty hold are influencing learning, in some cases these influences could be positive in others the assumptions held might be decreasing students learning. As a deep intervention into the system of education we are examining the assumptions we as faculty members hold about students. This work in progress paper is a first step in that direction. It is our intention to use this foundational taxonomy based on theories to continue investigating this issue. Our next step is to interview faculty and attempt to map an individual faculty’s assumptions onto this taxonomy. These individual taxonomy maps will serve to inform individuals as to where their assumptions fall on the full range of possible assumptions. We also hope to develop a collective picture of faculty as a whole.

We also are pursuing other research questions such as “How are pedagogical choices related to a faculty’s held assumptions?” or “Is there a correlation between faculty’s assumptions and actual students traits?”

We feel this is exciting and potentially transformative work in the area of psychology and engineering education that could potentially influence all of higher education.

Sociocultural approaches to teaching and learning in engineering education: Research-based applications in a pre-engineering course

Erika Mein, Christina Convertino, Angelica Monarrez

College of Education
The University of Texas at El Paso
El Paso, Texas

Abstract— In this paper, we propose a sociocultural approach as an alternate model of teaching and learning to replace existing and often ineffective models of direct instruction in engineering education. We discuss preliminary findings from a project funded by the U.S. Department of Education Minority Science and Engineering Improvement Program to demonstrate the implementation of a sociocultural model of teaching and learning in a freshmen pre-engineering course at a large, Hispanic serving institution located on the US-Mexico border. Specifically, we highlight four features of sociocultural teaching and learning as applied within the context of key activities in this course. These four features include: peer-scaffolding, learning-in-practice, distributed expertise, and engineering-specific writing. Findings from student interviews and focus groups, as well as classroom observations, show that student learning and engagement are positively impacted by class activities that are constructed with an emphasis on small-group social interaction and participation in authentic engineering tasks.

Keywords—sociocultural theory; situated learning; authentic engagement; participation; hands-on learning; student-centered learning.

I. INTRODUCTION

The National Academy of Engineering (NAE) identified student learning as a top priority to 21st century engineering education [1]. Specifically, this "new frontier" in engineering education aims to change the paradigm for the teaching and learning of engineering at the foundational level by moving away from lecturing, what is often referred to as a "sage on the stage" approach. In this paper, we propose a sociocultural approach as an alternate model of teaching and learning to replace existing and often ineffective models of direct instruction in engineering education. While there is emerging interest in the field of engineering education [2]-[4], few empirical studies have examined the ways in which sociocultural approaches impact student learning and engagement in actual engineering classrooms. In this paper, we discuss preliminary findings from a project funded by the U.S. Department of Education Minority Science and Engineering Improvement Program to demonstrate the implementation of a sociocultural model of teaching and learning in a pre-engineering course at a large, Hispanic serving institution located on the US-Mexico border.

At the center of sociocultural theory is the idea that learning is a social and cultural phenomenon rather than solely individual [5]. In other words, while "sage on stage" approaches to teaching and learning focus on cognition as an individual process that takes place solely within the learner's brain, sociocultural approaches to learning focus on social interaction, authentic engagement and the learning environment. Some of the principal characteristics of a sociocultural model include: the importance of authentic activities to promote learning; the importance of the collaborative construction of knowledge; the need for coaching and scaffolding at critical moments; and the importance of reflection to encourage the formation of abstractions [6].

In what follows, we illustrate how these features of a sociocultural model were visible in three key course activities and highlight how these activities facilitated student learning in the freshman pre-engineering course. The three activities that we present are: (1) peer math groups; (2) a robotics project; and (3) the use of engineering notebooks. It is worth noting that our use of the term "activity" rather than assignments is purposeful and merits a brief definition given the focus of this paper. According to sociocultural theories of learning and teaching, in particular *cultural activity theory* [7]-[8], *activity* is a foundational component to socially situated sense making interaction and engagement. Within the context of our study, course activities were the primary unit of analysis to explore the role of sociocultural approaches to learning in engineering education.

II. METHODOLOGY

This study is part of a larger funded project aimed at fostering metacognitive practices to support the persistence and timely completion of students who are historically underrepresented in engineering, namely Hispanic women and English Learners [ELs]. The project represented a collaborative effort between educational researchers in the College of Education and researchers in the College of Engineering at the university. Drawing on the tradition of educational anthropology, we employed an ethnographically-informed qualitative approach to identify and analyze the role of sociocultural approaches in promoting student learning in a freshman pre-engineering course at the center of the project.

With the goal of describing and interpreting the social world, ethnography involves immersion into the everyday interactions and experiences of participants in order to “see firsthand how people grapple with uncertainty and ambiguity, how meanings emerge through talk and collective action, how understandings and interpretations change over time, and how these changes shape subsequent actions” [9]. By being immersed in the freshman pre-engineering course as participant observers, we were able to observe and describe the actions and interactions of students within this one particular setting, and then make sense of those actions in light of sociocultural theories of learning.

Data were collected across two sections of the pre-engineering course during the Fall 2014. Four primary sources of data were collected: (1) a demographic survey soliciting information about language and schooling; (2) participant observations during class meetings; (3) in-depth interviews with select participants; and (4) focus groups with all participants. The in-depth interviews conducted with select participants included one interview at the beginning of the semester and a follow-up interview towards the end of the semester. In order to have a diversified group of students to be interviewed, students were selected based on their language background, location of K-12 schooling (e.g. Mexico or U.S.), and gender. Individual interviews were conducted with 12 students, seven females and five males. Nine of these students attended K-12 schooling in the United States, while three attending K-12 schooling in Mexico. In addition, ten of the selected students reported both English and Spanish as their native languages while one student reported only English and another reported only Spanish as their native language. The focus groups, which were conducted with all participants in both course sections, lasted 60 minutes on average. Finally, more than 50 combined hours of classroom observations took place over the course of the semester by all three authors.

All interview and focus group data were transcribed and coded in the qualitative software NVivo 10 using an “open coding” and a “focused coding” approach [9]. A total of 22 interviews as well as the two focus groups and observational notes were analyzed and coded for themes and patterns that emerged across the data sources. For this analysis, we focused on the three principal activities of the course – peer math groups, the robotics project, and the use of engineering notebooks - to examine students’ perspectives on and experiences with these activities in relationship to their learning. Key themes (codes) that emerged in NVivo included *students as resources*, *student collaboration*, *student negotiation*, and *problem-solving*. The authors of this paper participated in a series of data analysis sessions at each stage of analysis to discuss emerging themes, which ultimately led to the presented findings below.

III. FINDINGS

A. Peer math groups

Peer math groups were the first activity introduced in the pre-engineering course. Specifically, expert-novice groups were formed to promote mathematical learning on six pre-defined pre-calculus topics: polynomials, functions,

exponentials, logarithms, unit circle, and trigonometric functions. These topics were chosen because the majority of students enrolled in the course were simultaneously enrolled in pre-calculus. Using a random process of assignment, six “expert” teams were created. Each of the six expert teams was responsible for developing expertise in one topic. Expert teams used multiple resources to facilitate their becoming “experts” on their math concept. For example, expert teams consulted math texts, online tutorials and other experts, like the course instructors, family members and friends. Additionally, students in each of the expert groups had varying degrees of prior expertise on the math concept. In sum, expert teams drew on a range of resources and competencies to develop shared expertise on the topic.

Novice teams were formed by randomly assigning one student from each expert group to a novice group so that each novice group included one “expert” in polynomials, one in functions, one in exponentials, one in logarithms, one in unit circles and one in trigonometric functions. Once the expert-novice groups were formed, students worked in their expert group to acquire expertise with fellow expert group members on the assigned math concept during one week and then on alternate weeks students would work in their novice group. Within the novice group, each student was responsible for “teaching” the math concept from their expert group to the rest of the novice group.

A central sociocultural feature of the expert-novice groups was *peer-scaffolding*. Scaffolding is shorthand for the *zone of proximal development* (ZPD) in sociocultural theories of learning [10]. ZPD is the idea that learning occurs through socially situated interactions with peers or adults who have different levels of understanding relative to a given task or concept. In keeping with a “societal” perspective of ZPD [11], the math groups constitute a collective activity in which learning represents “the changing relations between newcomers and old-timers in the context of a changing shared practice” [11].

By designing collective activity systems, like these math groups, novice students were able to learn new math concepts as a consequence of the interactions and authentic engagement with expert or “old-timer” students. For example, during an interview, Clara, a Latina student, described herself as “not good at math,” “really slow with math,” and “not as smart as” other students in her math class; at the time of the interview she was enrolled in a pre-calculus college course, even though she had taken a semester of calculus in high school. She also indicated that her pre-calculus professor “teaches by just writing it out” with little to no explanation, about which she said, “I’m not used to this.” However, in contrast to the “sage on the stage” approach of this professor, Clara talked enthusiastically about how the high levels of engagement and interactions in her novice-expert math groups had a positive impact on her understanding of math concepts. Specifically, she explained that she learned “a lot more” from the math-novice group than from her pre-calculus class, stating “...because I was seeing it, I was doing it, and the way we would have to teach it... it helped me learn more.” She also emphasized the importance of interactions in her math expert-novice group, drawing a contrast with the note-taking that took

place in her more teacher-centered pre-calculus course: "...when the other groups present it also kind of kept my attention 'cuz of the way they would present it and the way they would interact with us. That also helped a lot for me to memorize...those [concepts]."

Importantly, data from this study also demonstrate that a sociocultural rather than an individual approach to learning benefits students at all stages of understanding and not just novices. For example, Ana, another Latina student, talked about the effects of engaging as the "expert" in the context of the novice-expert groups on her learning, "I can learn hands on and visual as well but I also learn by explaining to others and I think that's something that a lot of us should do more often because then we actually know and understand the material better."

While it is beyond the scope of the current paper to explore other sociocultural features that were a part of the math groups, we want to highlight the significance of ZPD or peer-scaffolding as forms of authentic engagement and social interaction rather than more traditional models of teacher-centered lecturing.

B. Robotics project

The second key activity in the pre-engineering course was a small-group robotics project. This project took place in the second half of the semester following the math expert-novice groups. In this project, small groups worked together to design and build their own robot using Lego Mindstorms. The small groups were formed randomly, using different configurations of students than the math expert-novice groups. Like the math expert-novice groups, this activity illustrated the ways in which participation in authentic engineering activities contributed to student engagement in learning. Two sociocultural features were particularly visible in this activity: *learning-in-practice* [11] and *distributed expertise* [12].

Learning-in-practice makes reference to the ways in which learning is facilitated by engagement in authentic tasks and activities and participation in the social practices tied to those activities [11]. One student, for example, describes the trial-and-error process that was involved in creating a soldier robot to replace human soldiers as part of their Systems Engineering project: "we started building a robot and well first we like I don't know it just kind of developed because like as we were building our robot we realized we kind of needed a tank and then like we were just experimenting." Learning in this instance did not occur solely in the abstract or in the minds of students; rather, it occurred through participation in the social and material act of constructing a robot. From a sociocultural perspective, the building of a robot represented "learning [as] doing" within a particular context [3].

While the physical artifact of the robot served as an important tool for learning, such learning transpired primarily through peer-to-peer interactions within and across robotics groups, which consisted of 3-5 students each. These groups became an important site for "distributed expertise," which emphasizes the ways in which knowledge and expertise can be spread among participants in a given setting, and the ways in

which participants "mutually appropriate" such expertise through social interaction [12]. Within these groups, students had to negotiate their roles in order to accomplish the robotics task at-hand. In both interviews and focus groups, several students from different groups highlighted the ways in which different team members contributed different skills to the design process. One student, for instance, described the importance of role and tasks within his group: "What helped a lot was knowing what each teammate has to do, I mean, to move fast because every teammate has a specific function within the group and I mean if you do that you can finish your project..." Several other students highlighted the need for specific programming knowledge to complete their robots. In one group, two participants volunteered to be the programmers, thus offering a particular skill set in the robot development process. If no group members held that expertise, participants looked to known programming experts from other groups. Such practices illustrate the ways in which expertise was distributed both at the small-group activity level as well as the classroom level.

C. The use of engineering notebooks

The third key activity in the pre-engineering course was the use of engineering notebooks as part of the robotics project, where students documented their robot design and development process. The use of engineering notebooks represented an engineering-specific writing task situated within the robotics activity. This task can be seen as a key illustration of writing as a form of social action tied to authentic settings and tasks, in this case, the engineering-specific task of designing a robot [4], [12]-[13].

All of the robotics groups in the pre-engineering course utilized the engineering notebooks, but the notebooks took on different meanings to different groups. In one group, for example, the engineering notebook played an important mediating role as the four group members negotiated the type of robot they would build. One group member, Daniela, explained in an interview that the rest of her teammates, all male, wanted to build a very complex robot, "something really big, something really spectacular." Concerned about time constraints and also about not wanting to make a decision "in an authoritative way," Daniela encouraged her team to brainstorm different possibilities for robots. The group used the engineering notebook to draw and discuss models of different robots; Daniela reported that, through the process of brainstorming ideas in the engineering notebook, the group discovered that some of their original ideas were "too complex [and] maybe not so useful for engineering." They instead chose to pursue a robot of simpler design, one that prevented accidents by "cleaning up" color-coded hazardous waste materials.

In addition to playing a mediating role in some groups, the engineering notebooks also played an instrumental role in many groups, serving as a mechanism of communication between group members. Several groups reported using the notebooks to document their progress on the robot and to communicate about next steps needed in the process, as

different configurations of group members met at different times. In all of the groups, the writing that occurred through the notebooks was closely tied to the task at hand; in other words, students participated in authentic forms of engineering communication that were situated in an authentic engineering activity [4].

IV. DISCUSSION

In this paper, we highlighted four features of sociocultural teaching and learning as applied within the context of key activities in a freshman pre-engineering course. These four features included: peer-scaffolding, learning-in-practice, distributed expertise, and engineering-specific writing. We showed the ways in which peer-scaffolding in math expert-novice groups better facilitated student learning of fundamental pre-calculus concepts in ways that differ substantially from traditional “sage on the stage” approaches. We also showed how student engagement in the hands-on development of a robot encouraged learning by trial-and-error through participation in an authentic engineering task (learning-in-practice) and paved the way for different group members to contribute different kinds of knowledge to complete the task (distributed expertise). Finally, we demonstrated how the use of engineering notebooks as part of the robotics project represented a form of authentic engineering communication tied to an authentic task. Findings from student interviews and focus groups, as well as classroom observations, show that student learning and engagement were positively impacted by class activities that were constructed with an emphasis on small-group social interaction and participation in authentic engineering tasks.

In total, these findings highlight the ways in which undergraduate courses can be designed using sociocultural principles in order to foster greater student learning and engagement. Following, this study also illuminates the need for more systematic research on the implementation of sociocultural approaches to teaching and learning in engineering education. The shift from individualized notions of cognition and learning to social understandings of distributed cognition and learning through participation holds great promise not only for engineering education. Such approaches are especially critical to broadening the participation of traditionally underrepresented students in engineering education, who stand to gain the most from teaching and learning that actively promotes collaboration over isolation..

ACKNOWLEDGMENT

The “Developing Metacognitive Learners to Persist and Achieve Timely Completion of Engineering” project is supported by a grant from the U.S. Department of Education under the Minority Science and Engineering Improvement Program (MSEIP), Award #P120A130041

Abstract— Since 1993 nine universities in the University of Texas System and several affiliated community colleges have worked collaboratively to promote STEM undergraduate research through the Louis Stokes Alliance for Minority Participation. In 2012 the Alliance was recognized as a model Senior Alliance by the National Science Foundation and to expand on its work an international research component was added: the Summer Research Academy Abroad (SRA-A). Our first cohort of eight students travelled abroad during the summer of 2014. The students participated in an intensive undergraduate research experience for eight weeks and thus became part of the global STEM community. Prior to their departure these students enrolled in a spring 2014 online seminar to prepare them for both the scientific and cultural components of the SRA-A experience. They learned to operate with confidence in new, unfamiliar environments and gained a multicultural perspective. They also acquired early membership and credibility in the global science arena and began to understand the competitiveness that drives the international research community. This paper discusses program details, participant profiles, and assessment after the program's first year of operation.

Keywords—undergraduate research, international experience, underrepresented minorities

I. INTRODUCTION

The demographic landscape in the state of Texas is changing at an astonishing rate. According to the US Census Bureau, in 2010, African Americans and Latinos accounted for nearly 50% of the Texas population. However, enrollment of and degrees received by underrepresented minorities (URM) in postsecondary education have remained below targets set by

the Texas Higher Education Coordinating Board. Given these disparities in educational attainment, the University of Texas System is taking steps to close these gaps for low income and URM students. The University of Texas System Louis Stokes Alliance for Minority Participation (UT System LSAMP) was inceptioned to improve enrollment, retention, performance, and graduation of URM students in Science, Technology, Engineering and Mathematics (STEM).

As a senior alliance we have three main goals: (i) enhancing our Summer Research Academy (SRA) to include national laboratory and international experiences, (ii) matriculation to STEM programs at UT System universities for participating community college students, and (iii) creating synergy with other NSF research training projects. These goals will prepare our students to be more competent and competitive for graduate studies or in the STEM workforce. The SRA-A is our response to the need for true globalization of higher education. These goals will allow us to continue providing URM STEM students with valuable research opportunities at UT System universities, US Department of Energy National Laboratories, and international research sites.

II. PROGRAM DESCRIPTION

The following description of the program reflects lessons learned from the first cohort of participants. Planning for the SRA-A begins a year in advance of the participants' time abroad. Potential applicants are informed about the program details and application deadlines via email and through various presentations. In addition, interested students are encouraged to access weekly blog posts by previous SRA-A participants. Recruitment efforts also take place at the annual LSAMP conference held each September. Previous SRA-A participants are prominently featured at the conference and are available to speak individually with interested students. The

application deadline is set for mid to late October of each year, allowing time for students who attend the conference to submit the required application materials.

After the application deadline the individual campus directors evaluate applications submitted by students from their home institutions. With fourteen partner institutions and eight funded placements each summer, each campus can send one of their students abroad nearly every two years. Students are notified of the offer by email in mid-November and given two weeks to accept or decline.

Following acceptance in November, an individual video conference is held with the program coordinator and each participant. The goals of the meeting are to:

- Test-run/troubleshoot the video conferencing technology employed;
- Introductions and discussion of roles and expectations;
- Review the program timeline and confirm availability for the mandatory spring seminar;
- Discuss research interests, plan strategies, and assign the next steps for securing a research placement;
- Address potential barriers to participation such as obtaining a passport, family concerns, and time conflicts.

This initial meeting is critical as the search for the research placement abroad starts almost immediately. A discussion of roles and expectations at the outset clarifies that the student and the program coordinator are partners in planning for the time abroad. The student understands that s/he must take ownership of preparations and that the program coordinator will act as a coach, providing support, guidance, and expertise.

Searching for the research placement abroad is the first task students undertake as part of the pre-departure process. Each participant secures a placement in a research group or laboratory abroad that fits both the student's area of interest and his/her country or language preference. There is no list of prearranged placements or mentors; however, students are encouraged to take advantage of previously-formed connections made by prior SRA-A students. For the application, students select their top three destinations from a list of approved countries. If a student wants to secure a placement in a country not on the list, the student needs to demonstrate that costs are within budget, that the appropriate visa can be obtained, and that the country is not on the US State Department Travel Warning list.

To reduce anxiety and uncertainty about the process, on-going communication is key. To ensure this communication takes place, participants are required to send a brief email update to the program coordinator each Friday until the placement is confirmed. This informal check-in creates an additional opportunity for trouble-shooting, devising next steps and strategies, and building the partnership between the student and the program coordinator.

To facilitate communication with potential supervisors abroad, students are given an LSAMP program information sheet which outlines the program and expectations and is written with the potential research mentor in mind. Sample introductory email messages are also provided as templates to use when contacting faculty abroad.

There are three possible strategies for securing a research placement:

- The student consults with their current research supervisor at their home institution to consider international placement with a research collaborator abroad.
- The student searches the web on his/her own for research groups and labs doing work in-line with interests, identifies appropriate faculty members to contact, and makes initial contact.
- The program coordinator asks LSAMP campus directors, faculty members at the home university, and faculty supervisors abroad who have hosted SRA-A students in prior summers for advice and leads.

The first approach has proven to be the most efficient means of securing a placement that is a good fit for the student, although students have been successful finding excellent placements by searching and contacting potential supervisors on their own. Placements will preferably be confirmed for all participants by January, before the start of the preparatory seminar.

From February to May students participate in a weekly, one-hour, non-credit seminar via video conference from their respective campuses. The seminar prepares participants for the time abroad, and also creates a virtual space for the students to create a community. Topics include:

- Course introduction: Introductions; review of the syllabus; research placement updates and next steps;
- Program expectations: Behavioral expectations; code of conduct; drug and alcohol policy;
- Travel planning and budgeting: Scholarship funds; how to create a budget; tools for estimating expenses; currency exchange; emergency funds; how to book the flight; how to find housing;
- Culture, language and country specific information: Learning about the host country (culture, language, history, geography, government; racism, sexual orientation, gender);
- Health and safety, emergency preparedness: Staying safe while abroad; immunizations, medications, International SOS, international health insurance, US and in-country emergency contacts, US State Department STEP program;
- Expectations at the home university: Informing the local university study abroad office of the LSAMP program and the trip abroad, purchasing of international health insurance; providing all required documentation;

- Research readiness: Final preparation for the research experience, communication with the faculty mentor abroad;
- Flight/day of arrival: Travel tips, transportation from airport, jet lag, notifying family of safe arrival;
- Communication and summer blog: Connecting with family, cellular telephone coverage, internet access, blogging expectations;
- Final check-in: Packing tips, troubleshooting last minute details.

Each participant receives \$7,150 in support: \$3,800 for travel, room/board, and a \$3,350 stipend. Funds are disbursed as two scholarship payments. The first, for \$3,800, is paid in late February so students can purchase flight tickets and pay housing deposits. The participants receive the second payment, for \$3,350, at the beginning of May, giving them sufficient time to deposit funds prior to departure.

Participants must meet the requirements for travel abroad set by their home institution's Study Abroad office. These requirements vary by campus, but usually involve providing emergency contact information, an itinerary, and arranging for international health insurance coverage. In addition, by April 30th participants must provide the SRA-A program coordinator a document with the following: research placement information, including name, email, phone and address for the faculty supervisor; flight itinerary; student's cellular phone number and physical address while abroad; name, address, phone of emergency contact person in the US (usually a parent, friend, or spouse); name, address, phone of emergency contact person in the host country (usually the research supervisor); and contact information for their home university study abroad office.

The primary focus during the summer is participation in the eight-week international research experience, dedicating approximately 40 hours per week to the effort. Additionally, students are required to blog about their time abroad, writing about their experiences both in and out of the lab.

Upon their return in September, participants present their research at the annual UT System LSAMP conference. They also participate in a panel discussion about their international experience. Finally, they are required to complete a post-program survey and participate in focus groups.

The 2014 SRA-A program included a total of eight student participants; seven male and one female student; five seniors, two juniors and one sophomore; three Latinos, one African American, two multi-racial, and two Caucasian students. The students came from a variety of academic disciplines: engineering and computer science, life/biological sciences and chemistry. The students traveled to four European countries: England, Germany, Italy, and Switzerland. With the exception of the student in England, none of the students were fluent in the language of their assigned locations.

III. PROGRAM EVALUATION

In order to assess the impact of the SRA-A program on the participants, the students were required to take a survey and participate in focus groups upon their return.

A 32-question survey queried the students about their level of satisfaction with the just-completed SRA-A experience and their perceived gains in six pre-determined categories. Of the eight participants in the 2014 SRA-A there were six valid surveys; one student did not take the survey and another registered for it but did not answer any of the questions. It is unknown why these two students did not complete the survey. All the students were participating in their first international student experience. Below are some interesting trends and data tables that explain the important facets of the survey.

An important consequence of participating in the SRA-A is the ability of the students to focus ahead more sharply and make better choices for further studies and career plans. In every instance, the majority of the students found that the experience had a positive and helpful impact on their graduate school plans. Other survey questions revealed that before participating in the 2014 SRA-A, three of the students definitely planned to go to graduate school and two had thought about going to graduate school. After the SRA-A, four of the students planned to definitely go to graduate school and one was considering doing more research abroad. Two planned to pursue a doctorate and one a masters in a STEM discipline; one planned to earn an MD/PhD; and another an MBA. Three of the students were not sure where they would pursue graduate school, but two were planning to attend their present institution and three had not yet decided.

The focus group, with *all* eight SRA-A participants in attendance, lasted approximately 1.45 hours. During the focus group meeting, the students were very open regarding their impressions, experiences, and recommendations for future SRA-A cohorts and placed particular importance on sharing these thoughts. The general agreement was that, albeit some glitches, each of them would go through the experience again. It is important to note that the time spent during the focus group on the discussion of the topics listed below was extensive and considered very important by the participants, thus overshadowing any extended discussion of other areas, which to them were less important. Following is a summary of the participants' most salient and emphatic comments:

- The Alliance must start the whole process of preparation and coordination earlier, possibly even before students leave for their winter break so that they can use that time to research and work on their preparations; students found the blog to be very useful;
- The program coordinator and students must pay special attention to the "comparative perceptions" of the same field in a different country: for example, is the definition of industrial engineering the same in Italy as it is here?

- The program coordinator must better explore the housing issue, especially the possibility of university housing at area institutions;
- Students need better training regarding money exchanges and finances; especially about the cost of living in the host country and the different rates of exchange, which dictate how far the stipend can stretch;
- Although students found that language issues were not relevant in the lab setting, they would benefit from some type of language training for emergencies and basic needs, and some additional language training suggestions should be provided;
- All students agreed that they should develop “what if” strategies to address possible problems, and that there needs to be a “back-up” plan in case the assignment does not work out to enable the participant to switch to a more meaningful experience mid-stream, if necessary.

Level of agreement with the following statements regarding the SRA-A experience					
	Strongly Agree	Agree	Disagree	Strongly Disagree	n/a
My SRA-A exceeded my expectations	3	1	1		
Instructions I received were very helpful	3	2			
I was happy with living arrangements	3	2			
I was happy with my research assignment	2	2		1	
My staff supervisor was excellent teacher & mentor	3	1		1	
My faculty mentor provided excellent guidance & direction	3	1		1	
Working with the other students was best part of summer	3	1		1	
I will definitely seek to participate in another	4				1

SRA-A					
I would recommend the experience	5				

My SRA-A experience has allowed me to . . .						
	Strongly Agree	Agree	Disagree	Strongly Disagree	Neither	n/a
Improve my overall research skills over the summer	2	2		1		
Be more ready to cope with the demands of a project	2	2	1			
Enhance my familiarity with research tools	4				1	
Improve my ability to analyze data	3	1	1			
Improve my skills in analysis results interpretation	3	1	1			
Improve my laboratory techniques	1	3				1
Better manage information	2	2			1	
Improve understanding & interpretation of literature	2	2	1			
Be more open to the discovery of new ideas	2	2				1

IV. CONCLUSION

The data demonstrates that SRA-A is providing a valuable research experience and a global perspective. It is also allowing participating students to identify professional options to solidify their future career plans. A new group of seven students is doing research abroad during the summer of 2015, and data will be collected and analyzed by mid-September. Recruitment for SRA-A 2016 began in June and the application will be available until October. The UT System LSAMP SRA-A team will begin publishing and disseminating the results of this work to identify partners and opportunities for funding beyond the current phase and future institutionalization.

Abstract— The Center for Engineering Pathways to Innovation (Epicenter)'s initiative for faculty development and institutional change – called Pathways to Innovation (Pathways) – is working with U.S. engineering schools to embed innovation and entrepreneurship learning opportunities into the undergraduate experience. Pathways' program design is grounded in the literature that identifies "best practices" in faculty development and institutional change. Each participating institution begins its work with a process of documenting resources (assets) and identifying gaps at their school to create a "landscape analysis." That analysis then becomes the basis for identifying well-defined objectives for focused work to create meaningful change over a short period. The mapping process itself becomes a vehicle through which a large number of stakeholders throughout the institution are engaged. While this process of asset mapping is well-referenced in change literature, its application to curricular change is novel. The specific objectives of the Epicenter project are to increase the access to innovation and entrepreneurship learning opportunities for undergraduate engineering students; however, aspects of the landscape analysis process are relevant to a much wider audience of faculty and administrators seeking to implement curricular change beyond one instructor and/or one course. This paper reviews the research underpinnings of the landscape tool and describes its evolution based on early formative evaluation. Further, the paper illustrates the tool's use in more than 35 engineering schools with widely-varying profiles (*i.e.*, public/private, small/large, rural/urban) and reports on how the tool has been used by teams to identify appropriate change strategies and increase engagement in their project by stakeholders. Finally, the paper identifies future directions and uses for the tool as well as possible topics for future research.

Keywords—*institutional change, curricular change, entrepreneurship, innovation, faculty development, evaluation*

I. INTRODUCTION

The Pathways to Innovation program (Pathways) is a faculty development and institutional change initiative of the Engineering Pathways to Innovation (Epicenter) project, funded by the National Science Foundation and managed by Stanford University and VentureWell (formerly NCIA). Epicenter's aim is to equip engineering students with the knowledge, attitudes and skills needed in a world marked by rapid technological transformation. Based on a preliminary

literature review of effective strategies for faculty development and change in higher education [1], Pathways uses a team-based guided change process to help faculty and institutions introduce and embed innovation and entrepreneurship (I&E) into curricular and cocurricular educational experiences for undergraduate engineers.[2]

Schools participating in Pathways assemble a team of faculty and administrators (and students in some cases) to explore exemplary models for including I&E in engineering and then implement appropriate strategies on their own campuses. The two-year process is highly context-specific; the program provides teams with a range of possible opportunities and avenues and provides coaching as they select and combine those most appropriate.

II. GOALS FOR THE TOOL

The literature review identified key themes for staff to incorporate into the program, two of which became the goals for a tool to support teams in their work.

The first theme emphasizes context-specific changes, rather than the "imposition" of a single approach. The tool should therefore foster strategic change by providing teams with a clear assessment of their environment and the institutional strengths they might leverage in the service of a range of approaches.

The second theme is the need for a mechanism to provide outcomes-based feedback to Pathways institutions themselves, Pathways program staff, and evaluators. Ideally the mechanism would be a tool and accompanying process that efficiently, systematically and (where possible) quantifiably documents the state of the institution before and after the program intervention. By describing the status of the campus at a point in time, it could also serve as a mechanism to confirm campus awareness of said institutional changes. The tool should also evaluate the degree to which Pathways provides effective tools and processes for effecting change on a campus.

III. RESEARCH UNDERPINNINGS

Higher education institutions typically employ a number of different assessment strategies. One mechanism that often lies underneath such assessments is the rubric; rubrics improve the reliability of scoring assessments, and foster self-assessment and reflection, which leads to improved learning outcomes.[3]

This work is supported by the National Science Foundation: DUE 1125457.

Rubrics need not be restricted to learning outcomes, as illustrated by the PULSE “Vision and Change Rubrics”[4] which is used to help institutions gauge the degree to which recommended curricular innovations in life sciences are happening on their campus. A rubric’s ability to improve reliability, while also fostering reflection and enabling the assessment of change undertaken, led to the use of a rubric-type approach as a starting point for the type of evaluation tool sought.

However, a rubric is not intended to help teams leverage aspects of a multi-faceted environment; for this purpose an approach known as “asset mapping” is a more appropriate starting point. While not a part of educational institutions’ traditional planning processes, asset mapping is readily recognizable in other disciplines, particularly community development and public health. There is a body of knowledge around its use and impact in those settings [5], much of which is relevant to higher education.

Asset mapping has its roots in geographically mapping an organization’s physical assets. Kretzman and McKnight [6] extended the approach by transferring the conceptual framework to the civic sector, where it became known as a cornerstone of “asset-based community development (ABCD)” or one of its variants, including the appreciative inquiry facilitative approach.[7]

Asset mapping avoids a deficit-based perspective that focuses primarily on what is lacking and yields mixed results: incremental improvements but no significant transformation. Instead, asset mapping takes as a starting point the collective knowledge of a community or institution, with the aim of subsequently building on those strengths (assets), to create change. Beyond forming a repository of information, the process of asset mapping is a collective activity and itself becomes a vehicle for developing social capital and a basis for consensus about future actions.[8] Crucially, it shifts the locus of control for change from a positional leader to the community being engaged in the mapping process.[9] The customary role of the facilitator or organization leading the planning process also shifts from one of control to one of partnership in a form of “action research.” [10]

The qualities of asset mapping that make it effective for community development are also useful toward the Pathways goal: change that goes beyond an isolated course or program and change that is widely embraced within the institution. In a university setting, no one individual - even the president - can mandate changes that will be adopted across the institution.[11] Asset mapping acknowledges this reality and helps equip a larger campus network to effect change rather than relying on positional leaders. The Pathways team serves as the nucleus of this new network. The landscape process also accelerates the formation of a “community of practice”[12] with social capital, including connections (especially across departments or colleges) and relationships characterized by trust and mutual obligation, and a common vocabulary.[13]

By combining a rubric-type approach with asset mapping, the landscape tool provides a strategic and context-appropriate starting point for each institutions’ plans to integrate innovation and entrepreneurship, a mechanism for growing the network of

stakeholders attached to the change initiative, and may also provide an evaluation feedback loop.[14]

IV. TOOL DEVELOPMENT

When developing the landscape tool, the PULSE rubric, with its focus on institutional change in a STEM discipline, was influential. Several themes found in the rubric were highly relevant: faculty development and training, development of learning spaces that support desired outcomes, and leadership support of faculty professional development.

Another source of inspiration when developing the landscape tool was the the Kern Engineering Education Network’s (KEEN) “Activity Matrix” that documents the strategies initiated by schools that form part of that network.[15] The KEEN matrix is not a rubric *per se*, in that there is no assessment of outcomes. Rather, it provides a format for cataloging the presence or absence of different curricular and infrastructure components at institutions, rendering it similar to the asset mapping approach outlined above. These different components aligned well with the different components of the innovation and entrepreneurship (I&E) ecosystem that Pathways was interested in fostering and measuring (*i.e.*, co-curricular and curricular programming, learning spaces, faculty training).

The resulting tool was a spreadsheet comprised of six worksheets, each cataloging different parts of an institution’s ecosystem that might foster I&E knowledge, skills, attitudes and experiences. In the “Courses,” “Programs” and “Extra-curricular” sheets, teams documented curricular offerings; in the “Spaces” sheet teams listed physical spaces that foster I&E learning; in the “Leadership” worksheet, teams captured initiatives and strategies emerging from either central administration or engineering that could ultimately foster I&E education on campus (*e.g.*, incentives for new course or program development, or faculty professional development); in the “Champions” worksheet, teams identified individuals that might have the enthusiasm, skills, knowledge and time to assist teams in their efforts. In keeping with the assessment goals of a traditional rubric, a “scorecard” column was included on each sheet, along with the number of students served by different programs where appropriate.

Given the Pathways focus on the integration of I&E, various concepts deemed critical to this field of study were also incorporated. The tool included recommended definitions for innovation and entrepreneurship to promote a common understanding of the two terms, given the myriad of definitions currently in use.[16] [Also included were matrices that invited institutions to consider whether their institution focuses more entrepreneurship or innovation, and the overall degree to which classes are taught using experiential learning, an approach deemed critical to effectively teaching and learning entrepreneurship.[17] On a more granular level, the “Co-curricular” and “Spaces” worksheets included drop down boxes to select the types of assets that promote I&E learning.

The resulting spreadsheet was shared with the team leaders of the first participating schools at a one-day training workshop at the project’s launch in January 2014, with an accompanying short training overview. Team leaders were asked to complete

the tool with their teams over the next month and to bring the completed tool with them to the project's next event, an in-person gathering of all twelve teams at which they would draft a strategy for integrating I&E into their engineering programs by identifying specific ways in which existing strengths could be amplified or leveraged to address gaps in educational offerings.

V. EVOLUTION OF THE LANDSCAPE TOOL

While many teams found the process of completing the landscape inventory challenging, evaluation feedback revealed that the tool provided them with the hoped-for foundation for planning. However, observations of the way the landscape tool was completed, along with an increased understanding of what was important (and conversely unimportant) for the teams to document, pointed out several shortcomings of the tool.

First, completion of the landscape tool is intended to be a group activity, consistent with its roots in asset mapping. However, the static Excel spreadsheet format made this difficult, as members could only contribute information asynchronously unless they were physically in the same room. This meant that often a single individual entered most data, or

the data entered was limited to information that could be easily recalled, and/or made readily available to group members during a meeting. Additionally, the completed landscape tools contained an enormous amount of data, but it did not provide a summarized version of their data along any of the dimensions collected, or tools to compare an institution's own landscape with another school's or aggregated across all the Pathways schools. Finally, soon after the release of the tool, the project staff and evaluators began to grapple with the fact that while the landscape provided a robust baseline, it did not incorporate any mechanism for tracking changes over time, other than a general intention to have the teams update their tools at a later date. In response to these observations, the tool was revised in several ways and introduced to the second group of participating schools in January 2015 (a screenshot is included as Fig. 1):

The tool was converted from a standalone Excel document to a cloud-based spreadsheet using Google Sheets. All members of the Pathways team from a school are given access to the document and can work on it, synchronously if desired, from their own computers. This approach also facilitates the process of knowledge sharing[18] across the team. By ensuring the landscape tool can be completed by a broader group, teams

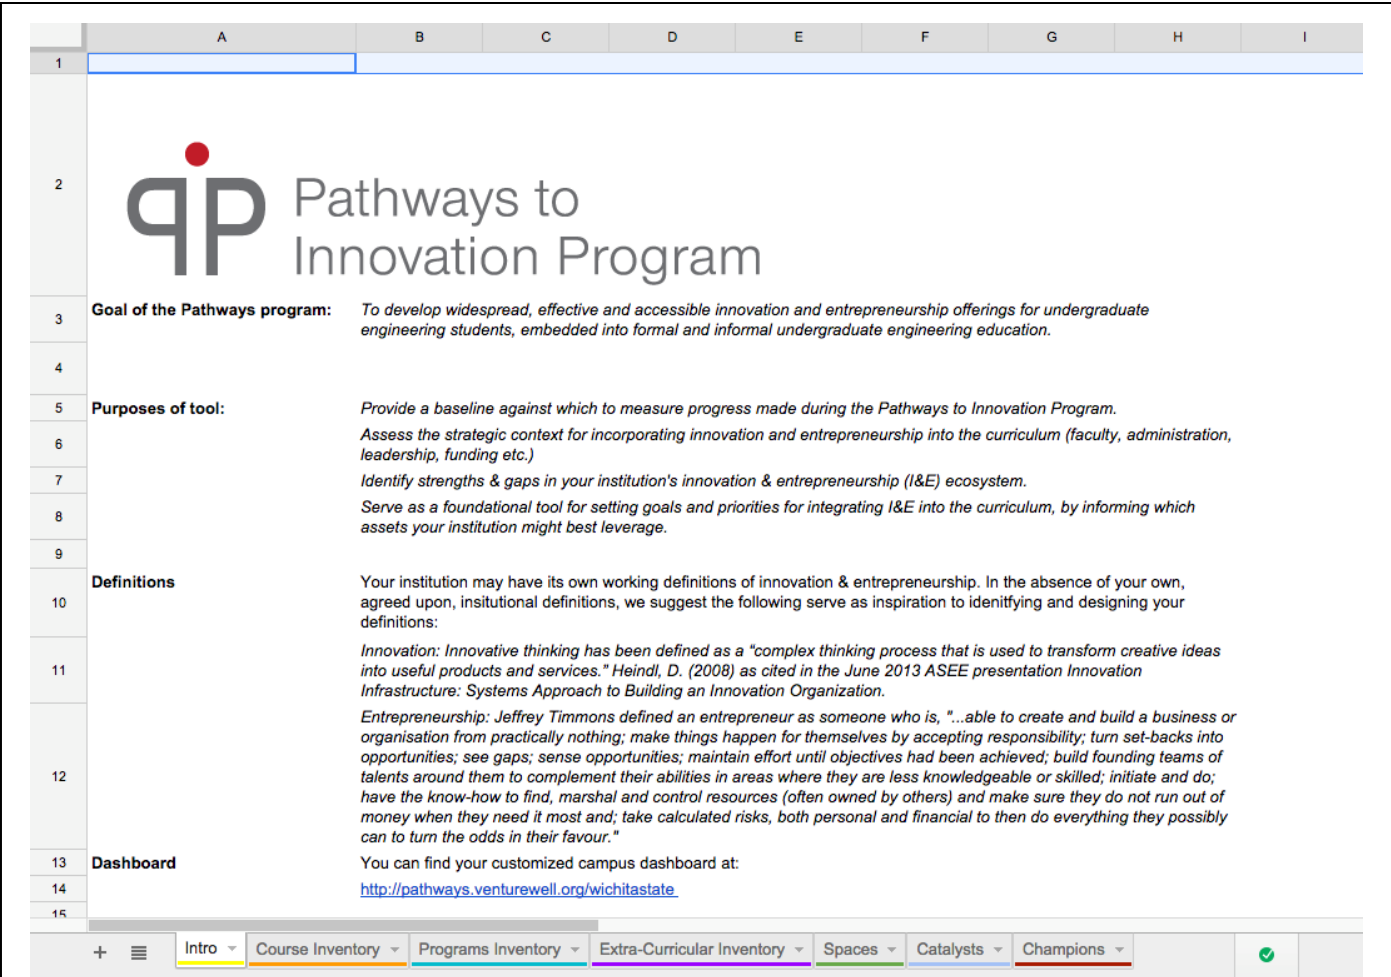

Fig. 1. Screenshot of Landscape Tool

are also better able to engage those beyond the core team, including faculty from other disciplines, students on campus and possibly even off-campus partners in this process. By engaging a broader group in the landscape completion process, the team members may develop a more expansive view of their campus ecosystem, an increased understanding of the opportunities available to students and the possibilities for cross-campus strategic collaboration.

A data visualization capability was added. This was deemed critical for two reasons: (1) given the complex nature of the tool, institutions, Pathways program staff and evaluators needed a way to be able to efficiently draw broad conclusions about the data, and (2) staff and evaluators needed a process for capturing and quantifying changes in the landscape over time. The resulting landscape data is now aggregated in a separate file and reviewed for accuracy before being stored in the cloud. Pre-defined queries on this data create data-driven websites with “snapshot” visualizations for each team that illustrate the status of their campus ecosystem on key dimensions using pie charts (a sample, illustrating the affiliations of individuals a team has identified as champions, is shown in Fig. 2). The visualizations also compare their institution to the entire group of Pathways schools on these dimensions.

An update capability (and supporting data structure) was introduced. The landscape data is now stored together with the date of any changes made including modification to existing assets and new assets. This allows teams to make changes to their landscape, both in real time if they discover new information, but also at designated times for evaluative purposes. Those changes are presented in updated charts in the dashboard, and are also available to the teams and to program staff and evaluators to measure the impact of the program at individual institutions as well as in the larger cohort of participating schools.

I&E-specific modifications better aligned the tool with the project’s underlying theoretical base and with teams’ information needs. Some data points collected in the original sheets were deemed too granular and removed. The recommended definitions for entrepreneurship and innovation became suggested rather than imposed, to encourage a team conversation about their institutions’ definitions. Other elements were more fully incorporated into the tool because

they were considered important to the work being undertaken. For example, teams now identify where each individual course lies on Duval-Couetil’s “innovation education continuum”[19] and the degree to which each course and program listed integrates active learning. To ensure teams consider change strategies that move beyond changes to curriculum and space, Graham’s characteristics of a balanced and effective entrepreneurial university [20] were incorporated with specific focus on student-driven change, collaboration with the off-campus ecosystem and campus policy and culture..

VI. CURRENT USE OF TOOL

The updated tool and user feedback from teams (and the significant technical assistance that was required from staff to assist teams) - informed changes in the way the tool is introduced and supported. The team leader workshop now includes a more comprehensive overview of assets and how a wide range of assets might be used to implement change. In the introduction to the tool, the basic architecture of the tool is described, with attention to how the categories of items collected are aligned with Graham’s taxonomy of successful university entrepreneurship ecosystems. Participants “try out” the tool’s categories with a hands-on exercise in which they identify a set of activities already underway on their campus and place each within the corresponding category.

After the team leaders return to campus, they meet with their team and decide on a plan to populate the tool with the activities at the institution. Leaders are encouraged to make the process one that takes advantage of the cloud-based character of the tool and include all team members in the collection process (however, even with a cloud-based tool, not all team leaders choose to approach the task in this way).

The team has approximately one month to complete their landscape in preparation for the meeting of all Pathways teams in which each crafts a strategy for embedding I&E in undergraduate engineering. During that meeting’s opening session, the teams open their landscape documents and review the (newly-added) data visualizations of both their school’s information as well as the aggregated data. Teams reflect on how (and why) their school’s profile might be similar or different from the aggregate.

With that learning as a backdrop, over the course of the next two days, teams are exposed to a wide variety of different approaches for integrating I&E on campus - all presented by faculty from institutions with robust I&E programming. Teams follow this exposure by identifying ways that they can adopt and/or adapt a set of these models to address a strategic objective, while simultaneously identifying ways they can “link and leverage” one or more of the assets on their landscape[21] to help teams quickly take actions to launch the change process.

Now that an update capability has been added to the landscape tool, teams will be asked to update their tool before they attend the next in-person Pathways workshop in October 2015. This data will be drawn into the aggregated data file, allowing teams, program staff and evaluators to measure what impact the team’s work might have had in expanding I&E activity on each campus. Activities directly attributable to the

Fig. 2. Sample Data Visualization: Affiliation of Champions

team's work, such as a new course are considered, but also less-direct results, such as a general increase in participation in I&E courses or extra-curricular activities are incorporated. This data will also help teams to think strategically about how best to grow and sustain their efforts

Findings from this pilot update process will be result in further refinements to the tool, the update process, and team line for subsequent updates.

VII. THE LANDSCAPE AS A STRATEGIC TOOL

The landscape tool helps teams identify many different kinds of opportunities for intervention on their campus by identifying a wide range of existing strengths/assets to build on. That knowledge can then be employed to address the institution's needs – some of which may have already been known by the team, but also those that might be revealed by the tool itself. The information in the completed tool may:

- highlight the lack of a particular kind of asset, such as a makerspace;
- reveal specific existing assets that could be targeted for improvement - *ie*, those rated by the team as “needs attention”;
- provide guidance on the degree to which courses were (and were not) being delivered using active learning strategies;
- identify individuals and organizations (both on- and off-campus) that could be engaged to support the team's efforts;
- show areas in which the campus was significantly “out of step” with the larger Pathways community; and
- identify a lack of strategies that fall outside of the more typical faculty driven intervention like curriculum and space (*e.g.* students driven efforts, departmental policy initiatives and off-campus collaborations).

At the team planning workshop and beyond, teams match these observations to potential program models to formulate a strategy for change, characterized by a series of projects chosen by the team. This process continues over the course of the two years - teams complete tasks, start new ones, and adjust strategies based on new information about their campus as well as increased knowledge about possible interventions. Regularly scheduled virtual meetings provide a window into implementation as each team starts with a single modest project and then expands their work rapidly as they gain momentum and attract other faculty and administrators to their efforts.

This context-specific, asset-driven approach results in the pursuit of a wide variety of projects as shown in Table 1. The data includes projects from both schools that began the program in 2014 and those new to the program in 2015. Potential impact reflects the total number of undergraduate engineering students at the campuses pursuing each type of strategy.[22]

TABLE 1.

<i>Project^a</i>	<i>Completed</i>	<i>In Development</i>	<i>Potential impact (total undergraduate engineering enrollment at schools using strategies)^b</i>
New or redesigned courses	13	25	53,139
New or renovated makerspaces	7	20	36,816
Credentials (minors, certificates or degrees)	1	12	22,325
Infrastructure (new classrooms, IP policies, champion development)	7	12	36,088
Non-credit learning (workshops, internships)	9	12	30,406
Competitions	10	6	27,110
Consolidations of I&E activity across campus	5	5	17,738
Other	1	4	7,903

^a Projects shown are current as of June 2015.

VIII. THE LANDSCAPE AS AN EVALUATION TOOL

While still in the early stages of using the landscape as an evaluation tool, its usefulness in that regard is already apparent. Having a baseline snapshot of the campus landscape allows evaluators to determine the degree to which institutions have created I&E change since joining the Pathways program. Pre-determined response options also allow for easy comparison across institutions and time points, so that data can be analyzed in an efficient, systematic and quantifiable fashion.

Once updates to the landscape are collected, these updates will contribute to answering key evaluation questions including: “Is the Pathways program an effective process for affecting change in I&E offerings on a campus?” and “How are participating campuses’ I&E ecosystems changing as a result of their participation in the project?” In the interim, landscape categories have guided the evaluation team in the development of interview protocols aimed at capturing some of the ‘what’ and ‘how’ behind their institutional change projects.

Although the I&E changes at the institution level cannot necessarily be attributed directly to involvement in the Pathways program, updated landscapes will provide a mechanism whereby these causal links can begin to be explored. Programmatically, the tool will also contribute directly to program outcomes identified in the program's logic model, including a mechanism for cross-referencing whether

“school leadership understands the current I&E environment at their school.”

The combined programmatic and evaluation benefits of the landscape tool provide teams, program staff and evaluators with a large body of knowledge to inform their associated roles..

IX. POTENTIAL ENHANCEMENTS AND EXPANSIONS TO THE TOOL

While the landscape tool provides for the knowledge sharing, team-building and evaluation needs initially outlined, there are enhancements currently under consideration that would improve and/or extend the usefulness of the tool.

First, it is becoming increasingly important to find ways to onboard faculty, students and administrators that join Pathways teams after the initial landscape training. A self-paced orientation is in development that will orient teams to the landscape tool, its uses and the process for completion.

The next enhancement under consideration relates to security. The data visualization process is currently a cloud-based solution that takes full advantage of the Google ecosystem. These tools are free and offer many built-in advantages including free management of hosting, security updates, service outages and backups. However the approach can also be problematic from both a security perspective and in terms of what one can achieve with the data. Use of a server would eliminate security concerns and would also maximize the potential uses of the data. School data could, for example, be anonymized and schools could search for landscapes of schools fitting various criteria.

Moving beyond these initial refinements, more ambitious ideas include the development and design of a data warehouse. The warehouse could incorporate the landscape data along with historical information about other activities the institutions have engaged in; IPEDS data could also be incorporated into the data warehouse. These kinds of technical modifications would enhance the end user experience by providing access to more extensive and customizable data sets. More sophisticated graphical outputs could also be incorporated to enhance the end user experience.

To date the landscape tool has been conceived of as something that provides only Pathways teams, program staff and evaluators with information to better understand a campus ecosystem. However, the data collected could also be used to inform other campus constituents about I&E resources and spaces, for example through the design of self-service interactive campus maps that highlight I&E hotspots.

The final change under consideration would add value to the Pathways program, but poses significant challenges: designing a component that helps track and “grade” the outcomes of team’s campus-specific interventions. The project’s external evaluators currently gather this data through surveys and interviews with team members, and manually map the teams’ efforts to the assets in their landscapes. Integrating this process into the landscape tool is under consideration.

X. OPPORTUNITIES FOR RESEARCH

The rich set of data gathered across institutions and over time presents many exciting research possibilities. An immediate opportunity is the examination of the growth of campus entrepreneurial ecosystems over time and the degree to which location, institution size, public or private status, Carnegie classification and an institution’s initial assets impact that trajectory and the kinds of strategies undertaken. As part of this examination, one could, for example, canvas a suite of institutions of a similar Carnegie classification and determine which offerings are most prevalent and use these findings as a springboard for rich qualitative investigations into how and why this might be the case. Such research might also inform best practices for modifying a campus ecosystem: for example, whether a school should undertake a more modest grassroots approach first, such as the launch of an extracurricular project, or a more ambitious project, like the launch of an entrepreneurship center.

Further research into how the landscape is used might also be undertaken. Some teams adopt a collaborative approach, while others treat it as a solitary task. One team used the tool as a foundation for creating a visual representations of their campus ecosystem. Another institution shared their landscape with high level administrators to realize a goal of strategically combining spaces and creating a new position. Additional research into these and other practices will increase the understanding of best practices for completing and sharing the landscapes.

If the more ambitious enhancements to the tool are undertaken, the research possibilities broaden. For example, through the inclusion of IPEDS data, one might research the extent to which I&E activity impacts retention and graduation rates.

XI. CONCLUSION

The development and deployment of a landscape tool has proven to be a highly useful strategy in helping faculty teams plan and implement curricular changes in the domain of innovation and entrepreneurship education for engineering students. The data gathered through the tool will provide ample opportunities for ongoing research, particularly as the tool is enhanced and expanded in future versions. While some of the data collected through the tool is specific to this domain, the underlying rationale for the tool - to collect a robust array of information that can inform decision-making while also developing the social capital and team behavior that will enable implementation of change - is broadly applicable to many of the challenges in engineering education.

Abstract— This paper presents a multi-course problem-based learning (PBL) experience to foster the entrepreneurial mindset in the junior and senior mechanical engineering curriculum. Previous senior project students designed, fabricated, and validated a fluid-powered gantry crane that exhibited areas for improvement. To improve upon the project gantry crane, junior- and senior-level students implemented concurrent problem-based learning activities in three courses: Fluid Mechanics, Heat Transfer, and Mechatronics. Even though the PBLs targeted both technical and entrepreneurial objectives, only the results of entrepreneurial mindset attributes are discussed in this paper. Assessment results including student commentary are detailed and discussed in the paper. Preliminary results indicate extensive student practice of entrepreneurial skills.

Keywords—*problem-based learning; entrepreneurial mindset; multi-course; mechanical engineering.*

I. INTRODUCTION

In collaboration with the Kern Entrepreneurial Engineering Network (KEEN), Lawrence Technological University seeks to instill in engineering students an entrepreneurial mindset ^{[1][2]}. The entrepreneurial mindset includes many facets, and KEEN has identified example behaviors (i.e., outcomes) which include the ability to integrate information from many sources, persist through and learn from failure, apply creative thinking to ambiguous problems, apply systems thinking to complex problems, work in teams, convey engineering solution in economic terms, substantiate claims with data and facts, and fulfill commitments in a timely manner ^{[3][4]}. Previous work has shown the effectiveness of problem-based learning (PBL) in improving these qualities in students ^{[5][6]}. By its very nature, a well-posed PBL exercise includes an ambiguous, complex, team-based problem, requiring the students to synthesize material from a variety of sources, while persisting through pitfalls and "wrong turns." Therefore, as part of Lawrence Tech's six-year process to foster the entrepreneurial mindset in the engineering curriculum, courses throughout the Colleges of Engineering and Arts and Science have been modified to incorporate PBL ^[7].

Unfortunately, PBL in a specific course often does not convey the complex or multi-disciplinary nature of an engineering problem; the PBL assignment will focus on the content of that particular course. Recently, a PBL assignment with a common theme was identified that can be incorporated across multiple required courses in Lawrence Tech's BS Mechanical Engineering program. In particular, the PBL exercises are focused on a fluid-powered gantry crane. Originally funded by a teaching grant from the National Fluid Power Association, a prior year's senior project team designed, fabricated, and experimentally validated a gantry crane that used fluid power for material handling ^[8]. During fabrication and testing of the fluid-powered gantry crane, a number of areas for improvement of the student design were identified. Among these were the inclusion of a control system to limit load swing, redesign of the fluid distribution system, redesign to reduce friction and binding between the trolley and crossbar, and new design of a heat sink for cooling the electrical system. Rather than fixing the deficiencies with a second capstone project, PBL exercises were developed to target both technical and entrepreneurial objectives in courses including Mechatronics, Fluid Mechanics, and Heat Transfer. In turn these PBL activities emphasize the multi-disciplinary nature of an engineering design, while allowing a single theme to span multiple semesters. As a result, many facets of the entrepreneurial mindset are emphasized.

Following concurrent PBL implementation in two sections each of Mechatronics, Fluid Mechanics, and Heat Transfer courses, student surveys were used to quantitatively and qualitatively assess the effectiveness of the PBL in fostering the entrepreneurial mindset. Rubrics were used to directly assess student performance. Assessment results, including student commentary are detailed and discussed in the paper.

II. DESCRIPTION OF THE PBL MODULE

Senior mechanical engineering students designed and fabricated a fluid-powered gantry crane (shown in Fig. 1). A number of areas for improvement were identified during the fabrication, assembly, and testing processes. Based on this real-world design exercise, multi-course modules are developed and

carried out in three different courses: Mechatronics (2 sections), Fluid Mechanics (2 sections), and Heat Transfer (2 sections) taught in Fall 2014 to instill entrepreneurial mindset learning for junior and senior students. The PBL activities are briefly summarized below. The detailed assignment description and guidelines are presented in a previous publication [9].

Fig. 1. Student-designed fluid-powered gantry crane

A. PBL activities in Mechatronics

Three thematically connected PBL exercises were created to augment lecture and lab material in four topic areas: modeling and analysis of dynamic systems, integration of mechatronic systems, and feedback control systems. Students were provided with a mix of lecture and lab time to work in teams, however additional work outside of class was required. PBL exercise deliverables included a team report, confidential individual peer evaluations, and individual surveys for indirect assessment of student learning in both technical and entrepreneurial dimensions.

Scenario: The Joint Systems Manufacturing Center (JSMC) is a government-owned, contractor-operated facility which makes armored vehicles such as the M1A2 Abrams main battle tank. During the fabrication process, workers weld together thick steel plates to form the vehicle hull, turret, and side walls. The JSMC uses an overhead gantry crane system to move extremely heavy armor sections from the staging area into a work cell and then to move completed turrets, hulls, and sidewalls from the work cells to an assembly area (Fig. 2). The crane is operated by a trained worker who uses a handheld pendant to control motion of the load in six axes. You are tasked with addressing the following questions:

1. Under what circumstances could a suspended load swing beyond the intended pathway?
2. Could any single fault in the crane control systems have caused the injury?
3. Can the faulty crane operation be demonstrated in a dramatic fashion?

Fig. 2. An overhead gantry crane system

B. PBL activity in Fluid Mechanics

Fluid Mechanics is a junior-level course and two sections were taught in Fall 2014. During the final four weeks of the course, students were tasked to work in a self-selected team of three (with some teams of two) to design the fluid system of a hydraulic gantry crane. Each team was required to submit one technical report describing their detailed design.

Scenario: Your rich uncle, Mortimer, has built a large storage that contains many of his prized possessions. His snowmobile happens to be in a far corner of the garage behind his 2002 Ferrari Enzo. He has asked you to design the fluid system for a hydraulic gantry crane that can lift and move the snowmobile out of the corner. You must keep in mind that Uncle Mortimer is miserly with his expenses; he did not get rich by wasting money. If you can design an efficient and cost effective system, you will not only be paid well, you will likely inherit some of the garage contents!

C. PBL activity in Heat Transfer

Heat Transfer is a senior-level course covering the principles and applications of heat transfer by conduction, convection and thermal radiation. Two sections were taught in Fall 2014. During the final four weeks of the course, a problem-based learning project was assigned and students were tasked to work in a self-selected team of three to address a solution to overheating transistors on a gantry crane. Each team was required to submit one technical report describing their detailed solution.

Fig. 3. Transistors stacked together causing poor heat dissipation (illustration to students)

Scenario: Once Uncle Mortimer started using his gantry crane, he noticed that the electronics package is poorly designed (multiple transistors are stacked together as illustrated for the students in Fig. 3). The electronics package heats up quickly and causes failure. After learning of your vast new knowledge of heat transfer, he has asked you to design a system that would

keep the surface temperature of the electronics at a maximum temperature of 40° C.

III. ASSESSMENT METHOD

In order to evaluate the outcome of the PBL modules and collect valuable feedback for future improvement, a survey was distributed to students to acquire their perceptions and suggestions about their design process. The students were given the following statements and were asked to provide their perception in five scales:

1. Strongly disagree
2. Disagree
3. No opinion
4. Agree
5. Strongly agree.

Survey question statements:

- a. My project design satisfied the customer's needs and goals.
- b. I consider the results of my project successful.
- c. I found my work on the project to be satisfying.
- d. The real-world application of the project motivated me to do my best work.
- e. The open-ended nature of the project motivated me to do my best work.

The students were asked to answer questions in regards to example behaviors of the entrepreneurial mindset (directly addressing the KEEN student outcomes), in the format of "During the course of this project, to what extent did you:" with answers provided in 5 scales:

1. None at all
2. Slightly
3. On some occasions
4. Many times
5. Throughout most of the project

Survey questions:

- f. Integrate information from many sources to gain insight.
- g. Assess and manage risk.
- h. Persist through failure.
- i. Apply creative thinking to ambiguous problems.
- j. Apply systems thinking to complex problems.
- k. Understand the motivations and perspectives of others.
- l. Convey engineering solutions in economic terms.
- m. Substantiate claims with data and facts.

Following the questions above, the students were also asked about their team dynamics:

- n. To what extent did you work as a team?

Answers are provided in 5 scales:

1. Almost never
2. Rarely
3. Sometimes
4. Often
5. Almost always

Besides evaluating the students on entrepreneurial mindset learning, they are also directly and indirectly assessed for

technical skills [9]. A problem-based learning rubric [10] [11] was used for evaluating the quality of the problem solutions. There are a total of 9 rubric criteria, which are graded as five scales:

1. No demonstration
2. Attempted demonstration
3. Partial demonstration
4. Proficient demonstration
5. Sophisticated demonstration

Problem based learning rubric criteria:

- o. Identification of problem
- p. Data collection
- q. Representing data
- r. Verify and evaluate information
- s. Draw conclusions and make appropriate applications
- t. Justify and support decisions, strategies, findings and solutions
- u. Communicate purpose and/or main idea for audience
- v. Organization
- w. Supporting details and/or visuals

The students were also asked to provide commentary statements about their problem-based learning experience. They were asked what they liked or appreciated about the project, what should be changed, and any other additional comments/observations.

IV. RESULTS AND DISCUSSION

The data shown in Table 1 are the student feedback to the three PBL activities implemented in Mechatronics class. As shown in the Table, these three activities allowed students to gain various practice of entrepreneurial skills. For example, the students agreed that during the first PBL exercise they were able to "integrate information from many sources to gain insight" (average feedback of 4.0 to question "f"), and also worked as a team more than often (average feedback of 4.2 to question "n").

Table 1. Survey results in Mechatronics Class

Q #	Modeling and Analysis		Sensor and Actuator Integration		PID Controller Design	
	Mean	SD	Mean	SD	Mean	SD
a	3.7	1.14	3.9	0.77	3.87	0.74
b	3.6	1.09	4.0	0.52	4.00	0.50
c	3.6	0.96	3.9	0.44	3.87	0.64
d	3.7	1.01	4.1	0.62	4.07	0.46
e	3.1	1.26	3.6	1.02	3.47	0.99
f	4.0	0.63	3.81	1.05	3.93	0.88
g	3.3	1.16	3.13	1.31	3.53	1.13
h	3.9	0.89	3.63	0.89	3.93	0.80
i	3.9	0.77	4.00	0.65	3.67	0.62
j	3.9	0.96	3.80	0.86	3.87	0.74
k	-	-	4.40	0.63	4.00	1.13
l	2.4	0.91	3.80	0.94	3.67	1.11
m	3.1	0.85	3.60	1.06	2.20	1.08
n	4.2	0.66	3.87	0.52	3.79	0.97

Student feedback to the same survey questions in Fluid Mechanics and Heat Transfer classes are shown in Table 2. It is clear that collaborative activities in both classes greatly facilitate team work (average feedback of 4.38 and 4.06 to survey question “n”). The Fluid Mechanics project particularly addressed the student outcome of “substantiating claims with data and facts” (average feedback of 4.29 to survey question “m”), while the Heat Transfer assignment greatly helped students to “understand the motivations and perspective of others” (average feedback of 4.32 to survey question “k”). Overall, the PBL exercise in Fluid Mechanics class received the most positive student feedback.

Table 2. Survey results in Fluid Mechanics and Heat Transfer Classes

Q#	Fluid Mechanics		Heat Transfer	
	Mean	SD	Mean	SD
a	4.05	1.02	3.82	0.95
b	3.95	1.00	4.24	0.56
c	3.81	1.08	3.94	0.83
d	3.81	0.93	3.94	1.09
e	4.00	0.77	3.41	1.00
f	4.19	0.81	3.88	0.70
g	3.81	0.68	3.06	0.83
h	4.19	0.68	3.65	1.06
i	4.05	0.80	3.65	0.93
j	4.19	0.68	3.56	1.17
k	4.00	0.63	4.32	0.85
l	3.81	0.93	3.65	0.93
m	4.29	0.64	4.12	0.60
n	4.38	0.74	4.06	0.75

The results from direct assessment are summarized in Table 3 (Mechatronics class) and Table 4 (Fluid Mechanics and Heat Transfer classes). The students in Mechatronics class performed well on criteria “q – representing data” and “v – organization”, evaluated as average of 4.6 and 4.4 respectively. The students in Fluid Mechanics and Heat Transfer classes learned to use a variety of supporting details to help with the audience’s understanding (average evaluation of 4.1 and 4.0 to criteria “w”). However, note that the direct assessment results in Tables 3 and 4 are not individual performance, because evaluation was through team design reports. Therefore, less deviations were observed in the data.

When asked to comment about their learning experience through the PBL exercises, many students mentioned that they liked applying theoretical knowledge from class to a real-world problem, and they appreciated the open-ended nature of the problems, which exactly addressed survey questions d and e. Several student comments are listed as examples:

- “There is no exact answer for the question, but you should find one that best fits.” (Mechatronics, part 1)
- “Working as a group, work well as a team. Learning more about options for motion control was a rewarding/valuable experience.” (Mechatronics, part 2)

- “Project created dialogue among students in engineering topics.” (Fluid Mechanics)
- “I prefer learning through projects because we are not confined to a ‘box’ in our problem solving like a test. It represents real world engineering.” (Fluid Mechanics)
- “It related to everything we learned in class.” (Heat Transfer)
- “I appreciate the idea and concept behind this project. It gives me a real world problem, gives me a chance to understand problems which are not completely set up/lead for me.” (Heat Transfer)

Table 3. Direct assessment rubric results of PBL in Mechatronics Class

Criteria	Modeling and Analysis	Sensor and Actuator Integration	PID Controller Design
o	3.0	4.0	4.0

u	3.8	4.0	2.5
v	4.5	4.3	4.5
w	3.8	3.5	3.5
Average	3.78	3.86	3.78

Table 4. Direct assessment rubric results of PBL in Fluid Mechanics and Heat Transfer Classes

Criteria	Fluid Mechanics	Heat Transfer
o	3.4	4.0
p	3.7	4.0
q	3.8	4.0
r	3.4	3.5
s	3.8	4.0
t	3.6	3.5
u	3.7	4.0
v	3.8	4.0
w	4.1	4.0
Average	3.68	3.89

V. CONCLUSIONS

Based on a student designed fluid-powered gantry crane, problem-based learning modules were developed and implemented spanning across the junior and senior Mechanical Engineering courses including Mechatronics, Fluid Mechanics, and Heat Transfer. These collaborative learning activities allow students to work in teams, integrate information from many sources, and apply creative thinking to ambiguous problems. Assessment results indicate that students gained extensive practice in various aspects of entrepreneurial skills.

Abstract— Our institution has recently committed to develop five new entrepreneurially-minded elective courses called “IDEAS studios”. The entrepreneurially-minded aspects of IDEAS studios include close interaction with industrial partners and an emphasis on topics such as value proposition, opportunity recognition, intellectual property, and customer engagement. We hypothesize that in addition to specific topics and competencies these courses facilitate develop *attitudinal* skills needed for an entrepreneurial mindset. Such skills—which include persistence, curiosity, conscientiousness, optimism, and self-control—typically cannot be measured using standard assessment methods.

In this work-in-progress, we have identified seven structural attributes of IDEAS studios which we hypothesize support the courses’ ability to foster the attitudinal aspects of an entrepreneurial mindset. We have designed and are in the process of conducting a study of students enrolled in these courses to assess the impact of both the courses as a whole and the individual attributes on students’ situational motivation and curiosity. We hypothesize that the open and student-centered nature of IDEAS studios will foster greater curiosity and intrinsic motivation than will courses that lack these seven attributes. This paper reports on a pilot study of students enrolled in IDEAS studios to assess the impact of these seven structural attributes on students’ situational motivation and curiosity.

Keywords— *entrepreneurial learning; motivation*

I. INTRODUCTION

IDEAS courses were developed with the goal of instilling an “entrepreneurial mindset” in engineering students. Our operational definition of this mindset is that students will display curiosity, make connections, and create value (3 C’s) [4]. IDEAS courses are two-credit-hour elective studio-based engineering courses that have been designed to foster these

outcomes. We identify seven core attributes of IDEAS courses that will compliment course content in instilling the 3C’s:

- 1) The class is voluntary;
- 2) In the course, students create a physical artifact;
- 3) Student work is motivated by real problems;
- 4) Students apply broad perspectives to their work;
- 5) An open-process is applied to create solutions;
- 6) The course environment contains an interdisciplinary mix of students;
- 7) The number of students in the class is small.

Ultimately, six sections of four different courses will be taught, each on a different topic but all embodying the seven attributes listed above. The exact manner in which these characteristics are realized will vary slightly from instructor to instructor, but in general items 1, 6, and 7 are controlled through the course registration process. Items 2-5 are introduced through use of problem- or project- based learning as the main pedagogy for the course. The problem or project based upon on or more open-ended design problems, typically created in collaboration with an outside customer. For example, the customer for on IDEAS course was a surgical research team at a hospital. In the context of IDEAS course projects, students are encouraged to consider broad perspectives through topics including value, societal benefit, cost, scale, and marketability.

Our conceptual framework is that intrinsic motivation is key to development of students’ ability to achieve an entrepreneurial mindset. We expect that fostering students’ intrinsic motivation in a course based on entrepreneurial thinking will result in students who are most curious, best able to make connections between disparate ideas, and create value based on their insight. Using self-determination theory as our guide [5], the seven course characteristics were developed to

create an environment favorable for intrinsic motivation. Self Determination Theory states that motivation stems from autonomy, relatedness, and competence [5]. In the IDEAS courses, attributes 1, 4, and 5 relate to autonomy, attributes 2, 3, and 4 relate to relatedness, and items 2, 6, and 7 relate to competence. While these attributes are not entirely unique to these courses, we believe the combination of all of them might be, and might therefore be essential to creating the attitudinal change we are seeking in the students.

The data from this study are being analyzed to determine the impact of IDEAS courses overall on curiosity and motivation as well as determining the impact of each structural attribute on these outcomes. The results will serve as a pilot to design a larger study that considers other additional attitudinal skills and that seeks to understand the relative importance of the class' attributes.

II. METHODS

The study used a sample of convenience. Students enrolled in the Fall 2014 IDEAS course were invited to participate in the study. All 13 students elected to participate and signed an informed consent form. Both the study and the form were approved by the Bucknell IRB. Students were compensated for their participation: \$10 for each of the four surveys completed, plus a bonus \$10 if all four were completed.

Students were asked to consider their situational curiosity and motivation in both the IDEAS course and a "control" course designated "Course X". Course X is independently and anonymously selected by each student as a course in which they are concurrently enrolled that, in their opinion, shares as few of the IDEAS attributes as possible. Students were asked to select their own Course X for a number of reasons. The most significant reason is that students enrolled in the IDEAS course are from a variety of majors, there is no one other course in which they are all enrolled. In addition, because the student perception of the course may be different from the faculty intent, we felt students themselves would be the best judge of which other course is most different from their IDEAS course, with respect to how those differences impact their own attitudes.

Approximately every four weeks the situational motivation survey and situational curiosity survey were shared. Existing scales developed by Guay, Vallerand, and Blanchard [3], as applied by Stolk, Gross, and Zastavker [6] for situational motivation (SIMs instrument) and Chen, Darst, and Pangranzi [1] for curiosity were used. The combined survey consists of 5 items on situational curiosity from the Chen, Darst, and Pangranzi [1] instrument, and 16 items from the SIMs instrument, plus demographic questions. Students completed this twice during each instance – once, thinking of their IDEAS course, once thinking of the course they had identified as Course X.

At the very end of the semester, the "wrap up" survey was shared. This survey asked about each of the seven characteristics given above and the extent to which they were perceived to be present in both the IDEAS course and Course X.

Analysis of student responses used the item groupings for the SIMS questions as identified by [3]: Intrinsic-motivation; Identified-Regulation (I'm doing this because it's good for me); External-Regulation (I have to do this); and Amotivation (I don't know why I'm doing this). Item responses for both scales is a "strongly agree" (=5) to "strongly disagree" (=1). For the present preliminary analysis, the mean sum of all students' responses for each question group is presented.

III. PRELIMINARY RESULTS

Of the planned three-semester study, one semester has been completed, yielding student survey results (n=13) for one IDEAS course. As such, results are considered preliminary. By the conclusion of this study, we expect an n>100. The current sample is 69% male, and 69% white, consisted of 6 juniors, 6 seniors, and one sophomore, and 8 mechanical engineers, 3 computer/electrical engineers, and 2 biomedical engineers.

There are apparent differences in motivational state and curiosity between students when they are in the IDEAS course and Course X, as can be seen in Table 1. Table 1 combines responses for IDEAS and Course X for all three survey instances and all 13 students throughout the semester. Students' intrinsic motivation, identified regulation, and curiosity are all higher for the IDEAS course, consistent with course design. Students report higher external regulation for Course X, which is consistent with it being a required course (the case for most students, see Table 2).

TABLE I. MEAN STUDENT RESPONSES

Average of all questions in group (5-point scale) n=13		
Motivational State	IDEAS Mean(std.dev.)	Course X Mean(std.dev.)
Intrinsic motivation	18.39(1.76)	13.15(3.56)
Identified regulation	17.92(1.75)	14.92(2.33)
External regulation	6.85(2.41)	12.92(4.86)
Amotivation	6.31(2.10)	10.15(3.13)
Curiosity	22.15(1.73)	18.39(4.75)

Using a Wilcoxon test, the differences between the IDEAS course and Course X in intrinsic motivation, identified regulation, external regulation, and amotivation were all significant at the $p<0.01$ level. The difference in intrinsic motivation is consistent with our initial hypothesis, that intrinsic motivation would be fostered by the IDEAS course environment. The difference in identified regulation was not as expected, but seems consistent with the design of the IDEAS course to be driven by "real problems", giving students a sense of importance – they recognize that they will benefit from doing course work. Course X has a significantly higher score for external regulation and amotivation, which suggests that students in required courses do not always see the ultimate goal of their study. The curiosity result was significant at the $p<0.05$ level with the same test, suggesting students were more curious in the IDEAS environment.

A Wilcoxon Signed Ranks Test is the appropriate test for results with multiple modes and small sample size, as was seen in this case [2].

At the end of the semester, students were asked to characterize both the IDEAS course and Course X according to the seven attributes. Note one student chose not to participate in this survey. We anticipated when students selected Course X at the start of the semester, they might not have sufficient information to completely judge its similarity to the IDEAS course, therefore the request to characterize the course in terms of the seven attributes was at the end of the semester. We also asked students to characterize the IDEAS course to inform us if the student perception of the course design aligned with our intent.

TABLE II. COURSE ATTRIBUTES

Course alignment with 7 attributes		
List of attributes	IDEAS	Course X
1. Voluntary	Yes (12) No (0)	Yes (3) No (9)
2. Physical artifact	Yes (12) No (0)	Yes (5) No (7)
3. Multidisciplinary	Yes (12) No (0)	Yes (6) No (6)
4. Agreement: Real problems	4.8 / 5.0	3.4 / 5.0
5. Agreement: Broad perspectives	4.3 / 5.0	3.0 / 5.0
6. Agreement: Open-ended	4.8 / 5.0	3.2 / 5.0
7. Class size	15	25

There is a high level of agreement that the students perceived that the IDEAS course embodied the seven characteristics, as intended. These data also suggest that while Course X was dissimilar from the IDEAS course in some ways, for most students it was not entirely dissimilar.

The ultimate goal of this work is to not only characterize the differences in motivational and curiosity state for both IDEAS and X courses, but to use responses to these attributes

to determine the importance of each to students' motivational state. For example, because there are students who had attribute 3, an interdisciplinary mix of students, in IDEAS and in Course X, we should be able to assess the extent to which this attribute correlates with motivational state and curiosity. By the end of the study, we should have over 100 students' responses, which will enable this examination.

In conclusion, this preliminary study suggests that IDEAS courses are better environments for fostering students' situational motivation and curiosity than more typical courses. This observation is consistent with self-determination theory, where the greater levels of autonomy, purpose, and mastery are expected to result in higher levels of intrinsic motivation among students. As the study continues, we will see if this observation continues to be borne out with a larger sample size.

Abstract — This paper shows the course designed by COPEC – Science and Education Research Council education research team, for engineering students what is called “working with communities course”, which provides the students of engineering in 3rd year the chance to work with consultancy for the entrepreneurial community, in the region. It is for an engineering school of a private university and the goal is provide the needed resources to enable interdisciplinary efforts to prepare engineering students to tackle real-world challenges in engineering, entrepreneurship and new business ventures as professionals. The process is designed in order to offer a space that has been named after “innovative office”, where local entrepreneurs go with a problem or project to discuss and to find sustainable solutions under the consultancy of young engineers. So far the program has been working well and is opening doors for young engineers.

Keywords — *Entrepreneurship; sustainable solutions; project development; innovative office; working with communities.*

I. INTRODUCING

At the present engineers with technical skills must also learn how to work in interdisciplinary teams, how to develop designs rapidly, how to manufacture sustainably, how to combine art and engineering, and how to address global markets. It is imperative to provide future engineers opportunity in the work market has become now part of university formation, as a way to assure also the future of university. Enterprises and universities have still in many places difficulties in working together, it is up to the engineering schools and universities to have the initiative to enhance their programs, to assure the proper formation for future professionals that can perform in this mutant work

environment of 21st Century. In accordance with the National Academy of Engineering, USA report “The Engineer of 2020” paints a picture of a dynamically changing and evolving world: “The successful future engineer will need strong analytical skills, practical ingenuity, creativity, good communication skills, business and management knowledge, leadership, high ethical standards, professionalism, dynamism, agility, resilience, flexibility, and the pursuit of lifelong learning”, the report says.

Presently the opportunities for professionals seem to be very narrow once economic crisis is impacting countries and communities worldwide, as the result of a natural cyclic wave of economy until a new economic model starts to work somehow. To provide future professionals an opportunity in the work market has now become part of university training as a way to assure the future of university.

This paper describes a course designed by COPEC – Science and Education Research Council education research team, for engineering students which is called “Working with Communities Course”, providing 3rd year engineering students the chance to work with consultancy for the entrepreneurial community in the city. The goal is to offer a space that has been named “Innovative Office”, which local entrepreneurs can refer to with a problem or project to discuss and to find sustainable solutions.

Engineering students then work using their creativity to design and present solutions within the constraints of ethical practice grounded in science and engineering methods and standards. The process involves face-to-face meetings and discussions with entrepreneurs of the city, from the presentation of the problem until the delivery of the plans.

Once engineers are part of society it is important that they have a stronger interaction with the wider public. So the goal of including this course in the program is to provide students the opportunity to work closely with the real local entrepreneurship environment. Apart from this, engineers need to develop broad fundamental understanding of their professional responsibilities as well as the need to be entrepreneurial in order to understand and contribute in the context of market and business pressures. If engineers can work with the public to explain how engineering can help address their problems, and to help them to decide which are the most effective and affordable ways to address their concerns, the community can make great progress and improvements. It will surely be a great acquisition for the city business community as well as for the students themselves, once they can get a glimpse of what it is to engineer in real world. This project is being developed in partnership with a City Hall as a way to improve entrepreneurship in the region, aiming at fostering employment and private initiatives to change the community's profile.

II. DISCUSSIONS ABOUT EDUCATIONAL ASPECTS

New work environment takes place worldwide and today millions of professionals are also unemployed, even in advanced economies. On the other hand, businesses in advanced economy countries claim that they often are not able to find workers with the required skills. It is a fact that this is a symptomatic dysfunction due to the structural changes that are transforming the nature of work and reshaping employment opportunities. This shows that organizations and policies are not keeping up with the changes in business practices and new technologies that are defining what kind of jobs will be created and where they will be located. So there is a need for companies to redefine how and where different tasks have to be carried out requiring new skills and new employer and employee relationships [1].

Another aspect is that globalization has been expanding access to low-cost talent professionals and creating a greater need for workers with higher levels of education and specific skills in order to perform in advanced economies. Under skilled workers are disappearing due to automation and low-cost labor market abroad. In this world scenario, education and training should be seen as vital economic priorities by governments. However, it is still possible to observe the neglect of some nations, perhaps due to lack of political interest other than electoral. Although governments need to invest in the entire system that builds workforce skills, in some places it is up to private initiatives to offer opportunities for young ambitious talented professionals, who can cooperate for a better future of generations to come. There is no better place than universities to offer these opportunities, pushed by the enterprises. It is important for nations to train highly skilled native-born citizens as well as to attract highly skilled immigrants in order to be competitive in a global scale and assure a future for the people [2].

Finally, govern agents should be aware of the fact that if there is no production system there will be no financial resources to maintain social assistance system. This idea of an innovative office will help generate more quality services for the betterment of service industry as well as the productive

system generating opportunities and generation of jobs, which is a need everywhere in the world today [3].

III. COPEC: SCIENCE AND EDUCATION RESEARCH COUNCIL

COPEC's history started with an idea shared by some scientists of creating an organization to foster the research mainly in sciences and education. This idea seized larger proportions and after some meetings the Council became reality. This is a group of scientists, professors and professionals whose vision of future has driven them to start this work.

The main mission of COPEC is to promote the progress of science and technology for the welfare of humanity. Through its activities, COPEC maintains relations with universities, institutions of education, enterprises and the society of several countries for the discussion of sciences, technology and education directions. COPEC - Science and Education Research Council has been very active and has developed many achievements of great importance for the Country in which it is located. The Council is an organization constituted by scientists of several areas of human knowledge committed with education and the development of science and technology.

Its members believe that education is the main beam in the construction of a better society and that sciences and technology are the main agents in fostering progress to promote the welfare of human being [4].

IV. METHODOLOGY

The whole process has been developed in steps and it required a person in charge of the project, which in this case is the professor specially hired as the Head Director of "The Innovative Office" since the very beginning. The Head Director will keep the project working and collect all data for enhancement of the process throughout its development.

The project starts with adding a course named "Introductory Economics Topics" which may include an overview of: economic theory, econometrics, macroeconomics, microeconomics, economics research methods, economic policy, game theory and mathematical methods for economic analysis. The main goal is for students to have a glimpse of economics aspects necessary to understand and boost the economic commonwealth of the region. The hired teacher is a professional who is also prominent in his field in order to attract students and enhance the quality of the program. The model chosen is the one-week intensive class about the topics, in order to provide them the basic knowledge and the means to research further information when necessary. This step will take nine weeks before the students can start their journey in the project.

The legal aspects are up to the consultancy of law office of City Hall in order to assure that some other issues related with legal actions and measures are avoided.

The research team proposes to offer this course for all engineering programs of the Engineering School of the university involved in the project, to have a critical mass of specialties to perform in the consultancy field for the

community. However students are invited to join the project, which in fact reduces the number of interested students. The key is to have really interested students involved in a first stage, so that it can be expanded to all school programs as a way to increase the quality of the program [5].

FIG I. WORKSPACE

Once the number of students interested from all the programs of the referred engineering school is established, the next step is to hold a meeting with students and define a schedule for the activities to be held at the office, located in the City Hall building which is offering this service to the community. The workspace is basically a clean, neat room with tables, chairs, computers and a telephone line.

It is up to the City Hall to advertise the service offer “The Innovative Office” to the local community. The university is responsible for providing the students and the necessary laboratories. In case a laboratory is used, a fee is charged to the consultant to cover basic material and energy. There is another professor in charge of mentoring the students’ team for a determined period as volunteer work, in order to help refining their proposed projects to their clients.

Next step is to have students working in teams at the offices, available to receive possible clients. The students welcome the client; start a professional relationship and work in order to solve the presented problem. Their work starts with a visit to the enterprise where the business takes place, collecting all data, followed by the search for ways to best solve the client’s issue. This means that they have to work hard in teams to find out “The Best Solution” for the presented problem in a “Certain Period of Time”, which the team can establish and must honor. It is a simple concept that works because of the commitment of all people involved in the process. Both the university and the City Hall are committed to provide this service for a determined period of time in a first moment and the enlargement of this service, if there are conditions for it. An agreement is signed between both organizations for a certain period, which can be terminated by mutual decision. The implementation of the project started in 2013 and the office started working effectively in August 2014, mainly due to City Hall bureaucracy.

V. DETAILS OF THE ENTREPRENEURSHIP

The students interested in the project register for economics classes. After three weeks of classes they take part in a training class and learn how to cause a first good impression with their future clients. This is followed by a period at The Innovative

Office, in the City Hall. Their work starts when they register for the project, which is an opportunity of intensive internship early in the program.

The main aspect of the project is that students have to be committed with sustainable and feasible simple solutions for medium and small business problems and as low cost as possible. These are the headlines and main idea of the entire training that they have prior the practical period.

FIG II. MEETING

Once at The Innovative Office, for a period of at least four months, students have to establish goals and work towards achieving them. Students are challenged to start a professional relationship with a possible client, leading them to be open and honest. They will start identifying a problem, and then find a theoretical background and a methodical approach to solve the problem within a realistic time frame towards the completion of the project and at reasonable expenses. This is followed by the implementation period and the refinement of procedures in order to solve the problem and deliver the project.

After the accomplishment of the project, students send a report to the Head Director of The Innovative Office to be included in both the program’s and the students’ portfolio.

VI. SCHEDULE FOR 2015/2016

The maximum number of groups per period is 5 with an average of 4/5 students each. Each group can work with maximum 2 clients in order to have a good performance once it is submitted to the availability of the students because of the classes and studies in the university. The project must be delivered at least before the end of their period at the office.

FIG III. SCHEDULE

1st period	March/April/May/June	4 groups with 4 people
2nd period	July/August/September/October	5 groups with 3 people
3rd period	November/December/January/February	3 groups with 4 people

It is important to have the office working all year round, so that students can choose the best suitable period. In any case, the schedule is up to the Head Director of The Innovative Office to set together with the students.

VII. OBJECTIVES OF THE PROJECT

The project objectives are essentially the development of engineers with skills to perform in the future work market especially in economics, as high skilled professionals are a demand in every country, which widens their job opportunities. The following skills are important once they are already required:

- Broad knowledge of different fields in economics;
- Enhanced research skills for researching for clients;
- Entrepreneurial skills;
- Knowledge of theoretical and empirical approaches to economics;
- Management skills;
- Solid understanding of economic practices, principles and theory;
- Strong command of economic models, tools and techniques including particular statistical techniques;
- Strong numerical and analytical skills;
- Strong oral and written communication skills, including preparation and delivery of professional, technical and non-technical reports and presentations;
- Time management skills.

At the end of the period the students will be able to understand the real economic and social impact of engineering in this century. Another target goal to be achieved is to foster among them the entrepreneurial mind to pursue other opportunities than find a job in a company [6]. Another aspect is that for the university the goal is to attract more students and enlarge the number of students in engineering programs. For the City Hall, this is another community service funded by federal government, which could be turned into votes for future elections.

VIII. PROJECT STATUS

The groups and the director of the project as a type of swot are doing the assessment of the project in order to identify the weak and strong points in order to make adjustments for future activities.

Presently the project has worked relatively well. Student groups are working hard and the results have been positive. Customer satisfaction has been very good. This information is based on the result of a research that is completed at the end of the project in participant companies. The students claim that the project is a very good opportunity to know their own limits and capabilities. The difficulties they face are related to the fact that they have to combine the project work with studying hard to accomplish the engineering program. They have provided good feedback and are working hard to finish the engineering program, certain that engineering is what they want to do in life.

The City Hall evaluates it as a good service offered to the community and intends to keep "The Innovative Office" open for another year. The constraints are related to the political environment, meaning that the project will last as long as there is political interest by the current government bodies at least until 2016.

IX. CONCLUSIONS

May be the best outcomes of the project are the skills that the students develop along the process in the "Innovative Office", along the perception that they have to take risks and turn today's failures into the seeds of tomorrow's successes. A first result seen during this process is that the project helps the students to experience what it is to be an engineer early during their studies.

Another relevant conclusion is that they can evaluate their own performance and make adjustments. Furthermore, they develop skills such as human interaction, work in team, and work under deadlines and how really to engineer for sustainable, feasible solutions.

The pedagogical aspects of the program are the key factor for its success, which are the extra courses of economics taught by specialists and the research practice that students have to develop in order to get the basis for project development.

It is a very rich experience for students and shows them that they need to be very much self disciplined and to avoid procrastination.

ACKNOWLEDGMENT

This work has been supported by Portuguese national funds, through FCT - Fundação para a Ciência e a Tecnologia, on the framework of projects UID/CTM/00264/2013 and UID/CEC/00319/2013.

Abstract— In this work-in-progress research paper, we explore the task choice of students in first-year, team-based engineering design project courses, with the goal of gaining insight on how to best structure and scaffold team projects so that all students have a positive, effective experience. What factors affect student task choice? Do students select tasks that they feel the most confident about completing, or do they challenge themselves to learn new skills? Do gender or team dynamics or self-imposed roles affect how students participate? If students are asked to develop individual learning goals for the project, does that influence the activities that they engage in, and does articulating learning goals lead to a more beneficial project experience? We are using a mixed-methods approach to investigate the experiences of a small cohort of students engaged in a first-year design project, in order to better understand how students choose to undertake different tasks in team projects.

Keywords—confidence; first-year; project-based learning; self-efficacy; teams

I. INTRODUCTION

Team projects can be beneficial learning experiences for students, encouraging the development of both technical and non-technical skills, allowing students to take on authentic, open-ended problems that cannot be completed individually. They also provide students with engineering “mastery experiences”, one of the main contributors to engineering self-efficacy, the belief in one’s ability to succeed in engineering tasks [1], which is associated with motivation, retention and persistence in the field [2].

However, it has recently been observed that the effects of projects on student engineering self-efficacy is non-uniform, including being affected by the gender of students [3]. Team projects are typically designed with the expectation that all students will engage similarly in both technical and non-technical tasks. However, student participation varies, both within the project as a whole but also with regards to hands-on engineering tasks within the project [4], [5]. Male students take on more engineering tasks (non-personal, goal-focused, and technical), while female students are more likely to take on group-focused, organizational, non-technical tasks [4]–[6]. Students with lower engineering self-efficacy may not take on more technical engineering tasks. Differences in personality can cause some students to assert themselves and take on the

tasks they most enjoy, leaving less assertive students to take on the roles that need to be filled. Finally, a “learning goal” orientation (as opposed to a “performance goal” orientation) can encourage students to participate in tasks that they want to develop skills in, rather than focusing solely on completing the project [4], [7]. Student task choice in team projects is therefore likely to result from a complex interaction of these factors.

This study is part of a larger project focused on the development of engineering self-efficacy in hands-on courses, which includes data collected on students across several universities and a range of courses. The work presented here is a mixed-methods analysis of a small cohort of students to investigate task choice. Was it based on where their existing confidence or self-efficacy lies? Was it based on the roles they played within the team, or perhaps the roles they desired to play on the team? When students are assigned to develop learning goals, do those guide their task choice? Are there gender differences in task choice or roles?

II. METHODS

A. Participants

This analysis focuses on 19 first-year student participants enrolled in a hands-on engineering design course at a small, private engineering college. The course consisted primarily of two projects: the first was an individual project to build a small mechanical toy and the second was a team project to build a more complex toy, suitable for fourth-graders, which typically contained both an electrical and a mechanical component. Teams consisted of 5-6 students and were structured based on reported student interest. Most teams were mixed-gender. Nine students identified as male (students A, D, E, K, L, M, N, O, R, S), nine as female (B, C, F, G, J, M, P, Q, T), and one student did not report gender (H). Six students participated in 2013 (students B, D, M, N, P, and T) and the rest participated in 2012, with an identical project structure and a similar set of course instructors in both years.

The course design incorporates two key learning interventions. One, the carefully scaffolded individual project allows students to develop engineering design skills, regardless of their background. Two, students were asked to formulate individual learning goals for the team project, to share these

goals with their teammates, and to design project plans that addressed each team member's individual learning goals.

B. Data Collection

Participating students were asked to complete pre- and post-course surveys, weekly activity logs, and post-course semi-structured interviews.

The pre-course survey included questions about demographics, personality (using the Big 5 Personality Test [8]), and prior engineering experience and exposure. Both the pre- and post-course surveys included instruments for students to self-assess their commitment to and confidence in completing an engineering degree, their academic self-confidence in open-ended problem-solving, math/science skills, and professional/interpersonal skills [9] and their self-efficacy in engineering and in "tinkering," or hands-on tasks [10]. Each instrument asked students to rate their agreement on a Likert scale from 0-7 (the academic self-confidence instruments) or 0-5 (all other instruments).

Students used weekly activity logs to report time spent on the course in total and on forty different project tasks (with the opportunity to write in tasks that were not listed).

Semi-structured interviews provided further insight into the students' project experience, with a focus on teaming. Students were asked questions pertaining to their perceptions of engineering, their experience with their team, and about factors that may affect their self-efficacy or confidence (including social affirmation and role models). Students were also asked to identify roles played by each team member, including themselves, using "role cards," which named fifteen potential roles they could have played on their team: mechie (focused on the mechanical design), planner, helper, CAD person, eclectic, finisher, servo person (focused on the servo motor/electrical system), communicator, idea person, scheduler, artist, shepherd, leader, builder, and cheerleader (students could also name roles not listed on the cards). Students were then asked how they felt about roles, and which roles they wished they had played on the team but had not. The students were also asked to identify their learning goals for the project, and to assess whether they achieved those goals.

C. Data Analysis

This study used a concurrent triangulation mixed-methods approach to analysis, relating quantitative factors from surveys and activity logs to student descriptions of their individual learning goals and their teaming experiences from the interview data.

a) Quantitative Analysis

Activity logs were analysed to determine the proportion of time devoted to tasks relative to the total time reported for the project. The tasks were grouped into twelve "activity clusters:" brainstorming (ideation), calculations, communication with peers, documentation, hands-on work, modeling/CAD, preparing and giving oral presentations, project management, research, sketching (2D and 3D), teamwork, and preparing a written report. The tasks were also divided into five "mastery clusters," each of which map onto a specific instrument used in

the pre- and post-course survey to measure self-confidence or -efficacy: academic self-confidence in open-ended problem solving, academic self-confidence in math and science skills, academic self-confidence in professional and interpersonal skills, engineering self-efficacy and tinkering self-efficacy. Pearson's correlation tests were performed between relevant parameters, with statistical significance set at $p < 0.05$.

b) Qualitative Analysis

For this study, we focused on aspects of the students' interview data related to task choice: which roles they played on the team, which roles they wished to play, and what their learning goals were, to determine if students are completing activities in line with their original learning goals or their perception of their role aligns with the activities they performed. This qualitative analysis (students' descriptions of learning goals and team roles) was then related to quantitative data from the activity logs. In order to relate this data to what the students were reporting in their end-of-course interviews, we assessed the following: if the student spent a large proportion of their time on a particular task compared to other tasks, if a task cluster was within the top five clusters in which they spent the most time or how the time on task compared to the average of all students. In line with our emphasis on the individual student experience, we did not compare specific students to each other.

III. RESULTS

We first analyzed how students reported spending their time. Fig. 1 shows how each student divided their time among tasks, in terms of proportion of total project time devoted to each of the thirteen activity clusters. Every student spent the most time on tasks within the Hands-on Work cluster (ranging from 17% to 48% of their total time). Students also spent a large proportion of time on Modeling, Brainstorming or Project Management tasks. Students generally spent the lowest amount of time on the Written Report, Documentation, or Calculations activities.

We then considered this data within the context of the students' experience to investigate how they related to the tasks undertaken in the team project: were they based on their incoming self-confidence or self-efficacy levels, the roles they played or wished to play within the team, their learning goals, or gender roles?

A. Academic Self-Confidence and Self-Efficacy

To investigate if students chose tasks based on their confidence or self-efficacy levels, we determined the Pearson's correlation coefficient between academic self-confidence or self-efficacy and the proportion of time spent on different tasks. Although there were several correlations between incoming confidence or self-efficacy levels and time on tasks, there were no direct correlations between any confidence or self-efficacy measure and the corresponding mastery task. For example, academic self-confidence on professional and interpersonal skills did not correlate to spending more time on professional tasks, but did correlate to spending more time on math and science tasks.

Fig. 1. How students divided their time on activities throughout the project. A, D, E, K, L, M, N, O, R, S identified as male; B, C, F, G, J, M, P, Q, T as female.

B. Roles

As part of the semi-structured interviews, students were asked to identify one to three roles that they played on the team, and roles that they wished to play on the team but did not. These answers were compared to how students reported spending their time on the project.

Students most often identified themselves as a helper (7 students), idea person (7), builder (6), CAD person (5), servo person (5) or planner (5), which corresponds to the high proportion of time reported spent on Hands-on Work, Brainstorming or Modeling tasks. Almost every student demonstrated consistency between their self-described roles and the tasks that they chose. For example, students B and M identified as ‘CAD person’ and spent a large proportion of their time on Modeling activities; it was their third and second most time-intensive activity, respectively. Students B, C, and R identified as ‘idea person’ and spent the second, second, and third largest proportion of their time doing Brainstorming tasks. Student H identified as artist and spent much of his time in Sketching and Modeling tasks. The only apparent discrepancies were with students who self-identified as taking on organizational roles such as planner, scheduler or communicator who in fact spent a relatively small proportion of their time on Communication (or Project Management) tasks compared to more technical tasks like Hands-on Work or Modeling. However, these students did spend much more time in these roles than their counterparts who did not identify themselves with these roles. For example, student F identified as a scheduler and planner and spent 14.3% and 10.8% of her time on Communication and Project Management, respectively, compared to averages of 5.1% and 7.4%, respectively. Student D identified as a Communicator and spent 9.6% of his time on Communication; he explained his role trying to be a planner and communicator for his team: “It was—at the end it was very busy... So I think running from team to team did take a lot out of me...” Even though students did not report spending a large *proportion* of their time on these task clusters (perhaps because of the nature of the work required), the students were likely correct in reporting that they took on these tasks to a greater degree within their team.

Students were also asked what roles they *wished* to have played on their team: “Ideally, which roles would you want to describe you?” Students answered with both the roles they did play as well as identifying other roles. For example, student B identified as a CAD person, idea person, and helper and wished to be more of a CAD person and mechie:

“My role...I was a bit of the CAD person...and then I guess I was an idea person...I guess I was overall, like, a helper...I’m happy with the roles that I played, though I think I could’ve done a bit more. But I think the issue was also because we didn’t have a lot of time...I would have liked doing a little more CAD than what I did and then being a mechie...”

Students most often wanted to be a CAD person (4 students), finisher (3), idea person (2) or in an organizational role such as leader (3), planner (2), or scheduler (1). There were also relationships between the roles that students wished they played (but did not identify themselves as taking on) and the tasks that they performed. Students G and K, who wished they played the CAD person role, did in fact spend much of their time on Modeling; students E and P wished they were more of an idea person, even though they reported a relatively high proportion of their time spent Brainstorming. Students who wanted to play organizational roles actually spent a higher proportion of their time on Project Management tasks compared to their peers. For example, students A, D and T wished to be a leader, planner, or scheduler and spent 7.6%, 9.6% and 9.4% of their time within the Project Management activity cluster, respectively, compared to the average of 7.4%.

C. Learning Goals

During the interviews, students were asked to share their learning goals for the course and to assess whether they achieved those goals. While some students identified vague goals (“learning how to do stuff was my biggest goal”) or simply wanted to complete the project “make something that worked”), many students identified specific and achievable goals, and seemed to consider them throughout the course. For example, student L stated early on in his interview:

One of my goals, I don’t know if you know, we had to make goal statements in the beginning of the course saying what we

wanted to accomplish and I did that. So I accomplished my goals. So I wanted to work more on drawing and the CAD.

There was a clear relationship between learning goals and tasks undertaken. Seven students mentioned wanting to get hands-on building experience or learning about mechanical systems, which they accomplished (all students spent the most time in Hands-on Work). Eight students had a goal of learning how to CAD, and most of these students did spend a large proportion of their time on Modeling. Less common goals also matched up with reported tasks: student A had a goal of “learning how the group dynamic worked” and student H had a goal of “teamwork” and they reported spending 21.9% and 6.4%, respectively, of their time on Teamwork, compared to the average of 5.0%; student D wanted to gain experience “managing a team” and spent 9.6% of his time on Project Management compared to the average of 7.4%; Student J wanted to “be an idea person” and Brainstorming was within the top five activity clusters that she devoted time to.

D. Gender

Pearson’s correlation coefficients between gender and the proportion of time spent on tasks were also calculated. Although previous studies reported gender differences between the tasks completed by different team members [4], [5], in this cohort, the only task that correlated with gender was the proportion of time spent on research, which was higher for female students.

Gender differences in the roles that students played within their teams were more pronounced. More male students identified as a helper (five male students versus two female students) and in more technical roles, like builder (four versus two), servo person (four versus one), or mechie (three versus none). Male student O, who self-identified as a builder, idea person, artist, and helper, did not identify with a non-technical role, despite spending far more time on the Written Report and Oral Presentation tasks (19.5% and 19.0%, respectively) than average (1.4%, 6.8%). More female students identified as playing less technical roles, like idea person (five female students versus two male students), communicator (two versus one), and scheduler (three versus none). Female student J self-identified as a communicator and idea person, but spent 19.4% of her time on Modeling and 11.8% on Sketching, far more than the averages of 12.3% and 7.1%. This suggests that gender schemas may influence of student’s self-perception of the role they played.

There were few gender differences in the roles that students *wished* to have played: interest in both technical roles (builder, mechie, CAD person) and non-technical roles (leader, scheduler, planner) were similar. The learning goals of students were also similar. Many students wanted to learn how to build (four women, three men) or CAD (five women, three men). However, only male students reported a goal of “learning how to design”, and only female students wanted to “be an idea person.”

IV. DISCUSSION AND PRELIMINARY CONCLUSIONS

Our original hypothesis for this research project was that incoming academic self-confidence or self-efficacy levels

would significantly affect student engagement in project tasks. No clear correlations were observed, however, and the evidence is that many factors affect tasks students undertake, including team and gender dynamics. As well, activity log data cannot be used to distinguish between productivity or difficulty: a large proportion of time spent doing CAD, for example, may mean that the student was efficiently completing many CAD tasks or that they took longer to do each task.

However, there is evidence that the learning goal intervention, originally designed to reduce gendered task choice [4], is having the desired effect. The relationship that we found to be the most distinctive was that between proportion of time spent on tasks and the students’ reported pre-project learning goals. The effects of goal-setting have been well-studied in other fields [11]; here, formulating and sharing goals provides students with the opportunity to focus their project time. This intervention can easily be implemented in project-based learning experiences; the shift from a ‘performance orientation’ to a ‘learning orientation’ meant that students took on personally meaningful tasks or roles.

The tasks that students completed during the project not only seemed to align with the roles that they felt they played on the team (as expected) but were also consistent with the roles that they wished they had played on the team. This may align with our original hypothesis: having performed these tasks extensively over the course, students may have higher self-efficacy in those tasks, and thus be more inclined to continue to take them on. However, it may also be because students were struggling with some tasks, and they wished to have the opportunity to improve.

Finally, while no gender differences in how students engaged in tasks were observed, male and female students differed in their self-perceived roles. Although the activity logs demonstrated that there was no significant gender differences in students’ self-reported time-on-task data – men and women participated equally in technical and non-technical tasks – female students were still more likely to think of themselves as taking on non-technical, organizational roles while male students placed themselves in technical roles (mechie, builder). This suggests that gender schemas around the perceived “male” nature of technical roles may still be prevalent.

These findings from a cohort within a larger project suggest that is the result of a large number of interacting factors, of which self-efficacy is only one. However, the learning goal intervention implemented in this course seemed to have a pronounced effect on task choice, at least in this specific academic setting. Analysis of data collected on the experiences of students from other academic environments and types of project courses is ongoing.

The Impact of a Peer Learning Strategy on Student Academic Performance in a Fundamental Engineering Course

Shaobo Huang; Elizabeth Pierce
Department of Mechanical Engineering
South Dakota School of Mines & Technology
Rapid City, United States

Abstract—One of the main reasons that engineering students withdraw from their major programs is the discouraging academic performance in fundamental engineering courses. It not only limits students' access to advanced engineering courses, but also diminishes students' attitudes toward engineering. The purpose of this pilot study is to investigate the effect of the proposed peer learning strategy on students' learning of Dynamics, a fundamental engineering course. Research questions of this study include: Q1: To what extent does the proposed peer learning strategy improve students' understanding of engineering dynamics? Q2: To what extent does the proposed peer learning strategy change students' attitudes toward engineering?

Seventy students who enrolled in the Engineering Dynamics course in the fall 2014 and spring 2015 participated in this study. Students' performance by question type (PQT) were defined and analyzed to identify students' academic needs and to assign peer learning teams. Results suggested that peer learning strategy proposed in this pilot study had positive impact on students' learning of dynamics and attitudes toward engineering. Limitations and future studies were discussed at the end of this WIP.

Keywords—Peer Learning; Academic Performance; Engineering Attitudes; Engineering Dynamics

I. INTRODUCTION

Engineering mechanics dynamics is a core course for many engineering undergraduate students. It introduces numerous engineering concepts and is the foundation for advanced engineering courses, such as thermodynamics, solid mechanics, machine design, and structural design. It is also acknowledged as a challenging course because it not only requires applications of mathematics skills (i.e. algebra, calculus, and differentiation equations), but also covers a broad spectrum of engineering concepts and principles [1-2]. For example, students need to learn through kinematics and kinetics principles of Force and Acceleration, Work and Energy and Impulse and Momentum for particles and rigid bodies within 15 weeks of time frame. Many students indicated that they "remembered" and "understood" the principles learned in Dynamics; however, they had difficulties in applying the learned principles into problem solving. In the standard Fundamentals of Engineering examination in 2009 in the

U.S.A., the national average score on the dynamics exam was only 53%.

Relatively low engineering self-efficacy and motivation are the other primary reasons that lead to high attrition in engineering. Studies showed that self-efficacy is significantly correlated with students' tenacity, persistence, and achievement [3]. It determines students' confidence and use of cognitive strategies in learning [4]. In addition, high self-efficacy leads students to set new challenging goals for themselves [5]. Santiago and Hensel [6] reported students' reasons for transferring majors from engineering at colleges and universities and the #2 reason was "I don't think I can succeed in engineering."

Peer learning strategy in this study refers to learning activities that involve intellectual interactions of a group of students. Students' interactions are often emphasized in collaborative/active learning. For example, Stump et al. [7] issued a survey to 150 mechanical and aerospace engineering students in sophomore through senior level core courses to determine the effects of peer learning. The survey consisted of questions evaluating through student perceptions of classroom knowledge-building (SPOCK) which focuses on knowledge building, teacher directedness, and collaborative learning, and motivated strategies for learning questionnaire (MSLQ), the portion of which used in the study focused on self-efficacy. Results to these surveys were scaled and analyzed using multiple regression to compare student opinion with performance. These scores indicated a significantly positive correlation between collaborative learning and self-efficacy, knowledge building, and course performance, and a correlation between self-efficacy and knowledge building, course grade, and teacher directedness. The study also predicted course grades based on collaborative learning and the results suggested students participating in collaborative learning performed better in the course than those working independently.

Another example is the study conducted by Freeman etc. [8] to test the influence of lecturing on learning. The examination scores or failure rates in undergraduate STEM courses reported in 225 studies were meta-analyzed. The results indicated that the average examination scores were 6% higher in studies with active learning than others, and students

learned through traditional lectures were 1.5 times more likely to fail than those in active learning. It is believed that collaborative/active learning increases knowledge transfer between students, strengthening each other's weaknesses, and increases overall student performance.

However, these studies assessed the overall effect of collaborative/active learning, including interactions between students and/or the instructor. This study focuses on the role of peers, referred to as peer learning strategy in this paper, in the learning of an engineering course.

II. VALUE OF CURRENT STUDY

A number of studies have investigated the effectiveness of peer learning in different student groups. Some studies suggested that interacting with peer students at the same cognition level, while in other studies, interactions happened among non-competent students. Both strategies have been found beneficial to the students [9-10]. However, asymmetry of knowledge exists among competent peers. Few studies have explored peer learning among competent students with asymmetry of knowledge.

The primary research questions of this pilot study are:

- 1) To what extent can peer learning affect students learning of Engineering Dynamics when team with competent peers with asymmetry of knowledge?
- 2) To what extent does the proposed peer learning strategy change students' attitudes toward engineering?

III. RESEARCH METHOD

Students enrolled in the engineering dynamics courses in fall 2014 and spring 2015 semesters participated in the pilot study. Students in the fall 2014 semester were in the control group and those in spring 2015 were in the experimental group. The following paragraphs describe the research method step by step.

Step1: Collected baseline data from the two groups through a 30-minute pre-test. The pre-test includes 11 multiple-choice questions and 4 open-ended questions that align with ABET's requirements on problem identification, interpretation, formulation, and mathematical application [11].

Step 2: Calculated the grades of students in each category mentioned in Step 1 in the pre-test

Step 3: Strategically grouped students into teams according to their total points and achievement in each category in the pre-test. Each team consisted of 3-4 students with similar total points (points differences were smaller than 2 out of 15 points) while asymmetry points in at least on category.

Step 4. Students in both control and experimental groups were provided with one problem for practice during each lecture in the engineering dynamics course and ten practice questions covering key knowledge at the end of each chapter. Students in control group did individual work on the practice questions; while those in the experimental group worked as teams with emphases on problem analysis and identification. The teams in the experimental group

- summarized the theories/principles they had learned in the dynamics course,
- described the patterns and/or features of the theories/principles,
- identified the situations that confirmed or contradicted with the pre-assumptions,
- applied proper theories/principles to solve problems,
- analyzed advantages and disadvantages of a potential solution with peers, and
- explored and analyzed other options to solve specific types of problems with peers.

Step 5: Compared students' performance in the experimental and control groups in the three exams in dynamics. Both groups used the same questions. The questions were designed with the guidance of ABET requirements and the textbook of Engineering Mechanics Dynamics [12]. To control the validity of the two exams in two continuous semesters, questions were reviewed in class using the projector within one week after each exam. No exam questions were released to the students after the exams.

Step 6: Investigated students' attitudes toward engineering using engineering attitude survey. The survey was adapted from the author's previous study on students' engineering attitudes [13].

IV. DATA COLLECTION

Quantitative data were collected from students in Engineering Dynamics at a public 4-year engineering school in the State of South Dakota. As shown in Table 1, a total of 70 students were involved in this pilot study.

TABLE I. STUDENT DEMOGRAPHICS

Groups	Genders		Majors ^a		Grades ^b		
	Male	Female	ME	CEE	SO	JR	SR
Control Group	23	1	23	1	10	11	3
Experimental Group	45	1	43	3	20	22	4
Total	68	2	46	4	30	33	7

^a ME: Mechanical Engineering Department; CEE: Civil and Environmental Engineering Department

^b SO: Sophomore; JR: Junior; SR: Senior

In response to the ABET criteria, the practice activity was designed with 3 problem identification questions, 4 problem interpretation questions, 5 problem formulation questions, and 3 mathematical application questions. Table 2 shows the distribution of questions in the pre- and post-tests in the four categories as described above. Students' responses to the pre-test were graded with the same weight for the 15 questions. For example, a student can gain 1 point for answering one question completely correctly or 0 points for an incorrect answer.

TABLE II. DISTRIBUTION OF THE QUESTIONS IN THE FOUR CATEGORIES

Category	Question Number
Problem identification	6, 8, & 9
Problem interpretation	1, 3, 5, & 11
Problem formulation	2, 4, 7, 10, & 12
Mathematical application	13, 14, & 15

Students in the dynamics course filled the Engineering Self-Efficacy Survey at the beginning and the end of the spring 2015 semester through Qualtrics, an online survey platform. Students with more than 10% of missing data were excluded from the assessment of Engineering Self-Efficacy.

V. RESULTS

Fig. 1 compares students' achievement in the pre-test in the control and experimental groups. To compare the performance of the students in the two groups, the following criterion is defined as (1) in this study:

$$\text{Percentage of correct response (PCR)} = \frac{\text{(The average number of students who selected the correct answer to questions in one category/ Total number of students in the group)}}{\text{Error! Reference source not found.}} \times 100\% \quad (1)$$

For example, assume 15 out of 30 students answered question A correctly and 10 for question B. Question category I consists of question A and B. The average number of students who selected the correct answers to the question category is $(15+10)/2 = 12.5$; while the PCR of question category I is $12.5/30 \times 100\% = 41.7\%$.

Fig. 1. Comparisons of the PCRs of pre-test.

Data indicate that, on average, students in the experimental group were at similar cognition levels than those in the control group at the beginning of dynamics course, except for mathematical application.

The average of students' academic performance in the three exams are compared in Fig. 2.

Fig. 2. Comparison of average exam scores.

A total of 34 students at the beginning and 32 at the end of the spring 2015 semester filled the engineering self-efficacy online survey. As shown in Fig. 3, no significant differences were found in a 95% confidence interval in students' self-efficacy, perceived inclusion, intrinsic motivation, or extrinsic motivation. However, considering the small sample size and short treatment (one semester), we adopted a 90% confidence interval and students had higher self-efficacy and perceived inclusion in the post-test ($p < 0.1$).

Fig. 3. Comparison of students' attitudes toward engineering.

VI. DISCUSSIONS

The preliminary results showed above suggest that the proposed peer learning strategy can improve engineering students' learning of dynamics and attitudes toward engineering. Although the students in the experimental group had higher average PCR in mathematical application, they did not achieved higher average score in the first exam. Two potential reasons are discussed in the following paragraph.

First, the students were not familiar with peer learning strategy and they were not benefit much from it at the beginning of the semester. One of the authors noticed that many students did not put much effort in analyzing the problem nor discussing with team members during in-class practice time in the first two weeks of the semester. Fortunately, the situation was significantly improved at the end

of the first month and most students actively involved in the discussions.

Second, although mathematical application skills are necessary to learn dynamics, it is not a sufficient factor. A student needs to apply mathematics based on skills in terms of problem identification, interpretation, and formulation. Limited by the three skills mentioned above, students in the experimental group could not succeed in dynamics, as shown in the results of exam #1.

Students in the experimental group had slightly higher self-efficacy and perceived inclusion after one semester of peer learning experience; however, no differences were found in intrinsic and extrinsic motivation in engineering. Considering the improved academic performance in dynamics and self-efficacy as well as perceived inclusion, motivation in engineering can be improved through the proposed peer learning strategy if adopted for more than one semesters or multiple courses.

By the time of submission of this pilot study, the students in the experimental group have not taken the post-test yet. Comparisons of the pre- and post-tests of the control and experimental groups will be conducted in the future study.

Checkable Answers: Understanding Student Behaviors with Instant Feedback in a Blended Learning Class

Xin Chen, Jennifer DeBoer
School of Engineering Education
Purdue University
West Lafayette, IN
chen654@purdue.edu, deboerj@purdue.edu

Abstract—Online learning platforms can provide automatic instant feedback on students’ activities with formative assessment tasks such as homework assignments. However, the various ways that students interact with feedback features add to the uncertainty of the effectiveness of automatic immediate feedback on student learning. We study student behavioral patterns with an instant feedback feature: “checkable answers,” powered by the edX learning platform. We show how these behavioral patterns are related to student course performance and other factors such as self-efficacy and student perceptions of the utility of the course for their future.

Keywords— *immediate feedback; learning analytics; edX; blended learning*

I. INTRODUCTION

Feedback serves to close the gap between learners’ current understanding and the desired understanding [1]. Timely and informative feedback can keep students from holding onto misconceptions, actively engage learners in knowledge acquisition, and increase confidence and motivation to learn [2], [3]. Yet, in the context of higher education, it is usually not possible for instructors to provide timely feedback to every individual student. Online learning platforms offer a solution to provide students automatic instant feedback on their interactions with online formative assessment tasks. However, how students choose to interact with these features and how these features have influenced students’ learning experiences are rarely well understood, especially in blended learning [4].

We utilize rich quantitative data including a large volume of server tracking log data of students’ interactions with the online platform, survey results regarding student perceptions of the checkable answers and self-efficacy to perform in the course, and student course performance metrics. The findings provide implications for improvements to instructional practice in blended learning for STEM courses.

II. FRAMEWORK AND RELATED LITERATURE

A. Conceptual Framework

Based on social constructivism learning theory [5] and numerous theoretical and empirical studies of how people learn

[6], we know that students develop their understanding of a concept based on their prior knowledge and experiences. Feedback plays an important role in closing the gap between current understanding (built from prior knowledge) and the desired goal, enhancing student performance and achievement.

To understand the effect of feedback on learning, we need to first understand the levels and timing of feedback. Hattie and Timperly [7] conducted a thorough review of studies on feedback effects, and they proposed four levels of feedback, from specific to generic: (1) feedback on task execution, (2) feedback on learning strategies, (3) feedback on metacognitive skills, and (4) feedback on the self as a person. Studies note that there is an interactive effect between feedback on task execution and learning strategies [8]. Feedback at the task level can help students who already demonstrate metacognitive awareness develop appropriate learning strategies on their own. Though the “checkable answers” in the course we study only provide simple corrective feedback at the task execution level, it is reasonable to assume that students with strong metacognitive awareness could develop effective learning strategies because the task level feedback is available.

In terms of the timing of feedback, much debate exists in the literature over the effectiveness of immediate versus delayed feedback. Proponents of delayed feedback refer to the superiority of delayed over immediate feedback as the Delay-Retention Effect (DRE) [9]. However, many recent studies argue against DRE, which may be more effective in laboratory settings [10], [11]. In the context of this study, “checkable answers” provided automatic immediate corrective feedback on students answers’ to online homework problems.

B. Background Literature

1) Blended learning

A blended learning class in post-secondary education is usually defined as a class that has a significant online component, while the students and instructors still meet face-to-face regularly [12]. Researchers argue that the blended learning format combines the “best of both worlds” [13] and could support deep and meaningful learning [14]. However, empirical studies report mixed evidence of the effectiveness of the blended learning format [12], in part because there are

virtually countless instructional and platform design possibilities for blended learning classes in various contexts. As [4] states, and we concur, studies merely answering “big” questions such as “is blended learning effective” yield few actionable insights for educational practices. This current study does not intend to justify whether blended learning is effective or not. Rather, we take a very focused approach to understanding and improving blended learning, here, by studying the component of immediate feedback within a blended learning context.

2) *Student behaviors in online learning platforms*

Solely understanding the effect of feedback on student learning is not enough to provide practical guidelines for the design of automatic instant feedback features. Even if we provide the right level of feedback at the right time, there can still be numerous ways in which students interact with these feedback features online outside of the controlled classroom environment [15]. In a work-in-progress study [16], the researchers seek to develop measures for students’ “productive persistence”—strategic behaviors that benefit learning in an online learning platform. Such measures could be used by instructors for pedagogical improvement. Similarly, in our study, we investigate whether we could identify student instrumental vs. strategic behaviors using the “checkable answers” feature, and we estimate the relationship between these behaviors, course performance, and self-efficacy.

C. *Research Questions*

Based on our conceptual framework and existing literature, we ask three foundational questions in our study: (1) How can we characterize the behavioral patterns that students demonstrate while using the “checkable answers” feature? (2) How are these behavioral patterns related to students’ performance? (3) How are perception, attitudinal, or self-efficacy factors related to student behaviors using the instant feedback feature?

III. DATA

The course studied in this paper is a residential physics course, “Classical Mechanics,” required for all first-year students at an elite private university in the northeastern United States. In Fall 2014, a total of 474 students were enrolled in this course. The course was a blended learning course, including active learning face-to-face class sessions during the week and a large number of learning materials and assessments online powered by the edX learning platform (www.edx.org). This current study focuses on the rich quantitative data from students’ interactions with the course platform, survey results, and student performance.

A. *“Checkable Answers”*

Using an instant feedback feature called “checkable answers” on the edX platform, the students could check an unlimited number of times whether their answers to the online homework problems were correct indicated by a green check mark or a red cross mark. No answer or hint was available before the due date. There were 22 online homework problems over the semester, and students had 10 days to work on each

problem before the due date. In total, online homework problems were worth 2% of the course grade.

B. *Data Sources*

1) *Tracking log data*

From September 1st to December 31st, 2014, students’ interactions with the edX course website resulted in more than 30 million interactive events. These interactive events include students’ interactions with all kinds of online materials and assessment tasks: the e-textbook, lecture slides, videos, and homework problems. One event with the “checkable answers” is referred to as a “check”. In total, with 22 problems, students made 58,422 checks. The total number of correct checks is 9,545, and that of incorrect checks is 48,877: only 16.3% of the checks were correct.

2) *Survey data*

During November 2014, we administered a Qualtrics survey to the students. The survey measured, using a 1-7 Likert scale, students’ perceptions of the utility of the “checkable answers” feature (e.g., whether the feature helped their learning by “helping me check for errors”); their self-efficacy to perform in this course; and the perceived utility of this course for their future. For each of the three metrics, we constructed a scale (average score of items to which one student responded). The within-scale reliability for the new scale of perceptions of the utility of the checkable answers is high (Cronbach $\alpha=0.98$). The self-efficacy measure and the measure for students’ perceived utility of this course for their future are adapted from [17] and [18], respectively.

Out of the 474 students, 266 students completed the survey, resulting in a response rate of 56.12%. Tests show that students who completed the survey performed significantly better in both cumulative and final exam grades ($p<0.01$). These systematic differences between students who did or did not complete the survey represent a limitation to our study.

3) *Performance metrics*

We collected cumulative grades and final exam grades for all students enrolled in this course. Besides final exam grades, the cumulative grades take into consideration students’ homework scores, quiz scores, reading assignment scores, and participation in problem-solving sessions and experiments, therefore representing students’ effort more broadly [19].

IV. METHODS

We extracted 10 variables from the server tracking log data to describe student behaviors with the “checkable answers”. We supplement behavioral data with the survey results as described above and run appropriate correlations.

A. *Extracting variables*

For each homework problem, a student submitted a set of answers, to which the system returned a set of True (T) or False (F) symbols indicating the correctness. Different students had different numbers of Fs and Ts on each homework problem, with different time intervals in between. We constructed the following ten basic variables for each student on each homework problem to summarize the the student

behaviors in their use of the “checkable answers”: (1) the time between the first check and the homework due time; (2) the number of Ts; (3) the number of Fs; (4) the total number of checks; (5) the ratio of the number of correct checks out of the total number of checks; (6) the time between the first check and the last check; (7) the time between the first check and the second check; (8) the average time interval between each check; (9) is the first check a T?; and, (10) is the last check a T? With 22 homework problems, we have 220 descriptive variables for each student.

B. Analyses

We normalize each feature by a “difficulty” proxy for all students within each homework problem before proceeding to the correlation analyses. For variables 9 and 10 above, which are binary, we weighted using the total number of incorrect checks for each homework problem. Our logic is to use the total number of incorrect checks for each homework problem across all students to approximate the difficulty level.

For each of the 10 normalized or weighted variables, we then found the mean value over the 22 homework problems for each student. Then, we calculated the Spearman rank correlation coefficients between the mean values of each feature and each students’ final exam scores and cumulative grades. For students who completed the survey, we also calculated the correlation between the 10 variables and the scale scores.

V. RESULTS

Initial results indicate that some of the student behavioral variables are significantly related to performance and attitudinal outcomes, though only a few are strongly so.

A. Descriptive statistics

The maximum number of checks for a homework problem summed across all students is 6,127, while the minimum number is 579. The average number of checks for a homework problem across all students is 2,656. On average, one student checks each problem 5.6 times. Fig. 1 is a stacked bar graph illustrating the number of correct and incorrect checks for each student (ordered based on total number of checks). We can see that students who checked more than 300 times had a relatively lower percentage of correct checks. We might hypothesize that the students who checked more than 300 times are demonstrating frequent guessing behaviors, and their performance might be hurt by this behavior. However, as we will show in correlations, frequent checking in this blended learning context does not appear to hurt student performance.

B. Skewness

Fig. 2 demonstrates that the distributions of the variables are skewed, which is the case for the other 8 variables as well. This is the rationale for our choice to use Spearman rank correlation instead of Pearson correlation in our analysis.

C. Correlations

We show a correlation coefficient visualization in Fig. 3. The order of the 1-10 variables is the same as the ordering in the list we describe in section IV.A.

Fig. 1. Total number of correct and incorrect checks for each student over all 22 homework problems (Stacked)

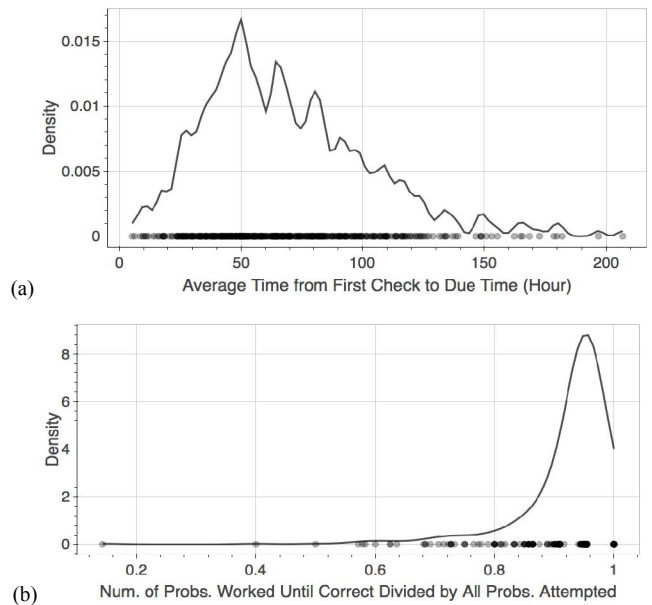

Fig. 2. Density plots for (a) the average time the first check to the homework due time for a given student (variable 1) and (b) the ratio of number of problems where the student worked until correct divided by number of all problems attempted (variable 10)

VI. FINDINGS

We find that some of the behaviors that research has shown to be important in face-to-face classrooms (e.g., conscientious study strategies) are also significant in the blended classroom. We also find that higher engagement with immediate feedback in the simple ways in which we measure this construct is positively related to achievement in the course.

A. Student behaviors using “checkable answers” feature

We observe a great deal of heterogeneity in the range and types of behaviors students demonstrate as they engage with the “checkable answers” feature. Although these behaviors represent a great deal of diversity and demonstrate a high level of skew, they are not as notably skewed or widely varied as behaviors in the MOOC context [20].

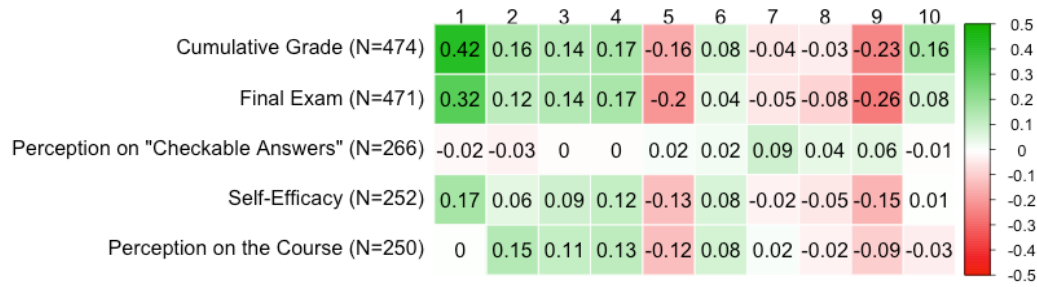

Fig. 3. Spearman correlations between the 10 variables and student performance and attitudinal scores (see section IV A. for descriptions of the 10 variables)

B. Relationship to student course performance

From Fig. 3, we can see that many of the behaviors we study are related to achievement in the course. Some are significantly related to student attitudes or perceptions. Further, some, but not all, of the relationships are in the direction we had hypothesized.

The time between the first check and the homework due time is the metric most strongly related to students' course performance. This indicates that "early starters," on average, perform well. This may be due to their higher level of metacognition or more mature study strategies. Our subsequent multivariate regression models will help us better parse out the variance attributable to different student behaviors.

Number of checks, no matter whether it is the number of correct, incorrect, or total checks, has a positive correlation with student performance. We hypothesize that this might indicate that, even if a check is incorrect, the student receives feedback on his/her response and can utilize that feedback, which may then result in higher learning outcomes. The positive relationship between number of checks and achievement may also be a proxy for the student's effort, which would positively contribute to performance compared with no check at all [19].

We had hypothesized that students getting the correct answer on their first tries (variable 9) might be a proxy for higher prior knowledge of the course content, which would likely positively correlate with performance. However, our current results show the opposite. It is actually students working until they get the correct answer (variable 10) that is more important and beneficial for achievement than getting the correct answers on the first attempts.

C. Perceptions and self-efficacy

We find that some of the behaviors are related to the three key survey scale metrics: students' self-efficacy to perform in the course, their perceptions of the utility of the course for their future, and their perceptions of the utility of the "checkable answer" feature. These key attitudinal metrics may be related to both student performance directly and also to the way in which students use the feedback feature, which could in turn mediate their learning.

Interestingly, students' perception of the utility of the "checkable answers" feature is not actually correlated with any of their actual behaviors with the "checkable answers." This

may reflect the fact that, regardless of how students perceive the benefits of the tool, it is their realized behaviors and the ways in which they engage with the feedback system that ultimately impact their performance. On the other hand, students' self-efficacy scale scores are correlated with behavioral measures, and they follow the same positive/negative pattern of correlation as behaviors related to performance outcomes. In addition, students' perceived utility of the course for their future is positively correlated with their number of checks (perhaps a proxy for effort).

VII. DISCUSSION, IMPLICATIONS, AND LIMITATIONS

We find three key implications for instructors and platform designers across STEM undergraduate courses. First, "effort" as measured by the number of checks appears to be an important behavior, regardless of whether students get the answer correct or incorrect, and therefore, instructors should encourage or reward students' "trying" over their getting the correct answer right away. Also, the extent to which students start the homework before the due date is very strongly tied to their achievement, and instructors or platform designers could encourage or remind students to practice thoughtful study strategies in the blended setting as they ideally would in a face-to-face class. Finally, the lack of a correlation between students' perceptions of the utility of the "checkable answers" implies that instructors and designers should reconsider the way they gather student perception measures and ask corresponding research questions.

We highlight two additional limitations that we have not already mentioned. First, we did not have direct measures or strong proxies of crucial student background factors such as prior knowledge and metacognitive skills. And, second, we cannot actually observe everything that students are doing in between checks in order to affirm our hypotheses about why we observe the relationships that we find in our study. In future work, we will include student background factors in our analyses in order to look into students' other behaviors associated with the usage of "checkable answers" during the problem solving process.

ACKNOWLEDGMENTS

The authors gratefully acknowledge supplementary support from the university (blinded) where data were collected for this study. Also, we would like to recognize the contributions of undergraduate researcher Xingyu Zhou (Purdue University) in data cleaning and understanding the data generating mechanism of the platform. We are also grateful for the comments and feedback of Lori Breslow and colleagues at the Teaching and Learning Laboratory at MIT. We would like to thank the instructors and researchers at the university studied for their participation and help with the ongoing study.

Abstract—Visual algorithm simulation (VAS) is an activity in which students practice their understanding of algorithms: They simulate the steps of an algorithm by manipulating a bespoke visualization within a supporting software system. Multiple instances of a VAS exercise may be automatically generated for different learners or for repetitive practice by a single learner. In this work-in-progress report, we discuss how misconceptions might be automatically detected in students' solutions to VAS exercises and how misconception-aware feedback might be provided in VAS. We identify two strategies for producing multiple instances of VAS exercises and evaluate them against several criteria. The trade-offs so identified are also pertinent for similar process-simulation practice beyond VAS and computing education.

Keywords—*computing education, algorithm visualization, visual algorithm simulation, process-simulation practice, automatic assessment, feedback, misconceptions, individualized instances of exercises, input generation*

I. INTRODUCTION

Consider an activity in which a student is supposed to learn about a well-defined stepwise process, standard procedure, or algorithm. To this end, an exercise is provided in which students start with some input, practice applying the procedure on it, and, if all goes well, produce the intended outcome. The path they are expected to follow depends on the input and the procedure.

An example of this kind of learning activity within computer science education is *visual algorithm simulation* (VAS) [1]. In VAS, students use a computer to manipulate a visualization of a data structure in order to learn about how a particular algorithm works on that structure and to demonstrate their understanding. Since the algorithm is well defined, the activity can be automatically assessed and scales to online or blended courses with large numbers of students.

For a software system to support VAS or a similar form of practice effectively, the following features are desirable:

- The system should be capable of automatically generating numerous instances of the problem, i.e., different inputs on which the algorithm can be practiced.
- The system should be sensitive to common misconceptions of the algorithm that is to be learned. The generated instances of the activity should be such that a student with these misconceptions is unlikely to succeed unless they address the misconception.

- The system should provide formative feedback that targets particular misconceptions. This feedback should be generated as automatically as possible: it should be able to assess when a particular student might have a particular misconception.
- Ideally, the system would also aid teachers and developers in determining which student errors and misconceptions are common.

This article is a work-in-progress report. In it, we explain why the above goals make sense, highlight certain difficulties in achieving all of them at the same time, and promote a discussion on how to work towards them. In the following sections, we elaborate on visual algorithm simulation and empirical studies of it, present the above agenda in some more detail, and discuss two alternative strategies for generating inputs for VAS exercises. We then turn to the research community for advice.

II. VISUAL ALGORITHM SIMULATION

Although the problems of input generation and misconception-aware feedback in computer-supported process-simulation tasks arise in many contexts, our current interest in this topic revolves around computing education and, more specifically, algorithms courses and the *visual algorithm simulation exercises* [1] which may be employed in them. Visual algorithm simulation is an interactive form of *algorithm visualization*, and, more broadly speaking, of educational *software visualization* [2]. In the form that we discuss in this article, VAS requires a purpose-built software system that facilitates practice.

In a VAS exercise, a learner is asked to trace an algorithm by manipulating a given visualization of one or more data structures. Typically, these manipulations are carried out using the mouse on the visualization: clicking, dragging, and dropping, for instance. Learners produce a trace of a specific algorithm: Mouse events signal transitions between the states that constitute the trace. As the learner operates on the visualization, the corresponding modifications are made to real data structures in computer memory. The states of the data structures are recorded at each step.

An example of a VAS exercise is shown in Fig. 1: A new key has just been inserted into a Red Black Tree. In this example, the learner is supposed to click the nodes and

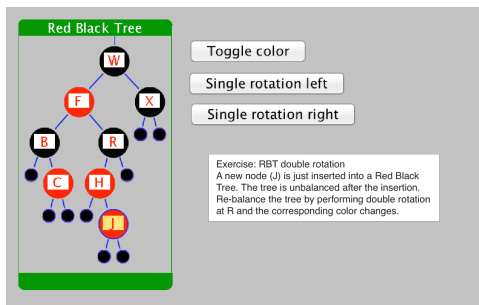

Fig. 1. A snapshot of a VAS exercise. The learner is supposed to insert a number of keys into an initially empty balanced search tree. A new key has been just inserted into a Red Black Tree (the red node *J*, in yellow). The tree is currently unbalanced (the rule “both children of every red node must be black” is violated at *H*). Next, the learner is to choose and perform the correct operations to re-balance the tree.

push buttons on the screen in order to re-balance the tree. The balancing is performed by selecting a node and choosing the correct push button. In this case, the learner is supposed to do a double rotation at *R* and the corresponding color changes. However, this is a complex operation that requires multiple steps (as this VAS exercise does not offer a double rotation operation as a primitive). The corresponding states produced during these steps constitute the trace. The correct re-balancing sequence begins with selecting the node *H* and performing *Single rotation left*, after which *Single rotation right* is required at *R* and *Toggle color* at both *J* and *R*.

VAS exercises can be embedded in instructional materials such as OpenDSA that is targeted for data structures and algorithms courses [3]. OpenDSA integrates a textbook with algorithm visualizations and a collection of “proficiency exercises” in the form of VAS. The learner can submit their answer — the sequence of states — to the back end simulation system and receive a grade and/or feedback.

The automatic assessment of a VAS exercise can be implemented as a stepwise comparison of learner-generated states with a model sequence; an example is shown in Fig. 2. Each state in the student’s sequence must match the model answer in order for the student to receive full points. Automatic assessment not only removes the burden of marking those exercises manually, but also makes it possible to give the students immediate feedback.

In existing VAS exercises [1], each exercise is typically initialized so that the system generates random input data within exercise-specific parameters. This has several benefits:

- The system can provide a model answer for each instance of the exercise: A student may request to see the model answer and compare their answer with it, and then start over with a new instance (fresh inputs) to try and gain the marks for the exercise. This provides an opportunity to students to learn from their mistakes, assuming they are able to understand the model solution.
- Students can practice on an algorithm using fresh data even after successfully solving the exercise once.
- The system can provide students with individualized instances of the exercise so that they cannot simply

copy each others answer directly. This may reduce cheating.

It is not trivial to choose the parameters within which inputs are generated. For example, consider the sequence of keys to be inserted into an initially empty Red Black Tree. The sequence should be such all the different balancing scenarios are covered. The snapshot in Fig. 1 covers only the case where a double rotation is needed. In a complete exercise, also a single rotation and simple color change scenarios should be covered. In addition, there is a case where the procedure needs to be recursively performed upper in the tree after a color change. Not all random input sequences feature such scenarios with a feasible small amount of keys and steps. We will return to this issue below.

III. RELATED EMPIRICAL WORK

Seppälä et al. [4] introduced an approach to recognize misconceptions related to the Build-Heap algorithm. They examined recorded sequences from a VAS exercise to discover misconceptions related to the algorithm. Afterwards, they manually implemented misconceived algorithm variants and matched student solutions to these. According to the authors, a relatively large body of incorrect student answers can be matched against these misconceived algorithm variants:

“Of all the incorrect answers, one fifth could be explained by the three most common [misconceived] algorithms alone. If algorithms that do not end with the heap property restored are considered, only one fourth of all submissions to the exercise were left.” [4]

Seppälä et al. also extended the idea of modeling misconceptions beyond manually implemented algorithm variants [5]. They made small changes — mutations — to the code of the implemented variant algorithms. This allowed subtle variation within the variant itself as well as modeling non-systematic behavior such as slips.

Karavirta et al. [6] also studied misconceptions in the context of VAS and found out that some VAS exercises have problematic input data: Some instances of exercises could be solved with full marks even by students with a misconception. This is possible if the correct trace does not include a state or step that is needed to reveal the misconception. For example, in the Build-Heap algorithm, the input could be such that swaps occur only with a parent and its child, but this “percolate-down” process (also known as sift-down or heapify-down) never continues at the lower levels. In other words, the tail recursion at the end of the algorithm never happens. Many well-known misconceptions are related to students’ weak understanding of recursive functions. In this case, the student might never realize the recursive nature of the algorithm if the input data is badly chosen.

Logged traces of student behavior in software simulations have also been found to be a potentially useful form of data in the context of *program visualization* (i.e., the visualization of concrete programs as opposed to general algorithms): Sirkiä and Sorva [7] explored students’ solutions to visual program simulation exercises and found evidence of multiple misconceptions of introductory-level programming concepts.

Fig. 2. A comparison of two selection sort sequences. The top sequence is the model solution, and the bottom sequence is an incorrect solution produced by a student. The comparison proceeds by stepping through the states of the model solution and trying to find the corresponding state from the student sequence. The process continues until either sequence runs out of states.

Beyond from computer science, specific processes that a student should follow and the related misconceptions have been studied in the context of mathematics education [8]–[10]. Work has also been done on the automatic analysis of students’ systematic stepwise processes in the context of chemistry education [11] and Lisp programming [12].

IV. TOWARDS MISCONCEPTION-AWARE VISUAL ALGORITHM SIMULATION

In this section, we first outline our goals, which are related to improving feedback in VAS exercises. With these goals in mind, we discuss four desirable characteristics of the input generation facilities of VAS systems. There are tensions between these requirements, which become even more apparent as we then consider some alternative strategies for implementing input generation.

A. Goal: Improving Feedback

There are two interrelated aspects to our overall goal of improving the automatic feedback given by VAS exercises: 1) detecting that a particular student might have a particular misconception and 2) discovering new patterns of incorrect solutions which are common among a student population. The first aspect is important from the perspective of teaching and learning; the second is additionally concerned with advancing computing education research.

1) *Targeting students with feedback:* Knowledge of students’ misconceptions is a part of pedagogical content knowledge (PCK) [13]; knowledge of common misconceptions improves the effectiveness of a teacher [14]. Some aspects of PCK may be encoded into software such as a VAS system.

We would like to have a system that analyzes students’ mistakes in VAS exercises, and, upon detecting a possible misconception, adjusts the feedback it gives to the student. This is challenging for a number of reasons. One challenge is that a single misstep is often not enough for reliable analysis, and a sequence of consistent mistakes may be required. Even then, there may be multiple misconceptions or other explanations for any given sequence of simulations steps. Some misconceptions may lead to inconsistent behaviors, and more research is needed to establish which misconceptions can be reliably detected.

Another topic for future research is the effectiveness of different forms of feedback. For instance, might it be useful to present code or pseudocode that represents the *incorrect* version of the algorithm that matches the student’s attempt

and to highlight the differences between that version and the correct one?

2) Computer-aided discovery of common error patterns:

Some misconceptions may be detected by observing students, discussing with them, or analyzing their answers to problems. Solution attempts to VAS exercises are one such source of data, one which has potential for the semi-automatic discovery of new misconceptions and other common sources of error such as usability problems in a particular VAS interface.

If we had a system that could group large numbers of erroneous solutions on the basis of their similarities, these groups could be then analyzed by a human researcher or teacher to form hypotheses about the misconceptions or other issues that led to them. Such analysis could take place after a course is finished, to improve future course offerings. Or it could even be carried out while a course is still running so that the teacher immediately writes feedback to students with a particular error pattern upon being informed by the system of a new common pattern. Other options could also be explored: For instance, in a massive online course, the system could automatically create threads on a discussion forum for common solution patterns and direct students to them. The resulting discussion could help them learn and also aid teachers and researchers in getting to the reasons behind the patterns. Even on a smaller scale, students could be automatically prompted to explain their reasoning in case they are getting an exercise wrong multiple times, consistently repeating an erroneous pattern.

B. Useful Characteristics of Input Sets

On the basis of the earlier studies reviewed and our own experiences, and targeting the goals just discussed, we describe four characteristics of that input sets of VAS exercises may have: 1) dissimilarity, 2) sensitivity to misconceptions, 3) randomness and 4) similarity. All of these characteristics are desirable in one way or another, but as the names already suggest, there are some trade-offs involved.

1) *Dissimilarity:* Each instance of a VAS exercise — each set of inputs, that is — should be different from the other instances seen by the same student. The chances of a student and their friend having an identical or near-identical instance should be small. In addition, there are benefits to allowing students to redo the exercise with different inputs. From the teaching and learning point of view, this is desirable for the reasons discussed above in Section II.

2) *Sensitivity to misconceptions*: Knowledge is commonly (or always) viable for some situations but non-viable for some rarer or more complex situations. Even many so-called misconceptions might be viewed as not incorrect as such but as a limited form of knowledge that work for some purposes [15]. For incorrect or limited knowledge to evolve into more generally useful knowledge, the learner needs to be placed in situations in which their earlier understanding is insufficient; we learn from difficulties [16]. Making mistakes can create dissatisfaction with existing knowledge and promote conceptual change. Taking all that to the context of algorithm simulation, we suggest that instances of VAS exercises should be carefully configured in such a way that the exercise is difficult to solve if the student has a known misconception about the algorithm. That is, knowledge about the algorithm that is not viable in a wide variety of contexts should also not be viable in the context of the exercise.

3) *Randomness*: From a research point of view, we need a wide variety of highly variable inputs spanning as many of the valid inputs of each algorithm as possible. This can help with the discovery of entirely new misconceptions as some misconceived algorithms will produce behavior different from the correct algorithm only when conditions specific to that misconception are met during the solving process.

4) *Similarity*: For research purposes, we might also benefit from students using the same or very similar input sets so that it is easier to categorize different solution paths within an exercise. If a group of students all solve the same exercise instance in an identical way which is notably different from the correct solution this is possible evidence of a misconception or a problem in the exercise itself.

C. Strategies for Input Generation

Input generation is the process by which a VAS system or a similar learning environment produces instances of an exercise for different learners to solve. We discuss two alternative strategies for input generation, which we will call the constraints style and the preconfigured templates style.

1) *Constraints*: In the constraints style of input generation, an input set is generated by choosing randomly among all valid inputs, then checked against exercise-specific constraints which invalidate certain kinds of input sets. The process is repeated until a valid input set is produced. The constraints are designed to prevent instances of an exercise from being too easy. (An already-sorted input for a sorting exercise is an extreme example of an excessively easy instance.)

Moreover, the constraints may be designed so that the exercise is sensitive to misconceptions. One way to achieve this is that each candidate instance is checked against a number of incorrect implementations of the algorithm which correspond to specific misconceptions, and only instances where incorrect algorithms produce different steps are accepted. One downside of this approach is that it multiple incorrect variants of the have to be manually implemented. A particular strength of this approach is that it can achieve a high degree of desirable dissimilarity. Current VAS systems [1] use the constraints approach in a limited, largely misconception-insensitive form, mainly to require that the problem instances require different aspects of the algorithms (e.g., a Red-Black Tree balancing

exercise covers all the different balancing scenarios: single rotation, double rotation, and color change, but possibly also recursive balancing if required after a simple color change).

2) *Preconfigured templates*: Dissimilarities between input sets can be grouped into 1) *superficial* ones: the inputs use different specific values, but lead to the same sequence of solution steps, and 2) *categorical* ones: the inputs require a different sequence of steps to complete correctly. This difference is exploited in the preconfigured categories strategy of input generation. In this strategy, teachers or system designers manually configure a small number misconception-sensitive *input templates* for each exercise. All possible instances that conform to a template are categorically similar to each other, but may be superficially dissimilar. Several templates can be generated for each exercise. The number of these templates should be large enough that a student can practice on multiple structurally different instances of each problem; prior work suggests that half a dozen categories per exercise might be enough (because students typically need between 1 and 5 attempts to solve a VAS exercise). To individualize the exercises, each actual instance that a student sees is generated from a template by randomly choosing the superficial features of the problem within the bounds of the template.

In many cases, generating instances from a template is fairly straightforward. If the input is, say, an array of keys to be inserted into a binary search tree, the keys themselves are not important for the purposes of the exercises, only their relative order is. Thus, we can, for example, substitute each key with its predecessor without affecting the correct solution sequence. This approach has the additional benefit (towards the goal of similarity identified above) that we can bring all the instances that match a template to a canonical form.

A downside of the preconfigured templates approach is that the generated instances do not necessarily span the entire space of valid inputs, which may hinder the discovery of new misconceptions. On the other hand, this method could also be used to test students with essentially the same random data and then look for possible new misconceptions where a group of students solve the problem in a new, previously unknown way.

V. CONCLUSION

In this work-in-progress report, we have highlighted issues in how visual algorithm simulation systems generate distinct instances of exercises and provide feedback to students. The discussion is also pertinent in the context of other similarly interactive forms of practice that target the learning of processes, procedures, or algorithms. We have outlined an agenda for improving the automatic detection of misconceptions in visual algorithm simulation exercises, and commented on two alternative ways to generate inputs suitable for misconception-aware exercises, each with their own sets of strengths and weaknesses. We invite the research community to discuss and improve upon these ideas and to share best practices in the design of computer-supported process-simulation exercises.

Formulation of a predictive model for academic performance based on students' academic and demographic data

{smerchanr,jduarteg}@unbosque.edu.co

Abstract— This work is based upon the results of an evaluation process applied over data mining techniques, in order to find the most adequate ones to extract classification rules from first-year students' academic and demographic data in relation with their academic performance. As a result of this, the formulation of a predictive model for academic performance is presented; model whose construction was achieved by analyzing, selecting and defining the classification rules that properly predict the academic performance of Systems Engineering students, at Universidad El Bosque in Bogotá, Colombia. Classification rules that make up the model are analyzed from a contextualized academic point of view; consequently evaluating the pertinence of the relationships between attributes contained within these rules and their ability to predict poor academic performance (through academic risk). Also their applicability to datasets from other academic programs is contemplated, in order to generate useful strategies to prevent academic desertion, being poor academic performance one of the most influencing factors over this phenomenon.

Keywords—educational data mining; classification; predictive model; academic performance; academic data; demographic data

I. INTRODUCTION

Academic desertion in higher education is understood as the situation in which a student cannot conclude its educational formation, and a deserter is an individual who exhibits no academic activity during two or more consecutive semesters [1]. Due to the impact that academic desertion has in society, Colombia has progressed in understanding and addressing the phenomenon through the National Education Ministry, which has successfully documented it [2] and generated specific strategies for its diagnosis and treatment. By diagnosing the phenomenon, it has been found that most of the desertion rates occur during the first year of university studies [2]. It also was found that low academic performance is one of the most influencing factors in student desertion [3].

At Universidad El Bosque the whole concept of academic desertion prevention has evolved into assuring students' success. For this, the Students' Success Program (PAE) was created [4], which aims to provide adequate learning environments in favor of the students' quality of life and

integral wellbeing throughout their formative process. It also aims to design and develop practices which allow for the improvement of retention and graduation rates. Within these strategies a follow-up is done over the students' academic performance in every one of the three major testing times along each semester. This way, according to the students' academic performance they are classified within defined risk levels: no risk, low-risk, medium-risk and high-risk. Accompaniment-related actions are triggered by these risk levels for students who have been classified within a high academic risk. Even though these accompaniment strategies are useful, they take place when the students' performance has already been evaluated and classified. This makes them post-facto, or non-preventive strategies.

Because of the above, it becomes necessary to obtain a profile of the students' academic performance anticipatedly, in order to generate preventive accompaniment strategies. These strategies should diminish the probability of student desertion when implemented, mainly through the first year of university studies.

Educational Data Mining (EDM) rose to be a very useful tool to analyze academic information to serve different purposes within educational scenarios [5]. EDM helps reveal relationships between data stored in institutional information systems, allowing the modelling of educational phenomena, such as academic performance. Several studies demonstrate how this technology is proven useful for academic performance prediction [6-16].

The objective of this work is to formulate a predictive model for first-year students' academic performance, from analyzing classification rules product of a data mining process applied over the students' academic and demographic data. In particular, the demographic data is provided by the students as they are admitted to the academic program. This paper is presented in four sections. The first one describes the conceptual framework and theories upon which this work is constructed. Next a methodological development is presented which is composed by the data mining process' execution and the predictive model's formulation. In the third section of this article the results obtained throughout the whole exercise are

analyzed, to finally establish some conclusions presented in the fourth and final section.

II. THEORETICAL FRAMEWORK

A. Data Mining and Educational Scenarios

EDM has been defined as an emergent discipline, concerned with developing methods for exploring the unique kinds of data that come from educational settings, and using those methods to better understand students and those settings in which they learn on [5]. Currently there are entities such as the International Educational Data Mining Society [17] and the Society for Learning Analytics Research [18], which are two very important hubs to the international research community. They provide a common ground for this field of study, educational and pedagogical analysis and exploration through data mining. EDM is an invaluable tool to educational institutions for it has allowed them to profile, predict and adjust students' academic performance as well as providing support in decision-making processes involving both teaching and administrative staff. It is possible to discover the reasons that lead to academic success by inquiring on the factors that cause students to fail academically [8].

Data mining provides an accurate and systematic way of inquiring and discovering knowledge in settings like educational institutions. "Data mining can be used effectively in educational institutes for leading education activities in an effective way, for watching students' performances continuously and directing students in course and profession choosing". Thus, "the level of students' success can be raised"[8]. Also "data mining is a powerful analytical tool that allows academic institutions to better assign resources and personnel, manage proactively students' results and improve the alumni's development effectiveness"[19].

B. Additional concepts and theories

Academic performance represents "the efficacy level in the consecution of the curricular objectives for a diversity of subjects, and is expressed through a qualifier" [20] which is a value within a numeric interval. In this work, academic performance is represented in four different values: the weighted average from all the students' first year grades, and three separate averages for different academic areas (professional, basic and complimentary areas). Each of the academic area averages is calculated using the grades of the subjects that make up each area in the study plan. Performance within each representation is presented as three possible values: outstanding, average or risk.

A model is understood as a theoretical scheme -generally in a mathematical form- that represents a system or a complex reality, that is developed to further study and more easily understand its behavior. In this work, the predictive model will be given by classification rule sets shown as logic propositions that relate academic and demographic variables with a determined academic performance level.

In the field of data mining, prediction addresses the ability to infer a singular aspect of data (predicted variable), from a combination of other specific data aspects (predictive variables)[21]. Therefore predictive modeling is a statistical

technique commonly utilized to predict future behaviors. Predictive modeling-based solutions are a form of data mining-based technology, that makes use of historical and current data analysis, in order to generate a model that predicts future outcomes[22].

There are diverse factors and variables –academic and demographic- that can influence the students' academic performance. Just as proposed, studied and demonstrated by Baha Sen and Emine Ucar, factors such as age, gender, type of high school education and kind of higher education (distance or attendance-based) have a direct impact on students' academic results[9]. Other studies have found important correlation between variables such as gender, age and academic performance on admission and graduation tests [23, 24]. In other investigations correlation between academic performance and other variables such as parents' educational level was found [25].

III. METHODOLOGY

The model's formulation is composed of two great phases. In the first one, a data mining process is executed using the J48 and PART[26] algorithms in order to extract an initial set of rules; all this bearing in mind what was learned in previous exercises on data mining, which allowed the recognition of the necessary procedures and adequate techniques for the data mining process. These addressed matters such as data extraction and preprocessing, relevant attribute selection and identification, data mining techniques for results optimization and the behavior of the J48, PART and Ridor algorithms (with the studied dataset). Secondly, the predictive model itself will be formulated by analyzing, selecting and defining the rule set –composed of the previously extracted rules- that will be included as part of the model. This selection will take into account factors such as classification coverage for each independent rule, precision of the data mining models generated and their accuracy to predict academic performance –particularly risk-.

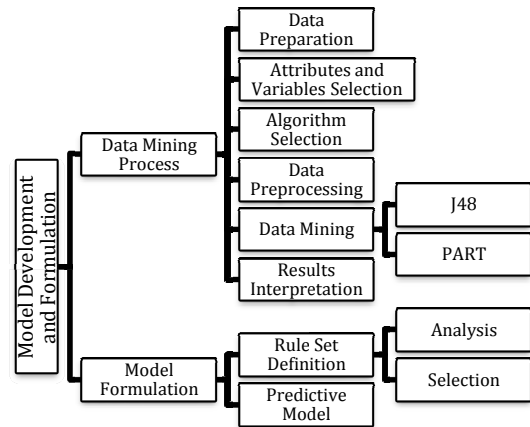

Fig. 1. Methodological development chart

A. The Data Mining Process

The algorithms selected to accomplish the data mining task were J48 and PART. J48 implements a C4.5 decision tree and PART implements a decision list. The latter uses separate-and-conquer techniques, builds a partial C4.5 decision tree in each

iteration and makes the "best" leaf into a rule [26]. These algorithms were selected due to their adequate mining results of the dataset in previous data mining exercises, rendering a classification and precision rates between 70% and 85%.

The data preparation step begins with its extraction from the database system that registers the students' information as they enter the Systems Engineering Program. The information corresponding to 932 students was selected, of which 61.38% where male students and 38.62% where female. Regarding the sample's socio-demographical characteristics, it was found that 6.65% of the students belong to higher social stratus, 73.07% belong to middle social stratus and 20.28% belong to lower social stratus. Also 19.74% of the students come from other cities, most of them are single (92.49%) and the majority of them don't have a job (71.56%).

The total dataset was split randomly in two subsets of 465 and 467 instances respectively, in order to obtain an experimental group to be used during the data mining process, and a control group for the predictive model's validation. Similarly, due to previous experience, the attributes selected for this study were the ones that remained of interest and behaved the best (as a group) throughout the data mining process. Said attributes are presented in Table I:

TABLE I. SELECTED ATTRIBUTES FOR DATA MINING

Student Demographics -predictive variables-	Student's ICFES test scores -predictive variables-	Classes/Output Variables -predicted variables-
<ul style="list-style-type: none"> • age • gender • distance to university • city of origin • social stratum[0-6] • marital status • day/night classes • job status • registers a mother [true/false] • mother's education level • registers a father [true/false] • father's education level • number of siblings 	<ul style="list-style-type: none"> • biology • philosophy • physics • geography • history • english • language (spanish) • mathematics • Chemistry • average ICFES score 	<ul style="list-style-type: none"> • basic area average • complimentary area average • professional area average • first year weighted average

Academic performance was characterized within three possible values: risk, average and outstanding (or above-average). In accordance with institutional policies at Universidad El Bosque, a student presents academic risk when its weighted average is below 3.3/5.0, so anything below this value defined the values for risk. The average weighted average for the Systems Engineering program was found to be around 4.0/5.0, therefore average performance was defined between 3.3/5.0 and 4.0/5.0. Thus, any scores with a higher value than 4.0/5.0 are defined as outstanding academic performance.

Additionally, academic performance was measured over four different aspects of the students' first-year academic grades: overall weighted average, basic area weighted average,

professional area weighted average and complimentary area weighted average. The later three aspects describe three different learning paths regarding the students' study plan. The basic area covers subjects like calculus, logic and algebra; the professional area covers programming courses and General Systems Theories; lastly the complimentary area covers subjects like academic writing and elective courses.

Having laid out the structure for the data to be used in this study, the data –which was loaded into a relational database engine- was normalized and standardized. Then the previously defined data subsets were extracted from the database in structured comma-separated-value (CSV) text files, which then were transformed into an Attribute-Relation File (ARFF) –the default file format used by the data mining suite *WEKA*- [26].

Once the data was loaded into *WEKA*'s *explorer* view it was preprocessed. First, instances without an output variable were removed quickly by hand. Then, instances that didn't contribute positively to the model were removed using the *removeMisclassified* unsupervised instance filter, using a non-parametrized J48 algorithm. Finally each algorithm was executed over each dataset several times –tweaking their parameters on each execution- until better results could not be obtained. Also, all algorithms were executed using tenfold cross-validation, as it is the standard for model metrics and validation [26]. These steps were performed on each data subset; each one of having a different output variable to be modeled for prediction corresponding to the four defined aspects for academic performance measurement.

Through cross-validation, *WEKA* is able to present metrics for the generated model's precision and accuracy, allowing the comparison between the results of different algorithm executions over the same dataset. In tenfold cross-validation "the data is divided randomly into 10 parts in which the class is represented in approximately the same proportions as in the full dataset. Each part is held out in turn and the learning scheme trained on the remaining nine-tenths; then its error rate is calculated on the holdout set. Thus, the learning procedure is executed a total of 10 times on different training sets (each set has a lot in common with the others). Finally, the 10 error estimates are averaged to yield an overall error estimate"[26].

The data mining process' results are presented in Table II:

B. Predictive Model Formulation

1) Relationship Analysis Between the Attributes Within Classification Rules

a) First-year Overall Weighted Average Prediction

Because of the result metrics obtained by both algorithms for this aspect, only the rules extracted by the J48 decision tree were taken into account. Regarding this classification rules, it was found that 53% of the correctly classified instances were predicted by combinations of the following conditioned attributes: *social stratum* = 3 and *marital status* = single. Such findings correspond to the characterization of the studied population. Within this classifier's subset, the variable *student_gender* appears in the next level of the decision tree, in which men account for 35% and women for 18% of these

correctly classified instances. Of the above men, 54% were attributed to have a *risk* level for their academic performance, and the rest were classified as *average*. Regarding the women, 15% of them were classified as *risk*, 69% as *average* and 15% as *outstanding*. In the next level of the decision tree, attributes such as *student_age* and some various *ICFES*

(standardized test similar to the SAT in the United States) test scores show up. Nonetheless they are not representative in terms of classification rate and don't seem to hold any important correlation with academic performance.

TABLE II. DATA MINING PROCESS SUMMARY TABLE

<i>Algorithm</i>	<i>Output Variable</i>	<i>Correctly Classified Instances</i>	<i>Kappa Statistics</i>	<i>Mean Absolute Error</i>	<i>Root Mean Squared Error</i>	<i>Precision for RISK prediction</i>
J48	Basic	73.63%	0.427	0.18	0.3767	0.829
	Complimentary	73.75%	0.5553	0.1968	0.3788	0.548
	Professional	85.36%	0.7795	0.124	0.2801	0.855
	Overall Average	82.41%	0.6963	0.1264	0.3062	0.851
PART	Basic	72.13%	0.3847	0.2274	0.3698	0.816
	Complimentary	64.70%	0.403	0.2573	0.3997	0.355
	Professional	68.29%	0.5217	0.2711	0.3969	0.694
	Overall Average	66.33%	0.4215	0.264	0.4061	0.683

In the other relevant portion of correctly classified instances, 24% of the students have a social stratum of 4 and are also single. For this subset, academic attributes like *ICFES* physics scores appear in the next level of the decision tree. This classifies students as having *risk* and *average* performance if the score is below or equal to 50; above this value classifies a student within *outstanding* academic performance. Contrasting these values with the admission requisites demanded by the Systems Engineering department for physics scores on the *ICFES* test, a minimum of 45 points is required.

According to these findings, in order to predict the students' first-year overall weighted average, demographic characteristics such as their social stratum, marital status and gender should be taken into account. Regarding academic attributes, *ICFES* physics score seem to be a determining factor for a student's weighted average. It should be noted, that the precision rates for *risk* and *average* performance prediction were over 80%, contrary to the rates for *outstanding* performance, which did not exceed 70%.

b) First-year Basic Area Average Prediction

Classification rules obtained for the prediction of this aspect with the J48 algorithm exhibit several notable characteristics. To predict academic performance in the basic area, one attribute appears as a great classifier splitting the subset in two: *day/night classes*. Rules for daytime students cover 49% of the instances, and rules for nighttime students cover 51%. It is then found that 24% of the male daytime students are attributed *risk* if their *ICFES* Biology score - which appears in the next level of the Tree- is below 40 points. This draws significant attention, for this *ICFES* score is not taken into account during a student's admission process to the academic program. The present variables in women's classification for this aspect exhibit very low relevance.

Only 15% of daytime students with an *ICFES* Biology scores greater than 50 points are classified as *risk*; these rules also include -non-significantly- other variables such as *ICFES* chemistry, philosophy and average score. 27% are classified within *average* performance, taking into account these same variables and their place of residence. The missing 16% of the daytime students are attributed *outstanding* performance in this area. Based on the precision achieved for each of the performance levels, the only dependable one is the one for *risk*, which exceeds 80%. The other levels exhibit a low precision.

Regarding the nighttime students, attention is drawn to the fact that -without the participation of any additional attributes- 42% of the students are immediately classified as *risk* for this area. This classification varies only in a 5% when age and place of residence are taken into account. Also, 5% of the nighttime students are classified as *average* in this area, and only a 2% are classified as *outstanding*. Even though -in comparison with the institutional context- there is no apparent reason for the high rate of *risk* classification, relevance should be given to this due to its precision rate of 82%.

c) First-year Complimentary Area Average Prediction

Precision rates for the PART algorithm were low, and error rates were high. In accordance with the rule set obtained by the J48 algorithm for this area, those students who register a father and mother in the system are attributed *risk*; 25% of the students with a social stratum of 3, mostly men (and a few with a social stratum of 4) are also classified as *risk* if their *ICFES* chemistry score is below 45. Bearing in mind that these are the variables that commonly describe the program's student population, these classification rules are non-important, especially when they exhibit a precision rate of 54% for this performance level. The PART algorithm also shows that the level *risk* is unpredictable for this area.

Instances predominantly classified as *average* are mostly selected by social stratum. 21% of them are those students with a social stratum of 2 and that currently don't have a job;

26% of them are males that have a social stratum of 3, and scored above 45 points in physics on their ICFES test.

TABLE III. CORRELATION FACTORS

Area	Predicted Academic Performance Level		
	Risk	Average	Outstanding
Overall Weighted Average	marital status (single) social stratum (2,3) gender(male) ICFES physics(<50)	marital status (single) social stratum (3,4) gender(male) age female (<=24) ICFES physics(<50)	marital status (single) social stratum (3,4,5,6) gender(female) age female (>24)
Basic Area Weighted Average	day/night classes(nighttime) ICFES biology(<=50)	Unpredictable (52% precision)	Unpredictable (50% precision)
Complimentary Area Weighted Average	Unpredictable(54% precision)	social stratum (2,3) gender(male) ICFES physics(>45)	doesn't register (father, mother) social stratum(3,4,5,6)
Professional Area Weighted Average	siblings(>1) job status(no)	siblings (0) job status (no) ICFES biology (<55)	Siblings (1) father's education level (university) job status(no)

Classification rules for the rest of the instances in this area are not representative and are related to attributes like gender, parents' education levels, ICFES English and physics scores. Noting the quantity of correctly classified instances, correlation for these variables rises in relation with *average* performance, but it's not significant (66%).

The fact that *outstanding* performance is attributed to instances that don't register a mother or father in the system, which represent 30% of the correctly classified instances for this particular model. Regarding those who do register said information, a higher correlation with the social stratum is achieved; here 7% of the instances have a stratum value of 2, 17% a value of 3, 12% a value of 4 and 12% account for the sum of stratum 5 and 6. From the above, it is logical that the precision rate for *outstanding* academic performance in this area is 83%, which makes of the variable *social stratum* a more reliable attribute for prediction.

In summary, for this particular area the *risk* level seems unpredictable and *average* is predictable with a 66% precision -through social stratum as a higher classifier attribute-. For the *outstanding* performance level, the fact that a student doesn't register parents in the system seems as a very influencing variable when accompanied by the social stratum.

d) First-year Professional Area Average Prediction

For this area, rules obtained by the J48 algorithm are accounted for. In these, an important correlation emerges

between the fact that a student has siblings and if he or she is currently unemployed. When a student has no siblings (6% of the total classified instances), his/her academic performance for this area is predicted as *average*. If the student has only one sibling it is immediately classified as *outstanding* if his/her father's educational level is *university studies*. However, if the student has more than one sibling, his/her performance classification will depend on this job status. The fact that a student does not have a job presents a higher correlation in the classification, for it directly classifies 34% of the students as *risk*, 19% as *average* and 19% as *outstanding*. 28% of the students that were classified without the use of this attribute (job status), present other determining factors such as gender and father's education level as important. It is worth noting that, within classification rules that mind if a student is unemployed, the attribute that then plays a relevant part is ICFES biology score for the *average* performance level.

2) Rules Selection and Definition

For each weighted average, factors that showed the highest correlation in prediction for the different academic performance levels are shown in Table III. Each factor's values that had the greater influence over each of the levels are shown in parentheses.

IV. RESULTS ANALYSIS

According to the results obtained in this study, the ruleset allows identifying -with an adequate confidence

level- the sociodemographic variables that influence academic performance prediction the most; these are marital status, social stratum, whether the student takes day or night classes, gender and number of siblings. The academic variables with the higher influence are ICFES scores for biology and physics.

In relation with academic risk prediction for the overall weighted average, this one impacts more over students with a low or medium social stratum, which corresponds with the historical students' academic performance information for the academic program –bearing in mind that most of the program's population belongs in these social strata-. It is valid that the students' ICFES biology score allows for academic risk prediction for the Basic Area subjects. What actually draws more attention is the fact that whether a student takes classes at night or during the day is the most influencing factor for this aspect.

When the social stratum ranges from medium to high, average academic performance is favored. The fact that ICFES physics and biology scores are also determinant attributes for this performance level must be carefully noted. Even though the siblings variable has a high correlation, it doesn't seem to hold any meaning within an institutional context.

Regarding outstanding performance levels, the same socio-demographical variables mentioned earlier reappear, but in this level for social strata in the range medium to high. No academic variables emerge in this level, which may suggest that there is no academic determinant in a student's career choice and its performance in it. Concerning prediction for this level, attention is drawn to the fact that situations such as having just one sibling and having a father with a university degree might be a influencing factor over academic performance.

By drawing a comparison between the variables that explain educational desertion as a phenomenon in Colombia's higher education system [2], and the variables found to influence academic performance –as an influencing factor for desertion-, academic risk is linked to a (subject) repeating rate; rate which implies the existence for an academic risk as it reflects an underachievement in a student's overall subject weighted average. ICFES scores also appear as an influencing factor in desertion, which for this case –and the Systems Engineering program- it's useful to pay particular attention to physics and biology scores. Both number of siblings and gender coincide as influencing factor for both phenomena (academic desertion and academic risk).

V. CONCLUSIONS

Taking into account previous works, and the results obtained by this study, it is proven that Data Mining is a useful tool when applied in educational contexts. It aids in comprehending phenomena that exhibit a variable behavior depending on the particularities of each educational scenario. Specifically, first-year academic performance prediction reduces the possibility for academic desertion. It also improves the quality of students' formative processes,

enabling the orientation of preventive accompaniment strategies for individuals with a real possibility of suffering academic risk.

The classification rules found in this study are useful contextually speaking and regarding this work's objective; however they must be improved for they encompass a very small set of instances, seemingly due to the absence of data in the instances discarded in the preprocessing stages.

As for future, work in the near future, verification experiments must be performed using the obtained rule sets. They should be applied over similar and larger datasets in order to evaluate their applicability to other formative processes and academic programs that gather similar information from their students. In the medium term, an application that allows to reutilize the model within the institution is expected to be developed; thus transforming it into an everyday tool that supports and aids in the University's Coordination for Academic Success.

Predicting the students' academic performance implies a conceptual change within the Colombian and Latinamerican educational systems, due to that their thought structure and actuation is mostly coercive; guided by post-facto strategies that pretend –in the best of cases- to correct any problem that might turn up within the system, instead of preventing them and thus diminishing costs.

The results here presented imply that the Institution, and particularly the Coordination for Academic Success, must start thinking about risk prevention strategies based upon students' socioeconomical classification for the Program's new students. Taking into account that the Basic Area of the study plan is one of the areas that represents the largest amount of effort and difficulty for Systems Engineering students, the ICFES biology score should be added as a relevant metric in the admission process; specially for students that attend nighttime classes.

ACKNOWLEDGMENT

Both authors thank María del Mar Pulido for being an important guide and support for this work. It will be useful for her job.

J.A.D thanks Camilo Peña for his support and aid in database querying, which made data extraction and normalization a much easier task.

francisco.neto@icompu.fam.edu.br, alberto@icompu.fam.edu.br

Abstract—This article presents an ongoing investigation that uses mining tools to analyze a large volume of data from students of online courses in a LMS platform to discover Association Rules used to identifying dropout situations. These ARs are used along with several explicit (formalized) rules elicited from course operators and are intended to be used by a software agent to detect individuals within a certain risk region, triggering a communication process to a student support team.

Keywords—learning analytics; distance education; knowledge representation; mining

I. INTRODUCTION

Dropout is a complex issue and even more critical on distance education. Prevention to it have included several resources, many based on ad-hoc or other tacit choices, and have progressed towards a formalization of the knowledge elicited from teachers, course authors, tutors and other operators involved with management of those courses. The widely spread use of Learning Management Systems and other technological learning platforms have amplified ability to record course activities to a point where unassisted inspection/analysis became impractical. In such context, the process of data mining has been used, with success, to find patterns and Association Rules (AR) in large educational datasets.

This article presents an ongoing investigation that uses mining tools to analyze a large volume of data from students of online courses in a LMS platform to discover Association Rules used to identifying dropout situations. These AR could be used by a software agent to detect individuals within a certain risk region, triggering a communication process to a student support team. For example, a software agent with the ARs found in this study would classify a student as a dropout before he actually becomes one (maybe in the middle of the course). With this information a teacher or tutor could take action and help the student before it is too late.

A real world dataset was obtained from a Brazilian Federal university. The platform used was Moodle-based and so it had logs of all actions within that environment – sending internal messages, reading forum topics, doing assignments and about 200 other that a fresh installation allows it. We were especially interested in actions related to interactions between students, some resulting from assignments plainly specifying collaboration. Some ARs were found mining the dataset and

have been tested with current course instances. Other rules were elicited from course operators and have been formalized as first order logic sentences. Both sets of rules (mined and elicited) are now being tried on courses of different categories with encouraging results and an agent-based service monitoring students will be integrated to the intelligent layer of an innovative web platform.

II. DROPOUT IN ONLINE COURSES

Investigation on student dropout in online courses reported in [1] and [2], describes some models people have used to explain dropout process. Among these, one of the more traditional is SIM (Student Integration Model), created from studies on traditional student behavior and focused on internal reasons leading to dropout. Another model is SAM (Student Attrition Mode) an improvement upon SIM that considers nontraditional students and emphasizes the effect of external variables on decision of persisting or dropping out a course. Another well-known model is CPM (Composite Persistence Model), capable of combining these two models in order to obtain a better balance among external and internal factors especially when dealing with students of online courses.

A revised and improved version of CPM outlining a theoretical framework for dropout on online courses is described in [3]. According to this framework, there are factors affecting the decision of dropping out a course, some of these factors are prior to the course, some are prior to the course and still persist during the course and other are present only after the course start. Factors also can be classified as external or internal to the course. Students' individual characteristics (age, genre, education degree, etc.) also affect dropout, although not at the same scale that internal and external factors. There is no strong empirical evidence that other aspects (learner skills, for example) affect decision on dropping out.

In Brazil, reports on distance education dropout like [4] and [5] have special interest on investigating this phenomenon in Learning Management Systems (LMS), the most used technological platform to that goal.

This work contributes with the discussion about dropouts in online course by approaching the problem in a novel way. The combination of educational data mining tools and expert knowledge about dropouts turns possible to foresee the problem before it happens. Currently, a dropout candidate

This work was sponsored by FAPEAM (Amazonas Research Supporting Agency), Grant n.116/2014, Ed.016/2013 – ProTI – Pesquisa.

might be identified through a slow process based in analysis of LMS statistics and subjective clues interpreted by a tutor or teacher, but with results from this work it would be possible to create rules to automate the detection of dropouts. This type of automation can imply in better use of materials and human resources required by distance learning education projects.

III. EDUCATIONAL DATA MINING

According to [6], Educational Data Mining (EDM) is a research area that applies tools and techniques from Data Mining (or Knowledge Discovery in Databases – KDD) in the context of education research. EDM aims to discover new information by identification of relations between educational data as a way to discover new knowledge and make scientific progress. As an example, is possible to use EDM to analyze the relationship between a teacher's method and students learning progress so that any new knowledge discovered can be used to make better new methods.

EDM is a multidisciplinary and still recent area involving several Computer Science subareas. There are, nonetheless, several works aiming at improving teaching and learning by mining data stored at online courses. [7], [8], [9] and [10] are examples where some gain was obtained. This shows that EDM can be used with relative success at exploratory research to answer questions in the area of education.

In this work, an EDM tool named Association Rule is used to analyze and generate useful knowledge about dropouts in the context of online courses. An approach that resembles the one presented here is described in [11]. The goal was to predict which students would dropout a regular course by using data mining, although there was no use of more recent techniques like Frequent Itemset to generation of Association Rules (AR).

IV. ASSOCIATION RULES

One of the main data mining techniques used nowadays is the formulation of Association Rules (AR) through the search of patterns in a database. An AR is a rule with the following format

$$A, B, C \rightarrow D$$

This rule can be interpreted like “if (A and B and C) is True then D is also True”. In this study, all variables A , B , C and D represent facts about the same student and the facts are extracted from a database of a online course. For example, a fact could be “Posted 10 messages in the forum One” or “Finished 2 assignments”. So, we can have rules like: If “Made 2 posts” and “Read lesson One” and “Attended chat session One” are True then “Finished Assignment One” is True. It is worth to note that the same rule can emerge more than one time, because it can be extracted again with respect to some other student.

To an AR be considered a “good” rule it should have attended two requirements. The first requirement is to have occurrence (number of times a rule shows up in dataset) greater than or equal to a predefined number S . S is called of rule support and can be expressed as a percentage. The second requirement is that occurrence of a complete rule on the

database should be high enough when compared to the frequency that the first part of the rule occurs in the same database – this characteristic is the rule confidence.

An example of AR in educational context is reported in [13], where they are used to associate students to companies with internship or full job opportunities linked to practical works developed at university.

As described in [12], ARs can be used in classification problems, and to detect dropout risk can be seen as a classification problem where students of a specific course are classified as either “dropouts” or “non-dropouts” and therefore we can use ARs to predict situations about a certain student.

V. METHODOLOGY

Mining and analysis of ARs expressing student dropout involved the following activities:

1. Analysis and selection of data repositories used in experiments
2. Selection of variable to be used to ARs generation. This task was not limited to choices given by the virtual environment but also included expert-described variables
3. Preprocessing on the database for data “cleaning” and normalization
4. Database transformation for a reduced format able to be used as input to data mining algorithm
5. AR extraction through data mining algorithm
6. Test and validation of AR with databases not used during generation phase
7. Results interpretation and evaluation

These activities are detailed throughout the next sections of this work.

VI. DATA SELECTION

For this work we have used databases from courses available at ColabWeb¹, a Moodle²-based LMS implemented at the Institute of Computing of a Brazilian federal university. ColabWeb is used to support courses carried out by that institute. It is left teachers and course organizers to balance between in-classroom and distance activities and so there are student profiles from both in-classroom and distance activities.

Firstly, all finished courses with more than 10 properly enrolled students were selected. That filter was necessary because we planned to use statistics of student interaction in data treatment and fewer students would imply less variation and more deficient data.

The next step was a search in the university records. The goal was to check grades and attendance of students at every selected course and to confirm dropouts. Initially we considered a dropout as a student who abandons a course. It

1 <http://colabweb.ufam.edu.br>
 2 <http://www.moodle.org>

was necessary to redefine this concept because to succeed at a course, a student must comply with two requirements: to attend more than 75% of classes and to have a minimum grade of 5 in a 0-10 scale. For this reason sometimes a dropout might be missed and wrongly marked as a low grade student. So, on the scenario of this work, a dropout is a student that failed to attend 75% of classes or got a final grade smaller than 3. This grade value was defined to accommodate situations with students that drop out towards the end of the course, due to a higher demand from tests and practical exercises. The effect of students giving up a course that way is not on attendance (most would reach the minimum level) but at the final grade. Grades bigger than this threshold value but smaller than the minimum allowed grade would only indicate a poor performance throughout the course.

Thus, 87 courses were initially selected, and further “filtering” stages were necessary to tackle problems like multiple accounts for a same user or users that rarely had accessed that environment (none or too few access to the environment suggests a user that has not effectively started the course) and so students with less than 10 operations recorded on the environment were not considered. After that, only courses with 10 or more students left (for reasons similar to the ones at the first filter) were considered to take part on the experiment. At the end, 27 courses were maintained with a total of 1421 students and 252 among them were dropouts (17,73%). From these courses, the more recent three were put apart and used to test ARs found and the remaining 24 were used in mining process.

VII. VARIABLE SELECTION

All variables used in our experiments were extracted from events recorded on the environment. However, for variable specification, two methods were adopted and their results combined.

The first method consisted of associating variables in the course log with events recorded and so variable names were changed to mirror event names and their values for each student was defined as the number of entries (records) of that specific student during the period of the course considered. An event was any action carried out by a student within the environment (for example: sending a message, uploading an answer to an exercise, consulting an assignment) and so the first variables obtained were total of messages sent, total of answers uploaded, total of logins in the environment, etc.

It is worth to mention that what was done was just a counting of the number of times an event appeared in the table log of Moodle. In some events it would be possible to extract more information, but even in those cases we still get only the total counting. For example, when we counted the number of times a student hands in an assignment it was possible to know if he was handing in a new assignment or a new version of a previous handed assignment, but in this phase we just got the total number of times he handed any assignment without care whether the assignment handed was one he already handed in

or not. The Moodle version used during experiments could record 183 events, generating 183 variables to each student.

For the second method it was reviewed information about a student that could be extracted from data in Moodle log. That large amount of data brought no useful insights and we decided to adopt expert opinion (from teachers, course authors, education managers, etc.) on which variables would affect (either in a positive or a negative way) student tendency to drop out. This elicitation process was done in two stages, as follows.

The first stage involved a literature review on educational data mining to survey which variables would be indicated on those reports. Although variable equivalence was not too easy to establish, we managed to find new variables to add to our experiment. The works described in [9] and [14] were the main source of indicators matching those variables available at ColabWeb, as shown on Table I.

TABLE I. VARIABLES ELICITED FROM [9] AND [14]

Variable	Description
<i>n_access</i>	Total of access
<i>n_post_forum</i>	Total of forum postings
<i>n_post_ans_forum</i>	Total of forums postings commenting/answering other students postings
<i>n_post_rev_forum</i>	Total of revisions/modifications upon previous forums postings
<i>avg_freq_access</i>	Frequency of students access to LMS
<i>n_days_first_access</i>	Amount of days between course start and the first access
<i>n_post_ask_stu</i>	Amount of posts replied/commented by other students
<i>n_post_ans_stu</i>	Amount of replied/comments done upon other students posts
<i>n_msg_ask</i>	Amount of messages received from other participants during the course
<i>n_msg_ans</i>	Amount of messages sent to other participants during the course
<i>n_msg_ask_teacher</i>	Amount of messages sent to the teacher/tutor during the course
<i>n_msg_ans_teacher</i>	Amount of messages received from the teacher/tutor during the course
<i>n_assign</i>	Number of assignments handed in

The second stage involved a review on factors reported as influencing dropout. Works reported on [4], [1] and [2] were the main source of discussion of this topic. To each one of factors pointed out as a main factor influencing dropout decision, a relevant new variable was defined, using data collected from the environment logs. Thus, the variables and factors shown on Table II, were added to our initial set.

TABLE II. VARIABLES DEFINED TO MATCH FACTORS FROM [4][1][2]

Variable	Factor	Collected Data
<i>avg_days_bef_due</i>	Difficulty with deadlines	Average of difference between deadline and actual exercise upload
<i>msg_ask_ans_teacher</i>	Difficulty with obtaining feedback	Difference between amount of messages sent to teacher/tutor and amount of answers received
<i>total_global_msg</i>	Interpersonal Relationships	Total of sent and received messages to/from other users in the environment

A total of 199 variables were used in our experiments.

VIII. DATA TREATMENT

The data was organized in a table format where each row represented a student and columns represented variables from this study. There were separated areas for each course. For clarification, an example is show in Table III.

TABLE III. VARIABLE ORGANIZATION

Course 1				
	Var1	Var2	Var3	...
Student 1	1	23	5	
Student 2	2	15	5	
Student 3	3	4	5	
Student 4	4	43	5	
...				
Course 2				
	Var1	Var2	Var3	...
Student 1	45	10	3	
Student 2	89	10	3	
Student 3	27	30	3	
Student 4	65	30	3	
...				
...				

For a more efficient mining of ARs in databases, it is useful to have variable values categorized in small sets. Assuming that we wanted to find differences between dropouts and non-dropouts, our categorization was based on a basic quartile separation. To each quarter a concept was associated, suggesting an adherence level to dropout influence.

TABLE IV. VALUES CATEGORIZATION

Quarter	Concept
1	LOW
2	MEDIUM
3	MEDIUM
4	HIGH

This categorization considers only value distribution within a course, not the distribution throughout all courses and so

after categorization, variables have only three possible values: LOW, MEDIUM or HIGH.

Applying this categorization to the example table the result is show in Table V.

TABLE V. VARIABLE ORGANIZATION (AFTER CATEGORIZATION)

Course 1				
	Var1	Var2	Var3	...
Student 1	LOW	MEDIUM	HIGH	
Student 2	MEDIUM	MEDIUM	HIGH	
Student 3	MEDIUM	LOW	HIGH	
Student 4	HIGH	HIGH	HIGH	
...				
Course 2				
	Var1	Var2	Var3	...
Student 1	MEDIUM	MEDIUM	HIGH	
Student 2	HIGH	MEDIUM	HIGH	
Student 3	LOW	HIGH	HIGH	
Student 4	MEDIUM	HIGH	HIGH	
...				
...				

After apply categorization on all selected courses, results were grouped in one single file and submitted to a last filter in order to optimize AR generation. That filter identifies variables with the same value for all students in the experiment and, since they have no variation on the entire universe considered, they were discarded. In the example table the variable Var3 should be removed from the experiment.

After all these processes, only 37 variables were used in our experiment.

IX. EXPERIMENT

When AR mining is in a planning phase, it is possible to make a choice in the process to find any type of rule or a specific type of rule called Class Association Rule (CAR). CAR are rules where the last part of the rule is compose of only one variable (the rule example showed in session IV is a case of a CAR). In this study the variable is the condition of be or not to be a dropout. Been more specific, the interest of this work is only when the variable is a dropout. Since dropouts are 17,73% of population in this study it is not possible to find a AR, useful in this work, with a support higher than this number. Because of this, AR mining was not done using standard data mining algorithms.

Normally, AR mining aims at high support and high confidence but in our case, it would not be possible to find AR with support higher than 17,73%. and smaller support rates also would imply significant increasing of processing times.

To resume, in our case we are interested in rules with low support (reduced occurrences in the database) but with high confidence, leading to the same results. This kind of rules are known by academic community like 'sporadic rules' and can be found with algorithms like Apriori-Inverse, described in

[15].

In this experiment we have used SPMF³, a open-source tool with several mining algorithms including Apriori-Inverse. SPMF's APriori was used with minimum support of 1% and maximum support of 18% and 205 AR were found with dropout condition. From these, the 10 rules with greatest confidence levels were selected for use. These rules are show on Table VI.

TABLE VI. HIGHEST CONFIDENCE RULES

N	Rule	Conf.
1	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW	0,8857
2	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND n_msg_ans_teacher =LOW	0,8235
3	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW	0,8148
4	<i>avg_days_bef_due</i> =LOW AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND <i>forum_add_post</i> =MEDIUM	0,8095
5	<i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND n_msg_ans_teacher =LOW AND <i>forum_add_post</i> =MEDIUM	0,8095
6	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND <i>forum_add_post</i> =MEDIUM	0,8095
7	n_post_forum =MEDIUM AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND n_msg_ans_teacher =LOW AND <i>forum_add_post</i> =MEDIUM	0,8095
8	n_post_forum =MEDIUM AND <i>assign_view</i> =LOW AND <i>assign_upload</i> =LOW AND n_msg_ans_teacher =LOW	0,7917
9	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW AND <i>assign_upload</i> =LOW AND n_msg_ans_teacher =LOW	0,7778
10	n_post_forum =MEDIUM AND <i>avg_days_bef_due</i> =LOW AND <i>assign_upload</i> =LOW	0,7742

On Table VI, variables elicited from [9] and [14] are printed in bold and variables mapping factors from [4], [1] and [2] are printed in italic.

Next, these rules were applied to three courses used for test. Each rule was tested alone to check its accuracy and the same

was done with a combination of the 10 highest and again with a combination of all 205 AR found.

Rule combination was done using OR operator between the rules, so to be considered a dropout, a student must be identified as such for any of the combined rules. For example the combination of Rule 1 and Rule 10 is show bellow:

$$(\mathbf{n_post_forum=MEDIUM} \text{ AND } \mathbf{avg_days_bef_due=LOW}) \text{ OR } (\mathbf{n_post_forum=MEDIUM})$$

The first group had a total of 23 students with 1 dropout. Table VII shows the results.

TABLE VII. ACCURACY OF RULES ON TEST COURSE 1

Rule	Real Positive	False Positive	Real Negative	False Negative	Accuracy
1	1	2	20	0	0,9130
2,4,5,6,7,8,9	0	0	22	1	0,9565
3,10	1	1	21	0	0,9565
10 highest	1	2	20	0	0,9130
All 205	1	18	4	0	0,2173

The second group had a total of 15 students with 1 dropout. Table VIII shows the results.

TABLE VIII. ACCURACY OF RULES ON TEST COURSE 2

Rule	Real Positive	False Positive	Real Negative	False Negative	Accuracy
1,2,3,4,5,6,7,8,9,10	0	0	14	1	0,9333
10 highest	0	0	14	1	0,9333
All 205	1	2	12	0	0,8666

The third group had a total of 26 students with 5 dropouts. Table IX shows the results.

TABLE IX. ACCURACY OF RULES ON TEST COURSE 3

Rule	Real Positive	False Positive	Real Negative	False Negative	Accuracy
1,2,3,4,5,6,7,8,9,10	0	0	21	5	0,8076
10 highest	0	0	21	5	0,8076
All 205	0	6	15	5	0,5769

X. RESULTS ANALYSIS

Our initial approach to use elicited rules was to apply them after AR mining. However, analysis of possible scenarios

3 <http://www.philippe-fournier-viger.com/spmf/>

suggested that elicited rules produce better results when embedded in the mining process as variables to be considered. To illustrate this, let us consider a simple elicited rule:

$$A \rightarrow D$$

We can interpret this rule as: if A happens it means that student will be a dropout (D). This is an association rule and if it is a good rule it will have a high confidence level, meaning that quite often when A happens, D also happens and AR mining would corroborate this with high confidence. If, on the other hand, this rule would not be found to be so good, a low confidence would be associated and so no harm was done and there appears to be no advantage to include this on the discovery stage as another variable.

However, to include elicited knowledge as a variable to be used at the discovery stage will increase probability of finding new rules associated to that elicited knowledge, for example:

$$A \wedge B \rightarrow D$$

A is the elicited knowledge and B some other condition present at discovery stage. This new rule could be better than A alone, because the confidence level could be higher. To explain this we can imagine the case where A happens in all dataset (i.e. have low confidence) and B happens more when D happens. In this case, the confidence level of the new rule is higher than the rule with only A . To not include A in the discovery stage is equal to discard the possibility of a combination of A and any other variable (including other elicited knowledge) be better than A alone.

Another aspect observed in this work was the high accuracy of the AR in most cases. Once these AR have been submitted to more tests, they can be transposed to some knowledge base and used by recommendation systems that would inspect records of students indicated as potential dropouts and act accordingly.

Several of the elicited variables were present among the 10 best rated AR. It is worth to emphasize that variable '*avg_days_bef_due*', obtained by mapping the factor "difficulty with deadlines", has appeared in 7 of the 10 best rated AR. This seems to confirm that factor as important indicator of dropout tendency and suggests that LMS would benefit of specific resources for this sort of monitoring.

Lastly, there is the question of using RA combination and the impact in the number of false negatives and false positives. The best case should be to eliminate both, but in our case that is not possible because AR generation do not assure a 100% match in the classification. So to deal with this problem we used the rationalization showed in [11] that shows for the problem of dropouts in courses a false negative is worse than a false positive. For example, when we mark a student not been a dropout when in reality he is (a false negative) the teacher or tutor will think that student is not in a risk situation and he will focus in others students marked as dropouts, so this student will probably turn in a dropout case. On the other hand if we

mark a student as a dropout when in reality he is not (a false positive) the teacher will focus in this student and in other students marked as dropouts, in this case the only problem is that the work of the teacher or tutor will increase. In this work we noticed that a search for a good tradeoff between the false positives and false negatives should be made through the number of RAs combined.

XI. CONCLUDING REMARKS

Reducing dropouts in online courses mediated through LMS is a relevant goal that would imply better use of resources specially where, like the case with Brazilian federal universities, classes are limited to a certain number of students.

In this scenario, this work shows how tools like APriori-Inverse algorithm can be used to support early detection of potential dropouts, allowing teachers/tutors to intervening.

Further research with more data is necessary to corroborate findings from this work and to establish what could be a good tradeoff to the problem of false negatives and false positives.

xAPI-SRL: Uses of an Application Profile for Self-Regulated Learning Based on the Analysis of Learning Strategies

Mario Manso-Vázquez, Manuel Caeiro-Rodríguez, Martín Llamas-Nistal

Department of Telematic Engineering

University of Vigo

Vigo, Spain

mario.manso@uvigo.es, mcaeiro@det.uvigo.es, martin@det.uvigo.es

Abstract—Self-Regulated Learning (SRL) is being promoted and adopted increasingly because of the needs of current education, based on competences and student centered. At the same time, the use of technology for learning is now usual and also increasing. Nevertheless, current learning software offers poor support for SRL. Learners use different tools to organize their learning, to visualize content, to submit assignments, to answer questionnaires, etc. These functionalities are useful, but they are not relevant from the SRL approach. Particularly, monitoring students' development of SRL strategies and students' self-monitoring are not well supported in existing systems. This paper introduces a proposal to improve monitoring support in e-learning systems. The proposal is based on Tin Can API or xAPI, a recent standard to record data about users' activity in learning systems.

Keywords—Self-Regulated Learning; Learning Strategy; Monitoring; Application Profile; Learning Analytics.

I. INTRODUCTION

The development of competencies is crucial in current education, especially in higher education, where the students are required a high degree of autonomy compared to earlier stages. In this student-centered context, Self-Regulated Learning (SRL) is an appropriate approach to achieve these goals and actually it is becoming popular. SRL contributes to the development of learning skills vital to become an efficient and effective learner [1]. A key point is the development of metacognitive self-regulation processes. The final goal is that learners become more accountable for their own learning.

Another trend in the current educational scenario is the increased use of learning software. It has increased a lot over the past few years and it is still increasing. The proof is that both blended learning and distance learning are very popular and they are being adopted for formal and informal learning situations. There are many learning software tools that support different learning approaches: blended, flipped, cooperative, collaborative, etc. But, what about SRL? We have found that this type of approach is not supported by most learning software. Actually, it is supported partially by just a few learning tools [2][3].

Learning software should adapt to the new teaching and learning approaches, but for some reason, this process is slow and it never catches up with current tendencies. In many cases, software developers do not know the needs of the teaching and learning communities, and even if they do, it is hard to translate the vision of teachers and pedagogues into suitable learning tools, especially from the learners' point of view.

Existing SRL-oriented learning tools seem to be developed attending to the SRL theory, resulting in a general, shallow support. This may be due to two main reasons: (1) the lack of agreement among SRL authors, which makes the SRL concept rather diffuse; and (2) SRL theory is not specific or detailed in terms of methods and actions, which is something critical to design any software functionality.

One of the most remarkable initiatives related to the technological support of SRL was the TELEpeers project [3][4]. This project was aimed at the evaluation of the "potential of Technology Enhanced Learning Environments (TELEs) to support self-regulated learning". It considers a very general view, not distinguishing specific areas or functionalities. After reviewing it we realized that a different approach was needed, more practical and realistic. Focusing on what is taught in SRL promotion courses [5][3] and on what learners actually use to learn in SRL contexts, we selected self-regulation and learning strategies as the foundations of our research.

Therefore, our general goal is to improve the possibilities of software to support the implementation of SRL strategies. The idea is to facilitate the development of proper SRL functionalities or specific tools that support the implementation of the strategies. We understand this as "reducing or eliminating the limitations when implementing learning strategies through a piece of software" [6]. In previous works we defined the software design criteria to offer this support [7] and created a questionnaire for the evaluation of SRL support in software [2]. Both are based on the analysis of SRL strategies.

In this paper we focus on a big limitation that we found when analyzing the SRL support in existing tools: monitoring. There are two main goals. The first one is to measure how

well students are self-regulating by monitoring their activity in software tools and analyzing tracking data. A main issue is that there is a lot of relevant information missing, because there are many basic SRL strategies that are not considered by typical learning software. Besides, monitoring data and functionality is usually intended to help teachers to monitor the performance of their students, but not to support learners' self-regulation. This is the second goal: supporting learners' self-monitoring by providing them with monitoring functionalities. Learners "use information of their own activity to see how they are doing, to modify their plan if necessary, etc." [6], i.e., to self-monitor and self-evaluate their learning. A software tool could ease that process by capturing and showing this information in an adequate manner, but it needs to get all the information first. A self-regulated learner may use different tools for planning, executing, self-monitoring and self-evaluating his/her learning. We need a common way to record all the events derived from the implementation of the strategies in different tools if we want to work with this data to extract information using adequate techniques (learning analytics, process mining, etc.). In [6] we presented our proposal for an extension of xAPI [8], a standard for activity recording, in order to "improve its capabilities for recording SRL-related actions". This extension is an application profile for SRL, and was called xAPI-SRL.

In this paper we present how using xAPI-SRL to record data from different sources can allow us to extract valuable information to facilitate self-monitoring and self-evaluation, and also enable SRL assessment for educators, using some of the ideas introduced in [9]. First, we introduce SRL theory in section II, focusing on monitoring in section IV. In section III we discuss about SRL oriented software. Section V is dedicated to related work. In section VI we briefly explain xAPI to introduce the xAPI-SRL application profile that is presented in section VII. Section VIII is dedicated to conclusions and future work.

II. SELF-REGULATED LEARNING

There are several definitions of SRL, depending of each author's perspective, but all of them share a similar vision. The most referenced models are the ones from Zimmerman and Pintrich. Zimmerman defines self-regulation as "self-generated thoughts, feelings and behaviors that are oriented to attaining goals" [10]. In the words of Pintrich, SRL is "an active, constructive process whereby learners set goals for their learning and then attempt to monitor, regulate, and control their cognition, motivation, and behavior, guided and constrained by their goals and the contextual features in the environment" [11]. As we synthesized in [7], "the self-regulation process is based upon the students' consciousness about their possibilities and limitations, their task centered goals and their use of appropriate strategies. Students can improve their performance and academic success using strategies to control and regulate aspects of their cognition, motivation and behavior, to select and build learning environments and to set goals and monitor their compliance".

A. Self-Regulated Learning Model

We use a unifying model based on Zimmerman's and Pintrich's models, built following the conclusions of Solano

[12]. We consider three SRL phases, like in Zimmerman's model:

1. *Forethought, planning and activation.*
2. *Performance, monitoring and control.*
3. *Evaluation, reflection and reaction.*

"This is because the elements of each phase are concurrent within the learning episode" [13]. These phases work like a cycle that the learner performs for each task. Pintrich defined four phases, splitting phase two into monitoring and control, not specifying performance.

Following Pintrich's approach, we defined SRL areas. Pintrich defines four, considering cognition and metacognition as one. According to Solano, metacognition should be considered an area on its own as their processes are very different [12], so we have five: *metacognition, cognition, motivation/affect, behavior*, and (social and environmental) *context*.

B. Self-Regulated Learning Strategies

We can define SRL strategies as "the methods and procedures that the students can use to help them tackle their learning in the most effective and competent manner, to plan, monitor and evaluate the five SRL areas" [7]. There are many other definitions from relevant authors that were compiled by Gu in [14].

We selected and analyzed many strategies from different sources [5][15][16][17] and classified them into two big groups: *self-regulation strategies*, focused on self-regulation of learning; and *cognitive learning strategies*, focused on the acquisition and creation of knowledge [7]:

- *Self-regulation strategies* are metacognitive strategies (goal and task planning, self-monitoring and self-evaluation, prior knowledge activation, time estimation, etc.), behavior strategies (time management, help seeking, self-observation, etc.), motivation strategies (interest activation, reward, causal attributions, etc.) and context strategies (task changes and context conditions monitoring, evaluation of the task, etc.).
- *Cognitive strategies* provide a structure for learning for complex tasks aimed at managing and acquiring knowledge. Some examples are information strategies (selection, acquisition, transformation, etc.), memorization, problem solving, reading comprehension, etc. Many of these strategies are not easily embeddable in software as they involve "internal actions and interaction with external elements".

III. SOFTWARE AND SRL

In [1], Nussbaumer et al. affirm that "studies have shown that the application of SRL increases the effectiveness of education. However, this is quite challenging to be facilitated with learning technologies like LMSs that lack an individualized approach as well as a right balance between the learner's freedom and guidance". Those are interesting concepts, essential for a SRL approach with software. In

addition to that, LMSs in general do not offer support for the implementation of most relevant SRL strategies. These strategies, as we stated before, are what SRL learners use, so they are crucial.

Most tools offer partial support for some of these strategies, without offering full support for any of them or for any SRL phase or area [7]. For instance, LMSs are focused on educational content delivery and knowledge evaluation. Some LMSs have SRL features, allowing learners to reflect about what and how they did, but planning and monitoring are usually forgotten, and it is rare to find these features in learning software. Examples of LMSs with some SRL capabilities are ILIAS [18] and the ROLE Personal LMS, now ROLE sandbox [19], but both of them have their limitations. ILIAS is truly powerful and flexible, and supports partially some of the main SRL strategies with tools for planning, information management, note taking, etc. Full SRL support would require attention to detail in the implementation of the strategies, but ILIAS is a general purpose open LMS, not a specific SRL tool. The ROLE sandbox is based on widgets, and it has many SRL-oriented ones, but one of the main problems is that they are not able to communicate among them, preventing the system from being practical.

Another big problem is due to the confusion that this type of learning approach creates in non-experts when it comes to monitoring. Most tools get activity data, process it and then try to tell the learner what to do. A more appropriate approach for SRL would be to provide information that support learners drawing their own conclusions and reflecting about their learning processes, strategies and results. In this way, we can guide learners through this process at the beginning. The level of guidance is critical and should adapt for every student through time depending on his/her SRL skill level. We can learn from the gaming world in this aspect, which has focused on playability, usability and adaptability for years and has advanced a lot. For instance, it is very common to be able to select the difficulty level, to enable or disable hints depending on their type, to select the amount of hints when enabled, etc. At the same time, this guidance is offered at the beginning and tends to disappear progressively and automatically as the user gets more experienced, and users can reactivate or deactivate anything when they need it.

Another thing to consider is the use of reporting tools. Anyone would probably be able to name some task managers, LMSs, e-portfolio tools, etc., but, how many reporting tools do you know? Reporting tools are well known in the business world. They process raw data, usually coming from other software tools, and show information reports and graphs to the users. It is clear that a standard data format is needed in order to be able to share information and take advantage of these tools.

IV. MONITORING SRL AND SELF-MONITORING

Self-monitoring consists on tracking what you are doing as a learner and how you are doing it, what strategies you are using, whether if you are planning properly or not, whether if you are following your plan or not, etc. Self-monitoring refers specifically to this process performed by the learners themselves, tracking their own activity as part of the SRL

cycle, enabling control, reflection and evaluation, thus reaction.

Teachers can also monitor their students' activity in order to assess and guide them when they need it, and this process, in a SRL context, is known as monitoring. It is time consuming and not effective if learners use traditional tools (because teachers need to interview periodically each student to get the information they need to assess and guide) or even if they use common LMSs and/or e-portfolios (teachers need to read a lot of content from their students to do a qualitative assessment [20]). This process can be improved and optimized for both learners and educators using adequate software, with functionalities oriented to improve the implementation of the strategies and to track learners' actions focusing on the SRL process, especially if we have adequate and complete data from all SRL phases.

The monitoring system of any learning software tool "should provide both students and educators with useful information about the evolution of the learning process" [9]. It is very important to choose an adequate data set in order to be able to extract relevant information from raw activity data. In our case, we need to track the actions derived from the implementation of the SRL strategies, in order to know how learners are using them and help them to improve, and also in order to provide the learners with useful information that may help them with control, reflection and evaluation of their learning activities.

In [9] we presented our vision of a monitoring system that was embedded in a full modular system, and showed how to combine pieces of data to extract useful information. The problem there was that this monitoring system would not work outside that full system, and therefore we were missing important SRL information. This was because the whole system did not support some important SRL strategies, and therefore they had to be implemented in other tools. The system was not interoperable. To solve this, in [6] we presented the idea of a standard to get activity information from different learning tools, which may allow any compliant reporting tool to extract valuable information about the whole SRL process, performed in different software tools. We presented some examples of what to record and how to record it. The idea here is to specify that work and show how we can use activity data from multiple sources to get valuable information about SRL processes.

V. RELATED WORK

A. *SoftLearn*

One of the most interesting works about systems for monitoring SRL to ease assessment for teachers is the one presented in [20]. In their scenario, they chose a blended learning approach in which the students use ELGG as a PLE (Personal Learning Environment). ELGG [21] is an open source platform that "integrates an individual space and also a social network with forums, blogs, micro-blogging, details of the user profile, friend lists, activity screening, a personal wall, calendar, favorites and pages". One of the big problems of assessing SRL in this context is that "a rigorous monitoring process generates such a volume of information that it

becomes unmanageable: assessing a set of portfolios is much more complex than a simple note granting process". At the same time, the assessment is qualitative, and it "requires reading hundreds of inputs to know if the student has achieved the expected competencies", so it is "extremely time consuming".

SoftLearn is a process mining based tool that "automatically discovers and represents the learning process followed by the students". They tackled several problems: obtaining complete, precise and simple information about learning processes from large amount of traces, representing the learning process for visualization, etc. They obtained great results using process mining algorithms and creating their own visualization based on D/F-graphs. Using SoftLearn, teachers were able to save 54% of their assessment time.

B. The ROLE Project, BOOST and Learning Layers

Responsive Open Learning Environments (ROLE) [22] is a European collaborative project that comprises 16 research groups from six EU countries and China. It is aimed at supporting teachers in the development of open personal learning environments for their students where they can train their SRL skills. Their main outcomes are the ROLE PLMS (Personal Learning Management System) [23] and a big list of widgets available through a store. The PLMS was based on CLIX and allowed the integration of widgets that covered separately almost the whole range of SRL strategies. It is no longer available as it became a commercial enterprise oriented LMS. Widgets can still be used through the ROLE sandbox [19], a learning space whose functionality is provided by the widgets.

This widget-based system allows the students to build their own mashup PLE attending to their needs, but it has some limitations. The main one would be isolation. Although the system is powerful and tackles many tech-SRL common issues that other software misses, monitoring learners' activity is not really possible as we understand it because most widgets do not communicate between each other or record activity data in a common format so other widget or application could work with that data.

Other projects like BOOST [24] and Learning Layers [25] are also based in this concept and have improved the usability and the communication capabilities between the widgets used, but they are aimed at workplace learning.

VI. EXPERIENCE API

A. What It Is

Experience API, also known as Tin Can API or xAPI [8], is a specification for learning technology managed by ADL that "allows recording a wide range of experiences that a user can have in different technologies or tools" [6]. It is community driven and expandable, hence very adaptable. The way it has been designed makes it very flexible and versatile, being able to record any type of activity or event in different ways, which as we will see is an advantage and a disadvantage at the same time. It has many other advantages: activities are easy to code in it, statements are human readable, it has a layer to tackle the language issue, it is device independent, it

supports different technologies, it allows interoperability, records are traceable and quantifiable, it allows resumption across sessions (records the state of the activities), etc.

B. How It Works

It is based on statements in the form of "I did this" (noun, verb and object) that are recorded to or retrieved from a Learning Record Store (LRS). A LRS is a repository for learning records that can be accessed by any compliant software tool, including LMSs, reporting tools and other LRSs. Some of these possibilities are shown in Fig. 1, in which we can see several tools connected to different LRSs, also connected between them. The possibilities for sharing data are endless.

Activities are identified and described in the Activity Profile API, the state of each activity is managed by the State API and every user is identified through the Agent Profile API, even when using accounts from different tools.

C. The Statements

xAPI statements are JSON based objects comprised of a set of defined elements: UUID, actor, verb, object, context, result, timestamp, extensions, attachments, authority, stored and version. Some of them are commonly defined by the LRS: UUID is the identification of the statement generated by the LRS or by the activity provider, Timestamp stores the date and time when the statement is created, and is set by the LRS if it is not included by the activity provider, Authority indicates who asserts the statement, Stored represents the date and time when the statement is stored in the LRS and Version represents the version of the API.

The rest of the elements can be used to define the activity:

- *Actor*: The actor is who performs the action. It can be an agent or a group. It contains a name and an identifier, like and email, mbox, OpenID or an account (e.g. like a twitter account).
- *Verb*: The verb identifies the action. Past tense is used. Each verb has an URI that acts as a unique identifier. ADL created a list of recommended verbs that can be expanded if the action is not represented by any of the existing verbs. A display field shows a legible version of the verb in each language.
- *Object*: The object of the action can be an activity, an agent or a group, a statement reference or a sub-statement. Activity objects are the most common, and they are usually defined by the reporting systems. They have a type, a name and a description. Like the verbs, they are uniquely defined by an URI.
- *Context*: This allows us to add contextual information to a statement, and represents the context of the action, i.e., the instructor, the parent activity, the group, the platform, etc. All these elements are optional.
- *Result*: In these fields we can define the results of the action, if any. Here we can say if the activity was completed, if it was a success, we can define the score, etc.

Fig. 1. Combinations for sharing learning activity records.

- *Extensions*: Activity definitions, context or results can be extended with custom elements for specialized use. This increases flexibility, but it must be used with care if we want others to use our activity records.
- *Attachments*: This object was created to define a list of files that will be attached to the statement. It has some required fields to identify attachment's properties like type, length, name, etc.

An example of a xAPI statement will be shown in the next section.

D. Tin Can Profiles and Recipes

Tin Can Profiles are best practice guides for certain scenarios or certain groups of actions. They can be seen as application profiles for xAPI. Application profiles are “schemas which consist of data elements drawn from one or more namespaces, combined together by implementers, and optimized for a particular local application” [26].

There are just a few profiles up to this date, including profiles for video experiences, checklists, SCORM courses, and for Open Badges. Each profile has recipes, activities and a list of linked identifiers. It is in the recipes where all the activities and extensions related to the profile are defined.

VII. xAPI-SRL APPLICATION PROFILE

A. What it Is

xAPI-SRL is an application profile for xAPI that defines how to record SRL actions derived from the implementation of SRL strategies.

Tin Can API allows you to record any action in several different ways. This way you will not need to modify the standard, just adapt the way you use it to your needs. The main drawback of this approach is that two different developers could decide to record the same action using different verbs or coding it differently in xAPI, creating a compatibility issue, despite using the same standard. Besides, if they cannot find an adequate verb or activity type for a particular action in the xAPI Registry [27], they may propose different ones. xAPI-SRL is proposed as a solution to these

problems, providing the developers with a standard for recording and reading SRL actions, allowing them to create interoperable SRL tools.

B. xAPI-SRL Development [6]

We studied a large number of SRL strategies in order to know what information could be generated through their implementation in software. We attempted to minimize the complexity and focused on the data that should be common to the implementation of each one of them, no matter what tool is used. In order to define how to record these actions we: (1) selected the most appropriate verbs, activity types, etc. for each action; (2) selected the most appropriate fields to record the strategy derived data; (3) extended xAPI with new verbs, activity types, extensions, etc. to record actions that were not represented in xAPI Registry, thus in the current xAPI specification. All the information that is not represented in the application profile, probably not related to SRL, can be considered as proprietary information (exclusive for that tool) and can be recorded using the extensions fields.

C. Building the xAPI profile

Tin Can Profiles and recipes need to be structured. This became another big issue when creating the profile: classifying the strategies' implementation records into recipes. We cannot use the classification of the strategies mentioned in section II.B, as the profiles are meant to be used by developers that do not have to know about SRL theory. This classification should be coherent with SRL theory and, at the same time, practical and usable by techs. In order to achieve this, each recipe is composed by groups of strategies that belong to the same higher level strategy, and at the same time are related by functionality, being the latter primary. For instance, there is a planning recipe, and a time management recipe. There are some time management strategies that are also present in the *goal planning* strategy (e.g. time estimation), but we included them in the time management recipe because they are closer to these group functionality and strategies.

D. Capturing the data

In a SRL technology enhanced scenario, a learner would use, at least, the following functionalities, provided by one or more tools (see Fig. 2): organization and time management (provided by goal/task or project managers), content delivery (provided for instance by LMSs or MOOCs), self-monitoring and self-evaluation (provided for instance by a reporting tool and a tool oriented to record reflections like an electronic portfolio). Following the xAPI standard, each tool records the activities that the learner performs, and sends the activity records to a LRS instantly or when the connection is available. That activity data can be retrieved from the LRS anytime by any authorized tool. This way, any tool with reporting capabilities could work with a complete set of activity information.

E. Recording the activity with xAPI-SRL

Here we show an activity record of a time estimation for a task that uses xAPI-SRL. The task is represented in the object as a reference of the statement in which the task was created.

```
{
  "actor": {
    "mbox": "mailto:david@example.es",
    "name": "David", "objectType": "Agent"},
    "verb": {
      "id": "http://uvigo.es/xapi/reg/verbs/estimated-time",
      "display": {"en-US": "answered"}},
      "object": {
        "objectType": "StatementRef",
        "id": "6gf47cxdi-cb53-34c7e-ae32-44982ef22df4"
        "extensions": {
          "http://id.tincanapi.com/extension/duration": "PT45M" }
        "timestamp": "2014-06-30T14:36:18.2435Z"}
  }
```

F. Selecting the data

Monitoring systems usually record almost each of the movements of the user when using the platform, that is, the little steps of each action. With xAPI, each record references a complete meaningful action, not paying attention to each click or small step, which eases the process. Despite this, the data generated in a single learning episode is abundant and varied. We need to filter it and select only the data that would give us the information we want, and organize it if comes from different tools. This process has several steps (Fig. 3):

- *Author*: we filter the statements to select the records from the selected author.
- *SRL*: we filter SRL related actions.
- *Time*: we select the time window and organize the records time wise.
- *Object*: we filter or organize (depending on the intention of the query) the statements attending to the object, grouping related ones.
- *Grouping and analysis*: we analyze groups of statements attending to their related strategy and how they relate to each other.

This last step is not trivial as it implies knowing the relationships of the verbs, activity types, etc. with the strategies, and also how they relate to each other in terms of object of the action, parent activity, etc.

G. Processing the data

In [9] we presented a monitoring system that analyzed raw data from a learning organizer combining related variables to obtain valuable information by using comparative equations. Comparison is the most common and simple method used to see differences between two elements. That is why we based most of our information graphs, calculations and reports on comparisons of two elements, along with a reference element that could be a sequence of tasks, goals, time, etc. The idea here is to select two variables that will create a meaningful comparison following the process described in the last subsection and analyze the data to extract values to compare. In some cases, this is trivial (for instance, time estimations are a field that can be retrieved as it is), and other cases need some processing (for instance, knowing the time spent on a task implies getting the timestamp from several records: activity start, activity pause or stop and resume if they exist and activity complete, and calculate the time with simple math operations).

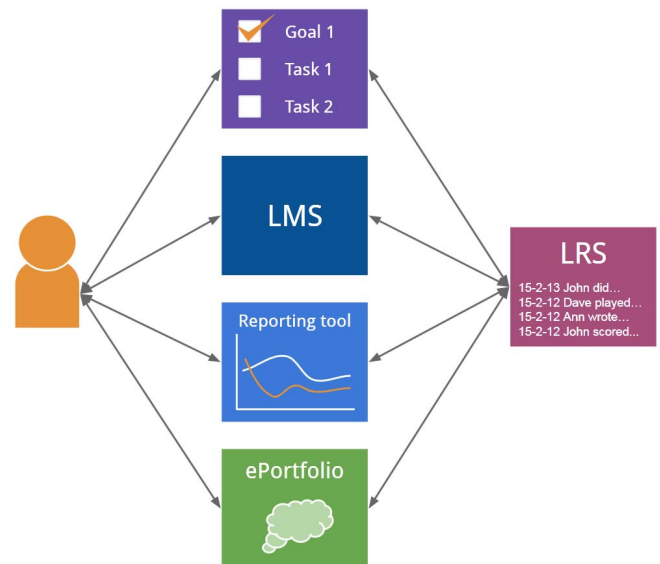

Fig. 2. SRL technology enhanced scenario.

Fig. 3. Data filtering and organization process.

The results that we obtain using this method are easy to understand and useful for both learners and educators. For example, in a scenario in which learners define their goals and plan their learning with subgoals and tasks, time estimations and results estimations are a common practice in SRL. Comparing these time estimations with the actual time used through several tasks or goals would give the learners an idea of how well they made their time estimations. Fig. 4 is an example of a comparative graph showing the time estimations for the tasks versus the time actually spent doing them. At the same time, it can show the details for each particular task or goal in the graph, the time difference in percentage and in this case, it has an option to record our reflection about the time difference. When focusing in each particular task, learners can see how well they performed (in terms of time use) compared to what they thought they would. This allow them to reflect about their performance with information to support their thinking, and would help them draw right conclusions.

Fig. 5 is an example of the number of doubts or reviews that the learner annotated for each goal, and it also shows their current state (pending or solved). It also shows the detail of a goal and how its doubts and reviews are distributed in its subgoals. This graph may help learners with: making decisions for their planning (they can see at a glance their most challenging goals or tasks, their pending doubts or items to review, etc.), reflecting about their evolution, focusing on their weaknesses, etc.

VIII. CONCLUSIONS AND FUTURE WORK

We need a standard way to record learners' activity if we want to share this information to use the most suitable tools for each purpose, specially reporting tools. This application profile would facilitate the creation of a common ground to work with SRL activity data and build tools with advanced learning process monitoring and evaluation support for both learners and educators. This work, along with the CESARAS questionnaire for SRL support evaluation [2] and the design guidelines for SRL that we provide could be a framework for developers to improve the level of support for SRL in software tools, and more specifically, for SRL strategies.

A. Validation

The validation process is not clear because there are no software applications that offer full support for SRL, and at the same time because there are no reporting tools for SRL purposes. The results will be partial in any case. Developing one or more applications to prove this is worthy is not an option for obvious reasons (the investment for the validation would be more than ten times the cost of the development of the standard), as it should include full functionality support, full activity data recording support and advanced reporting features, otherwise the validation would be partial. Using third party applications to validate it has its own problems, as the few existing SRL oriented applications do not use xAPI to record students' activities, but their proprietary solutions. Translating their data into the xAPI-SRL standard has its own problems, as we would need to fill the gaps not included in the original data, and the results obtained would be partial. We needed another approach.

This research was supported by pedagogy experts that provided a first conceptual validation. The next step towards a full validation is getting it published in the ADL website as a profile for SRL. ADL curators examine every proposal for profiles and recipes, suggest changes to the authors and publish their work once it meets their requirements. At present time, we have contacted ADL to start the process, which should resolve within the next months.

B. Future integrations

In the future, we plan to integrate this application profile and some SRL oriented functionalities in tools that we developed, and also to promote its use in the development community.

ACKNOWLEDGMENTS

Research supported by the Spanish Ministerio de Ciencia e Innovación under grant "Methodologies, Architectures and Standards for adaptive and accessible e-learning (Adapt2Learn)" (TIN2010-21735-C02-01), the European Regional Development Fund (ERDF) and the Galician Regional Government under projects CN2012/260 and GRC2013-006 "Consolidation of Research Units: AtlantTIC".

Fig. 4. Time estimation vs. time spent graph.

Fig. 5. Graph showing doubts and reviews pending or solved per goal.

These graphs show the power behind this concept. With adequate tools, learners would be able to implement the strategies using software, and that actions would generate activity records that, once processed, would give learners and educators means to actually use SRL techniques for monitoring and evaluation improved with software. It clearly enhances SRL phases 2 (performance, monitoring and control) and 3 (evaluation, reflection and reaction), supporting also phase 1 (forethought, planning and activation) as SRL is a cyclical process based on metacognition (with each iteration we increase our knowledge about how we learn).

{omar, isalamah}@utep.edu

Abstract— In this paper we present an approach used to enhance students' competency in software verification. Students were asked to apply software verification techniques to a complex formal specification system. The complexity of the system stems from its sophisticated requirements. Selecting such system for this study was intentional for the following two reasons 1) the system is difficult to understand and analyze because of the domain knowledge required to generate formal specifications in temporal logic and 2) the system is large and complex which lends itself to a wide range of applicable verification techniques, and thus highlights the differences in the capabilities of each of the software verification approaches. Students were assessed using multiple criteria including; examination in applying learned techniques, students' attitude toward the technique, perceived efficiency of the techniques in discovering software defects, and the ability of the technique to locate errors in the code beyond simply indicating their presence. The results of this work show that the students applied the learned techniques successfully and their attitudes towards software verification improved.

Keywords—Software Engineering, Computer Science Education, Debugging, Software Testing

I. INTRODUCTION

As our dependency on computer-based critical systems continues to increase, software systems will continue to grow in complexity and size. It has been reported that a significant number of software systems do not meet users' requirements and are of poor quality [13]. In addition a study from the National Institute of Standards and Technology revealed that software defects are so prevalent and detrimental that they cost the U.S. economy an estimated \$59.5 billion annually, or about 0.6 percent of the gross domestic product [14]. The estimated cost due to software errors in the aerospace industry alone was \$6 billion in 1999 [15]. Thus it is increasingly more important that efforts in software development focus on decreasing the number of defects within developed software systems. However, studies have found that senior-level college students and recent graduates lack adequate preparation in software verification, and have difficulty in testing software thoroughly [16, 17, 18, 19]. Therefore, there is an increasing demand for software professionals who have a strong background in software verification.

This paper presents the results of an approach in enhancing students' competency in software verification. Students are

asked to apply the techniques of interest to verify a system used to generate formal specification [7, 9]. The complexity of the system stems from its sophisticated requirements (specified using first order logic). The choice of such system was intentional for the following two reasons 1) the system is difficult to understand and analyze because of the domain knowledge required to generate formal specifications in temporal logic and 2) the system is large and complex which lends itself to a wide range of applicable verification techniques emphasizing the differences in the capabilities of each of the software verification approaches. Students were assessed using multiple criteria including; examination in applying learned techniques, students' attitude toward the technique, perceived efficiency of the techniques in discovering software defects, and the ability of the technique to locate errors in the code beyond simply indicating their presence.

The hands-on approach used in this work aims at exposing the students to the subtleties of each technique by allowing them to explore and learn by practice, and thus, gain expertise in software verification. This paper presents the results of the approach, focusing on the increased proficiency of the student's ability to leverage these software verification techniques in finding software defects and in the applicability of the chosen system in teaching these techniques..

II. BACKGROUND

One of the key aspects in software development is the assurance that the software behaves correctly, i.e., as specified by requirements. The most common software verification technique is that of testing. Software testing is the process of creating and applying test cases to a software system in order to check if the system's behavior was correctly implemented. A test must be efficient in such way that it either exposes a defect or gives some level of confidence on the absence of defects. The problem of determining efficient inputs for test cases has been tackled by different approaches, ranging from treating the system as a black-box [20] to white-box approaches [21].

A. Black-box Testing

In a black-box testing approach, which focuses on selecting input for test cases from the specified requirements and input ranges, it is easier to determine inputs for a test case, but a failed test case will not tell us the potential location of the

defect in the system. Our approach focuses on three black-box testing techniques:

Equivalence Class Partitioning. Equivalence class testing is a technique in which the input domain is partitioned into a finite number of valid and invalid classes. Input values within each equivalence class should behave the same. As such one test input selected from each equivalence class should be sufficient to determine the behavior of the whole equivalence class. By executing one test from each equivalence class, the amount of necessary testing is reduced.

Boundary Value Analysis. Boundary value analysis is a technique that selects tests from the boundary range of input values. These ranges can be defined from specifications or via equivalence classes. The test is selected from above, below and at the boundary of the range. Software defects are commonly encountered at these boundaries, and testing them is an efficient way to detect defects.

Pair-wise Testing. Software systems of any significance are, typically, too large to be tested for all possible input combinations. For these software systems, pair-wise testing [22] is useful because it focuses on testing all pairs of test case inputs instead of all combinations of inputs. The generation of test case input under pair-wise testing is mechanical in nature, only ensuring that each pair of input variables is accounted for from an orthogonal array of inputs. This leads to a automatic way of generating test case input data for the testing of a wide range of large systems.

B. White-box Testing

A white-box testing approach requires the analysis of the internal structure of a system in order to select sets of test input cases that provide adequate coverage of the source code. Determining test input data in white-box testing can be more difficult since it requires construction of control flow graphs (CFG) from source code to determine what input must be used to meet the desired coverage criteria. Because the executions paths are directly tied to the test case input, a failed test can provide the location of the defect.

Branch Coverage. A branch coverage criterion is one that requires that each branch of every control structure has been touched at least once by the testing. Test case input is selected by analyzing the CFG and determining what branches need to be tested. Test cases are created until every branch has been touched at least once. When every branch has been touched at least once, branch coverage reaches 100%.

Path Coverage. A path coverage criterion requires that every possible path is executed by testing at least once. In order to determine test case input, an analysis of the CFG must be done to generate test input data for every possible path that can be executed. This coverage criterion is deemed the most expensive type of coverage as the number of tests required grows exponentially with the number of conditions in the source code.

Def-use Coverage. A def-use coverage criteria focuses on generating tests that cover paths through the definition and use of variables in a program. The def-use requires that testing covers every path from every variable definition to every use

of that variable. This is done by examining the paths stemming from where a variable is first defined, down to every single use of that definition of the variable.

III. PROPERTY SPECIFICATION (PROSPEC) TOOL

A. Formal Specification Languages

Software specifications refer to properties that the system must adhere to. Specifications can be defined and used at the different stages of software development and can range in formality from completely informal (i.e., natural language) to completely formal (i.e., mathematical description). Informal specifications provide a simple mean by which stakeholders, who are, usually, not immersed in logic, can easily understand the desired system properties. On the other hand, formal specifications are more succinct and unambiguous. More importantly, formal specifications allow for the use of formal verification techniques such as model checking [1] and runtime monitoring [2].

There are numerous formal languages that can be used to express system behavior, e.g., first order logic, the specification languages Z and VDM, which have been used in the specification of software and hardware systems.

In the case of dynamic software systems, temporal logic has been used for many decades. In order to be able to describe truth in different moments of time, researchers have designated extensions of traditional logic called temporal logics. Linear Temporal Logic (LTL) [3] and Computation Tree Logic (CTL) [4] have been commonly used by formal verification techniques, especially model checking.

Formulas in LTL are constructed from elementary propositions (i.e., statements with truth value describing system conditions or events), and the usual Boolean operators for not, and, or, imply (\neg , $\&$, \vee , and \rightarrow , respectively). In addition, LTL provides the temporal operators *next* (X), *eventually* (F), *always* (G), *until*, (U), *weak until* (W), and *release* (R). These formulas assume discrete time, i.e., state s may be denoted as 0, or 1, or 2, or ... The meaning of the temporal operators is straightforward [3]:

- The formula Xp holds at state s if p holds at the next state $s + 1$,
- the formula $p U q$ holds at state s , if there is a state $s' \geq s$ at which q is true and, if s' is such a state, then p is true at all states s_i for which $s \leq s_i < s'$,
- the formula Fp holds at state s if p is true at some state $s' \geq s$, and
- the formula Gp holds at state s if p is true at all states $s' \geq s$.

B. Automated Support for Generating Formal Specifications

Specification Patterns System (SPS). A major reason for the lack of application of formal methods in software development is the difficulty in writing, reading, and validating formal specification, particularly those involving time. To assist users in the generation of formal specifications, Dwyer et al. [5, 6] developed the Specification Pattern System (SPS). The work defined a set of patterns to represent the most

commonly used formal properties and to guide the practitioner through the specification process. *Patterns* capture the expertise of developers by describing solutions to recurrent problems. SPS also defined a set of scopes of system execution where the pattern of interest must hold. Each pattern and scope combination can be mapped to specifications in multiple formal languages including LTL and CTL. Using the notions of patterns and scopes a user can define formal system properties without being an expert in the language.

The main patterns defined by SPS are: *Universality*, *Absence*, *Existence*, *Precedence*, and *Response*. The descriptions given below are taken verbatim from the SPS website [S6]:

- *Absence(P)*: To describe a portion of a system's execution that is free of event or state (P).
- *Universality(P)*: To describe a portion of a system's execution which contains only states that have the desired property (P). Also known as Henceforth and Always.
- *Existence(P)*: To describe a portion of a system's execution that contains an instance of certain events or states (P). Also known as Eventually.
- *Precedence(P, Q)*: To describe relationships between a pair of events/states where the occurrence of the first (Q) is a necessary pre-condition for an occurrence of the second (P). It can be said that an occurrence of the second is enabled by an occurrence of the first.
- *Strict Precedence(P, Q)*: To describe relationships between a pair of events/states where the occurrence of the first (Q) is a necessary pre-condition for an occurrence of the second (P). This pattern differs from the previous one in that in regular precedence the pattern is satisfied if both P and Q hold in the same state, while the *Strict Precedence* is only satisfied when Q holds in a state that *strictly precedes* the one in which P holds.
- *Response(P, Q)*: To describe cause-effect relationships between a pair of events/states. An occurrence of the first (P), the cause, must be followed by an occurrence of the second (Q), the effect. Also known as Follows and Leads-to.

In SPS, each pattern is associated with a scope that defines the extent of program execution over which a property pattern is considered. There are five types of scopes defined in SPS:

- *Global*: The scope consists of all the states of program execution.
- *Before R*: The scope consists of the states from the beginning of program execution until the state immediately before the state in which proposition R first holds.
- *After L*: The scope consists of the state in which proposition L first holds and includes all the remaining states of program execution.
- *Between L And R*: The scope consists of all intervals of states where the start of each interval is the state in which proposition L holds and the end of the interval

is the state immediately prior to one in which proposition R holds.

- *After L Until R*: This scope is similar to the previous one except, if there is a state in which L holds and proposition R does not hold, then the interval of the scope will include all states from and including the state where L last holds until the end of program execution.

SPS is presented as a website [6] with links to descriptions of the patterns. The website provides a mapping of each pattern and scope combination into different formal specification languages. For example, the property "A request always triggers an acknowledgment, between the beginning of execution and system shutdown." can be described by the *Q Responds to P* pattern within the *Between L and R* scope, where Q denotes "Acknowledgement is triggered.", P denotes "Request is made.", L denotes "Execution begins.", and R denotes "System is shut down.". Based on the selected pattern and scope combination, the LTL formula provided by the SPS website [S6] is:

$$G((L \ \& \ (!R) \ \& \ F R) \rightarrow (P \rightarrow ((!R) \ U \ (Q \ \& \ !R))) \ U \ R).$$

Composite Propositions (CP). Composite propositions (CP) [7] expand the expressiveness of patterns and scopes to include the specification of sequential and concurrent behaviors. In practical applications, we often need to describe properties where one or more of the pattern or scope parameters are made of multiple (i.e., composite) propositions. An example of such property is the one for sending data by a client and storing the data by the server. The English description of the property is "every time data is sent at state s_i , data is read at state $s_j \geq s_i$, the data is processed at state $s_k \geq s_j$, and data is stored at state $s_l \geq s_k$." Although SPS provides a significant support for property specifications, specifying such a property using SPS would require a significant effort by the user. In order to arrive at the formal specification for this property, the user will have to manipulate the different propositions within the property in order to make it fit the available patterns and scopes. This extra effort by the user might lead to erroneous specifications or user frustration, or both.

Even with the introduction of SPS' patterns and scopes, defining formal specifications for concurrent and sequential properties similar to the above example remains a huge obstacle in adapting formal methods in software verification. To describe such properties, SPS was extended by introducing a classification for defining sequential and concurrent behavior to describe pattern and scope parameters. Specifically, the work [7] defined the following CP classes along with their English description:

- *AtLeastOne_C*: At least one of the propositions in the set of propositions holds.
- *AtLeastOne_E*: At least one of the propositions in the set of propositions becomes *true*.
- *Parallel_C*: All propositions in the set of propositions hold.

- **Parallel_E**: All propositions in the set of propositions become *true* simultaneously.
- **Consecutive_C**: Each proposition in the sequence of propositions is asserted to hold in a specified order, one at each successive state.
- **Consecutive_E**: Each proposition in the sequence of propositions becomes *true* in a specified order, one at each successive state. Once they become *true*, their truth value in subsequent states does not matter.
- **Eventually_C**: Each proposition in the sequence of propositions is asserted to hold in a specified order and in distinct and possibly non-consecutive states.
- **Eventually_E**: Each proposition in the sequence of propositions becomes *true* in a specified order and in distinct and possibly non-consecutive states. Once they become *true*, their truth value in subsequent states does not matter.

The subscripts C and E describe whether the propositions within a CP class are asserted as conditions or events respectively. A proposition defined as a condition holds in one or more consecutive states. A proposition defined as event means that there is an instant at which the proposition changes truth value in two consecutive states. [7] Provides the LTL semantics for each of the CP classes.

Combining patterns and scopes with this notion of CP makes the formal specification of the sending/storing property above much easier. This property can be described using the *Existence of P* pattern within the *Between L and R* scope where *L* is defined with the proposition signifying “data is sent,” *R* is defined by the proposition “date is stored,” and *P* is a CP of type *Consecutive_C* composed of the two propositions p_1 and p_2 (data is read and data is processed, respectively).

One of the advantages of utilizing CPs in generating formal specifications is that it forces the user to consider the different possible relations among proposition within a property. This leads to more complete and correct specifications of sequential and concurrent behaviors which are characteristics of reactive systems.

Combining patterns, scopes and CPs. Although SPS provides LTL formulas for basic patterns and scopes (ones that use single, “atomic”, propositions to define L, R, P, and Q) and Mondragon et al. [7] provided LTL semantics for the CP classes described above., in most cases it is not adequate to simply substitute the LTL description of the CP class into the basic LTL formula for the pattern and scope combination. Consider the following property: “The delete button is enabled in the main window only if the user is logged in as administrator and the main window is invoked by selecting it from the Admin menu”. This property can be described using the Existence (Eventual_C(p_1, p_2)) Before(*r*) where p_1 is “the user logged in as an admin”, p_2 is “the main window is invoked”, and *r* is “the delete button is enabled”. As mentioned above, the LTL formula for the Existence(*p*) Before(*r*) is $[S6] \text{ “}(G \text{ !}r) \mid (! r \text{ U } (p \ \& \ \text{!}r))\text{”}$, and the LTL formula for the CP class Eventual_C, as described in [7], is $(p_1 \ \& \ X(!p_2 \text{ U } p_2))$. By replacing *P* by $(p_1 \ \& \ X(!p_2 \text{ U } p_2))$ in the formula for the pattern and scope, we get the formula: “ $(G \text{ !}r) \mid$

$(!r \text{ U } ((p_1 \ \& \ X(!p_2 \text{ U } p_2)) \ \& \ \text{!}r))\text{”}$. This formula however, asserts that either *r* never holds or *r* holds after the formula $(p_1 \ \& \ X(!p_2 \text{ U } p_2))$ becomes true. In other words, the formula asserts that it is an acceptable behavior if *r* (“the delete button is enabled”) holds after p_1 (“the user logged in as an admin”) holds and before p_2 (“the main window is invoked”) holds, which should not be an acceptable behavior.

As seen by the above example, the temporal nature of LTL and its operators means that direct substitution could lead to the description of behaviors that do not match the actual intent of the user. For this reason, it is necessary to provide abstract LTL formulas that can be used as templates for the generation of LTL specifications for all combinations of patterns, scopes, and CP classes. To address this issue, Salamah et al [8] defined a set of templates that can be used to ease the generation of LTL specifications for all pattern, scope, and CP combinations. The work defined nine templates to generate formulas within the *global* scope, 14 for formulas within the *before R* scope, and another five templates to generate the formulas within the *between L and R* and the *after L until R* scopes. The work in [8] also showed how formal proofs and software inspections were used to validate the correctness of the defined templates.

Using the templates defined by [8] allows for the generation of over 31,000 types of properties as described in the breakdown shown in Table 1.

The numbers for each combination of pattern/scope are results of number of possible ways to combine the different representation of P, Q, L, and R. For example, in the *Absence*

Table 1. Breakdown of Property Types

Pattern/ Scope	Global	Before R	After L	Between L and R	After L Until R	Total
Absence	8	64	64	512	512	1160
Existence	8	64	64	512	512	1160
Universality	8	64	64	512	512	1160
Precedence	64	512	512	4096	4096	9280
Strict Precedence	64	512	512	4096	4096	9280
Response	64	512	512	4096	4096	9280
Total	216	1728	1728	13824	13824	31320

of *P* pattern within the *Before R* scope, there are eight possible ways of presenting each of *P* and *R*, and as result there are 8x8 (64) combinations. On the other hand, the number of combinations for *Q Responds to P* within *Between L and R* is calculated as 8x8x8x8 to yield 4096 combinations.

Prospec Tool. The Property Specification (Prospec) [7, 9] is a prototype tool with a graphical user interface developed at the University of Texas at El Paso to help software developers create software specifications using SPS’ patterns and scopes as well as the aforementioned notion of composite propositions (CP). Prospec generates formal specification in Future Interval Logic (FIL) [10] and LTL. The tool guides practitioners in the creation of formal specifications by assisting the user in the identification and elucidation of

events or conditions that are used to specify behavior. Prospec makes use of decision trees to guide the user through a series of decisions to select an appropriate pattern, scope, and CP classes to match his/her property. □ □

C. Using Prospec in Teaching Software Testing

Considering the complexity associated with generating a large number of LTL specifications using the Prospec tool, we envision this as a perfect platform to teach software testing. The applicability of the Prospec tool stems from multiple factors:

1. The complexity of the LTL specifications generated by the tool requires significant domain knowledge in order for students to adequately test the generated specifications. This is typical of a real-world environment in which software quality assurance personnel must gain domain expertise in the system under test (SUT) before attempting to test such system.
2. The large number of LTL specifications (over 31,000 possible specifications) supported by the tool forces students to employ adequate testing techniques to select sets of test cases that provides appropriate coverage of the system.
3. The characteristics of patterns, scopes, and CPs considerably lend themselves to testing techniques such as equivalence classes and boundary testing. For example, in order to generate black-box test cases, students have to break the input domain into different possibilities, such as, a) the pattern holds but the scope does not, b) the scope holds, but the pattern does not, among many other cases.
4. The fact that the domain associated with the Prospec tool is that of formal specifications is an attractive one as it provides a way to introduce students to formalisms and formal specifications as part of formal methods within software development.

IV. APPROACH FOR USING THE PROSPEC TOOL IN TEACHING SOFTWARE TESTING

The Prospec tool and the associated patterns, scopes, and CPs were introduced as a semester project for the CS4387/5387 (Software Integration and V&V) course at the University of Texas at El Paso (UTEP) in Spring 2015. The course is a core requirement for students in the Masters of Science in Software Engineering (MSSwE) program at UTEP. However, the course also attracts students from other programs offered by the Computer Science Department.

A. Students' Profile and Team Structure.

The current addition of the course has a total of 22 students. Of those students one is a PhD. candidate in Computer Science, another is pursuing a Master's in Computer Science, two others are undergraduate students in Computer Students, and the remaining 18 students are MSSwE students.

Students in the class were assigned into five teams of four to five students. The course teams work on a semester long

project where they develop a complete test plan for a particular project. The test plan includes:

- Plans to test the system's requirements and design specifications as well as implementation using black-box testing techniques,
- Plans to perform white-box testing on system implementation, and
- Plans for system integration, and
-

B. Team Assignments

Using our approach, student teams were assigned three major assignments to verify correctness of LTL specifications generated by the Prospec tool. Below, we discuss each of these assignments, along with students' expectation, and actual students' performance in each of these assignments.

Using Pair-wise Testing. Each of the five teams in the class was assigned a pattern/scope combination where all four propositions are present. Namely, each team was assigned one of the following pattern/scope combinations:

- Q Responds to P, Between L and R
- Q Responds to P, After L Until R
- Q Precedes to P, Between L and R
- Q Precedes to P, After L Until R
- Q Strictly Precedes to P, Between L and R

According to Table 1, each one of these combinations yields a total of 4,096 possible LTL specifications. Because of the large number of formulas to consider when testing the system, students were introduced to the technique of pair-wise testing in which possible values of each pair of input are combined to generate a single test case. The students were asked to use pair-wise testing to reduce the number of candidate formulas to be tested under each combination.

While using pair-wise testing is part of the outcomes of this course, students were not required to manually generate the orthogonal arrays as part of pair-wise testing. Instead, students were asked to research tools that automatically generate pair-wise tests. All teams used the web tool Hexawise [11]. Using the Hexawise tool, each team generated a list of 78 formulas to consider for testing of their particular pattern/scope combination. The teams were also asked to verify that each pair of CPs representing the different proposition (*P*, *Q*, *L*, and *R*) is present in the 78 formulas suggested by Hexawise.

Black-box Testing. Once the teams generated a list of formulas to test using pair-wise testing, the generated formulas were divided among team members to test using black-box testing. As a result, each student was responsible for testing no more than 20 formulas.

Students were asked to use equivalence classes and boundary value testing techniques in testing each of their formulas. To start, the team as a whole was required to develop equivalence class partitioning for the general pattern/scope combination (without the introduction of CPs).

Considering the patterns and scope characteristics described previously, we can find a perfect symmetry with the conditions emphasized in equivalence class partitioning and testing boundary values. For example, scopes formally define the states of interest within system execution (i.e., define boundaries where a pattern is to hold). As a result, scopes characteristics provide sufficient examples to explain what constitutes a boundary value. For example, using the scope Before R, one can test whether the pattern of interest is upheld if that pattern holds immediately before the state where R holds, at the same state as R, and at the state immediately after R. In a similar fashion, patterns can be used to better understand equivalence class testing. For example, using the Q Responds to P pattern, we can think of multiple equivalence classes to choose tests from:

- P never holds, and Q holds,
- P and Q never hold,
- P holds and Q never holds,
- P holds and Q holds after P,
- P and Q hold in the same state,
- ...

Figure 1 shows the equivalence class partitioning and boundary testing of the Q Precedes P pattern within the Between L and R scope as produced by the designated team of students for that pattern/scope combination. The teams were required to provide multiple drafts of their equivalence partitioning and boundary test cases. The provided figure is a sample of the final breakdown of test cases after consultation with the teaching team (both authors). In Figure 1 the students used the notion of Traces of Computation to describe test cases and the behaviors accepted or rejected by a pattern and scope combinations. A trace of computation is a string representing a sequence of states that depicts the propositions that hold in each state. Each character in the string represents a state and a dash (-) implies that no proposition is true at that state. A letter symbol, e.g., P, Q, L, and R, denotes that the proposition is true in the designated state. Displaying more than one letter between parentheses implies that the propositions represented by the letters are valid at that state. For example, in the trace of computation “- - L - - R - - (QP) - -”, L is true in the third state, R is true in the sixth state, and both Q and P are true in the ninth states.

Once the candidate tests for each patterns/scope combination was agreed on, the students were then asked to provide equivalence partitioning of CP classes. For all CP classes the possible inputs fall into one of two cases; the CP holds or the CP does not hold. For example, in the case where P is of type EventualC (p1, p2, p3), possible equivalence classes are as follows (using traces of computations):

- P Holds:
 - p1p2p3
 - p1-p2p3
 - p1-p2-p3
 - p1p2--p3
 - ...
- P Does not hold

- p1-p2---
- p2-p1-p3
- p2-p3
-

Once both the equivalence partitioning of the simple pattern/scope combination and those for each of the CP classes was finalized, students were required to translate their original test cases (similar to those in Figure 1) into ones that consider CP classes. For example, the first test cases in Table 1 can be translated into the following case when both P and R are of type EventualC: “-----p1p2---p3-----r1r2r3”.

All the pattern/scope combinations had known defects to the teaching team but not the students. As is the case with any software system of significance, there are defects that are not obvious even for the original developers of the system. In the case of the Prospec tool, it is assumed that such unknown defects are present in the implementation. The expectations for students’ teams were that they will discover the majority of these defects. The teams discovered defects at the following rate:

ELUIVALENCE CLASSES ON P	TEST CASES WITH BOUNDARY ANALYSIS AND ELUIVALENCE CLASSES ON R	EXPECTED RESULT
Q Does not precede P in any state in the interval	1. The interval is not made: a) ----- P ----- R b) ---- (LRP) ----- c) ---- L ----- P ----- d) ----- P ----- e) R ----- P ----- L ----- 2. A single interval is made: a) L holds in first state: i. L - - - P - - - R - - - ii. L - - - Q - - - R - - - iii. L - - - P - - - Q - - - R - - - iv. L - - - (RP) - - - v. L - - - R P - - - vi. L - - - (PQ) - - - R - - - b) R holds in last state: i. ----- P L ----- R ii. ----- L - - - (RP) iii. ----- L - - - P - - - R iv. ----- L - - - P - - - Q - - - R v. ----- L - - - Q - - - R 3. Figure 1. Equivalence Partitioning and Boundary Analysis for the Precedence Between L and R Combination

- Two out of two known defects in *Response Between L and R*
- Two out of three defects in *Response After L Until R*
- Two out of two defects in *Precedence Between L and R*

- One out of two defects in *Precedence After L Until R*
- Two out of three defects in *Strict Precedence Between L and R*

White-box Testing. Through course lectures, the students were introduced to the notion of control flow graphs (CFGs) and the different types of white-box testing techniques and coverages such as *statement*, *branch*, *path*, and *def-use* coverages. The students were also asked to research tools that automatically generate CFGs for a particular implementation.

Using black-box testing techniques, student teams are asked to *discover the presence* of defects. The next phase of our approach is to require students to employ white-box testing techniques to *locate* defects within the Prospec implementation. For this purpose we have packaged two implementations of the *Response Between L and R* combination. Both implementations have representations of the two known defects within this combination. Both implementations were in Java. The reason for choosing two implementations was to make sure students do not share results with each other. The teams were asked to conduct white-box testing at the unit level, where a method is considered a unit. Teams were also asked to conduct white-box testing to ensure branch (edge) coverage.

While teams used different pattern/scope combination to conduct black-box testing, the choice to have all teams work on the same combination for white-box testing was two-folds; 1) We believe that the implementation for the *Response Between L and R* combination is the most straightforward one of all the other combinations. It is also one that we have had the most experience working with [12], 2) we feel that giving the teams the same combination allowed us to have the teams compete against one another to discover code defects, and as such, injecting some excitement into the class assignments.

The results of students' teams testing were as follows:

- Two teams located both known code defects, and provided the correct suggestions to fix the code,
- One team located both known defects and provided the correct suggestions to fix the code. In addition, this team located an extra defect within the implementation. This defect, however, was not domain-specific as it was I/O-related.
- Each of the remaining two teams located one of the two defects in the code, and correctly suggested a way to remove the defect.

V. ASSESSMENT

In this section we shed some light on the impact of using this described approach on students' experiences in learning the different testing techniques described in the paper. In doing so we assess students' abilities in using the different verification techniques, and we compare the performances of the students involved in this semester's course with those of previous semesters. We also, report on a survey conducted at the end of the semester which was meant to gauge students' feelings toward the semester-long project and the associated assignments and material.

A. Students' Performances Compared to Previous Semesters

To assess students' learning and mastery of the testing approaches discussed in this paper, we compare students' performances against students in previous editions of the course. This comparison is in the shape of final exam questions related pair-wise, black-box, and white-box testing. Students' performance on the same set of exam questions from the previous two additions of the course will be compared to those the current students. Below, we describe the expectations for each type of questions used in the comparisons.

Questions Related to Pair-wise Testing. In this question, students are given a description of a system with a large number of discrete inputs and asked to 1) identify an appropriate testing strategy for testing the system and provide a justification for this choice, and 2) provide test cases for testing the system.

Successful answer for this particular problem consists of Identifying pair-wise testing as the appropriate strategy as well as providing a correct mapping of input variables to elements of an orthogonal array (the students are allowed to use tools such as Hexawise [11] for this purpose.). Table 2 below provides the results of students in the current semester (22 students in total) compared to those in spring semester of 2013 and spring semester of 2014 (total of 21 students).

Table 2. Students' Answers to Pair-wise Testing Questions

Question Element	Percent of Students Correctly answering the question	
	Springs 13 & 14	Spring 15
Correctly identifying pair-wise testing as the testing strategy	90	95
Correctly mapping input variables into an orthogonal array	86	95

Questions Related to Black-box Testing. In this question, students are given a description of a problem and asked to 1) break the input domain into appropriate set of equivalence classes and identify boundary conditions within each equivalence class, and 2) develop appropriate test cases for each identified equivalence class and boundary condition. Table 3 below provides the results of students in the current semester compared to those in spring semester of 2013 and spring semester of 2014.

Table 3. Students' Answers to Black-box Questions

Question Element	Percent of Students Correctly answering the question	
	Springs 13 & 14	Spring 15
Identify correct set of equivalence classes and boundary conditions	71	77
Identify correct test cases for each equivalence class and boundary condition. A test case consist of input and expected output	62	68

Questions Related to White-box Testing. In this question, students are given a piece of code and are asked to 1) manually develop a control flow graph (CFG) of the code, 2)

identify test cases to ensure a) branch coverage, path coverage, and def-use coverage based on a particular variable. Table 4 below provides the results of students in the current semester compared to those in spring semester of 2013 and spring semester of 2014.

B. Students' Assessment of the Described Approach

In addition to assessing students' performance in the testing techniques discussed in this paper, we asked the students to complete an anonymous survey to gauge their feelings about the use of the described approach. The survey questions were meant to elicit students' attitude toward software testing both before and after completing the course.

Table 4. Students' Answers to White-box Questions

Question Element	Percent of Students Correctly answering the question	
	Springs 13 & 14	Spring 15
Correctly construct a CFG for the code	86	86
Identify correct set of test cases to ensure branch coverage	76	77
Identify correct set of test cases to ensure path coverage	71	69
Identify correct set of test cases to ensure def-use coverage	67	69

The students were also probed to provide their feelings towards the use of the Prospec tool material as a semester-long project in this course. Finally, the students were questioned regarding the applicability of the testing approaches in finding defects versus the ability to locate defects. In the following we provide the survey questions and Table 5 provides the summary of students' responses.

Question 1: My knowledge and awareness of the difficulties associated with software verification *before taking this* course were:

a)very high b)high c)average d)below average e)low

Question 2: My knowledge and awareness of the difficulties associated with software verification *after taking this* course are:

a)very high b)high c)average d)below average e)low

Question 3: The use of the semester project highlighted the subtle differences between the different verification techniques:

a)strongly agree b)agree c)neutral d)disagree e)strongly disagree

Question 4: Of the two major approaches, the one that is easier to use in generating test cases is:

a)white-box testing b) black-box testing

Question 5: Of the two major approaches, the one that is most effective at locating defects in software systems is:

a)white-box testing b) black-box testing

Table 5. Students' Answers to the Assessment of the Approach

	Number of Responses				
	a	b	c	d	e
Q1	0	6	8	7	1
Q2	8	9	4	1	0
Q3	5	9	5	0	2
	a			B	
Q4	13			9	
Q5	15			7	

Results show that overall the students performed slightly better than in previous semesters. However, this must be taken with a grain of salt due to small sample space and variances among the student's experiences and abilities. The general consensus among the student's responses is that using such hands-on approach yields a better appreciation for software verification.

VI. CONCLUSIONS AND FUTURE WORK

The use of this approach supports and enhances the teaching of software verification, such as black-box and white-box techniques, assisting in improving the education of software engineers. In particular, this approach requires significant domain knowledge in order for students to adequately test the system. Thus students are exposed to formal specifications domain knowledge which can serve them as they advance in their software engineering careers. This reflects a typical real-world environment in which software quality assurance personnel must gain domain expertise. One of the results of this work is that the Prospec tool is very appropriate for teaching classes in software engineering due to its complexity, large range of output formulas and need for high assurance.

A future goal of this work is to develop standalone teaching modules based on Prospec such that they can be used in courses that are not necessarily focused on testing, but can complement other software engineering topics. In addition, there is a need to conduct a more formal study to assess the applicability of this approach within other software quality assurance courses.

VII. ACKNOWLEDGMENTS

The authors would like to thank the students in the CS 4387/5387 (Software Integration and V&V) class. The students are listed alphabetically based on their last name:

1. Juan Angulo
2. Salah Atiyeh
3. Roberto Camacho
4. Arih Carrera
5. Julio Corral
6. Erick Ferreira
7. Roberto Fierro
8. Adrian Garcia

Abstract—Mutation analysis is a testing strategy that consists of using supporting tools to seed artificial faults in the original code of a software under test, generating faulty programs (“mutants”) that are supposed to produce incorrect outputs. Novice programmers suffer of a wide range of deficits due to defective training processes. We argue that the incorporation of experiences on mutation testing in programming courses adds valuable knowledge to the learning process. In this paper we evaluate the effects of using mutation testing to improve the learning process of students in programming courses. We present results of experiments and analysis involving undergraduate students. These experiments are the continuation of a previous work in which we raise empirical evidences that the adequate incorporation of mutation testing in programming courses contributes to form an effective environment that fosters learning. To do so, we provide a mutation testing tool to promote the practice of mutation testing by novice programmers. Through practical experiences and several analysis survey we measured the effects of using the mutation testing criterion to teach programming. In addition, we collected the opinion of senior students who already knew mutation testing concepts about their opinion on the usage of mutation concepts to teach novice programmers. Our findings reveal that the effective use of mutation analysis concepts contributes to the learning process, making students see the code as a product under development that is the result of a careful manual coding process which they need for measuring and predicting the effect of each command. The main contributions discussed in this paper are: (1) presenting results of an empirical analysis involving undergraduate students, thus giving us preliminary evidence on the effects of the novel practice; (2) exposing possible practices to explore mutation testing in programming classes, highlighting the limitations and strengths of such strategy; and (3) a mutation testing tool for educational purposes.

Keywords—mutation testing; experimental study; computer-aided instruction.

I. INTRODUCTION

Currently, in the information technology area, there is a high demand for highly skilled developers. There are several vacancies in the technology field due to the lack of well-prepared professionals. Part of this problem can be associated to “poorly” designed programming courses. Often, traditional programming teaching methods may not meet all students’ expectations [1]. Novice programmers suffer a wide range of deficits and professional limitations due to defective training processes [2]. Then, novice students have not had enough exposure to programming languages to develop strategies for

solving problems in a computer programming setting [3]. Even competent programmers make certain mistakes that can be used as experience to improve the learning processes. Among these mistakes, one is the off-by-one error, which happens, for example, when an iterative loop that was meant to iterate ‘ n ’ times iterates either ‘ $n - 1$ ’ or ‘ $n + 1$ ’ times. These errors arise when programmers use the wrong relational operator or fail to note that a sequence starts at zero rather than one.

A possible way to improve the learning process of novice programmers is by the practice of introducing software testing activities in the classroom [4]. Teaching testing techniques and criteria in the very beginning of programming courses may represent an effective practice to improve students’ skills [5]. Conceptually, Software Testing is the dynamic process of executing a software product (or a software module) aiming at checking whether it corresponds to its specifications, considering the environment in which it was designed [6]. Testers must use testing techniques and criteria to achieve more effective testing. Testing techniques and criteria provide systematic ways to find conditions to raise the probability of finding errors. Several researchers have been studying the application of testing practices in conjunction with programming fundamentals in programming courses [5, 7, 4]. Implementing this practice may lead to gains under two aspects: (1) supporting students to learn technical programming language concepts more quickly, and (2) creating the habit of applying testing techniques in their systems under development earlier.

Despite the fact of several researchers have been dedicated efforts on raise evidences on using testing concepts to support teaching programming, there are few studies on the effects of combining specific testing criteria and programming courses. In this context, in a previous study [8], we have presented a prototype of a mutation testing tool specially designed to supporting the learning process. *Pascal mutants* supports the mutation testing criterion of Pascal programs, being extremely useful to novice programmers. Mutation Testing [9] is a fault-based testing criterion that consists of introducing small syntactic changes into a *Software Under Test* (SUT), creating slightly different versions (so-called mutants) in order to obtain a test suite capable of identifying all of the seeded faults (small

errors) [9, 8]. Then, the tester has to analyze defective codes, providing test cases to produce distinct outputs for the SUT and its mutants [9]. Mutants are often similar to the faulty programs written by novice students in programming courses. However, the cost of mutation testing has traditionally been so high it cannot be applied without full automated tool support.

The main goal of this paper is to provide preliminary evidences and discussions on the effects of exploring the criterion mutation testing to teach programming foundations/fundamentals to novice programmers. To do so, we have conducted an experiment on using *Pascal mutants* and mutation testing in an undergraduate-first-year class. We have observed the students behaviors when in contact with the mutation testing criterion. Then, we have measured the effects on using mutation testing through a detailed questionnaire to assess the student's level of understanding over specific fragments of code. In addition to that, aiming to assess the opinion of senior undergraduate students enrolled in a software testing course, we have prepared a proper survey to assess their opinion about the premature contact with mutation testing by novice programmers. Empirical and survey-based studies have raised evidences the usage of mutation testing might improve the learning process under different aspects such as better general grasp levels and better understanding the abstract concepts that may result in the improvement of the professional skills. Then, the contributions associated to this paper are: (1) raise empirical evidences on the effects of exploring mutation testing criterion to teach programming; (2) highlighting the limitations and strengths of mutation criterion to teach novice programmers; and (3) a mutation testing tool for educational purposes. The main implication of our exploratory study is the indication of the importance of introducing software testing concepts to teach novice programmers.

II. RELATED WORK

Several researchers have been exploring the idea of using software testing integrated to programming courses in order to improve the learning process. Most of these approaches are associated to functional testing, which mean, they are not related to source code analysis. However, we consider these studies related to our research because they look to educational purpose of the usage of software testing. The main difference between our study and the group of studies presented below is the fact that we are interested on measure the educational effects of a single specific testing criterion.

Jones [7] revealed evidences on the benefits of presenting testing concepts in conjunction to programming classes instead of separated courses. The study states three points: (1) software testing represents a good topic to be inserted in the regular curriculum of technology courses; (2) students need the practice of testing activities to improve their educational experiences; (3) there is a basic set of recommended testing skills; and (4) regular courses should impart testing experiences.

Brito et al. [1] present an approach in which test cases (test input and test output) are rearranged and reused to improve the quality of activities performed by novice programmers in

programming courses. Empirical studies involving about 60 undergraduate students show that when students have some previous implemented test cases to evaluate their solutions, the quality of the programs produced by them increases significantly. Buffardi and Edwards [4] present an approach to quantitatively evaluate the effects on presenting software testing concepts to students. The study involves programs generated by 883 different students over five years. However, the study focuses on evaluating software testing behaviors that students exhibited in introductory computer science courses. Several (76%) of the students have designed different testing behaviors on different assignments, leading to good habits among students. Souza et al. [10, 5] believe that the integration of testing concepts and programming courses can improve the learning process in students. Then, the studies propose and validate a web-based tool that sets an environment in which students can submit their solution for a given problem, and then, their solution is "tested" against the reference program's.

III. METHODOLOGY

This section presents concepts and methodology for our investigation.

A. Mutation Testing

Mutation testing [9] is a fault-based testing criterion which relies on typical mistakes programmers make during software development. Mutation approaches seed defects into the SUT in order to examine its behavior. This criterion relies on the *Competent Programmer* and the *Coupling Effect* hypotheses. According to the former, the Competent Programmer's hypothesis states that due to the fact that programmers are competent, they write programs that are close to being correct. Therefore, it can be assumed that a program written by a competent programmer has simple faults; often, they are small syntactic changes. The Coupling Effect hypothesis states that complex faults result from the combination of small ones. As a result, fixing the small faults will probably solve the complex ones. Then, regarding the testing process, finding artificial defects allows the effective detection of real faults.

Mutation testing creates several versions of the SUT with slight faults. In practice, given an original program P , the criterion consists of creating a set of mutants, M , that are slightly modified versions of P . "Mutation Operators" define the modification that must be applied to P . Mutation operators are necessary to insert small defects into the original program, creating mutants. These defects are generated by using a set of simple syntactic rules. Then, for each mutant m , ($m \in M$), the tester runs the test suite T originally designed for P . If there is a test case t , ($t \in T$), and $m(t) \neq P(t)$, this mutant is considered dead. If not, the mutant is considered alive and the tester should improve T with a test case that reveals the difference between m and P . If m and P are equivalent, then $P(t) = m(t)$ for all test cases.

Creating mutants from an original program involves a set of rules established by mutation operators. These rules change the original program, creating mutants with syntactically valid

changes. Typical mutation operators modify expressions by replacing, modifying, inserting, or deleting either operators or variables. For instance, Figure 1 presents the original program and one of its mutants. In this particular case, a mutation operator replaces the logic operator (Line 3).

1	(**** Original *****)	1	(**** Mutant *****)
2		2

4	c := 1	4	c := 1
5	else	5	else
6	c := 0;	6	c := 0;

Fig. 1: Original and Mutant Source Code.

An undecidable issue in mutation testing comes out when the fault injection creates mutant programs that are functionally equivalent to the original program. Namely, original programs and *Equivalent Mutants* will always yield the same results. Detecting mutants that are equivalent to the original program is one of major obstacles for practical usage of mutation testing, requiring the full knowledge of tester who must perform this task manually through code analysis. However, using a mutation testing tool, once a tester has marked all possible equivalent mutants for an SUT, it is possible to compute the “mutation score”. The mutation score is a coverage metric and it is expressed as the ratio of the number of dead mutants over the number of non-equivalent mutants. Thus, when the tester reaches a 100% mutation score, all non-equivalent mutants are said to be dead.

B. Pascal Mutants

Pascal mutants implements the mutation testing criterion at the unit level of Pascal programs. *Pascal mutants* is available online as an open source tool in a Sourceforge repository, along with its supporting documentation and several example programs. The link to access the tool is <http://sourceforge.net/projects/pascalmutants/>

1) *General Structure and Wizard*: In Oliveira et al. [8] we have defined a prototype of a mutation testing tool for educational purposes. In this study, we have significantly improved that prototype composing *Pascal mutants*. Through seven specially designed mutation operators, testers (students) can generate faulty versions of an original program code. Students can select specific mutant operators, create testing projects, manage and execute testing data, check the mutation score and compare original and mutant codes. Technically, the implementation of *Pascal mutants* integrates six main modules: (1) a Pascal syntax analyzer and syntax tree generator, (2) a compiler and loader of mutants, (3) a test case manager, (4) a results evaluator (test oracle), (5) a mutant manager, and (6) a test reporter. Further technical details of *Pascal mutants* can be found in our preliminary study [8] in which *Pascal mutants* were presented as command-line based implementation.

Regarding the scope of this study, we have extended *Pascal mutants* to work under a robust wizard that supports all of the functionalities presented previously. After results of some pilot studies, we have designed this wizard towards

promoting the education purpose of mutation testing. Then, this wizard is important for novice programmers in order to explore mutation testing to understand parts of the source code. The wizard leads the programmer’s focus to important parts of the code instead of mutation testing details. It has an intuitive and user-friendly interface. Through a set of UIs (*User Interfaces*) provided by *Pascal mutants* students can perform several activities: (1) manage test cases, (2) analyze mutants and an original program, (3) mark equivalent mutants, and (4) visualize dead, alive, and equivalent mutants. Students can examine testing statistics (i.e., number of alive, dead, and equivalent mutants), including the mutation score. After defining a prototype for *Pascal mutants* in Oliveira et al. [8], we have implemented *Pascal mutants* in a way that it encourages the users to adopt an autonomous posture during the learning process.

2) *Mutation Operators*: *Pascal mutants* implements seven mutant operators that are presented in Table I. These operators are not a complete set with regard to the identification of an ideal test suite for testing purposes. However these mutation operators are sufficiently complete to produce sets of mutants useful for educational purposes. In addition, the generic structure of the tool enables testers to add new mutation operators.

C. Mutation Testing Supporting Novice Programmers

Defining inputs that differ between SUT and mutants requires testers to fully understand the programs’ data and information flow, from assignment of values to their use. Naturally, this full understanding depends on the specific program’s control structure of the programming language in which the SUT is written. The process of reading and understanding source code may be trivial for advanced programmers, however it may be challenging for novice programmers. On the other hand, reading source code to perform mutation testing may represent a valuable process of learning for novice programmers. Section IV presents empirical evaluations on using mutation testing and *Pascal mutants* in practical programming classes.

IV. EMPIRICAL EVALUATION

Aiming at verify the practical usage of mutation and *Pascal mutants* to support the learning process of novice programmers, we have conducted a two-fold independent evaluation:

(*Analysis 1*) A practical empirical evaluation of using *Pascal mutants* in an undergraduate course on “Computer Programming” for first-year students. This experiment aims to provide a direct assessment on using mutation testing in a programming course for beginners (Subsection IV-A). We have compared the process of code analysis and understanding by students using mutation testing criterion and regular compilers; and

(*Analysis 2*) A survey analysis involving senior students in an undergraduate course of “Software Testing and Inspection”. This survey aims at measuring the opinion of students who are familiar with mutation testing however had no contact with mutation concepts when they were novice programmers (Subsection IV-B).

TABLE I: *Pascal mutants* Mutation Operators.

	mutation operator	acronym	original code	mut. operator's effect
1	Change of Arithmetic Operator (for other arithmetic operator)	CAR	<code>c := a + b;</code>	<code>c := a - b;</code>
2	Change of Relational Operator	CRO	<code>if (a > b) then</code>	<code>if (a < b) then</code>
3	Change of Logical Operator	CLO	<code>if (a && b) then</code>	<code>if (a b) then</code>
4	Adding "NOT" Operator in Control Expressions (if, while, etc)	ANOiCE	<code>if (a > b) then</code>	<code>if (NOT(a > b)) then</code>
5	Removing A Command	RAC	<code>a := b; b := c ;</code>	<code>a := b; ;</code>
6	Change for a Scalar Constant for its Successor and Predecessor	CSCSP	<code>const average = 5;</code>	<code>const average = 6;</code>
7	Change the "Repeat" Command for "While" and vice versa	CRCfW	<code>repeat a := a*count; count := count+1; until (count < 7);</code>	<code>while (count < 7) do begin a := a*count; count := count+1; end;</code>

We now provide a detailed view of each analysis: research questions, the methodology we followed, and the experimental/survey strategies we have designed.

A. Analysis 1 – a practical experience on using mutation by novice programmers

This study is designed to answer the following *Research Questions* (RQ):

- RQ1: Can the mutation testing criterion facilitate the learning process of novice students in programming courses?
- RQ2: What are the trade-offs and recommendations of using mutation testing to support the learning process in programming courses?

We have followed the same protocol established in a previous pilot study detailed in Oliveira et al. [8]. Then, we were able to correct some imperfections, such as the need for a background on software testing by the students. In general terms, the idea of the experiment is to provide the very first contact of novice students in a programming course with mutation testing. To do so, we use the resources and functionalities provided by *Pascal mutants*

The subjects students involved in the experiment consisted of 28 undergraduate students enrolled in the second semester course on "Computer Programming" UNESP campus Rio Claro, São Paulo, Brazil (*Universidade Estadual Paulista*). The set of students were enrolled in a Bachelor of Computer Science's course and they had a prior knowledge of about fifty-hours course of algorithms in Pascal language. Then, one can conclude that the students were considered novice programmers with no background on software testing neither software engineering concepts.

The experiment was conducted in framework of a four-hour course. We have started our experiment presenting theoretical concepts on Software Testing, including definitions and practical examples. Besides the traditional test phases (*Unit, Integration, and System*), the main testing techniques and their particular criteria were presented. Then, we have focused on the mutation testing criterion, detailing each foundation of the criterion. Finally, we have present *Pascal mutants* to the subject students. We presented them a step-by-step on how to create a testing project and how to load test data, identify equivalent mutants, and compare original and muted code. However, during this step of the experiment, the students had no practical contact with *Pascal mutants*

After the aforementioned experimental setup, we conducted a controlled experiment in laboratory. This experiment was composed by a dynamic activity exploring a simple program and a survey to assess the student's level of understating on the program. We then started evaluating the behavior of each student in order to contribute to answering the RQ 2. First of all, we have divided the subject students in two groups. Group 1 (G1) was designed to conduct the experiment using a regular Pascal Compiler. Group 2 (G2) was designed to conduct the experiment using *Pascal mutants* and exploring the concepts of mutation testing. Then, we have set G1 to be a *control group*, and G2 to be our *treatment group*. We gave no further explanations and advises to any group to avoid potential biases.

The activity assigned to the students consisted of analyzing a blind code, trying to understand its functionality through code analysis and running it against different inputs. We did not provide any specification about the program functionality. Equally, the identifiers assigned to each variable offered no clues about their usage. The code represented a program to figure the classical sequence of numbers named *Fibonacci series*. Starting from one and one, Fibonacci series is a sequence of numbers in which each subsequent number is the sum of the previous two, for example: "1, 1, 2, 3, 5, 8, 13 ...". In our subject program, three parameters were accepted to represent, respectively, (1) the first element of the series, (2) the second element of the series, and (3) the limit of the series. During the previous classes, we did not offered prior contacts with the Fibonacci algorithm.

Aiming to provide empirical evidences to answer RQ 1, we elaborated a questionnaire that is able to measure the level of understating of the students. The questions were open about the program, possible specific changes in the source code, and they were designed to cover the students' attitudes toward: (1) general aspects about the program; (2) influence of the starting points in the algorithm; (3) influence of the stop conditions (ending points); and (4) relation among number of iterations and parameters. Table II presents all of the survey's questions.

Section V presents the results of this empirical evaluation.

B. Analysis 2 – a survey analysis with senior students

We believe, after having some experiences during an undergrad course, students are able to notice whether some activities could help them in some period of their student lifetime. Then, we designed a survey to assess the opinion

TABLE II: Analysis 1: Survey's Questions.

#	Questions
Q1	Describe what your thoughts are about the main functionality of this program?
Q2	Is there any difference if operator ' \leq ' were used instead of operator ' $<$ ' in the command ' <i>while</i> '? Regarding the variables ' <i>a</i> ', ' <i>b</i> ', and ' <i>c</i> ', in which situations may differences occur?
Q3	For the majority of inputs, would the number of interactions in the loop be different if the line 6 has the following command: ' <i>b</i> := 2 * <i>b</i> '? Justify your answer using examples.
Q4	What would happen in the case where line 6 has the following statement: ' <i>b</i> := <i>b</i> + <i>a</i> '? Justify?
Q5	Once ' <i>a</i> = 3', ' <i>b</i> = 5' and ' <i>c</i> = 40', how many terms would be printed in the program output if the operator '+' was replaced by '*' in the command ' <i>while</i> ' (line 1)? Justify?

of senior students about learning mutation testing during the very beginning of programming courses. Then, this analysis aims at identifying whether senior students, who are familiar with mutation testing, would advise novice programmers to practice mutation testing to improve their programming skills.

Unlike from the students involved in the previous experiment, the set of subject students that composed Analysis 2 consisted of 21 students enrolled in the undergraduate course on "Verification, Validation, and Software Testing" at USP (*University of Sao Paulo*). These students had prior knowledge of Software Engineering, concepts of Software Testing, and more than three programming language. Once the course is offered for a broad audience, the experiment involved undergraduate students from three different bachelor courses: (1) *Computer Science* (33%); (2) *Information Systems* (14%); and *Computer Engineering* (52%). Additionally, they had between 6 and 14 semesters of course, most of them having 8 semesters of course. During the course, the students faced several experiences on using the mutation testing criterion. In this context, one can notice the students were pretty experienced and some of them were already employed by software developing companies.

At the end of a complete course on Software Testing, we provided an eight-question survey aimed at assess what the students' feelings on using the mutation testing criterion as an activity to support the learning progress of novice programmers. The questions were focused on mutation testing practices and testing tool support for novice programmers. The complete survey, the possible answers, and the results are presented in Table III. The provided questions were objective and one can notice the possible answers and the percentage of the students' opinions about each issue through the column "Results". Section V provides further analysis and evidence collected from this questionnaire.

V. RESULTS AND ANALYSIS

In this section we present the results achieved from the aforementioned analysis. In addition, we present possible answers for the pre-defined RQs by Analysis 1. Results and conclusions provided from the survey assessment are presented. Finally, we raise some key points about the practice of using mutation testing concepts to add knowledge to the learning process in programming courses.

A. Results to Analysis 1

Regarding Analysis 1, we evaluated each response applying the following scale-point: 3 points for complete/correct response, 2 points for incomplete/partially correct responses, and 1 point for incoherent/wrong responses. Then, each student received a score based on his performance during the experiment. Regarding all of the five survey questions (Table II), the students must have a score varying from five to 15 points. To avoid bias during this process, at least two of this paper's authors checked each question's responses. In cases of disagreements about the scores, a third author was appointed to grade the response. Further, we made all these verification ignoring group distinctions, once there was no information about the groups in the survey. Then, after defining the scores, each survey was associated to a student and, consequently, the groups were identified.

Figure 2 contains two fan plots representing an analysis of each group performance. This analysis highlights the quantity of questions considered correct, partially correct, or incoherent/wrong for each treatment. This evaluation considers all of the questions answered by each group. Summarily, students using *Pascal mutants* (G2) answered 52% of questions correctly (Figure 2b), while students in G1 only 38% (Figure 2a).

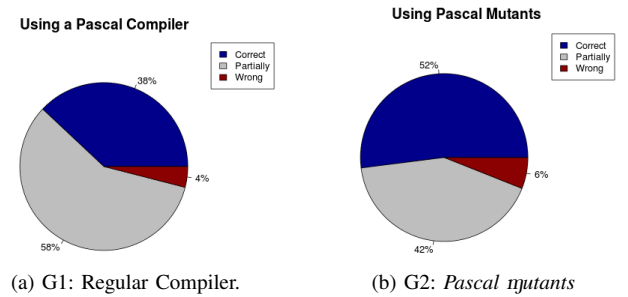

Fig. 2: Comparison between Groups' Performance.

Along the same lines, regarding a broad evaluation on each question included in our experiment, Figure 3 presents a bar graph comparing the percentage of correct, partially correct and wrong answers for each question, in each group. Briefly, it is possible to notice a considerable improvement from G1 (Figure 3a) to G2 (Figure 3b), particularly in the number of correct answers. This shows that the students in G2 were better able to understand the code than those in G1.

Similarly, Table IV shows a bar graph with a comparison between the mean score for each of the five questions. For three of the five questions, the average of the students who explored the mutation tool was higher than the average of students who used a Pascal compiler. For one question (Q5), the average was exactly the same. And only for Q4 the students using a regular compiler obtained better scores.

Another quantitative analysis we made considers the time it took each student to conclude the experiment. To realize this investigation, each student had specified a starting time and an ending time for their experiment. This analysis was performed

TABLE III: Analysis 2: Survey's Question.

#	Questions	Results
SQ1	What were your previous knowledge on software testing before the course?	None 42.86% Intermediary 57.14%
SQ2	Do you encourage mutation testing concepts to be presented in conjunction to programming foundations?	Yes 38.10% Yes, superficially 52.38% No 9.52%
SQ3	What might be the effects of practicing mutation analysis by novice programmers?	Better programs 61.90% Skilled better programmers 28.57% None 9.52%
SQ4	Do you consider regular testing tools useful to teach programming foundations?	No, they need to be alleviated 9.09% Yes, using basic functionalities 54.55% Yes 36.36%
SQ5	Do you consider the mutation testing tools useful to teach programming foundations?	No, they need to be alleviated 61.09% Yes, using basic functionalities 19.55% Yes 19.4%
SQ6	Disregarding the specific course on software testing, considering your course's curriculum, software testing concepts:	were not presented 27.27% were fairly presented 13.64% were poorly presented 59.09%
SQ7	Do you think specific educational testing tools might be useful on creating good programming habits?	Yes 59.09% No 41.1%
SQ8	Do you think designing test cases through mutation testing might be useful to improve the learning capacity of novice programmers ?	Yes 72.73% No 27.27%

Fig. 3: Percentage of Hits by Question.

TABLE IV: Mean Score for Each Question by Group.

Mean Score for Each Question					
Group	Q01	Q02	Q03	Q04	Q05
G1 – Regular Comp.	2.5	2.4	2.1	2.4	2.3
G2 – <i>Pascal mutants</i>	2.6	2.6	2.5	2.3	2.3

to help answering RQ 2, involving the trade-off analysis on applying the mutation testing criterion to teach programming. RQ 2 was actually designed to complement the results from RQ 1 including the statistics from the Analysis 2. Figure 4 represents three bar plots containing the total amount of time in minutes and the final score of each student separated by the groups they belong to. Students from G1 were quicker to complete the experiment than students from G2 (Figure 4a). Altogether, students in G2 took 17 minutes more than students in G1 to finish their experiments. On the other hand, students from G2 and obtained better scores (Figure 4b). Figure 4c presents a comparative analysis of the mean time and the mean score between the two groups.

In order to provide a specific comparison involving time and scores of the groups, we established a quantitative value named *Performance Factor* (PF). This factor is figured out through the score over the time in minutes. This number represents how effective the students were in considering their time and score. Table V presents the performance factor of some student divided by groups. G1 obtained an average PF of 0.40 and G2 obtained 0.25. Which means that the control group had a high PF and G2 spent a lot of time to complete their survey.

TABLE V: Performance Factors.

G1	.17	.22	.45	.36	.44	.45	.50	.43	.40
G2	.18	.23	.30	.25	.40	.40	.22	.17	.24

Through empirical analysis, effects of using the *Pascal mutants* tool and mutations testing to tech novice programmers are positive. It is possible to notice that stats and data collected from Analysis 1 revealed *Pascal mutants* positively affects the understanding about the source code. In general, students that have used *Pascal mutants* to conduct their activities obtained a better mean score in all of the questions with the exception of Q4. We noticed students in G1 tried to solve the survey's questions through trial and errors approaches. They explored the compiler with different inputs and observing the program behavior. On the contrary, students in G2 had to think more

carefully about the algorithm to “kill” mutants, consequently they were able to formulate more accurate answers about the program. Using the mutation analysis was a valuable experience for novice programmers.

We observed that students in G2 took a long time to finish their experiments. This reveals that the practical usage of a mutation testing tool instead of regular compilers may be considered a disadvantage. This is due to the fact that students in G1 had previously obtained skills to conduct the experiment using their preferred Pascal compiler. On the other hand, students in G2 had to dedicate more effort to understand all of the resources and functionalities provided by *Pascal mutants*.

Regarding RQ1, we obtained valuable evidence that, for novice programmers, the mutation criterion can facilitate the learning process. The process of finding inputs to generate different outputs for the original program and mutants aids in the learning process. Further, the comparative analysis among similar source codes leads the student to play a tester role. In this sense, novice programmers have to perform successive evaluations and take decisions that contribute to the complete understanding of the semantic rules associated with the programming language. Then, the tool implemented and the experiences reported in this paper have helped students in understanding more deeply the concepts of the Pascal programming language. Numerically and visually, Figures 2 and 3 represent how efficient is the mutation testing to improve novice programmers’ experiences.

Regarding RQ2, which was designed to define the trade-offs of our approach, we consider the experience reported in this paper reveals important findings. Through our experiment, the main trade-off we noticed was associated with the time to finish the activity. Students using a mutation tool will take a considerable time to figure inputs able to “kill” mutants. We noticed a need for specific strategies to make the usage of mutation testing faster, intuitive and efficient. Figure 4 presents some visual evidence on how efficient and cost effective is using *Pascal mutants*. During the experiment, students from G2 designed several manual outlines of the algorithm’s behavior, contributing to the delay finishing their activity.

Still regarding the RQ2, during this research, we noticed several efforts and prerequisites that can be considered trade-offs of using a mutation criterion in the learning process of programming. Among these trade-offs we highlight three needs: (1) supporting material about mutation testing, (2) basic knowledge of software testing concepts, and (3) introductory lessons of software testing. However, we define the lack of adequate tools as the major limitation to a wide adoption of this approach. Regular tools for mutation testing are not indicated for novice programmers. In this context, to apply this testing criterion in programming courses, teachers have to adapt modules from regular mutation tools or even implement their own tools. In this context, whether Pascal is the programming language to be taught, we strongly advise teachers to use Pascal Mutants or any other adequate supporting tool.

B. Results to Analysis 2

Regarding the survey assessment, whose results are presented in Table III, it is possible to notice that the senior students appreciate the idea of exploring mutation testing to complement the learning processes of novice programmers. Besides that, we noticed that before coursing a specific class focused on software testing, 42% of the students declared they had no previous knowledge on this topic (SQ1). That is a large percentage of concern that might directly effect the quality of the software developed by that student when he/she becomes a professional. It was notable the number of students (SQ2 – 90%) that agree with the practice of including mutation testing in programming courses. Besides several benefits such as, programmer skills, programs’ quality, good programming habits, results collected from SQ3, RQ4, and SQ5 revealed that the students think it is necessary to have software testing tools specially designed to teach programming, as regular testing tools might be quite complex. 90% of the students think that practicing mutation testing contributes to better programmers (SQ3). RQ4 and RQ5 show that most of the students believe that regular testing tools are not recommended for novice programmers. This result is even worse for mutation testing tools, as 61% of the student believe the functionalities of regular mutation testing tools need to be alleviated. SQ6 and SQ7 lead us to consider the association of software testing notions to novice programmers: 87% of the students were not introduced to testing concepts and when introduced, these concepts were poorly explored (SQ6); 60% of the students see a strong relation between specific education testing tools and good programming habits. Finally, SQ8 reveals almost 73% of the students agree that the process of designing test cases to feed a mutation testing tools is a good exercise to improve the learning capacity of the student.

Further evidence can be collected through the quantitative analysis provided by Table III. In front of this evidence, we have two different conclusions: (1) mutation testing is one of the most appropriate testing criterion to help teaching programming in different languages; (2) there are no mutation testing tools specifically designed for novice programmers. In the context of the second conclusion, we can define the *Pascal mutants* states a significant contribution, being a tool specially designed to help novice programmers.

C. Discussion

The results raise some key points related to our own point of view about the usage of testing concepts in programming courses. According to our experience, the contact between novice programmers and testing activities may be profitable, establishing positive habits starting at the beginning of their professional career. For instance, regarding the questionnaire, we believe that cases in which the mutation approach resulted in minor or slight endorsements (S5 and S7) are due to the fact that regular mutation testing tools are not implemented to educational purposes. Then, some students recognize the importance of exploring mutation, however they highlight that efforts are necessary on using mutation testing tools properly.

Fig. 4: Experiment: Times and Scores.

Most of the seniors believe mutation could be useful to complement their experiences when they were beginners, once testing tools specifically designed for educational purposes are explored. In addition, the students' contact with testing practices could contribute to revealing the importance of testing activities, providing the development of reliable applications.

Regarding Analysis 1, dividing the students into different groups may represent an effective environment for learning. In terms of code understanding, Table IV shows that mutation analysis leads the students to verify all of the code statements carefully, helping them to understand code issues more deeply. The score differences revealed by Table IV are small, however they are favorable to the group which has used mutation analysis to conduct the activity. The small differences are justified because the study conduct in this paper is considered small and the students were evaluated based on only 5 questions. Then, we still consider these results as significant. We believe this difference trends to be more representative with more deep studies, for example, a study comparing two different classes from different departments or universities in which only one group has previous knowledge on testing concepts. In addition, we believe the characteristics of our study (i.e., number of subjects, target systems, etc.), when contrasted with the state of the art in literature, represent a first step towards the generalization of the results achieved in this study.

In this scenario, additional ideas to explore similar environments may evolve into two scenarios: (1) simulating real teams of developers and testers, and (2) using a test case developed by one group in order to test systems developed by different groups. In this context, it is important to plan all of the activities before the beginning of the course because the mutation testing criterion will take more time than regular activities. We believe other similar activities may influence novice programmers to improve their skills and their knowledge about general program comprehension. It is important to conduct broader experiments to obtain a more in-depth validation of the ideas presented in this paper. A possible future experiment may involve the observation of two different groups of students during a semester-long course. Another

possibility is to reproduce the same experiment using different programming languages and compare the results.

D. Threats to Validity

An *internal* threat to the validity of our study concerns the better results earned by G2, once they spent more time analyzing the source code during the mutation analysis. Furthermore, an *external* validity to the study is the fact that the results observed in our analysis are provided by a small-scale study. Regarding the survey analysis presented in Table IV, we noticed a threat associated with its *conclusion* validity, since senior students may be too far from first-year students to really remember what it was like, leading them to misinterpret the survey. We consider mutation testing a powerful resource to catch students' attention and improve their learning processes, however students have to face continued experience on mutation testing to make their learning process more valuable.

VI. CONCLUSION

This paper advances a preliminary study on evaluating the mutation testing criterion as to improve the learning processes of novice students in programming courses. We present a two-fold analysis (an practical analysis and a survey assessment) on the effects of using mutation testing to improve learning processes in programming courses. As methodology, we developed and provided an open-source mutation testing tool. *Pascal mutants* is specially designed for education purposes. Results reported in this paper are enough to reveal that mutation testing criterion is profitable for programming courses. Two main contributions are associated with this study: (1) the analysis states that mutation testing can be seen as a promising testing criterion to support teaching programming foundations to novice students; (2) this study provides a more stable version of *Pascal mutants* which supports mutation testing to the educational purpose of teaching programming for novices students. We consider this second contribution as relevant, once there is a notable lack of testing tools for educational purposes. Also, we consider the usage of software testing concepts as a profitable strategy to teach novice programmers, composing the main implication of our research.

Abstract—In order to reduce students' test anxiety, collaborative testing was suggested as an evaluation strategy. However, few studies have focused on testing group construction, especially when an important factor, i.e., group diversity is taken into consideration. In this paper we conducted a case study to assess the association between group diversity and test anxiety in collaborative testing. The results observed may indicate that: 1) around 20% of students suffered from test anxiety to some extent in either an individual test or a collaborative test; 2) collaborative testing could alleviate test anxiety, whereas the effect is not statistically significant; 3) there exists a moderate positive correlation between group diversity and test anxiety in collaborative testing. The results of the study may suggest limiting group diversity in collaborative testing in order to alleviate test anxiety.

Keywords—group diversity, test anxiety, collaborative testing

I. INTRODUCTION

Test anxiety is a prevalent problem among the students of the world, and it hinders students' performance resulting in emotional or physical distress, difficulty concentrating, and emotional worry. In order to cope with the problem, the literature suggests various solutions. One solution is to evaluate students by collaborative testing where discussion and information sharing are allowed. It is a common belief that collaboration reduces test anxiety by removing the sense of competition and giving students a sense that they are not alone. A previous study showed that students rated collaborative tests as more pleasant. Students reported experiencing less anxiety and indicated they continued to learn about the material during testing [1].

When collaborative testing is used as evaluation strategy, an interesting question that arises is how to construct test groups. Group diversity has received considerable attention in enhancing group work achievement, however diversity may also introduce an additional problem from a psychological viewpoint. For instance, one problem is the free-rider or sucker effect where non-performing group members reap the benefits of the accomplishments of the remaining group members with little or no cost to themselves. [2]. This happens frequently when the group members have huge differences in functional ability. Also, other studies discovered evidence of the association between multiculturalism and uncomfortable feelings in a language class [2].

In this paper we conducted a case study to assess the associ-

ation between group diversity and test anxiety in collaborative testing. We address the following three questions.

RQ1: How prevalent and how severe is test anxiety? Previous literature has mainly focused on the prevalence and effects of test anxiety among children in compulsory education.

RQ2: Does collaborative testing alleviate test anxiety? To what extent is the effect? It is a commonly held belief that collaborative testing reduces anxiety. Therefore, it is of interest to measure the significance of the effect by using an existing scale and statistical inference.

RQ3: Does group diversity have any influence on test anxiety? In the literature, researchers have shown that diversity had significant influence on learning outcomes and several group construction models have been developed for the purpose of maximizing diversity within groups [3] [4]. Therefore, it is also of interest to investigate whether diversity affects students from a psychological viewpoint.

The rest of this paper is organized as follows. Section II describes the background knowledge of collaborative testing and group diversity. Section III provides a detailed explanation of a case study including participants, data collection and analysis. Section IV discusses conclusions and possible future research directions.

II. BACKGROUND

This section first presents the background knowledge including advantages of collaborative testing and testing anxiety, it then reviews group diversity, which is an important factor when constructing groups.

A. Testing Anxiety and Collaborative Testing

"Test anxiety is a combination of physiological over-arousal, tension and somatic symptoms, along with worry, dread, fear of failure, and catastrophizing, that occur before or during test situations" [5]. It is often caused by many factors like fear of failure, lack of preparation, poor test history. The symptoms are not only physical but also emotional and behavioral/cognitive. Symptoms include fear, disappointment, difficulty concentrating, thinking negatively and so on. It is a commonly held belief that test anxiety hinders the students testing and learning performance and has adverse effects on the students testing outcomes. According to a survey, test anxiety occurs frequently among college students especially

for the subject of math, and it is more likely to occur among women than among men and among students with inadequate high school math backgrounds [6]. Collaborative testing refers to a test environment where several people work together to come up with the solution and cooperation and discussion are involved. Individuals in the same group share resources including task-related knowledge, potentially useful information, possible solutions or ideas, so that collaborative learning leads to deeper understanding of the materials [7]. Collaboration reduces anxiety due to skills deficit since students know they will have the knowledge of other students to aid them [1]. Lusk et.al. argued that collaborative testing provided students with the opportunity to become more proficient with critical thinking and collaboration skills, and all students reported decreased test anxiety [8].

B. Group Diversity

In group organization theory, group work diversity refers to the degree of difference among group members. Although the effects of group diversity are still unclear and at times findings seem inconsistent, there is a lot of evidence in the literature showing positive effects of group diversity on group work achievement. It has been argued that people with different demographic backgrounds have qualitatively different life experiences and thus differ in their knowledge, attitudes, and opinions. This implies that demographic diversity increases the knowledge pool of the group and as a consequence has positive implications for group cognitive complexity [9]. Pelled et al. [10] studied the effects of functional diversity and their hypotheses implied that ability diversity would be positively related to group performance. Jehn et al. [11] found that informational diversity was positively related to group performance and commitment. The diversity in attitudes and values may be associated with positive outcomes (e.g., social integration) or may be unrelated to these outcomes. A number of researchers have argued that it is also important to take into account differences that may be neither readily visible nor job-related, such as differences in personality, attitudes, and values [12]. The use of interest and attendance to predict students' performance has been explored and the results verified their effectiveness. Also, it has been widely reported and commonly accepted that religion has significant effect on the personal behavior [13].

III. A CASE STUDY

We conducted a case study to explore our research questions. We first provide the information about participants, then describe the data collection procedure, then analyze the results, and finally report the threats to validity.

A. Participants

TABLE I. GROUP SIZE

Test2	collabrative	69	24	2.91

We conducted a case study in a mathematics class in the fall semester of 2014 at a university in Connecticut, USA¹. The

¹The experimental study was approved by institutional review board.

class (2 sections) consisted of 71 students. The students were enrolled in a first-year undergraduate mathematics course for non-STEM majors. Students took two monthly exams of the same complexity². It was announced that the grades of both the exams would count as parts of the final course grades. The first exam was an individual test, whereas, the second exam was a collaborative test. In order to ensure the diversity within group, the groups were constructed using a clustering-based grouping model proposed in our previous study [3].

B. Data Collection

With the purpose of quantifying the testing anxiety, we used the Westside Test Anxiety Scale, which is a brief instrument designed to identify students with anxiety impairments. The scale items cover self-assessed anxiety impairment and cognition which can impair performance [14]. We obtained this information by questionnaire shortly after the test. It is important to note that we revised some questions since the original Westside Test Anxiety Scale questionnaire is more general. For example, question 3 was originally:

“During important exams, I think that I am doing awful or that I may fail”.

whereas, we changed the object and the revised version was

“During this exam, I think that I am doing awful or that I may fail”.

Students answered questions about anxiety on a 5 point scale, from extremely or always true, to not at all or never true. The final anxiety score was computed by totaling the individual questions and interpreted from comfortably low to extremely high.

In order to formally measure the diversity within group, each student is represented as a d -dimensional real vector. In this study we employed three categories of diversity features; so-called demographic, functional, and personality diversities, following our previous study [3]. The diversity of the group is computed as the sum of distance between each pair of students in this group. For instance, for a group containing n student, the diversity is computed as:

$$diversity = \sum_{i=1}^{n-1} \sum_{j>i}^n d_{ij} \quad (1)$$

where d_{ij} is the Euclidean distance between students x_i and x_j . We obtained demographic and personality features by questionnaire. For the functional features, we simply exported the students' grades from the Grading Center in the Blackboard system³.

C. Results

We go back to address the research questions posed in Section I.

²We gave the two tests in a similar class at another university during the previous calendar year. Both of the tests were individual tests. The mean of students' grades were close, and the difference between the two projects were not significant (indicated by a hypothesis test). Therefore, we carefully claim the two test are of the same complexity.

³Blackboard is an online teaching system at this university.

Fig. 1. The percentage of different anxiety level in individual and collaborative test. CL: comfortably low; NA: normal average; MH: moderately high; H: high; EH: extremely high

RQ1: How prevalent and how severe is test anxiety? Figure 1(a) and Figure 1(b) depict the percentage of each anxiety level for the individual test and the collaborative test respectively. The percentage of comfortably low test anxiety accounted for around 20%, and normal/average test anxiety accounted for around 60%. The percentage of three levels of high test anxiety ranged from 1% to 12% in the individual test, and ranged from 3% to 14% in the collaborative test. We also observed that the differences in percentage for the same anxiety levels between the individual test and the collaborative test were negligible. To sum up, around 20% of the students in this class suffered some extent of test anxiety in either individual test or the collaborative test, and a small percentage, 1% to 3%, of students suffered extremely high test anxiety. The results are consistent with other surveys and studies.

RQ2: How significantly does collaborative testing alleviate test anxiety? As Table II shows, the mean of anxiety score was lower in the collaborative test compared to the individual test, and the difference was around 0.2, which may indicate that collaborative testing alleviated test anxiety. Figure 2 illustrated the distribution of detailed data for both tests. In order to further compare the difference of testing anxiety between the individual test and the collaborative test, we performed a hypotheses test which is an essential method in statistical inference. We formulated the null and alternative hypotheses as follows:

- $H_0 : \mu_{individual} = \mu_{collaborative}$
- $H_1 : \mu_{individual} \neq \mu_{collaborative}$

where μ is the mean. We employed the Wilcoxon rank-sum test. The Wilcoxon test is a non-parametric alternative to two-sample t-test, which does not rely on the assumption that data are normally distributed. [15]. As Table II shows, the p -value for the test is higher than the 0.05 threshold. We conclude that there is not evidence to support the claim that mean scores for the two testing strategies are statistically significantly different.

TABLE II. THE ANXIETY SCORE IN INDIVIDUAL TEST AND COLLABORATIVE TEST

individual		collabrative		p-value
mean	stdev	mean	stdev	
2.55	0.68	2.35	0.69	0.77

TABLE III. THE CHANGE OF ANXIETY SCORE

$\uparrow\%$	$\downarrow\%$	noChange%
17.39	57.97	24.63

Fig. 2. Boxplots of student anxiety in the two tests

A further consideration focuses on the change of anxiety score for each student, and a new variable *anxietyChange* was derived. If a student's anxiety scores were a and b in the individual and collaborative tests respectively, the *anxietyChange* value is $b - a$, which measured the difference of his/her anxiety for the two tests. A positive value of *anxietyChange* indicated an increase of anxiety, denoted as \uparrow in the table. Similarly, a decrease was denoted as \downarrow in the table. We computed the percentage of students in each category; increase, decrease, and no change. We observed that the occurrence of a decrease in anxiety score is most frequent, 57.97%, followed by no change with 24.63%, and increase with 17.39%. For our case study, collaborative testing alleviated testing anxiety, however, these results were not statistically significant.

RQ3: Does group diversity have any influence on test anxiety? We used the Pearson correlation coefficient to measure the strength of the linear association between the explanatory variable *diversity* and the dependent variable *anxietyChange*. The value was 0.58 which indicated there was a moderate positive linear relationship. We further used the Spearman's rho coefficient, which is often used to measure the association between two variables when at least one of the variables is

Fig. 3. scatter plots and regression

ordinal. The coefficient was 0.56, which means there was a moderate positive linear relationship. In order to have a better insight of the correlations, we performed a linear regression analysis and created a scatter plot of the two variables in Figure 3. The results demonstrated that there was a moderate positive correlation between the diversity and test anxiety.

We recorded some typical feedback from the students who had an increase in anxiety when taking the collaborative test. It is obvious that the uncomfortable feelings were caused by severe functional or personnel diversity, which verified that diversity may cause anxiety in collaborative testing.

"My partner actually can not even come up with one solution. I feel like I am doing everything, and also explain to him in that group."

"I believed my mark is destroyed in the terrible group."

"I hate group test, too much pressure when another one staring at you working all the time."

"It is good we share ideas to get to solutions, but I still prefer to working with my friends rather than a random peer."

D. Threats to Validity

We collected data from a single mathematics class. Different subjects have different characteristics. It is of interest to investigate whether the results can be applied to other subjects or not. In this case study, an individual exam was taken earlier than collaborative exam. Internal threats may be introduced by maturation, since the participants are likely to change in terms of their skills, abilities, understanding of the subject matter and proficiency of reading related materials. Further experiments are needed with a different sequence of exams. We used the features and techniques proposed in our previous study to measure the group diversity and to form the groups [3]. We defined a new quantity variable, i.e., *anxietyChange* for the purpose of measuring anxiety difference. In education academia, there are some other evaluation methodologies to assess the group diversity and anxiety level. It would be of interest to construct the assessment by other methodologies.

IV. CONCLUSIONS AND FUTURE WORK

In this paper we conducted a case study to assess the association between anxiety and group diversity for collaborative testing. We observed that around 20% students suffered some extent of test anxiety during either individual testing or the collaborative testing. We also found evidence that collaborative testing alleviates test anxiety, whereas, the effect is **not** statistically significant. Finally, we found there might be a positive correlation between group diversity and test anxiety. In order to validate the conclusion, further studies are needed, especially on other subjects and using participants from other majors. In the future we may also try to identify which diversity features have a positive influence on test anxiety, and which features have a negative influence.

Usability is a key element in successful software. Ensuring the technical usability of a learning solution enables users to focus on their main task, learning. The purpose of this paper is to demonstrate the results of heuristic usability evaluations of digital learning solutions. Heuristic evaluations were conducted on 24 digital learning solutions from one country (Finland) and two country groups (Asian countries and Spanish speaking countries) concentrating on the usability of the user interface of each evaluated solution. The main results of this study indicate that a few heuristics cover the majority of all usability problems (UPs) observed in learning solutions, but these heuristics contain a relatively low proportion of the UPs rated as severe. The results also indicated differences in the usability problems (UPs) observed between different types of digital learning solutions and between digital learning solutions from different countries or country groups.

Keywords—usability; heuristic evaluation; digital learning solutions; usability problems

I. INTRODUCTION

Use of digital learning solutions in learning and teaching has become more popular over past decades (e.g. [12]). There is a wide variety of different digital learning solutions available, but also digital solutions that have not been originally designed for learning are utilized [7]. However, in many cases digital solutions are used in ways their designers had not imagined [9]. Digital solutions that have not been designed for educational use like social media tools [2], virtual worlds [28] and mobile devices [9] are also used in teaching and learning. The use of digital solutions that have not been designed for educational use can lead to challenges with usability [15], particularly in light of usage purpose and context [9].

Evaluating the usability of a digital solution can be approached via various techniques. Techniques include methods for user testing and usability inspections conducted by usability experts. User testing methods range from simple user testing situations [8] to usability questionnaire techniques ([3] [27]). Usability inspection techniques are used mainly to assess

the technical usability of a digital solution by means of heuristic usability evaluations [16], cognitive walkthroughs ([20][29]), time-testing [25] and error counting [4]. These methods have value for various situations, with certain outcomes in mind and can be used on various types of software.

Usability challenges have been explored on various devices, software and services including medical devices [31], software for work contexts [19], e-learning platforms [5], digital textbooks [10] and e-learning courses [30]. Common usability challenges in devices, software and services cover various topics including consistency, informing users about system status, providing feedback and more guidance to users, navigational structures and aesthetic integrity of the user interface ([5][10][30]). Although the topics covered in previous research vary, based on the set of heuristics used, a commonly shared feature seems to be that the majority of usability challenges have concentrated only on a small amount of key issues such as consistency and informing the user about system status ([5][19][30][31]).

Mayes and Fowler [13] argue that the usability of digital learning solutions cannot be measured similarly to software aimed for work contexts. They point out a paradox in digital learning solutions, in that usability is not necessarily a prerequisite for deep learning and argue that approaching learning as a conventional task can be a misguided approach, since learning is commonly a “by-product of doing something else” and that it is this “something-else” that should be supported [13]. However, Kukulska-Hulme [9] raises the issue that for the most part, mobile learning happens on devices that have not been designed with educational use in mind. All devices and software, whether they are designed for educational use or not, could benefit from ensuring a basic level of technical usability, because it enables learners to focus on their learning tasks instead of tackling problems caused by technology [22].

II. HEURISTIC EVALUATION

In this study the aim is to further explore usability challenges in digital learning solutions. The paper is based on an ongoing Finnish research project “Systemic Learning Solutions (Systech)”, which aims at developing research-based principles for the design and use of digital learning solutions (see [6]), where usability evaluation is part of the principles for the design of learning solutions. Main aim of the usability evaluation was to identify usability challenges or problems (UPs) and their severity with heuristic evaluations of digital learning solutions. The study also examined tentative differences in two background variables: firstly, between types of digital learning solutions and secondly, between countries in which the learning solutions were designed.

The following sections address these questions through breaking down and explaining the nature of heuristic evaluations, as well as outlining the empirical process of this study. The results are presented in terms of usability issue type and distribution of usability percentages. Differences between country groups are reflected in the results discussions, which subsequently inform our conclusion which focuses on existing heuristic evaluation methods while proposing improvements based on this study’s findings.

Heuristic evaluation is a systematic method to evaluate the usability of a user interface of software [16]. The heuristic evaluation of software user interfaces is conducted by a small number of evaluators, who go through the interface and judge how well its design complies with commonly accepted usability principles called ‘heuristics’ ([1][17]). Heuristic evaluation is one of the most commonly used usability inspection methods, due to its low cost in comparison with other testing methods and intuitiveness of use [30].

Heuristic evaluations have been developed from extensive design principles [26] to more manageable sets of heuristics ([16][22]) that can be used in conducting these heuristic evaluations (Table I). Heuristic evaluations are commonly conducted in a way similar to that suggested by Nielsen and Molich [16], which have been further developed by Nielsen ([17][18][20]). Furthermore, Nielsen’s [20] work on improving the effectiveness and enhancing the explanatory power of heuristic evaluations has made heuristic evaluation a popular subject of study.

TABLE I. NIELSEN’S [21] TEN USABILITY HEURISTICS FOR USER INTERFACE DESIGN

Heuristic	Description
Visibility of the system status	The system should always keep users informed about what is going on, through appropriate feedback within reasonable time.
Match between system and the real world	The system should speak the users' language, with words, phrases and concepts familiar to the user, rather than system-oriented terms. Follow real-world conventions, making information appear in a natural and logical order.
User control and freedom	Users often choose system functions by mistake and will need a clearly marked "emergency exit" to leave the unwanted state without having to go through an extended dialogue. Support undo and redo.
Consistency and standards	Users should not have to wonder whether different words, situations, or actions mean the same thing. Follow platform conventions.
Error prevention	Even better than good error messages is a careful design which prevents a problem from occurring in the first place. Either eliminate error-prone conditions or check for them and present users with a confirmation option before they commit to the action.
Recognition rather than recall	Minimize the user's memory load by making objects, actions, and options visible. The user should not have to remember information from one part of the dialogue to another. Instructions for use of the system should be visible or easily retrievable whenever appropriate.
Flexibility and efficiency of use	Explanation: Accelerators -- unseen by the novice user -- may often speed up the interaction for the expert user such that the system can cater to both inexperienced and experienced users. Allow users to tailor frequent actions.
Aesthetic and minimalistic design	Dialogues should not contain information which is irrelevant or rarely needed. Every extra unit of information in a dialogue competes with the relevant units of information and diminishes their relative visibility.
Helping users recognize, diagnose, and recover from errors	Error messages should be expressed in plain language (no codes), precisely indicate the problem, and constructively suggest a solution.
Help and documentation	Even though it is better if the system can be used without documentation, it may be necessary to provide help and documentation. Any such information should be easy to search, focused on the user's task, list concrete steps to be carried out, and not be too large

One branch of heuristic evaluation study has focused on increasing the explanatory power of heuristics in analyzing the usability of digital learning solutions (e.g. [22][23][24]). Various attempts have been made to create a set of heuristics that includes both the technical [20] and pedagogical usability aspects [22]. The main aim of these heuristic sets, that combine technical and pedagogical usability has been to emphasize the need for inclusion of pedagogical features when assessing the usability of digital learning solutions ([14][22][23]). In addition, Magoulas, Chen, and Papanikolaou [11] have integrated heuristic evaluation with layered evaluation of adaptive learning environments.

III. RESEARCH DESIGN

The main aim of the study was to evaluate the amount and severity of usability problems (UPs) in digital learning solutions. In addition, the study aimed at exploring the tentative differences between country groups in which the evaluated digital learning solutions are designed and digital learning solution types.

A. Evaluation procedure

The usability evaluation of digital learning solutions were conducted via heuristic evaluation based on Nielsen's [21] ten usability heuristics (see Table I). The usability evaluations were conducted by two researchers who individually / independently evaluated each digital learning solution and reported their observations. Each of the observations was: marked with one or more heuristics to which it related to; a description of the usability problem (UP); a rating of the severity of the problem; and a suggestion on how to fix the problem. The severity of each UP was marked as either minor, moderate or major according to whether the digital learning solution could be used or if the UP prevents the use of the digital learning solution or a part of it.

The evaluators were researchers with a sizeable knowledge about usability and usability testing methods, but differed in their other expertise. One of the researchers was experienced in the fields of usability, user experience and design. The other researcher was experienced in the fields of usability, education and pedagogical use of information and communication technology.

B. Description of digital learning solutions

The heuristic evaluation was conducted for altogether 24 digital learning solutions from five countries. These digital learning solutions were selected based on suggestions from Systech research and company partners in five countries: Chile, Hong Kong, Finland, South Korea and Spain. These individual countries were later grouped based on cultural similarity to two country groups: Asian countries (Hong Kong and South Korea) and Spanish speaking countries (Chile and Spain). Finland was left as an individual country since the amount of digital learning solutions available from Finland (10) exceeded the

combined totals of learning solutions for either of the other country groups Asian countries (8) and Spanish speaking countries (6).

These digital learning solutions represent a diverse sample of technological learning solutions, with different use contexts (from classroom use to extracurricular activities), usage purposes, intended learning outcomes and user groups (from preschoolers to adult learners). They were divided into two groups, namely 1) content learning solutions (altogether 12 digital learning solutions), and 2) tools and platforms (12 digital learning solutions). Content learning solutions focused on teaching a particular preset of data or skills, with none or only minimal options for users to modify content. The selection of content learning solutions represented online learning environments for various subjects (e.g. mathematics, languages and music). They offered experiences in content enrichment, games and exercises. Tools and platforms were solutions for creating or distributing content from multiple sources or they were collections of materials. The tools and platforms were course material and other content (e.g. routes) creation software, solutions for testing knowledge, video and game platforms and platforms for applied learning, such as physics simulations or driver education.

C. Analysis

The data consisted of 24 heuristic evaluation report sheets, where one sheet combined all the observations made by two evaluators about a digital learning solution. Evaluator data was combined and observations of the same usability problem were combined to remove redundancy. There were altogether 418 observed usability issues in the 24 evaluated digital learning solutions. These observations consisted of description of the issue, severity rating, suggested solution for the issue and one more heuristics it violated. One observation could be a violation of one or more heuristics and these occurrences of heuristics were counted as usability problems (UPs). The total amount of usability problems for all 10 heuristics was 509, which is higher than the amount of observations (418), showing that there were numerous instances where individual usability issues addressed more than one heuristic.

The data was analyzed according to the amount of UPs and severity ratings for each heuristic. The UP amount and severity ratings were further analyzed according to country group the digital learning solutions belonged to and the type of digital learning solution they represented.

IV. RESULTS

A. Usability problems of digital learning solutions

1) *Amount:* The data analysis revealed large variation in the amount and severity of usability problems across the ten heuristics (Table II). It was realized that five heuristics covered altogether 73 % of the observed usability problems.

The most frequent heuristic was consistency and standards with 27 % of total UPs. The distribution of other four most frequent heuristics varied between 10-12 %. For the remaining five heuristic the distribution varied between 5-7 %.

2) *Severity*: Variation in the severity ratings within heuristics was for the most part shared by heuristics and only two showed a different variation of severity ratings. Eight heuristics had a clear pattern of having high amounts of minor usability problems (54-74 %); a modest amount of moderate UPs (12-31%) and a relatively low amount of major usability problems (3-16%). Out of these eight heuristics only one heuristic match between system and the real world had more major (16%) than moderate usability problems (12%), while others had more moderate (19-31%) than major usability problems (3-16%). The greatest difference in severity ratings could be observed in two heuristics: ‘error prevention’ and ‘helping users recognize, diagnose, and recover from errors’, which have 40-52% of major usability problems, 26% moderate UPs and 22-34% of minor UPs.

3) *Cross-analysis of amount and severity*: The five most frequent heuristics also share the feature of having more than 59% of usability problems connected to them given a severity rating of being minor usability problems. The three heuristics with the lowest to third lowest percentage of all observations show a similar trend by having more than 53% of all observed usability problems rated as minor usability problems and under 16% rated as major usability problems. The remaining two heuristics that deal with errors, ‘error prevention’ and ‘helping users recognize, diagnose, and recover from errors’ both share a feature of having more than 39% of all usability problems rated as major usability problems, which will be discussed in more detail later on in this paper.

B. Description of significant heuristics/usability problems

1) *Heuristic category - Consistency and standards*: The data analysis revealed large variation in the amount and severity of usability problems across the ten heuristics (see Table II). It was realized that five heuristics covered altogether 73 % of the observed usability problems. The most frequent heuristic was ‘consistency and standards’ with 27 % of total UPs. The distribution of other four most frequent heuristics

varied between 10-12 %. For the remaining five heuristic the distribution varied between 5-7 %.

TABLE II. UPS AND SEVERITY RATINGS

Heuristic	UPs (%)	Severity		
		Minor (%)	Moderate (%)	Major (%)
Consistency and standards	27.1	73.9	23.2	2.9
Visibility of the system status	12.2	59.7	24.2	16.1
Match between system and the real world	12.0	72.1	11.5	16.4
Aesthetic and minimalistic design	11.2	73.7	19.3	7.0
User control and freedom	10.2	67.3	23.1	9.6
Error prevention	7.5	34.2	26.3	39.5
Flexibility and efficiency of use	5.7	69.0	24.1	6.9
Help and documentation	5.1	53.8	30.8	15.4
Recognition rather than recall	4.5	69.6	21.7	8.7
Helping users recognize, diagnose, and recover from errors	4.5	21.7	26.1	52.2
Total	100.0	64.4	22.2	13.4

When looking at differences between three groups of countries (Asian countries, Finland and Spanish speaking countries) some differences in the severity ratings between country groups can be observed (Table III). The distribution of severity ratings in the heuristic ‘consistency and standards’ shows that digital learning solutions from both Asian countries and Spanish speaking countries have a high number of UPs rated as minor (82-85%). Differing distribution can be observed in the Finnish solutions where there are 60 % of minor UPs and 35% of UPS with moderate severity.

TABLE III. DIFFERENCES IN USABILITY PROBLEMS FOR THREE HEURISTICS IN FINLAND AND TWO COUNTRY GROUPS

Heuristic	All UPs (%)	Asian countries			Finland			Spanish speaking countries		
		Minor (%)	Moderate (%)	Major (%)	Minor (%)	Moderate (%)	Major (%)	Minor (%)	Moderate (%)	Major (%)
Consistency and standards	27.1	81.6	18.4	0.0	59.2	34.7	6.1	84.6	7.7	7.7
Error prevention	7.5	33.3	33.3	33.3	30.8	30.8	38.5	50.0	0.0	50.0
Helping users recognize, diagnose, and recover from errors	4.5	30.0	40.0	30.0	9.1	18.2	72.7	50.0	0.0	50.0

TABLE IV.

USABILITY PROBLEMS IN CONTENT SOLUTIONS AND TOOLS AND PLATFORMS FOR THREE HEURISTICS

	Content solutions	Severity			Tools and platforms	Severity		
<i>Heuristic</i>	<i>% of all content solution UPs</i>	<i>Minor (%)</i>	<i>Moderate (%)</i>	<i>Major (%)</i>	<i>% of all tools and platforms UPs</i>	<i>Minor (%)</i>	<i>Moderate (%)</i>	<i>Major (%)</i>
Consistency and standards	31.7	78.1	20.3	1.6	24.1	70.3	25.7	4.1
Error prevention	9.1	32.1	28.6	39.3	5.0	40.0	20.0	40.0
Helping users recognize, diagnose, and recover from errors	4.5	44.4	11.1	44.4	4.6	7.1	35.7	57.1

This difference could be further explored by looking at the distribution of usability problems within the heuristic consistency and standards between two types of digital learning solutions (Table IV). Overall trend in both content solutions and tools and platforms is similar when looking at UPs from all 24 digital learning solutions. Most of the UPs 70-78 % are rated minor, 20-26 % as moderate and 2-4 % as major.

2) *Heuristic category: Preventing and recovering from errors*: The heuristics ‘helping users recognize, diagnose, and recover from errors’ and ‘error prevention’ contain respectively 5 % and 8 % of all UPs (Table II). Even though the amount of UPs is relatively low in both heuristics the amount of UPs rated as major. ‘Helping users recognize, diagnose, and recover from errors’ and ‘error prevention’ have a distribution of 22-34% of minor, 26% moderate and 40-52% major UPs. UPs for the two heuristics consisted of issues with input formatting, password generation and recovery, nonfunctional items and error situations and messages.

The variation between Asian countries, Finland and Spanish speaking countries show some differences in the severity ratings of the heuristics ‘helping users recognize, diagnose, and recover from errors’ and ‘error prevention’ can be observed (Table III). These two heuristics have both in Asian countries and Spanish speaking countries a similar distribution within both country groups. Digital learning solutions from Finland show a clearly different distributions between these two heuristics. ‘Error prevention’ shows a pattern that is similar to the digital learning solutions from Asian countries in regards to the severity ratings, with all severity rating groups having almost one third of all UPs. However ‘helping users recognize, diagnose, and recover from errors’ shows a clear difference in distribution having 9 % minor, 18% moderate and 73 % major UPs.

When comparing digital learning solution types (content solutions and tools and platforms) in respect to the two

heuristics, ‘error prevention’ and ‘helping users recognize, diagnose, and recover from errors’ (Table IV), there are merging patterns in the distribution of severity ratings. Content solutions have a similar pattern for both heuristics with percentages of minor (32-44 %) and major (39-44 %) being similar and the amount of moderate UPs being the smallest (11-29%). Tools and platforms have similar pattern in ‘error prevention’ with 40% minor, 20% moderate and 40% major UPs, but not in ‘helping users recognize, diagnose, and recover from errors’. Tools and platforms a distribution of 7% minor, 36% moderate and 57% major UPs in helping users recognize, diagnose, and recover from errors.

V. DISCUSSION

The main results from this study verify the knowledge from earlier research ([5][19][31]) that a few heuristics cover the majority of all usability problems. Significant amount (27%) of UPs were categorized under one heuristic, namely ‘consistency and standards’, and the five heuristics with highest amount of UPs covered 73 % of all UPs. However, even though these heuristics covered the majority of all UPs more than half of the UPs in these heuristics were rated as minor. In general UPs in these heuristics were considered by the evaluators as issues that may hinder the learnability and efficiency of use and the overall user experience, but do not necessarily prevent completing tasks with the digital learning solution.

Heuristics that showed the largest proportion of major usability problems were ‘error prevention’ and ‘helping users recognize, diagnose, and recover from errors’. These two heuristics represent 12 % of all UPs, with more than half of the UPs rated as major UPs. This would suggest that UPs related to heuristics dealing with errors are mainly perceived as UPs that should be fixed most urgently. However, in this study the amount of observations under heuristics ‘helping users recognize, diagnose, and recover from errors’ and ‘error prevention’ is too low to make conclusions about the differences between country groups and digital learning solution types. The results of this study suggest that there is a

difference in the distribution of severity ratings of these two heuristics compared to the other eight heuristics that could be further explored with additional research. In previous research there has also been indications that the distribution of severity ratings might vary between heuristics ([19][30]).

The two types of digital learning solutions, tools and platforms and content learning solutions, showed a similar distribution of amount and severity ratings in almost all of the heuristics analyzed in more detail. Only one heuristic 'helping users recognize, diagnose, and recover from errors' demonstrated a shift in tools and platforms having more major UPs and moderate UPs than minor UPs. The category of tools and platforms consisted of a variation of digital learning solutions and in future research endeavors it might be relevant to divide the digital learning solutions in more precise subcategories.

There are four major limitations to this study: amount of digital learning solutions, digital learning solution types, number of evaluators and the set of heuristics used in the study. The first limitation is the sample size from each country or country group is not the same (6-10 digital learning solutions), which hinders the cross cultural analysis of the results. In future research the amount of learning solutions from each country or country group should be the same. Second limitation concerns the variation of digital learning solution types of from each country or country group and in future research each country should be represented by the same amount of each learning solution type. Furthermore the categorization of digital learning solutions might require additional research, since two large groups, content learning solutions and tools and platforms, might not be enough to explain the differences between digital learning solutions. Third limitation is the amount of evaluators, which in this study was two, while the recommended amount for heuristic evaluation is at least three evaluators [17], and in future research at least three usability experts will be used. The fourth limitation is the set of heuristics [21] used, which has been designed with the technical usability in mind and do not take pedagogical concerns into account. Pedagogical concerns in digital learning solutions will be addressed by further research of the digital learning solutions with pedagogical experts.

The suggested minimum number of evaluators for heuristic evaluation is three as was discovered by Nielsen [17] However as Nielsen's [17] results suggested, double specialists can find a significantly higher amount of UPs than regular usability specialists. Double specialists in Nielsen's [17] study consisted of usability experts who also had experience of the software type being evaluated. In this study two usability researchers, who had further experience of either learning solutions or interface design, which would classify them as double specialists in their respective fields. This would in general support the use of only two usability experts. However, additional experts could have benefitted the overall coverage of all UPs in the evaluated digital learning solutions and therefore in future research endeavors this matter should be addressed.

In general the set of ten heuristics [21] was considered by the evaluators to be useful, but for some usability problems it was difficult to find a suitable category and a broader set of heuristics might be needed. The evaluators noted that in particular problems regarding situations where errors had already occurred or features were not functioning at all, the current heuristics did not offer a category suitable to describe these types of UPs. These types of observations were categorized under the closest suitable heuristic such as error prevention, even though they do not completely fit the category.

Abstract—Some problems related to software process and project management improvement programs are detected during their implementation. Companies from the software projects segment have difficulty dealing with software Project management and quality models (CMMI, MPS-BR and PM-BOK) since the ways to implement the key areas of the process and the good practices inherent to Project management are interpreted with difficulty. This can be attested by the analysis of CMMI and CHAOS reports. In order to minimize the difficulties detected by the reports, the aim of this paper is to apply Mindstorms to the teaching and learning of software process and project management (key concepts used during process improvement and implementation). To validate the efficacy of the technique introduced in this paper, 8 experiments were carried out including university, high school courses and companies from the software production sector. Experimental results attest that the process of knowledge transfer in process and management using Mindstorms led to greater motivation, satisfaction and concepts consolidation.

Keywords— *Software Project management; Software Process; Teaching and Learning; Mindstorms.*

I. INTRODUCTION

Some problems related to software process and project management improvement programs are detected during implementation.

This fact can be attested through the analysis of CMMI and CHAOS reports.

In regards to process improvement, South America has 400 CMMI certified companies whereas India has 760. One of the greatest company's problems appointed by the CMMI report is to develop the necessary knowledge inherent to the creation and institutionalization of software processes.

In relation to management, 60% of 900 projects were either not concluded or had their time, cost or scope reduced. According to the CHAOS report, companies do not have efficient techniques to develop a project.

Universities are responsible for changing this scenario. To do so, they must create motivating processes to promote satisfaction and knowledge consolidation during their transference.

Within this context, the objective of this paper is to apply Mindstorms to the teaching and learning of software process and project management.

Currently, most research using Mindstorms as their teaching and learning object are found in the area of Programming (see Section 2). This paper's innovation is based on the use of Mindstorms as a resource for teaching process and process management.

Taking into consideration this context, this article tries to answer two questions:

1. Is it possible to apply Mindstorms as the object of teaching and learning process and project management?
2. Does the application of Mindstorms provide motivation during knowledge transfer in process and project management?

To validate the referred application, the authors of this paper carried out, from 2010 to 2014, 8 experiments, divided into two phases:

- A. From 2010 to 2012, the authors worked traditionally, i.e., without using Mindstorms as the object of process and software management teaching and learning. In this phase, 2 experiments were realized with 86 students from the Computer Engineering and Systems Analysis courses offered by Universidade Tecnológica Federal do Paraná (UTFPR), Campus of Cornélio Procópio.
- B. In the year 2013 and 2014, the authors carried out 6 experiments using Mindstorms as the object of software process and project management teaching and learning, with the duration of 345 minutes each. Four of them with Universidade Tecnológica Federal do Paraná (UTFPR) – Campus de Cornélio Procópio undergraduate courses; one with students (16) from the Systems Analysis Course; one with students (20) from the Computer Engineering Course and one with students (12) from the Graduate Program in Computing. One experiment was realized with 4 high school students and, finally, one in a company from the software production sector (4 collaborators). Total of students: 68.

During the experiment carried out in a traditional way - Phase A - 64.86% of the students absorbed the concepts related to software process and project management naturally. This percentage was captured by a formative evaluation¹ applied to students in subjects that deal with software process and project management concepts.

Experiments with Mindstorms - Phase B - It was possible to verify that 88.2% of the students absorbed the concepts related to software process and project management naturally, mainly under the perspective of activities planning and implementation. This percentile was captured by a formative evaluation and software project implementation, using a historical basis.

To verify whether Mindstorms promotes motivation in transferring knowledge about software process and project management, the authors of this paper mapped the level of satisfaction of the participants in the experiment - Phase B. Around 90% of them classified the level as 5 - very high level or 4 - high level (on the Likert scale).

To meet the proposed objectives, this paper was divided into 6 sections. Section 2 presents the works related to the use of Mindstorms in the academic environment. Section 3 proposes the application of Mindstorms to the teaching and learning of software process and project management. Section 4, introduces the methods and procedures used to validate the proposal. Section 5 presents the inferred results with the application of Mindstorms to the teaching and learning of software process and project management. Finally, Section 6 discusses the conclusions delineated by this work.

II. RELATED WORKS

The Mindstorms EV 3 is an evolution of the NXT version. The EV3 is a robotics kit focused on technological education and this kit contains a processor, a proprietary software and touch, light and sound sensors. More information about the Mindstorms visit the site: www.lego.com/en-us/mindstorms.

Currently, the use of Mindstorms [1] as a pedagogical tool includes the areas of Automation, Control, Robotics, Physics, Math and Computer Programming.

Brandt and Colton [2] use Mindstorms to teach Programming, mechanics and control to freshmen students from the Brigham University Mechanics Engineering Department. The objective of the work is to introduce interface and sensing. The authors conclude that Mindstorms is a versatile platform which is greatly accepted by the students. With its use, the authors have improved the learning of Mechanics, Sensors Calibration, Programming Language and the Principles of Physics.

A proposal to systematize the teaching and learning of Robotics with the use of Mindstorms was developed by Universidade Federal de Campina Grande in 2008. In this

paper, the authors [3] present a technical bias that permeates the proposal.

Tester [4] used Mindstorms to develop skills connected with innovation and communication management. The work was developed with 70 students from a Northern Arizona University Graduate Course. Results were collected by the author through direct observation of the students' behavior. The author concludes that most students gained considerable knowledge about the area of Communication Management.

Mindstorms has also been used Schumacher, Welch, Raymond [5] to teach Programming to Electrical Engineering and Computer Science freshman students from the Military Academy in the US. The authors conclude that the use of Mindstorms turned the solutions of complex problems by the students more dynamic and with a greater degree of accuracy.

Caci and D'Amico [6] used Mindstorms to develop cognitive skills in children. The authors work with cognitive principles focusing on non-verbal intelligence, visual communication, logics and robots programming. The authors worked with ten 11 -year-old students, divided in 2 groups with 5 students each. The groups worked on the physical construction of a robot and developed, in 12 meetings, a logic project using processes connected to Programming. After the development of the work, the authors conclude the cognitive skills go under significant improvement.

Calvo and Parianaze [7] propose the union of Mindstorms and PBL (Problem Based Learning) for the teaching of Programming in Electronics Engineering and Industrial Engineering Computing subjects. The authors report on experiences carried out in 2008 and 2009. The work concludes, qualitatively, that the students improved significantly their learning in questions related to Computer Programming.

Researchers from Dresden University and Málaga University developed 3 experiments at the graduate level, using Mindstorms [8]. Skills connected to the project and software development were delineated together with the students that used the referred robot. The authors proposed to the students a competition using Mindstorms. During the competition, the students had to develop software in which the robot was able to exit any maze. The authors concluded that the application of the technique improved significantly issues related to the development of structured programs and the understanding and the work with sensors and actuators.

Gandy et al. [9] used Mindstorms in the University of Sunderland Computing Department., UK in 2008 and 2009, to teach Java Programming. The work was developed with graduate students. The authors of the work used Lejos (Java Virtual Machine that works together with Mindstorms). The work was carried out with 49 students and 85% of them stated that the robot collaborated decisively with the learning of the language.

Finally, there are several other works that use Mindstorms as the object of learning [10]. They all apply the referred object to a restricted group of students to teach concepts connected with Computing and Engineering.

¹ The objective of the formative evaluation is to provide subsidies so that the students can understand their own learning process and the functioning of their underlying cognitive capacities during problem solving.

III. APPLYING WINDSTORMS IN THE TEACHING AND LEARNING OF SOFTWARE PROCESS AND PROJECT MANAGEMENT

The application of Mindstorms to the teaching and learning of software process and project management was divided into 3 phases (see Figure 1):

1. The objective of Phase 1 is to compose and introduce the theoretical background that will characterize the teaching and learning environment. In our case, this theoretical background is characterized by questions connected with software process and project management. In this phase, the teacher or tutor is responsible for composing the material and introducing it to the student. The introduction can be done during the lesson (traditional classroom) or use Distance Learning techniques.
2. In Phase 2, the teacher or tutor is responsible for the selection and composition of objects that will characterize the motivating environment for the teaching and learning. In our case, Mindstorms was the selected object. The responsibility of the professor/tutor in this phase is to define the way the student will work with the objects and map the abstract questions related to the theory, make them concrete.
3. The objective of Phase 3 is to assess the whole learning process. This assessment takes place in two steps: 1 - the student is evaluated through tests or practical works; 2- the teaching and learning process is evaluated by the students.

Fig. 1. Model used to compose this work

An analysis of Fig. 1 shows that it is possible to verify that the model can be used for the teaching and learning of any content. In this work, the model was applied using Mindstorms as the object of software process and project management teaching and learning. An example of the model is given in Table I.

Table I was constructed as a development plan for working in a teaching and learning environment. In this table, it is possible to find slides that compose the theory, the object (Mindstorms) and the evaluation criteria. The validation of this plan is the subject of the next section of this work.

TABLE I. MODEL FOR THE TEACHING OF PROCESS AND PROJECT MANAGEMENT USING MINDSTORMS

1. Theory Presentation	Process	Slides on software processes: https://dl.dropboxusercontent.com/u/3525445/mindstorms/softwareProcess.ppt	Worked during one traditional class (50 minutes). Available by Ian Sommerville [11]
	Project management	Slides on project management https://dl.dropboxusercontent.com/u/3525445/mindstorms/projectManagement.ppt	Worked during one traditional class (50 minutes). Available by Ian Sommerville [11]
2. Motivation Environment Composition	Classroom	Division of students into groups of 4 students.	Students developed projects, supervised by teachers, (see Fig. 2) using Mindstorms to concretize abstract concepts, tasks, activities, entry and exit artifacts, tools, skills, plans, project implementation, project control (150 minutes).
	Mindstorms	Presentation of Mindstorms to students. Presentation of the software that manipulates motors and sensors. Traditional class – 45 minutes.	
Object Selection			
Theory Application			
3. Evaluation	Students	In class evaluation, essay questions (see Table VI).	Evaluation was carried out after the students developed the projects using Mindstorms (see project scope in Fig. 2). Time (25 minutes).
	Teaching and Learning Process	After theory presentation and projects development, students evaluated the teaching and learning process (time: 25 minutes).	

IV. METHODS AND PROCEDURES USED TO VALIDATE THE APPLICATION

In order to answer the questions raised in Section I and evaluate the application of Mindstorms to the teaching and learning of software process and project management, the authors of this proposal developed, from 2010 to 2014, 8 experiments in academic (university) and business (software production sector) environments (See Table II).

Six experiments (realized from 2013 to 2014) were compared to other 2 experiments carried out from 2010 to 2012. The experiments carried out from 2010 to 2012 presented the concepts inherent to software process and project management traditionally (the authors of this paper worked the content on process and project management through lectures), i.e., without Mindstorms.

The experiments in the academic environments were carried out at the Universidade Tecnológica Federal do Paraná Computing Department, Campus of Cornélio Procopio. The Department offers 3 undergraduate courses: Software Engineering, Systems Analysis and Development Technology and Computing Engineering. In addition to these undergraduate courses the Department also offers a Graduate Program in Computing (GPC).

One of the experiments that used Mindstorms was realized with high school students. These students participate in the project Implementation of a Digital Wardrobe by High School Students from Northern Paraná as scholarship holders. The objective of this project was:

1. Recruit future professionals (female) for the Computing Engineering and Software Engineering or Technology;
2. Consolidate contents related to computer programming and software process and project management.

The project was financed by the Brazilian National Council for Scientific and Technological Development-CNPq.

TABLE II. INFORMATION ON THE EXPERIMENTS

Course	Application /Semester	Subjects	Students
Systems Analysis	6th semester (2010,2011,2012)	Software Project management (without Mindstorms)	47
Computing Engineering	7h semester (2010,2011,2012)	Software Project management (without Mindstorms)	39
High School (HS)	6th semester (2014)	Introduction to Project management	4
Software Engineering (SE)	1st semester (2014)	Introduction to Software Engineering	20
Systems Analysis	6th semester (2013)	Software Project management	16
Computing Engineering (CE)	7th semester (2013)	Software Projects Mangement	12
Graduate Program in Computing (GPC)	1st semester (2013)	Software Engineering	12
Company from the Production Sector (CPS)	IT professionals (2014)	<i>Consulting for the implementation of a software process</i>	4*

*Collaborators: Information System (2 collaborators). Systems Analysis (2 collaborators). Each group of 4 students manipulated Mindstorms.

Through the analysis of Table II it is possible to notice the presence of 6 experiments carried out in academic environments, 1 in a high school and 1 experiment realized in a company's production sector.

The company has a team of 9 people and 4 programmers from the production (programming) cell participated in the experiment. It is important to highlight that the authors of this work have not been formally authorized to disseminate the name of the company. The experiment conducted at this company was part of a software process improvement consulting developed by the authors of this work.

All experiments followed the model adopted by this work (Fig.1 and Table 1). Based on this model, the, as teachers implemented the following actions:

1. Presentation of two traditional lessons on concepts connected with software process and project s management. Duration of each lesson is 50 minutes. Support material to be used during software process [11] and project management [11] lessons can be found in the following links <https://dl.dropboxusercontent.com/u/3525445/mindstorms/softwareProcess.ppt>. and <https://dl.dropboxusercontent.com/u/3525445/mindstorms/projectManagement.ppt>.
2. Divide de students into groups of 4.

3. After having grouped the students, introduce Mindstorms to them. During the presentation, teachers work the motors, sensors and actuators. Presentation time was 45 minutes. It is important to emphasize that the teachers used the presentation this link https://www.youtube.com/watch?v=jh9u_B42ILo²
4. Definition of three projects using Mindstorms. Projects scope (a concept introduced during the Project management lessons) were based on Fig. 2.

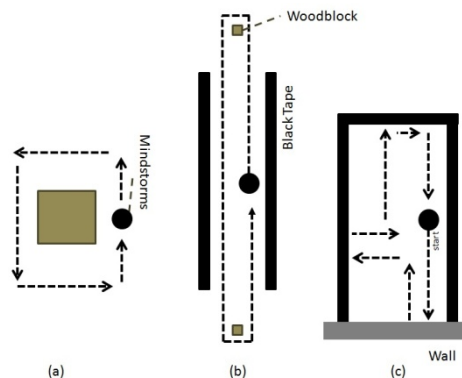

Fig. 2. Projects scope using Mindstorms

Figure 2 (a) presents the scope of project 1. In this figure, Mindstorms, represented by the circle, must go around a wood block. Figure 2 (b) represents the scope of project 2. According to this Figure, Mindstorms must go around two wood blocks and should not cross the black tape. Finally, Fig 2 (c) represents project 3, in which Mindstorms must touch one wall and return back to the initial position following the arrows – notice that by detecting the black tape, Mindstorms must change its route.

5. Definition of the development process. The process was divided into two activities: design and implementation. These activities were carried out by the students during the development of the project. The design activity has as an entry artifact the scope of the project. The exit artifact for this activity is characterized by the project specification document (see Table III). By using this artifact, the students configure (based on the scope – see Fig. 2) Mindstorms sensors and actuators parameters. Finally, it is important to highlight that the project specification document is characterized as an implementation activity entry artifact. This activity's exit artifact is the program to be embedded in Mindstorms (see Figure 3).

It is also important to emphasize that action 5 – development process definition, is based on action 1 – introduction of the concepts related to software process. Concepts such as activities, tasks, entry and exit artifacts and skills were characterized in action 1.

² YouTube Channel New Planet School. The video was translated into Portuguese and presented to the students in a traditional classroom.

6. Project development - action designed by the students with the supervisions of teachers (150 minutes). During the development of the project, the students must carry out planning and control activities. During the planning, the students create the WBS - Work Breakdown Structure (PMBOK) and estimate the necessary time and cost to execute each work package (see Figure 4). It is important to highlight that the students must develop 2 out of the 3 projects. During the development of the first project, the students do not have any information in the historical basis of the project to develop a consistent plan, which leads them to overestimate the time and cost for its execution. During the planning of the second project, however, the students have information in the historical basis, which leads them to develop more realistic estimates (see Table VII).

TABLE III SPECIFICATION PROJECT DOCUMENT

Sensor or Actuator	Parameter	Parameter Configuration
Medium Motor	On for Seconds	Second
	Power	75
	Second	4
	Port	A
Large Motor	On for Seconds	Second
	Power	75
	Second	4
	Port	D

Fig. 3. Program to be embedded in Mindstorms

7. Students Evaluation. During this action, after the development of the project based on action 6, the students prepare a formative evaluation. The evaluation is composed by questions inherent to software process and project management (see questionnaire in Table IV). Action time: 25 minutes.

Fig. 4. Work Breakdown Structure (WBS) used in the planning activity

It is important to mention that the questions presented in Table IV were also used during the evaluation of the students who participated in the experiments from 2010 to 2012, who worked under the traditional approach.

8. Evaluation of the Teaching and Learning Process. During this action, the students, after having developed the project based on action 6, answer a questionnaire on the

application of Mindstorms to the teaching and learning of Software process and project management (see Table V). It is important to highlight that the questions focus on extremely important variables, which help the internalization of any type of knowledge, stimulus, satisfaction and consolidation [12]. Action time: 25 minutes.

TABLE IV. STUDENTS EVALUATION

As a software project manager, you must estimate the time and cost for the execution of project X. Proponent X made the project scope available. Your company has a historical basis with 3 projects developed. The scope of project X is similar to the projects stored in the basis. Based on this information, define the strategies you used to establish the time and cost for the project.
A software production company has a defined process. The activities of this process involves: 1- Requirements elicitation (tasks: mapping of key users and interviews with users). 2- Software projects (tasks: mapping of the functional model and mapping of the data model). 3 - Implementation. 4 - Test (tasks: define test cases, collect test data, test and report) . Construct a Software Project WBS that uses all activities and tasks of company X

TABLE V. EVALUATION OF THE TEACHING AND LEARNING PROCESS

Do you agree that the use of Mindstorms promoted greater stimulus to help students follow the lessons on software process and project management?
What's your level of satisfaction with Mindstorms during the learning of software process and projects development concepts?
Do you agree that the software project management concepts were consolidated during the execution of the projects using Mindstorms?
Answers to these three questions were characterized by the Likert scale (5- very high, 4- high, 3 - medium, 2- low, 1- very low)

V. RESULTS MAPPING

In the previous section, the authors presented the implementation of 8 actions to validate the application of Mindstorms to the teaching of software process and project management.

Among the actions presented, it is possible to highlight initially two of them: the evaluation of the students (7) and the evaluation of the teaching and learning process (8).

The evaluation is characterized as formative and the questions included in this evaluation are presented in Table IV. The evaluation was conducted together with the students during the experiments from 2010 to 2014 (see Table II). After the evaluation, the authors of this paper, characterized as teachers, corrected it and consolidated the results in Table VI. It is important to emphasize that Table VI presents only the results from the evaluations conducted using Mindstorms in the teaching and learning of process and project management.

Table VI shows that 68 students participated in the experiment, 88.2% answered question 1 correctly (see Table IV), i.e., the students consulted the projects historical basis as part of their planning strategy.

In regards to question 2 (Table IV), the rate of correct answers was 82.4% (see Table VI). The students constructed an WBS correctly.

Some points stand out in Table VI, where 90% of the students from the Software Engineering Course answered question 1 correctly whereas among the students from the

Graduate Program this percentile was 91.7% and among the participants from the software production sector, this value reached 100%.

In regards to question 2, it is possible to verify that the students from the Systems Analysis Course and Computer Engineering went over 90% of correct answers.

TABLE VI. STUDENTS EVALUATION MAPPED RESULTS

Course	Sem.	Q1	%Q1	Q2	%Q2	Qtde.
High School (HS)	6	3	75	3	75	4
Software Engineering (SE)	1	18	90	15	75	20
Systems Analysis (SA)	6	14	87,5	15	93,8	16
Computing Engineering (CE)	1	10	83,3	11	91,7	12
Graduate Program in Computing (GPC)	1	11	91,7	10	83,3	12
Company from the Production Sector (CPS)		4	100	2	50	4
Total		60	88,2	56	82,4	68

Sem. - Application school semester. Q1- Question 1, Q2 - Question 2. %Q1- Percentage of correct answer for Q1. %Q2 - Percentage of correct answers for Q2. Qt - Number of students who participated in the experiment.

The high levels of correct answers to questions 1 and 2 are intimately related to the implementation of action 6 – project development. This fact was detected during a meeting with the participants of the experiments.

During this action, the students under the supervision of the teachers, created the Work Breakdown Structure and estimated the necessary time and cost to implement each work package (vide Figure 4). It is important to emphasize, once again, that the students must develop 2 out of the 3 projects mapped in Figure 2. During the development of the first project, the students have no information in the historical basis to develop a consistent plan (concept required in question 1 of the test) – see Table IV), which leads the students to overestimate time and cost. However, during the planning of the second project, the students already have information in the historical basis, which helps them raise more realistic estimates. This can be attested by the information in Table VII and Figures 5 to 10.

An analysis of Table VII shows that Group 1, formed with 4 high school students (HS) estimated for Project 1 (Pro 1), 25 minutes for the execution of the project activity and 5 minutes for the implementation of the activity. Project activity execution real time was 14 minutes, a difference of 11 minutes. Activity Implementation real time was 2 minutes, a difference of 3 minutes. The last column of Table VII shows the sum of these differences: 14 minutes.

For Project 2, group 1 planned 20 minutes for the execution of the project activity which was realized in 16 minutes, a difference of 4 minutes. For the execution of the implementation activity, the difference between the planned and the realized was 2 minutes, a total of 6 minutes (see Table VII). The differences between planning times and projects execution for all groups in all courses can be visualized in the last column of Table VII and Figures 5, 6, 7, 8, 9, and 10.

An analysis of Tables VII and Figures 5, 6, 7, 8, 9, and 10 shows that:

- Four projects were accurately estimated and executed (difference between the planned and the realized was equal to zero)
- Eleven projects were estimated and executed with a difference classified by the - 1 to 5 minutes interval.
- There are 17 projects in Table VII whose estimations were made based on historical information, in 64.7% of them the difference between the planned and the realized was between - 1 to 5 minutes.
- Sixteen out of 17 project estimated based on historical information had a reduction in their overestimated time.

TABLE VII. PLANNING: PLANNED VERSUS REALIZED

Experiment/Project/Group	Project (minutes)			Implementation/test (minutes)			Pr(P-R) + I(P-R)*
	P	R	P-R	P	R	P-R	
HS – Pro 1 – Group 1	25	14	11	5	2	3	14

P: Planned R: realized P-R: Planned –Realized
Pr: Project I: Implementation/test
*Sum of the differences between Planned minus Realized for Project activities (Pr) and Implementation (I)

Therefore, based on these results, it is possible to conclude that the projects planning concept with a historical basis tends to be internalized naturally by the students. Question 1 from the formative evaluation (Table IV) corroborates directly with this finding.

During the evaluation of the teaching process, the students that participate directly in the experiment were invited to answer 3 questions (using the Likert scale) mapped in Table V. The authors of this work collected the answers given by the students in Table VIII.

Fig. 5. High School – sum of the differences between planned and realized for Project 1 (14 minute) and Project 2 (6 minutes)

Fig. 6. Software Engineering - sum of the differences between planned and realized for Projects 1 and project 2 – the class was divided into 5 groups of 4 students.

Fig. 7. Systems Analysis and development – sum of the differences between planned and realized for Project 1 and project 2 – the class was divided into 4 groups of 4 students.

Fig. 8. Computing Engineering – sum of the differences between planned and realized for Project 1 and Project 2 – the class was divided into 3 groups of 4 students.

By adding the percentiles obtained for 4 – high and 5 very high (Table VIII), it can be verified that:

- Mindstorms promoted greater stimulus to follow the lessons on software process and project management in 92.3% of the students.

- The level of satisfaction brought by the use of Mindstorms during the learning of software process and project management concepts was 95.6%.
- The Mindstorms provided solidification about concepts project execution to 97.1% (see Figure 2).

Fig. 9. Graduate Program in Computing - sum of the differences between planned and realized for Project 1 and Project 2 – the class was divided into 3 groups of 4 students.

Fig. 10. Company from the Production Sector - sum of the differences between planned and realized for Project 1 (70 minutes) and Project 2 (5 minutes) .

TABLE VIII. TECHING AND LEARNING PROCESS EVALUATION MAPPED RESULTS

Questions (Table V)	Likert Scale

Level of satisfaction by using Mindstorms	54 79,4%	11 16,2%	2 2,9%	1 1,5%	0 0%
Consolidation of software process and project management concepts using Mindstorms	53 77,8%	13 19,1%	1 1,5%	1 1,5%	0 0%

VI. CONCLUSIONS

Problems related to software process improvement and project management is connected to knowledge transfer. The development of an environment that promotes the internalization of abstract knowledge of process and Project management can contribute to possible solutions to these problems.

In the literature, the Mindstorms is applied in teaching and learning computer programming. This paper provides a differentiated approach; the Mindstorms is used for teaching and learning process and management of software projects. The concepts inherent in computer programming are addressed however they aren't characterized as the main focus of the paper.

In this context, the objective of this work was to apply Mindstorms as a motivating object to promote the

internalization of knowledge about software process and project management. This is not a recurring topic in the literature (see section II).

To validate the application, the authors of this work developed 8 experiments from 2010 to 2014, with the participation of 154 students (86 in Phase A, without Mindstorms, 68 in Phase B, with Mindstorms – see section 1). Five experiments were carried with graduate students, one with undergraduate students, one with high school students and one in a company from the software production sector.

With the execution of the experiments, it was possible to verify that:

1. In the two experiments carried out in the traditional way – without the use of Mindstorms as the teaching and learning object - from 2010 to 2012, the concepts connected to the software process and project management were absorbed by 64.86% of the students (see Section 1).
2. With the use of Mindstorms, 88.2% (an index superior to that pointed out by the previous item) of the students absorbed naturally the concepts related to software process and project management, mainly under the perspective of activities planning (using the historical basis of projects) and execution (see Table VI). This finding deals directly with problems inherent to project planning appointed by the CHAOS report. This fact collaborates to qualify positively question 1 (see section 1).
3. 82.4% (higher index than that appointed by item 1) of the students absorbed the concepts related to the institutionalization of a software process by using the project analytical structure as the basis (see Table VI). This finding deals directly with problems inherent to the creation and institutionalization of software processes appointed by the CMMI report. This fact collaborates to qualify question 1 positively (see section 1).
4. Stimulus, satisfaction level and consolidation of concepts promoted by the use of Mindstorms as a teaching and learning object was classified as 5 - very high level and 4-high level (Likert scale) for 95.1% of the participants (see Table VIII). This finding qualifies question 2 positively (see section 1).

Teachers who work directly with subjects related to software process and project management attested that students that participated in the experiments showed better fluidity in relation to these concepts in the following semesters.

Mindstorms was also a motivating factor for about 90% of the participants (see Table VIII). It is also emphasized that motivation in the teaching and learning process is intimately connected to stimulus, satisfaction and consolidation, variables related to the evaluation of the teaching and learning process [12].

The realization of the experiments attested that software process and project management concepts are internalized by the participants, regardless of their stage (high school,

freshman year at college, senior year at college, graduate school and company worker). These data can be found in Tables VI and VII.

After the experiment, the company from the production sector started to plan its projects using the historical basis concept, improving significantly the level of corrected cost and deadline estimates.

Finally, the authors found that the model used to develop this work presented in Fig. 1 can be applied to the teaching and learning of any content. In this work, the model was instantiated by the use Mindstorms as an object for the teaching and learning of software process and project management.

Special Session on Design Metaphors

Rethinking the vocabulary of design education

Abstract—Metaphors help create realities for us, especially social realities. A metaphor influences behavior; to attract and/or divide. Metaphors for education provide symbolic representations of what we intend in education; insight into the philosophy that underlines both how we educate, and what we are trying to educate. E.g., "Education as a journey" conveys a different meaning and intention than "education as a manufacturing process." Similarly, "Education is not the filling of a pail, but the lighting of a fire" encapsulates both an educational philosophy and guide for action.

This special session focuses on exploring metaphors for engineering design education, and how these metaphors divide and limit engineering design. Facilitated by the session leaders, participants will share and discuss their own metaphors, and begin a process for evaluating how metaphors limit and exclude. Participants will leave with an expanded repertoire of engineering design metaphors and reinvent the vocabulary of how metaphors inform teaching and learning of engineering design. Opportunities for future collaboration will be explored.

Keywords—Engineering Design; Design Education; Philosophy of Engineering

I. INTRODUCTION

Engineering educators, engineering practitioners, and engineering scientists have been working very closely in the last part of 20th century. Their mutual goal has and will be educating the future workforce and creating engineering problem solvers who impact the world in a meaningful way. In addition these three groups have been influencing and changing each other. Based on the findings and research in engineering design, there are different cultures that pertain to these constituents. Our education system is predominately based on the production (factory, assembly line) culture. Administrators use vocabulary that is very close to the production lines. Each group has cultural biases, they each use words, descriptions, and metaphors. While the metaphors seem to use a common language, they are enriched with ideas, biases, and cultural beliefs of the users. They are lenses used to view the term, and define meanings for their goals and objectives. The research questions are "Are they the same?" "Should they be the same?"

Among other uses, metaphor is a lens through which we see how we educate. In this context, 'design metaphors' are metaphors used for teaching how engineering design is done,

better done, and best done. These metaphors are the lenses that we use, consciously or unconsciously to communicate and teach aspects of the complex and value-laden activity we call engineering design.

II. UNDERSTANDING METAPHOR USES

Metaphor affects both linguistic and conceptual understanding. Common terms to describe the language and conceptual components are *Topic* and *Vehicle* which refer to the lexical items and to the content domains that they label. In this sense, metaphors are a vehicle relating one topic/domain to another. The actual concepts and relations activated in discourse will vary with individuals and their previous experience and knowledge. Contextual frames involve (at least) physical, social, interactional, or linguistic factors. [1,2]

A. Theories of Metaphor

Three central theories have emerged on metaphor use: Substitution Theory: metaphor as renaming of the Topic by the Vehicle, *Comparison Theory* where the metaphor is used as an implicit comparison, or restatement of similarity and *Interaction Theory* that accounts for the creation of new understandings through metaphor that cannot be paraphrased with literal equivalents. [1] Lastly are *Cognitive Theories*. These theories, support the development of repertoires.

Metaphor repertoires are developed through participation in social action and interaction. There are different levels of metaphor understanding: 'comprehension' may take place in real time without 'recognition' of the presence of metaphor happening or without further 'interpretation' of metaphor through activation of entailments of the conceptual link. [1] The fact that metaphors are used in particular ways 'in the language' does not entail that every 'individual mind' thinks metaphorically using the same conceptual metaphor. One important role is the 'cultivation of intimacy', where intimacy can be taken for granted or enhanced through the use of metaphor, especially in the development of shared discourse among participants.

B. Metaphor in Education

The challenges of metaphor in education are multifold. Fundamentally metaphor use shapes our language, thoughts and viewpoints. They effect both how learners learn, what they learn, but also how we as educators view what we teach.

Often, root-metaphors are generated from everyday experience and then extrapolated by means of analogy to some other realm of experience, such as teaching and learning. It often functions as a philosophy, metaphysics or worldview which constitutes the ultimate presuppositions or frame of reference for our educational discourse. [2] The danger is that educators unconsciously adopt a particular metaphor without conscious acknowledgement of the limitations and potential conflicts

III. METAPHORS FOR ENGINEERING DESIGN

Design metaphors in active educational use, or recommended for educational use vary significantly both in their breadth and their focus. A small sampling of this breadth is provided:

Design as Behavior: "Design is behavior. Therefore, it can best be understood by means of behavioral theory and must be taught in a way consistent with the theory of behavior modification. This simple fact appears to have been overlooked by most, if not all, engineering educators who teach design courses or write textbooks on engineering design." [3]

Design as Hypothesis Testing: "Each new patent is akin to a new hypothesis – an assertion that the thing described is novel, unobvious, and will work. If we take the framing and testing of hypotheses as the defining characteristic of science, then any new design is something to be tested by the scientific method. Proposing a bold new bridge design... lays down the hypothesis that the design will in fact work as a bridge. [4]

Design as Art: "Design is the energetic acknowledgement of our own living world through the making of things and through communication. ... New things are not born of nothingness, and they are taken from our attempts to boldly awaken our everyday existences. Design is the provocation of the senses and a way of making us discern the world afresh. " [5]

Design as Functional Composition: "Designers are focused on our interactions with objects and their functions, generally operating at a bigger, user centric scale. " [6]

Design as a Way of Thinking: Design thinking is a formal method for practical, creative resolution of problems and creation of solutions, with the intent of an improved future result. [6]

Design as Creative Synthesis: "Engineering design encompasses many activities, including the creative activity of conceiving of new devices and systems, as well as the analysis, refinement, and testing of those concepts. Synthesis is the creative step itself: the conception and postulation of possibly new solutions to solve a problem. In most engineering design, this step is performed by creative human minds." [7]

IV. SPECIAL SESSION ACTIVITIES

The activities will increase participants' background with both theories of metaphor in education and an array of specific practical uses of metaphor in engineering design. Activities will be based both on examples provided by the session organizers and design metaphors suggested by participants.

Metaphors in Education. The first part of the workshop will be a brief overview of metaphor theory and the role of

metaphors in education. This segment will provide participants with a review of established analysis of metaphors and provide a common background to inform subsequent participant discussions.

Design Metaphors by Discipline. Participants will be grouped by discipline/interest to discuss engineering design metaphors. Grouping by similar discipline/interest is intended to benefit from common frameworks and vocabularies across disciplines. This will include a brief presentation of documented metaphors to streamline discussion. Group discussion will record different metaphors used by participants, address potential applications of the metaphors focusing on questions like "what aspects of engineering design does this metaphor clarify?" Also considered will be possible misconceptions or other issues – particularly those that lead to exclusion. This discipline-focused group work will be followed by a synthesis of the metaphors discovered by the participants.

Discussion by Mixed Disciplines. In response to the synthesis work, the third set of activities will have participants grouped randomly to explore design metaphor relationships across engineering disciplines. Questions include: "Are there engineering design metaphors that span disciplines?" or "What shared values are made manifest by particular groups of metaphors?" or issue-related questions like "How do particular design metaphors limit engineers' thinking?" or "How does a particular metaphor shape how an engineer views design and therefore limits the design solution space?" These responses will then be collected, and shared followed by a discussion of the results of these cross-discipline explorations. Opportunities for future collaborations will also be explored.

The goal of these synthesis steps is to allow all participants to leave with an increased repertoire of engineering design metaphors to inform their teaching and learning processes.

Helping Tomorrow's Engineers Ask Productive Questions

Frank V. Kowalski and Susan E. Kowalski

Department of Physics
Colorado School of Mines
Golden, Colorado, USA
fkowalsk@mines.edu

Abstract—Most engineers and scientists would readily agree that the ability to ask and pursue productive questions can lead to a more globally competitive workforce; students with this ability can also enrich the STEM classroom learning environment. Through demonstration, active learning, and small group activities, this special session explores how we can help tomorrow's engineers ask productive questions and evaluate which questions may lead to creative solutions to research problems or innovative new products.

Keywords— *questioning, curiosity, ideation, asking questions, generating questions, enhancing questioning, critical thinking*

I. INTRODUCTION

Students can use meaningful questions to guide their exploration of the frontiers of engineering in the classroom, in the laboratory, and, ultimately, in the workplace. Physiologically, curiosity changes the brain to enhance learning [1]. Psychologically, wanting to explore a productive question also motivates students to better understand content and exercise higher level thinking skills [2]. On the job, productive questions are seen as pathways to creative solutions to research problems or innovative new products. Google CEO Eric Schmidt said, "We run this company on questions, not answers" [3].

Engineering education is often focused on students answering questions, not asking. Faculty intent on covering content may misjudge students' ability to ask productive questions as innate and therefore not explicitly cultivate this in the engineering curriculum.

Through demonstration, active learning, and small group activities this special session provides a framework for participants to help their students ask better, more productive questions. The immediate- and long-term effects of productive questions can contribute to a globally competitive supply of engineering students in the classroom and engineers in tomorrow's workplace.

II. CONTENT OF SPECIAL SESSION

Assuming the role of students, session participants become familiar with a technique for increasing fluency in the number

and types of questions they can generate. This technique is anchored in the use of models presented in class to explain past observations and make sense of new ones; it has been shown to have a statistically significant impact on engineering physics students [4] and can be adapted to diverse teaching situations [5].

Session participants are exposed to a series of prompts or triggers, such as videos, demonstrations, photos, problems, etc. The questions that participants generate serve as examples of six categories of questions: incongruous, congruous, modifying, generalizing/analogy, causal/creative, and informational. Data submitted by participants will later be used to study the questions engineering "experts" generate, in comparison to data already collected from 450 "novice" students in an introductory engineering physics class and a class of 50 graduate students.

In a small group setting, participants explore further application of this technique within specific engineering disciplines as well as how to evaluate the usefulness of the questions generated. Thus the community of participants collaboratively constructs new knowledge in this area that will help future adopters.

III. GOALS AND EXPECTED OUTCOMES

At the conclusion of this interactive, hands-on special session, participants should:

- Have a renewed interest in cultivating curiosity in their engineering students;
- Be prepared to use a process in their classrooms to improve the quality and diversity of questions their students ask;
- Have provided some data for a novice vs. expert comparison of types of questions following a prompt; and
- Have generated guidelines for other educators to help students ask productive questions and subsequently evaluate which questions may lead to creative solutions to research problems or innovative new products.

IV. SUMMARY AND CONCLUSIONS

In engineering, mathematics, and science, it is difficult to develop a compass which guides you in either solving a problem, determining a novel solution, or just finding an interesting problem to solve. The first step is to ask questions. Then, one must decide which of those questions might be productive. Linus Pauling told his student, “The best way to have good ideas is to have lots of ideas and throw away the bad ones” [6]. This special session explicitly focuses on pedagogical efforts to a) generate many questions, and b) determine which should be pursued.

ACKNOWLEDGMENT

The material for this special session is based upon work supported by the National Science Foundation under Grant #DUE1044255 and the HP Catalyst Initiative program.

An exploration of Bloom's knowledge, skills, and affective-based goals in promoting development of freshmen engineering students' professional identities

Idalis Villanueva
Engineering Education
Utah State University
Logan, UT, USA
idalis.villanueva@usu.edu

Abstract—Engineering educators rely on taxonomies such as Bloom's taxonomy to create learning objectives used to develop course syllabi and activities. Many times, faculty use these learning objectives to assess student attainment of engineering competencies as they relate to Engineering Accreditation Criteria (Accreditation Board of Engineering and Technology-ABET) purposes. One flaw to this approach is that it fundamentally *assumes* that student performance and completion of an engineering course will reflect the level or extent of professional development by the engineering student. Furthermore, it *assumes* that through development of a professional competency, students will more readily identify with the engineering profession. The purpose of this work is to explore the extent by which Bloom's taxonomy promotes development of freshmen engineering students' professional identities in an entry level undergraduate engineering course. A lower-level engineering course was selected as studies suggest that attrition and drop-out tends to occur between the first and second year of an engineering degree. From this work, we will begin to shed light on the needs and areas of improvement for freshmen engineering curriculum design (specifically related to selection of curriculum objectives) to promote persistent and committed professional identities in engineering students.

Keywords—Bloom's taxonomy, engineering education, student professional identity

I. INTRODUCTION

In any course, three components must be considered to accurately understand the effectiveness of a curriculum: its content, the instructional methods used to deliver course content, and the assessment approaches used to ensure course goals are being met. The latter (meeting course goals) is extremely important in technical and technologically driven disciplines such as engineering where criteria related to professional competencies through ABET must be met [1]. Through successful completion of the course goals, students are allowed to move up on the ranks of their engineering degree with a fundamental *assumption* that a certain level of expertise and growing understanding about the engineering profession has been obtained as a result of the course. One of the most widely used methods to understand if levels of expertise have been attained is through the Bloom's

Taxonomy of Educational Objectives [2]. Bloom's Taxonomy along with their revisions over the years [2,3] provides a convenient way for instructors to describe the degree of student knowledge, connection with course content (affect), and skills attained as a result of a course. Over time, Bloom's taxonomy has been criticized for not being sufficiently comprehensive [2], its over simplicity [2,4], and focus on student behavior and not transformation of behavior [4].

While Bloom's taxonomy is intended primarily as a heuristic for course design [5], it has had a stronger effect on objectives-based evaluation [6]. As such, this taxonomy along with its revisions containing affective, knowledge, and psychomotor (skills-based) goals [7] are widely used by instructors nationwide. Thus, we need to understand the extent to which Bloom's Taxonomy guides student developmental from these three domains and how these are related to professional developmental of a student.

In addition, we need to understand the intersection between student growths of these levels to foster development of a professional identity within a curriculum. This work will focus on the utility of Bloom's taxonomy in the development of students' skills as outlined in the taxonomy as well as how these guidelines motivate student identification and understanding of the engineering profession.

This work is an exploration of a freshmen engineering design course as studies suggest higher attrition rates after the first year of an engineering degree [8]. This paper explores how planning of an engineering graphics and design that includes the three Bloom's Taxonomy domains (affective, knowledge, skills) and their influence on student development of an engineering identity.

II. BACKGROUND

A. Bloom's Taxonomy

Bloom's taxonomy was created in the mid-1950s by Benjamin Bloom [9]. Primarily used to understand the hierarchical schema of the cognitive domain of learning, it has been revised over the years to include affective and psychomotor domains [7]. The domains of Bloom's taxonomy

can function to assess learning objectives and guide instruction. Bloom's taxonomy is one of the most widely used ways of organizing expertise levels in the classroom [4]. Table 1 summarizes the three learning domains present in Bloom's taxonomy.

Table 1. Summary of Revised Bloom's Taxonomy

Expertise Levels	Knowledge Based Skills	Skills Based Goals	Affective Goals
1	Remember: Recall or recognition of terms, procedures, etc	Perception: Use of sensory cues to guide action	Receiving: Demonstrates a willingness to participate in activity
2	Understand: Translate, interpret, extrapolate but not see the full implications to other scenarios	Set: Demonstrate a readiness to take action to perform the task or objective	Responding: Shows interest in the objects or activity by seeking it out or pursuing it for pleasure
3	Apply: Apply abstractions, general principles, or methods to specific concrete situations	Guided Response: Knows steps required to complete task or objective	Valuing: Internalizes an appreciation for values, the objectives, phenomena, or activity
4	Analysis: Separation of a complex idea into its constituent parts and an understanding of organization and relationship between parts	Mechanism: Performs task or objective in a somewhat confident, proficient, habitual manner	Organizing: Begins to compare different values and resolves conflicts between them to form an internally consistent system of values
5	Evaluate: Creative, mental construction of ideas and concepts from multiple sources to form complex ideas	Complex Overt Response: Performs task or objective in a confident, proficient, and habitual manner	Characterization by a Value or Value Complex: Adopts a long-term value system that is "pervasive, consistent, and predictable"
6	Create: Make judgement of ideas or methods using external evidence or informed rationalizations	Adaptation: Performs task or objectives as above, but can also modify actions to account for new or problematic situations	N/A
7	N/A	Organization: Creates new tasks or objectives incorporating learned ones	N/A

B. Chickering and Reiser Model of Student Development

According to Chickering & Reiser [10], students have personal strengths and weaknesses that influences their character development during their education. While in college, students' interactions with their surroundings (e.g., curriculum, faculty, and students) promote growth along seven

vectors. Navigation through these vectors can foster student development of a professional identity (Table 2).

Table 2. Chickering and Reiser Student Development Model [10]

Vector Level	Vector Descriptor	Brief Explanation about Student Development for each Vector
1	Developing Competence	Student's growth in intellectual and interpersonal competence
2	Managing Emotions	Student's capacity to appropriately express feelings
3	Student's Dependency on Others	Student's move from autonomy towards interdependence
4	Development of Mature Interpersonal Relationships	Student's appreciation of differences and the ability to be intimate
5	Establishing Identity	Student's sense of self within social and cultural contexts
6	Developing Purpose	Student's ability to fulfill interpersonal and family commitments
7	Developing Integrity	Student's capacity to behave in a socially responsible manner

C. Engineering Student Identity through Self-Identification with Engineering Profession

Studies in professional development of engineering students rely heavily on criteria such as the Bloom's Taxonomy and the Engineering Accreditation Board of Engineering and Technology (ABET) [1] to guide studies on teaching and assessment strategies for a range of desired competencies. These guides are *assumed* to reflect the *level or extent* that an engineering student has gained a professional identity, an area that has been pointed out by engineering educators nationwide [11-23]. However, to our understanding no connections have been established to better understand the role these metrics play in a students' self-identification with the engineering profession.

Research in engineering education has suggested that despite the academic ability of many students, the "difficult nature" of engineering has resulted higher performing students leaving engineering at rates higher than their low performing peers [8]. Existing research in engineering attrition contend that undergraduate students fail to see connections between their coursework and what their engineering profession will look like in the future [16]. This disconnect results in turmoil in students [24] that ultimately impacts their sense of belonging in engineering and their perception of their identity as engineers [18-21].

III. METHODOLOGY

A pilot study was conducted during Fall 2014 in an engineering graphics and design freshmen course at Utah State University. Students were required to learn a 3-D sketching software and apply to an open-ended service learning design activity. Three sections (totaling 88 students) were sampled.

A. Research Questions

This work is partly funded through a Utah State University Research Catalyst SEED Grant.

For this work, the research questions were:

(1) In what way does Bloom's taxonomy when used to create course objectives for an authentic engineering design activity, promotes student development?

(2) In what way does Bloom's taxonomy when used to create course objectives for an authentic engineering design activity, promotes identification with and understanding of engineering?

B. Course Objectives Design

A freshmen level Mechanical Engineering graphics and engineering design course was created based on Bloom Taxonomy objectives (Table 1). A particular focus on Bloom's affective goals was purposefully included through incorporation of a service learning engineering design project, due to its limited exploration in engineering education [25, 26] and importance in the development of 21st century skills such as communication [27]. Additionally, course objectives were cross-aligned against ABET standards pertinent to Mechanical Engineering [1].

Course activities, particularly engineering design workshops and activities, were presented according to the UTeachEngineering engineering design cycle [28]. Each workshop contained group activities that were designed to tackle the knowledge-based, affective, and skill-based domains in Bloom's taxonomy while ensuring the ABET standards were being met.

C. Engineering Design Activity and Project in Course

The engineering design project was designed in coordination with a local disability employment facility. The organization hires individuals with disabilities to assemble and package several moving parts of a mining kit to be shipped overseas. One goal of the employment facility is to hire more people with disabilities but are faced with the issue of scale-up and proper assembly/training design.

As part of the project requirement, engineering students were asked to design a process around two choices: (1) Should a process be designed that is efficient but risked eliminating the role of the 'middleman' (employees with disabilities)?; or (2) Should a process be designed to enable the assembly to occur efficiently and in turn, create more jobs?

To aid students through the project, five engineering design workshops were taught around the UTeachEngineering framework [28] using Blooms' taxonomy objectives as a guide. At the end of the semester, students were asked to complete essays around six self-reflective questions aimed at understanding if they had developed an identification with the engineering profession. The questions are summarized in Table 3.

Table 3. Essay Questions

(1) What does the term 'engineer' mean to you?
(2) At this level in your education, do you consider yourself an engineer? Why or why not?
(3) Tell us a little about your personal and/or professional goals in becoming an engineer
(4) What professional and/or personal strengths and weaknesses did you

bring to this course's team project?
(5) What challenges arose in your team project? How did you handle or overcome this challenge?
(6) From this course, what did you learn about yourself and your stakeholders (clients, customers)?

D. Analysis of Essay Questions

Responses to the essay questions, which were de-identified according to IRB protocols, were qualitatively coded using NVIVO 10. *A priori* codes based on Bloom's Taxonomy (Table 1) and student development vectors (Table 2) were used to analyze the responses to the essay questions. Matrix coding query analysis was performed to cross-tabulate coding intersections between Bloom's taxonomy levels and levels of student development.

During instances that students indicated a decision to change career paths or to remain in engineering, these cases were quantitatively recorded. Finally, all students' responses to the first question (Table 3) was quantitatively recorded and split into four categories: (1) 21st century definition of an engineer (based on the National Academy of Engineering [NAE] definition: "Process of designing the human-made world...by modifying the world to "satisfy people's needs and wants"...[engineers] develop plans, design processes, and procedures" [29]); (2) engineer as a designer (a definition based from the Industrial Revolution [30]), (3) engineer as an inventor/tinkerer (a definition based from Da Vinci's days during the Renaissance [31]), and (4) an adopter of science and math (from the Scientific Era [30, 32]).

Each approach was done to understand the linear progression and results from the course: from presentation and use of Bloom's taxonomy for design of class activities, to understanding of student's development of professional competencies in engineering, to attainment or understanding of engineering by the students, which can impact their overall sense of fit or belonging to the engineering profession in response to exposure of an authentic (real-world and relevant to their immediate community) engineering design problem.

IV. PRELIMINARY FINDINGS

A priori codes using the three domains of Bloom's taxonomy (Table 1) were used to analyze students' responses to the essay questions. These responses were also coded to levels of student development posed by Chickering & Reiser (Table 2).

A. Bloom's Taxonomy Role in Student Development Vectors

Matrix coding query analysis was carried out for each to the three domains (affective, knowledge, and skills) and levels and were compared against student development vectors. Overall, engineering students did not demonstrate a sequential growth for all areas of Bloom's taxonomy with the exception of two areas: Knowledge-Based Skill (Level 7- Organization) and Affective Goals (Level 3- Valuing) were somewhat of a linear growth was seen. Below is a summary of the intersections in Table 3. All other items (not presented or left in blank) in Table 3 represents a non-intersection.

Table 3. Matrix Coding Query Analysis of Students' Responses

Bloom's Domains/ Level	Student Development Vectors (Increasing Vectors from Left to Right)						
	1	2	3	4	5	6	7
Affective/ Level 3	43%	100%	-	100%	-	100%	-
Knowledge/ Level 1	-	-	-	-	-	-	71%
Skills/ Level 2	32%	-	-	-	100%	-	-
Skills/ Level 7	25%	29%	100%	-	-	-	-

The results suggests that despite choosing course objectives and activities around Bloom's taxonomy and required engineering competencies, students are not growing in many of the expected areas. Semi-sequential growths were found for the affective and skills levels suggesting the importance of enriching engineering education experiences with affective and psychomotor domains, both of whom traditionally takes second-place against knowledge-based skills in engineering education [25, 26].

B. Role of Student Development, Self-Identification of Engineering with their Definitions of "Engineering"

Students that indicated an identification (or lack of) with the engineering profession were quantified. Each response was sub-categorized as a response that was influenced by external factors (such as interactions with peers and learning environments) and internal factors (such as mindsets and perceptions about the 'engineering culture'). An opposite effect was found for students that identified themselves with the engineering profession and the reasons for their responses (Fig. 1). Further exploration of the responses were done with respect to essay question 1 and their definition of engineering were sub-categorized by historical era (Fig. 2). Only a quarter of the engineering students aligned their definition of engineering to the NAE 21st century definition of the field suggesting a misunderstanding by the engineering students on what does the engineering profession consists of.

V. DISCUSSION/CONCLUSION

Preliminary findings suggest that establishment of course objectives and activities using taxonomies such as Bloom's taxonomy do not necessarily promote student development in desired domains. Furthermore, student development of these domains are heavily guided by students' perception of the field that they are studying.

In this work, only a fourth of the engineering freshmen accurately described the field. Interestingly, those that highly identified with the engineering profession attributed peer interactions, learning environments, and what they believed engineers are and do (mindsets) with their identification with the field. Those that did not identify with the field, primarily attributed this misidentification by their peer interactions and learning environments.

Overall, the data suggests that inclusion of affective and psychomotor activities promoted some growth but was

insufficient to drastically change students' perception about engineering. Interestingly, no sequential growth was identified in the knowledge-based realm suggesting that transient factors such as lack of familiarity on content may be at play [33]. These transient factors may not cement enough transferrable knowledge needed to create and establish an engineering identity. It is possible that more clarification activities to expose students to a 21st century definition of engineering may aid in further growth and development of desired competencies. An example of a clarification activity would be for an engineering educator to present students with an engineering design problem and ask them to outline the steps needed to solve the problem as if they were a professional engineer. Soon after students discuss their approaches, the engineering educator could present a video of a professional engineer describing the steps (s)he would take to solve the same engineering problem. Students can begin to self-assess the similarities and differences in their approaches and the engineering educator can premise this activity to speak about what a 21st engineer is and does.

**Figure 1.** Self-reported student identification with engineering**Figure 2.** Students' definition of "engineering"

ACKNOWLEDGMENT

This work was partly funded by the Research Catalyst SEED grant at Utah State University. I would like to acknowledge PARC: People with Disabilities Contributing to their Community in Utah (www.part-ut.org), Source America (www.sourceamerica.org), and the Disability Resource Center in Utah State for their invaluable mentorship and assistance in developing the workshops and course projects.

Building Information Modeling Laboratory Exercises in a Construction Science and Management Building Systems Course

Rogelio Palomera-Arias, Ph. D.
Department of Construction Science
University of Texas at San Antonio
San Antonio, TX, USA
rogelio.palomera-arias@utsa.edu

Abstract - This paper presents the development of Building Information Modeling laboratory exercises focused on Mechanical, Electrical and Plumbing (MEP) Systems in buildings. These laboratory exercises were developed to help construction science and management students better visualize and understand building systems and their relationship with each other as well as with other building components such as structural and architectural element. A popular BIM package was used to model the systems from an existing plan set, allowing the students to develop practical modeling skills, while providing a better understanding of MEP plan sets and system layout fundamentals. The BIM exercises were not used to replace, but rather supplement, the existing course laboratory exercises. The paper also discusses the perceived benefits as well as the challenges of using BIM as part of the teaching process. In addition to presenting the instructor experiences, a discussion of the results and observations stemming from student surveys collected at the end of the course is included. The paper ends presenting future changes to the course organization, as well as improvements to the course laboratory BIM exercises, that the author feels are required to facilitate the inclusion of BIM into the course.

Index Terms - Building Information Modeling, Computer Aided Instruction, Curriculum Design, MEP Systems.

INTRODUCTION

Starting with the 2014-2015 academic year, the curriculum of the Construction Science and Management (CSM) program at the University of Texas at San Antonio (UTSA) includes Building Information Modeling (BIM) courses as part of the degree requirements. The inclusion of BIM into the curriculum responds to current technology trends in the construction industry [1], as well as the CSM department goal of graduating well rounded students that are proficient with the software technology and tools currently being used in the construction industry, such as BIM, quantity takeoff (QTO) and estimating software, and scheduling software, among other computer programs [2].

Under the new catalog, BIM is covered primarily in three courses. The BIM software packages and fundamental concepts are first introduced in a dedicated course during the fall semester of the junior year, and then students are further exposed to specific aspects of BIM in the laboratory exercises of the program's Mechanical, Electrical and Plumbing (MEP) Systems course. Finally, students are required to use BIM as part of the program's final capstone project course during their senior year.

Reference [3] presents the computer laboratory exercises developed to introduce plan reading and quantity take off (QTO) software into various MEP systems courses taught previously by the author. The current paper presents the development of MEP focused BIM laboratory exercises used to expand and complement the current set of computer exercises used in the MEP systems course taught at the author's current institution. The MEP laboratory exercises presented here and in [3] have the objective of helping construction students develop some of the basic skillset and knowledge required and expected from them as it relates to the field of building MEP systems construction, such as plan reading, quantity take-offs (QTO), and estimating [4], [5].

In the following sections, the authors describe the MEP course, followed by the laboratory structure and topics covered, in both the new class format that incorporates BIM, and the previous class implementations prior to BIM. Then, a description of the general format used for the BIM-focused laboratory exercises is presented, as well as the instructor experiences with the development of the course together with the results and observations stemming from student surveys.

Lastly, the paper discusses future additions, changes and improvements to the course laboratory BIM exercises, as well as changes to the course organization and topics covered in order to ease the inclusion of BIM into the classroom.

MEP COURSE DESCRIPTION

The MEP course in the Construction Science Department at UTSA is structured as a 3-credit hour (2-2-3) course consisting of two hours of lecture, and a single two-hour

laboratory session per week. The MEP course goals and objectives are:

- Develop an understanding of the design principles of mechanical, electrical and plumbing systems.
- Develop an understanding of the principles, materials, and equipment used in plumbing/drainage, building electrical systems, HVAC, and fire protection and suppression systems.
- Read and interpret electrical, mechanical, plumbing and fire protection building construction plans and specifications.
- Conduct basic sizing and layout of MEP systems based on the building specifications, loads and demands.

The first two objectives are covered primarily through the lecture presentations, handout readings, and supplemental audiovisual materials, posted on the course Blackboard Learn® webpage, while the last two, more practical, objectives are covered primarily through the course laboratory exercises. Starting with the fall 2014 semester, Building Information Modeling became an essential part of the course laboratory component, as part of the department initiative to include BIM proficiency and knowledge in the program's graduate's skillset.

In the current implementation of the course, the lecture components and order of topics covered are not modified from previous incarnations, but rather the laboratory topics are arranged to follow the lecture subjects: electrical systems, followed by plumbing and fire protection, and finalizing with HVAC systems and building science fundamentals.

In the fall of 2014, the students taking the course were sophomores to seniors majoring in the Construction Science and Management (CSM) Bachelor program, and the majority of the students enrolled in the MEP course had either taken the program's first construction estimating course, or were taking it concurrently with the MEP class. Prior to the Fall 2014 semester, an introductory course to BIM was not a requirement of the program, so proficiency with BIM was not required nor expected from the students taking the MEP course at the time. However, a BIM course is now a requirement of the CSM program, and a pre-requisite for the MEP course, for any student enrolled in UTSA's CSM program under the 2014-2015 UTSA Course Catalog.

GENERAL LABORATORY DESCRIPTION

The laboratory exercises used and created during the fall 2014 semester were designed to introduce and develop practical knowledge in the following construction management areas as they apply to the most common MEP subsystems present in vertical construction:

- Plan reading and interpretation;
- Material quantity takeoffs (QTO);
- Basic system sizing;
- System modeling and layout, and;

- Fundamental principles calculations

Two software packages were used in the laboratory: On Screen TakeOff® (OST) published by OnCenter Software, Inc. [6]; and Revit 2014® (Revit) published by Autodesk, Inc. [7]. OST was used to perform the material QTO during some of the electrical and plumbing related exercises. A detailed description of the development of the OST based laboratory exercises was presented by the author in a previously in [3]. Revit was the only BIM software package used during the course, and it was required to perform the system modeling and layout exercises for the various MEP subsystems covered in the course. Finally, system sizing and fundamental calculations exercises were performed in the laboratory manually or using a spreadsheet program such as Microsoft's Excel®.

There were a total of ten laboratory exercises during the semester covering the areas described above. The order of the laboratories, as mentioned previously, closely follows the topics covered in the lecture component of the course. TABLE I lists the current laboratory topics, and the specific areas covered in each. All the laboratory instructions, handouts and supporting materials, were delivered, and the student work collected, using the Blackboard Learn® course management system. Students were required to submit a pdf file of their work, and in the case of BIM exercises, the Revit® model file (.rvt) or a pdf of a specific view of the model.

TABLE I LABORATORY WITH BIM FOCUS

Laboratory Description	Plan Reading	QTO	Sizing	BIM	Principles
Laboratory 1: Introduction to OST® and Revit®		x		x	
Laboratory 2: Electric Power and Loads					x
Laboratory 3: Power Distribution Systems	o	x		x	
Laboratory 4: Lighting Systems	o	x		x	
Laboratory 5: Electrical System Sizing			x

Laboratory 10: Heating and Cooling Loads			x		x

Legend: x-explicit focus; o-implicit focus.

Prior to the inclusion and use of BIM, the laboratory exercises focused on the following practical construction management areas:

- Plan reading and interpretation;
- Material quantity takeoffs (QTO);
- Basic system sizing;
- Basic material and labor estimating, and;
- Fundamental principles calculations

The main difference between this list and the one presented previously is the substitution of the estimating component of the laboratory with the system modeling and layout using Revit®. Also the number of exercises on each category was different than in the current implementation, with the five topics explicitly covered for each of the four MEP subsystems covered in the course, as presented in TABLE II.

TABLE II LABORATORY FOCUS PRIOR TO BIM

BIM LABORATORY EXERCISES DESCRIPTION

A total of six BIM exercises were created for the course during the fall 2014, one introductory exercise and five exercises to cover the following MEP subsystems: electrical power, electrical lighting, plumbing, fire suppression, and forced air HVAC.

The first laboratory was intended as an introduction to the two software packages that would be used in the course: Revit® and OST®. This introductory exercise provided the students with the opportunity to explore the software packages functions, and also served as the introduction to the building model that would be used throughout the semester. The building selected for most of the laboratory exercises is a single-story, open-floor plan, retail building with two small rooms and a single bathroom known as the "West Street Video Building". It contains full plumbing, including storm drainage, rooftop HVAC with ductwork, automatic fire sprinkler system, and a full electrical power and lighting system with a single electrical distribution panel. These are the systems covered in the course, at a relatively low complexity level. A full set of digital plans for the building was provided to the students in pdf format including architectural and structural plans, at a scale of an eighth of an inch to a foot ($1/8"=1'$) in an 11x17 page size (Fig. 1). The Revit® architectural base model (Fig. 2) was developed by the instructor based on the architectural and structural plans provided to the students. The model was

then distributed to the students using Blackboard® to allow them to add the MEP systems as the course progressed throughout the semester.

Fig. 1 Sample WEST ST. VIDEO BUILDING ARCHITECTURAL PLAN.

Fig. 2 West St. Video Revit Architectural 3D Model.

After the introductory laboratory, the other five problems focused on the individual systems, and were structured as step-by-step instructions that guided the student through the process of:

- setting up Revit® to define necessary floor-plans and 3D views in order to work with a particular MEP system;
- adding and defining required components to the library such as piping, fittings, ducts, equipment, fixtures, etc.;
- and placing the required system components into the provided architectural base model following the provided West St. Video Building plans.

The systems covered in these five laboratory exercises, and the order in which they were presented, followed the lecture schedule and is summarized by TABLE I presented in the previous section.

For example, Fig. 3 shows the bathroom detail available in the plumbing plans of the West St. Video Building, and Fig. 4 the resulting 3D model of the same space on Revit® that students following the "Laboratory 7: Plumbing Layout"

instructions were expected to produce using the basic architectural model provided. In order to complete the model, students had to perform, in addition to setting the appropriate model views, the following tasks

- Identify the plumbing fixture represented by the plan symbols, load the corresponding Revit family into the model file for them, and place the fixtures on the model
- Identify the required plumbing piping subsystems, such as water supply or sewer, identify the piping material and sizes, and load the required fitting families into the model in order to define the piping routing properties for the various piping systems
- Place pipes and fitting into the model at the appropriate elevations, connecting to the appropriate fixtures, and avoiding collisions (by visual inspection) with pipes already placed in the model.

Fig. 3 West St. Video Bathroom Plumbing Detail Plan.

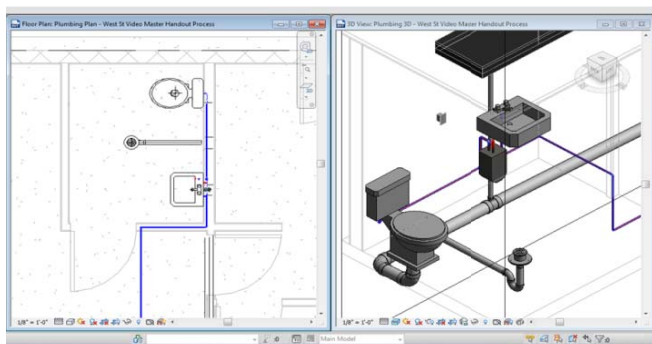

Fig. 4 Sample Revit® BIM Model of Bathroom Plumbing Detail.

Similar exercises to the plumbing systems were developed for the fire suppression and HVAC systems. These three MEP subsystems shared similar steps in the process to create the 3D Revit model, with the main difference being the Revit families that needed to be loaded into the model. For example in the case of air-forced HVAC systems, air terminals and mechanical equipment are loaded instead of the plumbing fixtures, and ducts and duct fittings are needed instead of pipes and pipe fittings.

Electrical systems followed a different approach as they focused more on generating “electrical plans” and “electrical circuiting” rather than visible 3D models of conduits and wiring layouts. Devices and lighting were placed on the architectural model in 3D, but only “electrical” connections were made between devices. Fig. 5 shows the generated electrical lighting 3D model (with HVAC and ductwork showing) with the corresponding Revit® produced lighting electrical floor plan. Notice the lack of a 3D model for the electrical circuit connections between devices as shown in the floor plan.

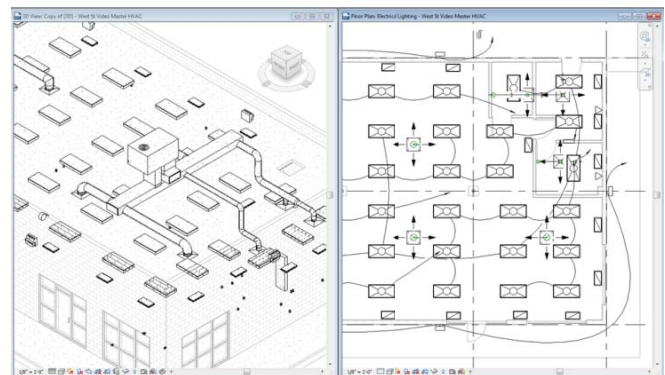

Fig. 5 Sample Revit® BIM Model of West St. Video Showing HVAC System and Reflective Ceiling Plan with Electric Lighting.

DISCUSSION

1. Instructor Perspective

From the author perspective, one of the main advantages of using BIM while teaching the MEP course is the ability to show and visualize system layout in three dimension, rather than relying only on two dimensional plans and drawings. The students are able to visualize layout issues that would otherwise not be evident, without prior experience or good intuition, from a collection of plans and riser diagrams. Among the issues that are better explained using three dimensional models are changes in elevation, overlaps, and special location of components in relation to other building components such as doors, windows, ceiling, etc. Also, subsystems can be easily classified and identified, and the relative scale of the components is clear from the BIM model.

One of the main problems encountered using the BIM software package was the learning curve associated with the software, which was accentuated by the fact that most of the students enrolled had no previous exposure to the software. Another caveat of the software relates to the working files size and the computer laboratory storage policies, which requires the use of external portable drives in order to allow students to work on the same project on different computers at various times during the semester, when the software is not installed on their personal laptops. Also, the instructor needs to plan accordingly to introduce the software package itself to the students, especially if it is the first time students are exposed to it.

Also, from the modeling perspective, Revit® requires extensive workspace setup, such as library loadings, systems definitions, and routing preferences to name a few, which requires a considerable amount of time and effort, as well as MEP systems knowledge, before the software can be used effectively. Also, the requirement of using a separate software package (i.e. Navisworks®), in order to run clash detection of systems in a building, requires additional class time, and possible resources, to take full advantage of the promises of BIM.

II. Student Perspective

The University of Texas at San Antonio follows a two-tier course evaluation procedure where students complete an online evaluation of the courses taken during the semester. This evaluation is used for administrative review purposes as well as assessment, and provides only a general measure of the course effectiveness and the instructor's teaching effectiveness without providing details on the individual course components.

In order to evaluate the perceived effectiveness of the BIM laboratory exercises, students were asked to complete an online survey on Blackboard® independently of the University's online course evaluation. The supplemental evaluation was used to ask the students questions regarding the following aspects:

- Usefulness and appropriateness of using BIM in a MEP course.
- Student proficiency with BIM software and effectiveness of laboratory problems.
- Laboratory problems organization and difficulty.
- And, appropriateness of the building models used in the exercises.

A total of 30 questions were asked, twenty-nine covering the topics above in a multiple selection scale format varying from 1 to 5, where 1 represents strong disagreement or highly negative feedback, and 5 represents strong agreement or highly positive feedback. The last question was included to allow students to provide written feedback on the laboratory exercises. Approximately 35 students were enrolled in the course, and the survey response rate was close to 50%.

The tables presented below summarize the student answers to the multiple choice questions asked in the end-of-class surveys. Each one of the tables presents the questions grouped by the categories or type of questions presented in the list above. TABLE III contains the questions regarding the usefulness and appropriateness of using BIM in the MEP course. TABLE IV contains the answer regarding the students self perceived proficiency with BIM before and after the MEP course, while TABLE V shows the students answers to the questions regarding the perceived effectiveness of the laboratory exercises in learning and understanding MEP systems.

TABLE III RESPONSES REGARDING BIM USE IN AN MEP COURSE.

Question	5	4	3	2	1
Do you think using Building Information Modeling, as part of the MEP System Course is a good idea?	27%	47%	20%	0%	7%
Does laboratory exercises, BIM or otherwise, should be part of the MEP course?	27%	60%	0%	13%	0%
Should an introductory BIM course be a requirement for the current MEP Course?	67%	27%	7%	0%	0%
How relevant were the BIM exercises to the CM profession?	13%	73%	13%	0%	0%
Does understanding BIM as it applies to MEP systems might help in your future CM career?	27%	73%	0%	0%	0%

TABLE IV STUDENT PERCEIVED BIM PROFICIENCY

Question	5	4	3	2	1
At the beginning of the class, how would rate your knowledge and proficiency of BIM software? (5=advanced)	0%	7%	7%	47%	40%
After completing the MEP class, how would rate your knowledge and proficiency of BIM software?	7%	40%	20%	27%	7%

TABLE V STUDENT PERCEIVED EFFECTIVENESS OF THE LAB EXERCISES

Question	5	4	3	2	1
Did you learn something useful from the BIM exercises?	7%	93%	0%	0%	0%
Using BIM in the laboratory, does it help understand MEP systems better?	13%	47%	27%	13%	0%
Using BIM in laboratory exercises, does it help understand how MEP systems are layout/routed?	20%	67%	13%	0%	0%
Using BIM in the laboratory exercises, does it help understand what components and pieces are needed?	13%	73%	13%	0%	0%
Using BIM helps understand electrical system better?	7%	40%	53%	0%	0%
Using BIM helps understand plumbing and fire suppression systems better?	7%	73%	20%	0%	0%
Using BIM helps understand HVAC systems better?	20%	60%	20%	0%	0%

TABLE VI and TABLE VII present the students answer to the questions regarding the laboratory organization and exercise difficulty, respectively. It is interesting to note that as part of the difficulty questions, students were also asked about how user friendly Revit® is, which resulted in almost an even split between students that feel the program is user friendly and those that feel it is not. Finally, TABLE VIII summarize the students answers to the questions relating to the appropriateness of the building used during the BIM exercises to model the various MEP systems covered in class.

TABLE VI STUDENT RESPONSES REGARDING THE LABORATORY FORMAT

Question	5	4	3	2	1
How do you feel about the number of BIM exercises done over the semester? (5=too much)	0%	20%	67%	13%	0%
Is one week to complete each exercise enough time? (5=too much)	0%	27%	67%	7%	0%

TABLE VII STUDENT PERCEIVED LABORATORY EXERCISES DIFFICULTY

Question	5	4	3	2	1
Ignoring the software learning curve, the tasks that you were asked to complete during the BIM exercises were difficult?	7%	27%	53%	13%	0%
In regards to the BIM software used in the	7%	40%	0%	40%	13%

Question	5	4	3	2	1
labs, is the software user friendly?					
Using REVIT is a distraction from understanding MEP systems?	0%	33%	13%	27%	27%
Does the content of the BIM exercises complement the lecture materials?	20%	40%	27%	13%	0%
Do the instructions provided in the lab handouts were easy to follow?	0%	53%	7%	33%	7%
Does the instructions provided in the labs were sufficient to complete the exercises?	7%	53%	27%	7%	7%

TABLE VIII STUDENTS RESPONSES REGARDING THE BUILDING MODELS USED

Question	5	4	3	2	1
Do you think the building model used (West St. Video Building) was a good choice?	27%	47%	27%	0%	0%
Was the other building model used (Kamp for Kids Basement) a good choice for electrical exercise?	13%	40%	47%	0%	0%
Should the same building be used for every exercise?	47%	27%	13%	13%	0%
Do you think that adding more detail to the building models, such as furniture, finishes, doors and windows is relevant while working with MEP systems in BIM?	0%	20%	27%	47%	7%
When working with a particular MEP system, should the model not have any other MEP systems on it?	7%	13%	40%	20%	20%
When working with a particular MEP system, should the model already have all the other MEP systems on it?	7%	13%	33%	40%	7%
If the same building model is used for all the exercises, should the MEP systems be added sequentially throughout all the exercises?	47%	53%	0%	0%	0%

Based on the feedback received and the results presented in the tables above, the majority of students feel that it was a good idea to have BIM as part of the course, and that the laboratory exercises were conducive to learning. However, students felt that the building model, as well as the laboratory handouts and problems could be improved, especially on the electrical systems part of the course. Also, the students strongly feel that a previous BIM course would be beneficial to student enrolled in the MEP course.

CONCLUSIONS AND RECOMMENDATIONS

Starting with the 2014-2015 academic year, the curriculum of the CSM program at UTSA encompasses BIM as part of the degree requirements. As part of this new requirement, the MEP Systems course was modified during the fall 2014 to incorporate BIM as part of the laboratory exercises.

The laboratory exercises developed during the fall 2014 semester are the first step in the ongoing process of

incorporating BIM into the MEP course offered in the Construction Science Department at UTSA. During this first stage, only the basic 3D MEP systems modeling capabilities of Revit® were explored. The BIM exercises were designed as step-by-step instruction that guided the students through the process of adding MEP systems into an existing architectural model, as a way to recreate an existing plan set.

The advanced capabilities and features of the BIM software package, such as automatic quantity take off, or schedule generations, to name a few, were not explored. Furthermore, clash detection of MEP systems and structural systems, which is one of the most important benefits, and drivers, for the use of BIM during design and construction of buildings, was not covered. These omissions would be the next logical additions to the laboratory exercises.

Finally, the order on which the MEP systems are covered in the course needs to be modified to reflect the prevalent (historically) coordination of MEP systems, and to facilitate the modeling of these systems in BIM: HVAC, followed by plumbing and fire suppression, and ending with power and lighting systems.

How the Web Was Won

Keeping the Computer Networking Curriculum Current with HTTP/2

Abstract— The Internet and the Web continue to grow in their pervasiveness and as new functionality and behavior emerge it is a challenge to keep the computer networking curriculum up to date. There are many excellent networking textbooks available but they cannot always keep pace with the rate of change. Recent developments in HTTP are a good example of this situation. Since around 2012 many of the web transactions between popular browsers and major web sites have been using a protocol called SPDY, which operates significantly differently from HTTP version 1.1 – the version covered in networking textbooks. SPDY has been largely adopted into the final standard of HTTP version 2. This paper seeks to fill the gap between current textbooks and the versions of HTTP now in use. It gives an overview of HTTP evolution from a technical perspective before suggesting materials and approaches that can be used as learning resources for the topic and how conceptual understanding can be reinforced through hands-on activities which use browsers' native network monitoring capabilities and other readily available tools.

Keywords—Computer Networking Education, HTTP Evolution

I. INTRODUCTION

As a consequence of the Internet boom around the year 2000 computer networking education has been well served in terms of textbooks. A challenge for authors of the more comprehensive networking textbooks however is keeping them up to date.

Table I: Frequency of networking textbook publication update

	Edition and Year of Publication						<i>average update interval</i>
	1	2	3	4	5	6	
T&W	1980	1988	1995	2002	2010		7 years
P & D	1996	1999	2003	2007	2011		4 years
K & R	2000	2003	2005	2007	2009	2012	2 years

If we take three major texts: Tanenbaum and Wetherall¹ (T&W) [1], Peterson and Davie (P&D) [2], Kurose and Ross (K&R) [3]; we can get a feel for the rate of change by looking at the frequency of new editions (see Table I).

¹ Andrew Tanenbaum was the sole author of editions 1 – 4; he was joined by David Wetherall as co-author for the 5th edition.

The more recently authored books show a greater frequency of revision and as revising a major textbook is a time consuming process it can be assumed that these updates are considered too important to delay for longer periods. Yet, at the same time, we do not have to look far to find an example of a widely used Internet protocol that is not covered by even the most recent textbooks – SPDY – the basis for HTTP/2.

Why is the HTTP family of protocols (HTTP 1.0, HTTP 1.1, HTTPS, SPDY, HTTP/2) an important part of the networking curriculum? Firstly, these are the application level protocols that carry the largest proportion of Internet traffic including social media, e-commerce, and streaming video. As such it is incumbent on networking education to explain the principles, operation, benefits and drawbacks of such a widely used set of protocols.

Secondly, in contrast to the traditional bottom-up networking pedagogy whereby the physical layer is covered first, then the link layer, and so on, a top-down approach starting with the application level has been introduced by books such as K&R, and widely adopted. Peterson and Davie's book is structured as bottom-up but for the 5th edition they issued an alternative pathway document on how to use their content in a top-down manner. HTTP is naturally one of the most relevant application level protocols to use in a top-down approach. Students can quickly feel a sense of achievement in designing and deploying their own web server which in turn promotes engagement with other aspects of the discipline.

Finally, through the critical study of this family of protocols students can gain insight into Internet protocol design, evolution and standardization. For example, there is educational value in covering HTTP/2 as it shows that key features of HTTP 1.1 such as pipelining, described as performance enhancement in textbooks, never actually worked in practice and were not adopted or deployed. While it is testimony to the value of layered model abstraction that few web users are aware when they are obtaining content via SPDY rather than HTTP 1.1 it is not an acceptable situation for students in computer networking classes, especially as they are still being taught about the operation of earlier forms of HTTP in major texts.

This paper proceeds by reviewing the HTTP story so far then makes suggestions for readily available resources which can

support the inclusion of HTTP/2 in an evolutionary context, within the networking curriculum.

II. THE HTTP STORY SO FAR....

The original Web was based around the hypertext transfer protocol (HTTP) and the hypertext mark-up language (HTML). There were numerous precursors in the form of distributed hypertext systems, but in true Internet tradition the simplicity and openness of the original HTTP and HTML standards allowed them to be readily implemented in forms that could be made to interoperate across the network. HTTP 0.9 was published in 1991 [4]; it was a subset of what was called “Basic HTTP” in 1992 [5] – much of which became known as HTTP 1.0 [6]. In 1993 a major boost came in the form of the Mosaic web browser [7] which was easy to use and brought multimedia web pages to life. It was not uncommon to hear the term “the Mosaic protocol” being incorrectly used to refer to the web at that time. As the use of the web snowballed, HTTP 1.0 (fully specified in 1996), attracted attention from network researchers and they discovered considerable space for improvement [2-5].

Figure 1. (a) http 1.0 (b) http 1.1

The most significant problem identified was the interplay between TCP and HTTP. Most interactions between a web client and a web server at that time were between a client and the same server. However, each HTTP response and request required its own TCP connection. As TCP uses three segments to set up a connection and up to four segments to close it down, the transport protocol overhead typically used more network resource in terms of Round Trip Time and bandwidth than the application level protocol. Figure 1a shows

HTTP 1.0 obtaining two web objects. This profligate use of TCP was seen as wasteful, and of course, congestion avoidance was also a big issue. In addition HTTP 1.0 is a “stop and wait” protocol so if a web page consisting of some text and a few images was to be built and rendered then multiple TCP connections were needed and enterprising browser designers decided to open these in parallel, reducing the overall Page Load Time (PLT), delivering a better user experience, but effectively subverting the aims of TCP’s congestion management mechanisms in the sense that one application was getting more than its “fair share” of available network resource. However, depending on the context consisting of the actual clients and servers, their platforms, the web page(s) being requested, and the network path, significant parts of the overall delay in PLT could often be traced to the browser, the server or the TCP protocol rather than the network throughput or HTTP protocol [8] [9].

A. HTTP 1.1

HTTP 1.1 [10] sought to improve over the previous version in the areas of: Caching, Bandwidth optimization, Connection management, Message transmission, Internet address conservation, Error notification, Security, Integrity & Authentication, and Content negotiation [11].

Briefly; IP address conservation was improved through the use of virtual hostnames for servers, specified in the new header “host” field; caching was better supported by the introduction of unique ETags for objects; in practice HTTPS (HTTP over SSL or TLS) was adopted rather than the proposed HTTP 1.1 mechanisms for security; message transmission encoding could be treated distinctly from content encoding.

The concern over the inefficient use of TCP was addressed by improved connection management in the form of persistent connections. This is supported by the “Keep-Alive” header field and is in widespread use. This means that a single TCP connection between a client and a web server can be kept open to support multiple HTTP request/response interactions (see Fig. 1b).

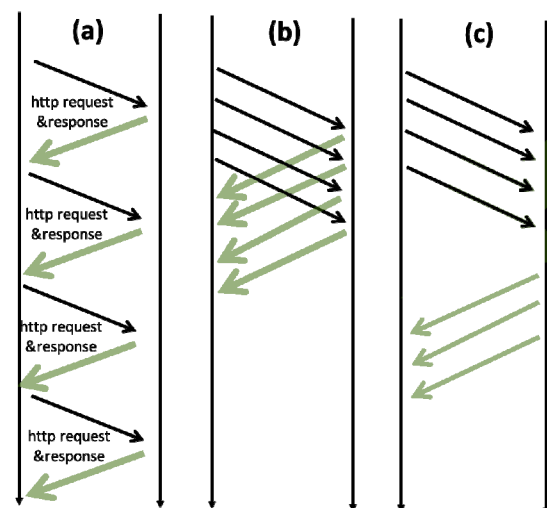

Figure 2. a) Stop & Wait; b) Pipelining; c)Head of Line Blocking.

It was hoped that the introduction of persistent TCP connections would reduce the number of parallel HTTP/TCP connections opened by a browser. In practice this did not happen.

Bandwidth optimization was addressed mainly by the introduction of pipelining, whereby a client did not need to wait for a response before sending a further request (see Fig 2a, b). In practice, pipelining was not adopted. It was partly thwarted by intermediary boxes such as proxies, but also by the “head of line blocking” situation (see Fig 2c), whereby servicing a single long-running request could hold up all subsequent ones, even though they could be answered relatively efficiently. In short, bandwidth optimization did not succeed.

Two points should be noted about HTTP 1.1. Firstly, it was designed to be backwardly compatible with HTTP 1.0, so older clients could still interact with newer servers and newer clients work with older servers. This was achieved by simply making none of the new features mandatory. Hence pipelining could be allowed to fail through lack of popular adoption. However, another new feature, the “Upgrade” header, was intended to allow for both client and server to switch entirely to an alternate protocol for content transfer. This added some future proofing to HTTP 1.1 and is now used for switching to HTTPS or SPDY.

B. HTTPS

As the global, public Internet became increasingly used for commercial and mission critical purposes it became necessary to provide security.

Application	Application
TCP	SSL
	TCP
IP Network	IP Network

Figure 3: The Secure Sockets Layer

The Secure Sockets Layer (SSL) or Transport Layer Security (TLS) does this for TCP at the transport level. SSL provides confidentiality, integrity & end-point authentication. Any networked application written using the TCP socket programming abstraction can readily improve its security by using SSL. This has led to many common networking applications being deprecated or firewalled and replaced by their SSL-based secure versions. The remote shell command `rsh` became `ssh`, `cp` became `scp`, `ftp` became `sftp` and so on. While some HTTP sites moved to HTTPS, the relative proportion of HTTPS/HTTP traffic remains small, even though there was a post-Snowden surge in May 2014:

“before the Snowden revelations encrypted traffic accounted for 2.29 percent of all peak hour traffic in North America, according to Sandvine’s report. Now, it spans 3.8 percent. But that’s a small jump compared to other parts of the world. In Europe, encrypted traffic went from 1.47 percent to 6.10 percent, and in Latin America, it increased from 1.8 percent to 10.37 percent.” [12]

While HTTPS provides a relatively high degree of security for web traffic compared with HTTP the flawed operation of the Public Key Infrastructure commercial market has partially undermined its reliability [13].

C. HTTP/2 and SPDY

HTTP/2 [14] [15] is a major enhancement to HTTP 1.1, principally motivated by the need to improve the Page Load Time (PLT) of modern, large, complex web pages. Average page sizes and their complexity in terms of the number of objects have grown from approximately 10 Kbytes in 1995 to 1600 Kbytes in 2014, and from two objects in 1995 to over one hundred objects in 2014 [16]. Not only has the number of objects grown, but they are more varied in type and come from an increasing number of different domains.

“Today’s Web bears little resemblance to the Web of a decade ago. A Web page today encapsulates tens to hundreds of resources pulled from multiple domains. Users access the Web from diverse device form factors, while browsers have improved dramatically.....A constant throughout this evolution is the underlying application layer protocol—HTTP— designed at a time of far less page complexity.....HTTP (1.1) is not optimal, with pages taking longer to load. Studies over the past five years suggest even 100 milliseconds additional delay can have a quantifiably negative effect on Web use, spurring interest in improving Web performance” [17].

Figure 4: Impacts of Bandwidth vs RTT on Page Load Time (from [18]).

While the network and protocol components are only part of the overall delay in Page Load Time, the latency engendered by HTTP 1.1 was seen as a worthwhile target, and hence Google launched the SPDY R&D project in 2009 to provide an alternative protocol.

“SPDY adds a framing layer for multiplexing multiple, concurrent streams across a single TCP connection (or any reliable transport stream). The framing layer is optimized for HTTP-like request-response streams, such that applications which run over HTTP today can work over SPDY with little or no change on behalf of the web application writer.....SPDY attempts to preserve the existing semantics of HTTP. All features such as cookies, ETags, Vary headers, Content-Encoding negotiations, etc work as they do with HTTP; SPDY only replaces the way the data is written to the network.” [19]

Internet access bandwidths have increased while pages have grown but the basis for much of SPDY’s design was the belief that the main gains could be achieved by reducing the aggregate Round Trip Time (RTT) in a session. The comparison provided by Belshe [18] (see Fig. 4) pointed towards the relative importance of reducing RTT as opposed to increasing bandwidth beyond e.g. 3 Mb/s. In 2014 Akamai reported the global average connection bandwidth as 4.5 Mb/s [20].

HTTP/2, which started as a copy of SPDY in 2012, was almost fully accepted as an Internet standard by early 2015[14].² A very significant point is that unlike the change from HTTP 1.0 to HTTP 1.1, a SPDY implementation must support *all* the SPDY protocol features. This is achieved by using the “UPGRADE” header in HTTP i.e. if the client and server agree to switch to SPDY then all the new features must be supported. All SPDY traffic is encapsulated by SSL, and uses port 443. HTTP/2 has left open the possibility of non-SSL based sessions, but by March 2015 this option does not appear to have been implemented, and it is not clear that it will be. HTTP/2 also seeks to reduce the number of concurrent TCP connections from a browser to the same domain.

By 2014 most of the global web-based service providers including Google, Twitter and Facebook supported SPDY at the server side, and most of the popular browsers, Chrome, Firefox, Safari and IE, supported SPDY at the client side, so in effect, SPDY had already conquered a significant part of the web before being repackaged as the HTTP/2 draft standard.

The following subsections outline the key features introduced by SPDY and mostly adopted in HTTP/2 [21].

1) Frames, Streams and Multiplexing

The unit of communication in HTTP/2 is the *frame*. There are ten different frame types: DATA, HEADERS, PRIORITY, RST_STREAM, SETTINGS, PUSH_PROMISE, PING, GOAWAY, WINDOW_UPDATE, CONTINUATION.

² SPDY and HTTP/2 are used interchangeably in many papers due to the great influence of SPDY on HTTP/2.

A *stream* in HTTP/2 consists of bidirectional sequences of frames flowing between two endpoints (client and server). The server and client can send data simultaneously. Multiplexing allows for multiple streams of request and response frames (of maybe similar or different data) on a single TCP connection.

2) Prioritization, Dependency of Streams

Streams can be interleaved and prioritized. This allows an endpoint to allocate more resources to what is being prioritized when managing concurrent streams. Priority information can be used to select the appropriate streams for transmitting frames when there is limited sending capacity for any reason. A client can assign a priority number for a new stream in the HEADERS frame. Reprioritization of reserved streams can be regulated by the PRIORITY frames. This allows for more effective pipelining than HTTP 1.1 in that Head of Line blocking (see Fig 2c) can be avoided.

Streams can explicitly depend on the completion of other streams. This also affects the priority of streams. Dependency is assigned a weight between 1 and 256 inclusive. Dependent streams share the resources assigned to their parent in accordance with the weight assigned to them. Dependent streams move with their parent stream whenever the parent is reprioritized. A stream that is not dependent on any other stream is given a weight of 0 [14].

3) Binary Framing Layer

The binary framing layer in SPDY “dictates how the HTTP messages are encapsulated and transferred between the client and server”[22]. HTTP/2 has kept the same semantics, such as verbs and headers of HTTP 1.x. Changes occur in how these semantics are encoded, encapsulated and then transferred. In other words, their encoding in transit is what is different.

4) Server Push

A server can send pre-emptively (or “push”) additional objects in addition to replying to requests from clients. For example, a server can send images, icons, CSS or JavaScript code before the client explicitly requests them. A client can however request that *server push* be disabled during a connection. Khalid et al. [23] have argued that this feature can be problematic in mobile devices because it can waste battery or bandwidth and proposes mechanisms for HTTP/2 that adjust the overall performance on mobile devices.

5) Header Compression

In HTTP 1.x, headers are typically repetitive and verbose. HTTP/2 compresses headers using the HPACK algorithm [24], based on Huffman encoding.

6) Flow Control

HTTP/2 Flow Control is used for both individual streams and for the connection as a whole. It is regulated through the use of the WINDOW_UPDATE frame; only DATA frames are subject to its effect. Receivers advertise how many octets they can receive for a specific stream or for the whole connection. The sender must respect the limits advertised by the receiver.

Flow control in HTTP/2 aims to make it possible to utilize network resources better by not allowing a particular stream to starve, and by dealing with slow/fast upstream and downstream connections adequately.

7) RTT and Liveness

PING frames have the highest priority. They are used to measure round trip time and check if the connection is still functional or the peer is still alive.

III. SUPPORTING HTTP IN THE NETWORKING CURRICULUM

This section suggests resources that can be used educationally to complement the accounts of HTTP in popular texts through contextualization and hands-on exercises.

A. Contextualisation

The story of HTTP evolution from HTTP 0.9 to HTTP/2 is in itself an educational topic, illustrating the standardization process in the W3C and IETF. Popular textbooks use HTTP 1.1 as a reference, some of them including the pipelining feature which has never been widely used in practice. It is recommended that the sections on HTTP in such texts are augmented by information on SPDY and HTTP/2. An accessible, if rather uncritical, overview of SPDY can be found in [17]. A short and readable account of the key differences between HTTP 1.0 and HTTP 1.1 can be found in [11]. Critical commentaries on SPDY and HTTP/2 can be found in [25, 26]. Table II gives a summary overview of key differences between the deployed versions of HTTP between 1995 and 2015.

Internet standards are published as RFCs. The nature of RFC content has been referred to as “...very technical, turgid and nearly incomprehensible” [27]. As a light-hearted poke at RFC 2068 (HTTP 1.1), RFC 2324 uses the same language style to describe the Hyper Text Coffee Pot Control Protocol (HTCPCP) [28], which amongst other features introduces the new error code 418 “I’m a teapot”.

These types of textual materials can be used by lecturers as the basis for learning resources, or can be passed directly to students as study topics for essays. Branches can be followed if there is time in the curriculum. For example a particular criticism from [26] is that all HTTP/2 sessions are being run over TLS. Empirical studies have shown that there can be a significant cost of using SSL [29] – so when is a secure connection really (not) needed? Do public library opening hours and bus timetables need to be rendered immune from eavesdroppers?

Another criticism of HTTP/2, possibly best suited for more advanced students, is that it violates the established network design principle of *layering and abstraction* by replicating much of the functionality already provided by TCP at the underlying transport level. For example, both protocols support flow control, window size negotiation and pipelining. A further consideration is that SPDY introduces explicit state to HTTP, by way of session initiation and closedown, in a similar way that a TCP virtual connection is managed in its macro state.

Studies have compared the performance of SPDY to previous HTTP versions [30] [31]. These give mixed, sometimes contradictory, results in terms of SPDY outperforming older versions of HTTP or the opposite. SPDY has been studied on mobile devices[32] and on high latency Satellite networks [33].

Other factors such as Web page characteristics, server load and browser processing also play an important role in the overall perceived page load time of course [25].

Part of the wider context includes the topic of making the web faster. This can include Content Distribution Networks (covered in major textbooks); increasing TCP’s opening window size [34], and domain sharding, whereby a browser is forced into making parallel connections due to deliberately placing web page components in different domains [35].

Table II: Summary of major differences in HTTP versions 1.0, 1.1 and 2

HTTP 1.0	HTTP 1.1	HTTP/2
“Stop and Wait”, strictly sequential processing of requests and responses over TCP	“Stop and Wait”, strictly sequential processing of requests and responses over TCP	Full duplex streams of binary frames over TLS/TCP
PDU: HTTP Message	PDU: HTTP Message	PDU: HTTP/2 Frame (10 Types)
New TCP connection opened for each Request/Response pair Browsers seek performance gain by opening multiple parallel TCP connections, even between client and server in same domain	Persistent TCP connections specified and adopted Pipelining specified but not mandatory and not adopted Browsers continue to open multiple parallel TCP connections within same domain	Aim: One persistent TCP Connection per domain Multiple concurrent streams within the TCP connection Pipelining mandatory Stream Multiplexing and Prioritization Dynamic stream dependencies and reprioritization
Caching, Content compression option	Caching, content compression option	Caching, Content compression Header Compression Server Push Flow Control

Figure 5: A waterfall view of page load time from www.webpagetest.org after accessing google.com

Web page content optimization is supported by systems such as ModPageSpeed [36], an executable Apache module that uses a complex set of rules to dynamically rewrites a page for particular connection.

David Wetherall has prepared a MOOC based on T&W 5th edition [1]; the videos can be accessed on demand, irrespective of the MOOC schedule. Video 8.8 [37] lasts for twenty minutes and addresses the future of HTTP, a topic not covered in the book. Around four minutes is spent on SPDY and HTTP/2 developments. The tentative nature of the discussion suggests the video was made around 2012. It is a useful high level introduction to the modern web.

B. Hands-on activities: observation and analyses

The use of Wireshark [38] in lab exercises has been popularized in supporting material by Kurose and Ross [3].

Recent Wireshark releases support both SPDY and HTTP/2 identification.

The *webpagetest* tool [39] is a free online service that is also useful educationally. Figure 5 shows a “Waterfall View” of the Page Load Time for google.com (from webpagetest’s point of view onto the Internet). There are also facilities built-in to Chrome and Firefox that allow students to observe the components of PLT. These can optionally be displayed in a waterfall style (Fig.6). Note that a Firefox add-on [40] signals in the address bar that SPDY or HTTP/2 is in use.

The web page at spdycheck.org tests user-specified sites for SPDY, TLS, HTTP/2 and HTTP 1.1 support. Networking students can progress from understanding to creating by writing their own code to carry out these tests.

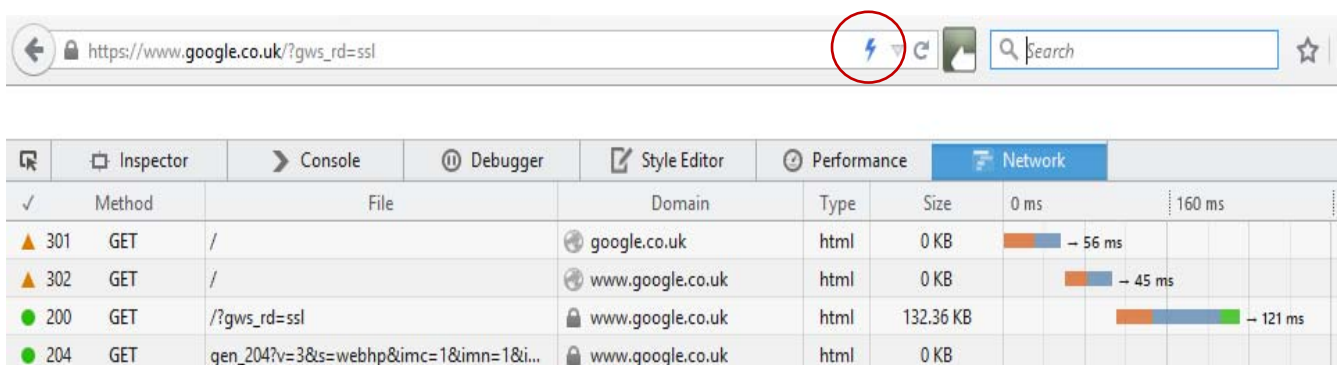

Figure 6: Screenshot of Firefox’s built-in network monitoring facility; an add-on [40] shows when SPDY or HTTP/2 is in use (circled)

```

```

Figure 7: A trace from Chrome's built in network monitor showing a SPDY session

It is possible to get a breakdown of a SPDY or HTTP/2 conversation in Chrome by initially using the URL: `chrome://net-internals/#spdy`. This brings up the following information:

- HTTP/2 Enabled: true
- Use Alternate Protocol: true
- Force HTTP/2 Always: false
- Force HTTP/2 Over SSL: true
- Next Protocols: http/1.1, spdy/3.1, h2-14

If a live HTTP/2 session is then selected, the working of the protocol can be observed, including streams, priorities and flow control window size (see Fig 7). It is interesting to note that in some cases e.g. Facebook, SPDY appears to act as an encapsulating layer for HTTP 1.1 whereas in an all-Google HTTP/2 conversation (Fig. 7) there is no explicit mention of HTTP 1.1 although the familiar header fields are listed.

Entering `about:config` and then searching for `spdy` in the Firefox address bar will elicit the list in Table III.

Table III: Firefox SPDY parameters

<code>network.http.spdy.allow-push</code>	true
<code>network.http.spdy.chunk-size</code>	16000
<code>network.http.spdy.coalesce-hostnames</code>	true
<code>network.http.spdy.default-concurrent</code>	100
<code>network.http.spdy.enabled</code>	true
<code>network.http.spdy.enabled.deps</code>	true
<code>network.http.spdy.enabled.http2</code>	true
<code>network.http.spdy.enabled.http2draft</code>	true
<code>network.http.spdy.enabled.v3-1</code>	true
<code>network.http.spdy.enforce-tls-profile</code>	true
<code>network.http.spdy.persistent-settings</code>	false
<code>network.http.spdy.ping-threshold</code>	58
<code>network.http.spdy.ping-timeout</code>	8
<code>network.http.spdy.push-allowance</code>	131072
<code>network.http.spdy.send-buffer-size</code>	131072
<code>network.http.spdy.timeout</code>	180

Students can be asked to research and explain the meanings of these parameters, and can also change the settings and record the effects when interacting with the same web site.

C. Hands-on activities: Simulators and Emulators

For students with adequate time the next stage beyond observation and analyses is to use a simulator to modify traffic characteristics such as bandwidth, packet loss and delay, to see how that impacts on performance. A good starting point is to give the student a pointer towards Belshe’s comparison of bandwidth vs RTT [18] with respect to impact on PLT (see Fig. 4) and ask them to see if they can reproduce these figures through simulation and measurement. Science is built on reproducible research results but in the case of Internet measurements, even simulations, reproducibility can be challenging.

There are various open source network simulation tools available, including ns3 [41] and Trickle [42]. Opnet is now called Riverbed Modeler [43] and is free for academic use.

In lab exercises the traffic shaping Linux kernel library (tc) [44] and NetEm [45] can be used to emulate delay and packet loss. Bandwidth control can be achieved using the Hierarchical Token Bucket control feature of the queuing discipline interface (qdisc) [46] in Linux. SPDY or HTTP/2 can be turned on and off in Chrome using the Chrome settings option. Sites including Facebook, YouTube and StatCounter can be used as test cases. In our experience it proved hard for any student to replicate the performance gains expected by moving to SPDY, but we should emphasize that this was an educational exercise rather than a robust piece of research.

IV. QUIC

Interestingly, when observing and analyzing live HTTP/2 connections we discovered the QUIC protocol [47] being deployed by Google.

“QUIC is an experimental protocol aimed at reducing web latency over that of TCP. On the surface, QUIC is very similar to TCP+TLS+SPDY implemented on UDP. Because TCP is implement in operating system kernels, and middlebox firmware, making significant changes to TCP is next to impossible. However, since QUIC is built on top of UDP, it suffers from no such limitations.” [47]

QUIC supports HTTP/2 functionality over UDP port 443. During a SPDY session the UPDATE header is used to switch to QUIC; this appears to be the current Google protocol of choice for short exchanges such as visits to sites which record advertising, analytics and marketing information. Entering `chrome://net-internals/#spdy` in the Chrome address bar reveals a comprehensive list of alternative QUIC based URLs for Google services.

Why QUIC? Part of the performance problem for SPDY and HTTP/2 lies in the behavior of TCP (see [48] [32]). A single TCP congestion avoidance window can put SPDY or HTTP/2 at a disadvantage compared with multiple HTTP 1.1/TCP connections each with a separate congestion window, which is often the case with HTTP 1.x.

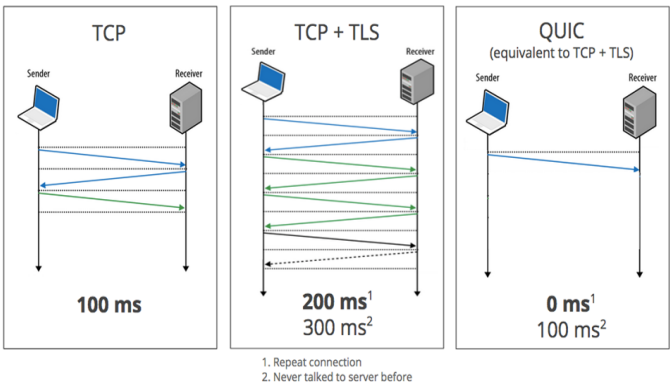

Figure 9: QUIC’s Zero Round Trip handshake

A single lost packet will impact on *all* the multiplexed streams in a single TCP connection. QUIC is UDP based so avoids this. In addition, QUIC has a *zero round trip handshake* capability, see Fig. 9, conveniently avoiding the TCP handshaking and close down exchanges (see Fig. 3) that would increase the number of round trips.

HTTP/2	HTTP/2
SSL or TLS	QUIC
TCP	UDP
IP Network	IP Network

Figure 10: HTTP/2 alternative protocol stacks

However, UDP lacks congestion control and SSL functionality so QUIC seeks to replicate these within itself: QUIC has a pluggable congestion control algorithm option which is currently TCP Cubic and supports its own TLS-like security protocol, thus seeking to recreate the semantics of HTTP/2 over TLS/TCP without the performance drawback. Figure 10 summarizes using networking layered models. Recent versions of Wireshark can identify QUIC.

V. CONCLUSION

Areas of the Internet are undergoing a rapid rate of change. A pertinent example is the HTTP 1.1 application-level protocol which has been superseded by SPDY in many of the web transactions between popular browsers and major web sites since 2012. While it is testimony to the value of protocol layering that web users are largely unaware of this major change in HTTP it is not acceptable that computer networking students remain ignorant of it. It is incumbent on educators to ensure that the curriculum reflects such significant changes in this pervasive web protocol. Most of SPDY has now been adopted as the HTTP/2 standard but even the most recent editions of established computer textbooks have not caught up with HTTP/2. This paper makes a modest contribution towards filling the current gap by giving recommendations for resources that can be used to contextualize and obtain hands-on experience of recent developments in HTTP evolution.

Abstract—

Engineering students need to learn highly effective processes for pursuing difficult design problems that require highly innovative solutions. Few studies exist of highly successful expert design teams. The current paper presents the results from a multi-million dollar department of energy research project which reduced the racking hardware and mounting installation costs for commercial applications by more than 50%. This was an extremely challenging goal which was met. This study focuses on the prototyping processes of the team in order to determine effective approaches. Structured interviews with documentations of the prototypes were conducted. Results show the team while the team started with prototyping the complete system they often iterated at the component then integrating it into the complete system prototypes. The early tests of the prototypes tended to be less formal and the number of test increased with each prototype. The professional team also reverted to earlier versions and restarting their processes when a given design path was not successful.

Keywords—prototyping strategy; expertise; product design

I. INTRODUCTION

In order for engineering students to be very successful designers, they need to learn effective design processes and practices to complete their technical skills. Included in these skills sets are strategies for effective prototyping that maximize the knowledge and design confidence gained while minimizing cost and time. Unfortunately, few studies provide highly detailed accounts of the prototyping strategies employed by highly innovative design teams. The lead authors of this paper were provided access to a team of designers that have made significant inroads to reducing the installation costs of solar panels. Through structured follow-up interviews, details account of the prototypes and their purposes was obtained from the designers. Some intriguing outcomes and potential strategies for students were obtained.

II. BACKGROUND

A. Prototyping Strategies

Prototypes are powerful tools in the process of designing a new product. They allow for the designers to strengthen their mental models of how a design will look and behave [1], effectively share ideas with other designers [2] and

provide a medium for validating or improving design decisions [3]. Prototypes have the ability to reveal shortcomings that may not be detectable by other methods [1, 4-6]. However, there are potential problems that can occur as a result of using prototypes. Due to the money, effort, and time spent on materials and fabrication of prototypes, design fixation can occur as a part of the “Sunk Cost Effect” [6]. This theory states that the more resources expended on a certain path, the less likely a designer will be to move on to a new idea. Design fixation and other shortcomings in the use of prototypes can be mitigated through strategy in the construction of prototypes [7-9]. It has also been observed that more experienced designers are more successful in mitigating design fixation [10].

While experts are better at mitigating fixation, physical prototypes have been found to help students overcome design fixation. In the experiment performed in [11], students were given a flawed prototype and asked to construct a more effective design. The participants fixated on the flawed design at first. However, the participants were able to quickly overcome their initial fixation through testing a rebuilding the prototypes. This shows that while prototypes can cause fixation, they can also be used to overcome it. Therefore, it is important for students to learn effective prototyping strategies. In a previous study [1], Viswanathan, et al. found that professional designers would purposefully implement strategies specifically geared towards avoiding shortcomings such as the “Sunk Cost Effect”. This paper looks to build off of the work done by Viswanathan, et al. by using more qualitative research methods to look specifically at what strategies were used and why they were implemented.

B. Classifications

Several classification systems have been created by researchers as they study prototypes. These classifications often characterize both the intent of the prototype, such as performing evaluations or communicating aesthetics [12], and the physical characteristics, such as the scale or the material used to create prototype [13]. Gaining a better understanding of these characteristics improves the researchers’ ability to record, analyze, and discuss data collected during the study of prototypes [14]. The classification system defines both the intended use of the

This material is based upon work supported by the Department of Energy under Award Number DE-EE0005441.001.

prototype as well as its physical characteristics. The classifications developed are shown in Table 1.

This classification system was divided up into different sections used to describe the overall prototype. An extensive literature review of past efforts in prototype taxonomy was conducted and used to determine the needed categories and categories available in each section. The first section was the overall Purpose of the prototype. The purpose of the prototype defines how the prototype was used by the designers. Ulrich and Eppinger [15] suggest that prototypes can have four major purposes: learning, communication, integration, and milestones. However, through the data collection in the previous work on this project, Viswanathan et al. [1] found that the designers on the SIMPLE BoS project had an informal taxonomy system to describe the purpose of a prototype: Design Intent, Functional, or Representation. The categories used for this classification system were based on the designers' current system as this allowed them to classify each prototype more easily during data collection. Adjustments were made based on literature to include other aspects not represented by this taxonomy and represent the clear differences between each category.

The Design Intent category describes a prototype used to communicate to other designers on a project how the product should look and/or operate. Communication is one of the major purposes behind creating a prototype as it allows all stakeholders in a project to possess the same mental model of how the product will look and/or function [1]. The Functional category describes prototype that carry out some or all of the functions intended to be performed by the final product. The Integration category describes prototypes that combine separately developed components or design ideas to investigate how they perform as a whole system [13]. Milestone prototypes are used for presentations or to benchmark a certain level of functionality [15].

The next section defines the evaluations intended to be performed on the prototype. Eggert [12] suggests that all prototypes can be grouped into one of three categories: Form, Fit, or Function. Form evaluations are used to determine if the product has an acceptable appearance. Fit evaluations determine how well the separate parts fit together properly and if the product fits well in the space it is intended for. Function evaluations test how well the product completes its desired functions. The designers were also asked to list the Function evaluations that were performed on each prototype.

The Manufacturing section defines how the prototype is created. The prototype may be made in-house by the designer or outsourced. Depending on the nature of the product being developed, the final prototype may be made at a

separate facility to test the production level on a mass quantity level. Prototypes made using the intended production method enable the evaluation of the design's compatibility with the intended manufacturing method [16]. The designers also described what materials were used to create each prototype and whether or not these materials differed from the intended production material.

The Scale section defines the size of the prototype compared to the intended production size. Otto and Wood [3] state that prototypes can be to-scale, large-scale, or small-scale. The classification system developed for this study allowed more specific options of a to-scale model or not-to-scale prototype. A rough scale model was also included as an option to classify models made nearly to scale, but no scale measurements were actually considered.

The Functionality section looks to define the level of functionality of the prototype. Otto and Wood [3] present useful ways to divide the functions of a product and discuss how each function can be improved individually. Therefore, not all prototypes are fully functional. That is, some prototypes are created only to address how one or some of the functions is address by the overall product. These prototypes are categorized as being partially functional while prototypes that address all of the intended functions are classified as fully functional prototypes. A prototype can also be non-functional, not possessing any functionality and created solely to represent the aesthetics of the final product.

Table 1 Prototype Classifications

Purpose-Why is this prototype being created?	
Design Intent	Used to convey design intent.
Functional	Used for functional tests (see below).
Integration	Integrates components of the product [13, 16].
Milestone	Used for showcasing progress [1, 13].
Evaluation-What evaluations are being performed?	
Form	Evaluates the aesthetics of the product [12, 13].
Fit	Evaluates how the components fit together [12, 13].
Function	Evaluates the functionality of the prototype [12, 13].
Manufacturing-How was this prototype made?	
Production Level	Manufactured as intended for the final product [16].
Outsourced	Manufactured by an outside source [16].
In-House	Manufacture in-house [16].
Scale-What are the proportions of this prototype? [3, 13]	
Full-Scale	Intended size of the final product.
To-Scale	Not intended for final product, but built to-scale of final.
Rough Scale	Similar to the scale of final product (within 20%).
Not-to-Scale	Built without regard to scale.
Functionality-What functions does this prototype possess?	
Fully Functional	Has all of the functions intended in the final product [3].
Partially	Has some functions intended for the final product [3].
Non-Functional	Is not functional/Appearance-only Model [3].
Components-What components does this prototype include?[16, 17]	
All	Includes all components intended in the final product.
Multiple	Includes multiple components.
Single	Is only of one component of the final product.

The final section defines how any components are included in the prototype. Moe et al. [17] discuss the benefits of prototyping separate parts of a product to reduce fixation along with other benefits. By creating a “less complete” prototype that omits component to be included in the final product, the prototype can be used to more fully evaluate the effectiveness of each individual component. This section classifies prototypes as either single component, including multiple components, or including all components intended to be included in the final product.

In previous efforts to create a prototyping taxonomy, orthogonality was considered to be a measure of success between the categories in each section [13, 16]. However, the authors of this paper found it more appropriate to allow the designer to choose all categories that applied to a prototype for the Purpose and Evaluation sections as this created a more accurate description of why the prototype was constructed.

It is important to note that this study used the presented categorization system to gather data. This allowed us to have a clear definition of why the prototype was constructed in the opinion of the designers and provided a tool with which to construct the interviews around. Future studies may be done to evaluate the strength of this classification system, but that is not the scope of the current study.

C. SIMPLE BoS

The study described in this paper is conducted on a project carried out by Georgia Tech Research Institute (GTRI) aiming to minimize the balance of system (BoS) costs associated with the production of solar energy. The BoS typically consists of mounting of solar panels and power-conditioning equipment to properly convert the generated DC to AC [16]. They may also contain batteries for operation on cloudy days [17]. Currently, BoS costs account for around 40% of the total installed cost of the solar energy systems.

The SunShot Initiative by the U.S. Department of Energy (DOE) aims to produce cost effective solar energy. This program aims to reduce the cost of solar energy production by 75% before 2020 [18]. As a part of achieving this target, the DOE provided a grant to the researchers at the Georgia Institute of Technology to develop commercially-ready, next generation solar PV BoS designs [19]. This project, titled “SIMPLE BoS” (Solar, Installation, Mounting, Production, Labor and Equipment), is led by the Georgia Tech Research Institute (GTRI). The final goal of the SIMPLE BoS project is to reduce the racking/mounting hardware and labor costs by greater than 50%.

As a part of this project, the team involved produced many prototypes at each stage. For example, Figure 1 shows an early stage mock-up of the supporting structure design during its design phase. Figure 2 shows a fully functional system on the rooftop of a commercial building. This design was a result of the team’s extensive design and prototyping process. Many times, these prototypes provide them useful insights and inspire significant changes in their ideas. As the

team consists of experienced professional designers, this project provides an ideal opportunity to learn about the benefits of prototyping for professional designers.

Figure 2: Installed, fully functional system on the rooftop of Install at Ponce City Market in Atlanta, GA

D. Framework

Extensive prior by Camburn, et al., has identified a set of decisions designs must make when defining a prototyping strategy [18-20]. This serves as one of the theoretical frameworks for this research guiding the type of data that is gathered. Camburn outlines the following set of ‘strategy variables’:

- *Parallel versus serial concept prototyping*- Design team may intentionally prototype multiple completely different design concepts simultaneously. Alternatively a single design concept may be chosen and only one concept is prototyped at a time.
- *Planned iterations*- Depending on the available time, design risk, and costs of individual prototypes, team may intend to create multiple iterations of a design or may plan for only very few.
- *Scaling*- Prototypes can be a different size than the actual size. Micro or smaller scale components may be scaled up to macro size. Large objects such as buildings and airplanes are often scaled down.
- *Subsystem isolation*- Only subsystem or partial systems may be prototyped. The design may be optimized and improved at the component level.

- *Design Requirement Relaxation*- Prototypes may perform at a lower level than required by the final design. For example, they may have lower strength, less corrosion resistance, able to withstand fewer cycles.
- *Physical vs Virtual*- The virtual prototyping can model a wide range of product performance parameters. Some virtual prototyping is extremely fast and efficient while other times physical prototypes provide either more accurate data or are simply faster and cheaper to build.

The systematic, empirical study of prototyping practices is an emerging area in design research and warrants much greater study. This paper seeks to add to this growing body of literature by providing an in-depth analysis of the prototyping process for a highly innovative team of designers.

III. RESEARCH METHODOLOGY

The research question sought to be answered through the study of the expert designers is: *What strategies are used by expert designers in the construction, implementation, and evaluation of prototypes to aid in the development of a final product?* The SIMPLE BoS project is an excellent opportunity to answer this question due to the number and variety of physical prototypes used during the design process. This study lends itself to more qualitative methods as it looks specifically at why something occurs and the impacts of certain design decisions [21]. A qualitative study such as this one can provide a deeper insight into the motivations of the designers and how the project looks from their point-of-view [22]. This insight allows for a more complete understanding of the strategies implemented by the designers. The semi-structured interviews of the designers with the use of the prototype classifications developed by the authors allow for an effective way for this data to be collected.

A. Semi-structure interview

The data in this study was collected through three semi-structured interviews with a lead designer on one of the SIMPLE BoS teams who was also a student pursuing his PhD in architecture. These interviews lasted about one hour each and were conducted by the first author. For the first two meetings, the second author was present and assisted in the interview by asking follow-up questions. Both interviewers collected data via pen and paper. After the first interview, a slightly modified list of classifications was created. This classification list was a simplified version of the original list, leaving off categories originally included that remained constant throughout all of the prototypes. For example, all of the prototypes were made to-scale. Therefore, after the first interview, the scale classification was left off the list. This allowed the interviewers to focus more on the aspects that were changing between the prototypes.

The data collected from this interview was aimed to gain a more in-depth understanding of the data collected in a previous study by Viswanathan, et al. [1] by using this qualitative approach. The designer was provided with a copy of the classification list along with pictures of prototypes collected from the previous study. These prototypes were developed during various stages of the design process. The designer was asked to use the classifications provided to describe each prototype. The classification system provided structure to the interview to be based around, but open discussion about each prototype was had with emphasis on the reasoning behind the purpose of the creation of each prototype, at what point in the design process they were created, and what was learned from the evaluations. The designer was also able to list which evaluations were performed on each prototype.

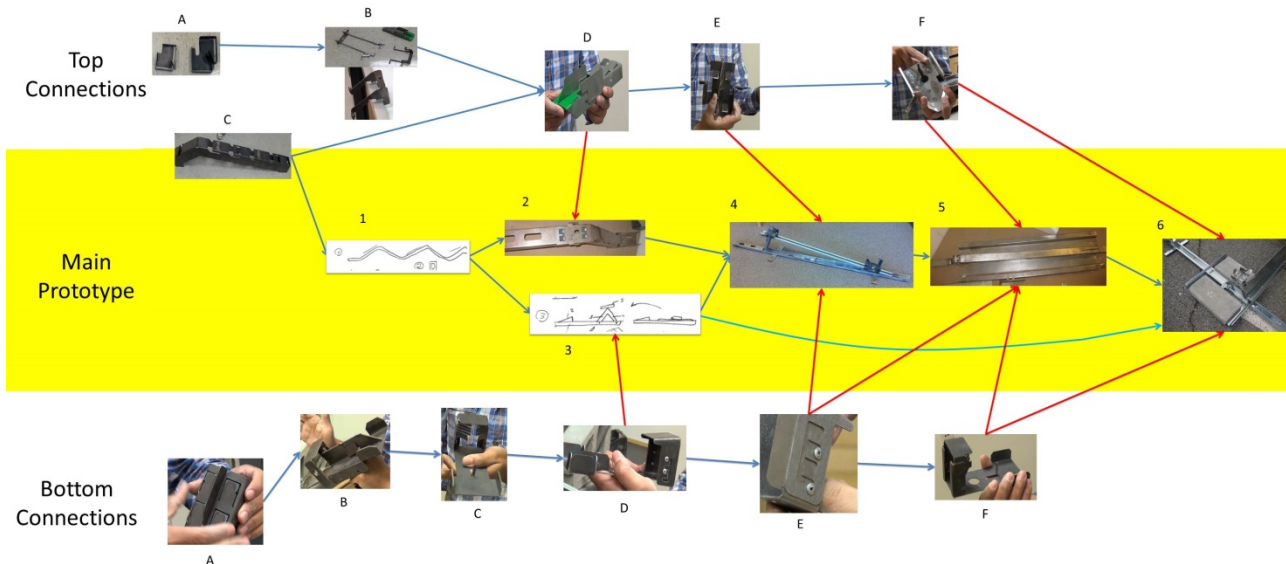

Figure 3: Overview of the prototypes. Prototypes are shown in chronological order with indicators showing influence from previous versions.

IV. FINDINGS

The results of the interviews are summarized in Table 2 and Figure 3.

Table 2: Total Number of Each Classification			
Classification	Total	Complete Prototype	Component Prototype
Purpose			
Design Intent	19	6	13
Functional	19	6	13
Integration	19	6	13
Milestone	3	3	0
Evaluation			
Form	19	6	13

Function	19	6	13
Manufacturing			
Final Production Level	0	0	0
Outsourced	0	0	0
In-House	19	6	13
Scale			
Intended Production	19	6	13
To-Scale	0	0	0
Rough Scale	0	0	0
Not-to-Scale	0	0	0
Functionality			
Fully Functional	13	1	12
Partially Functional	5	5	0
Non-Functional	0	0	0
Components			
All components	6	6	0
Multiple components	0	0	0
Single Component	13	0	13

Through analysis of the data collected in this study, three major findings arose answering the question, “What strategies are used by expert designers in the construction, implementation, and evaluation of prototypes to aid in the development of a final product?” The first finding was that the designers would begin each iteration of a design on the component level. The second finding was that the designers would revert back to previous version of a design if they reached a point in their design reached a local maximum. The third finding showed that the designers would continually build upon the list of evaluations they would perform on each prototype in both number and level of sophistication.

The designers on the SIMPLE BoS project were intent on being able to develop each component of the overall product separately. The team would then combine all of the components to test the entire prototype and determine how it could be improved upon. However, instead of trying to improve the entire prototype, they would focus on the separate components. This can be seen in Figure 3 as the

connection components that attached to the top of the solar panel were developed simultaneously with the connection at the bottom of the solar panel, and both connection components were continuously being improved upon as the overall design advanced.

A. Iterative Design Process on the Component Level

Through an iterative process the designers would build, test, and evaluate a single component prototype until it reached the level desired to be implemented with the other components. Once all the separate components met this desired standard, the entire prototype would then be tested with all the components. Based on those evaluations, it would be determined what design changes need to take place to the overall prototype which determined what adjustments needed to be made on the component level. The process would then begin again with a testing and evaluating each component. This process can be visualized as a flow chart as seen in Figure 4.

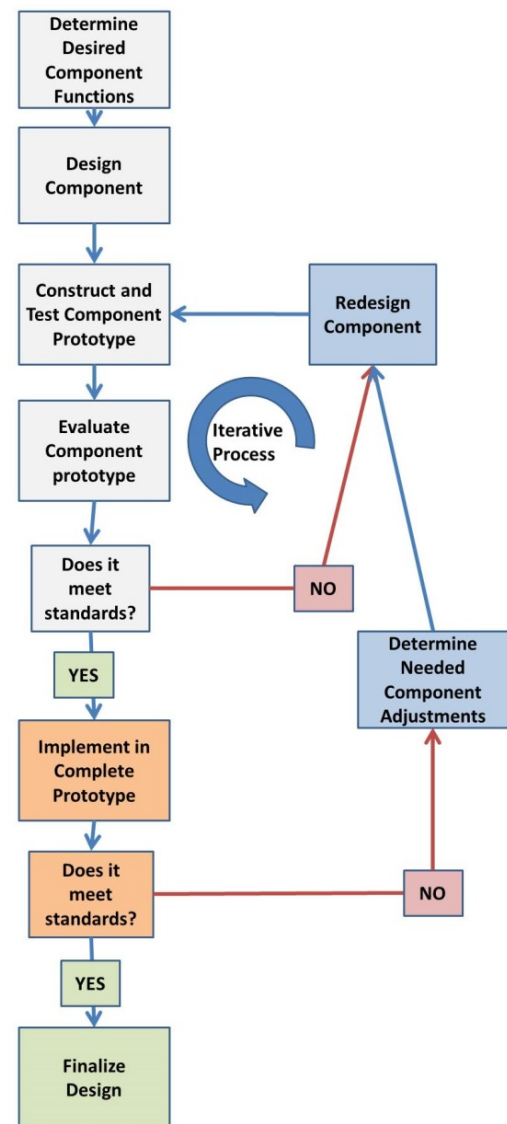

Figure 4: Iteration Design Process Implemented by the Design Team

This process was utilized to reduce the costs of prototypes as it was typically far less expensive to build and test a single component than to test an entire system. Therefore, the designers would want to ensure each component was designed properly before putting in the time and money into constructing and testing the full system.

Previous research has shown the effectiveness of iteration of prototypes in the design process [23]. It allows for an optimization of design and is effective at overcoming difficult requirements. Dividing the prototype and designing components separately as was done in this project also allows for an effective optimization and products of a higher quality [17]. *Back-tracking*

Whenever the design team found they had reached a local maximum in their design, they would often revert back to previous designs to determine what decisions were made to get them to their current state. They would then “backtrack” to a point of a major decision and then make the opposite one to see if that difference would help them to overcome that locally optimized design in search of a more globally optimized design.

The best example of this led to the final overall design of the system. A local maximum was reached near the end of the design process. The design would have been acceptable, except they were forced to change certain aspects of the structure due to a conflicting Intellectual Property. Therefore, they had to backtrack to a previous decision that lead them to the conflicting IP and find a different approach. When they reexamined a design a few iterations back, they discovered that they were able to combine aspects of their current design with aspects of that previous one and create a more optimized final design that also avoided the IP conflict (Figure 5).

Figure 5: Backtracking Flow Chart

C. Growing Evaluation Lists

The final major finding gathered from the data was the evolution of the evaluations. During the early stages of the design process, most of the evaluations were quick and easy tests. For example, the early prototypes were statically tested by loading the panels down with sandbags so see how much weight that could hold. By the end of the end of the design process, the designers were utilizing much more formal tests such as using loading machines to evaluate the structural integrity.

Not only did the tests become more formal, as they progressed through the design process, the number of

different evaluations steadily grew. As they evaluated each prototype, more tests were added to determine how effective their design was becoming. Every time a new test was performed, that test would be performed on every prototype evaluated thereafter. A prime example of this was a test the design team referred to as the “step on” test. During one of the evaluations of the complete prototype system, one of the designers noticed a section the frame that was not designed to hold weight looked rather fragile. To simulate a worker installing the panels, he stepped on that section of the frame to hoist himself to the opposite side. The section of frame was broken as a result and the designers quickly realized the adjustments that needed to be made to account for unanticipated loads during installation. After that evaluation, every complete prototype was tested by having a worker step on it as a worker may in the installation process.

By continuing to improve their evaluation methods, the designers were able to more confidently state that the final prototype was up to the standard that was desired. The final design was put through a complete set of formal tests including static loading, electrical grounding, packing space needed, ease of assembly, and the “step on test”.

V. CONCLUSION

The study of highly successful professional design teams has great potential to provide guidance on effective strategies for the design and prototyping process. Data collection on practicing designers can be extremely challenging due to intellectual property issues, the long-time spans of projects, large amounts of data and many other issues. This paper presents a study of the prototyping process for a multi-million dollar, very successful, department of energy project. A targeted approach collects data on the prototyping practices.

This paper first presented a prototype classification approach based on an extensive literature review and then used the prototype classification to provide insights into the team’s prototyping process. Data collection was targeted at the prototyping process using structured interviews. This design team only implemented full-scale (production scale) prototypes that had the design’s final intended form, fit and function. This paper only illustrates one of the three designs that this team worked on and all designs contained a relatively high number of full-scale prototypes. This strategy choice may be significantly impacted by the type of product being designed and the team’s goals. The goals were centered on installation cost reductions, a characteristic that is difficult to predict without a physical prototype at full-scale or very detailed mental models due to extensive experience in installing solar panels. For very innovative designs it can also be very difficult to make accurate predictions based on a person’s mental models.

This team also implemented a very extensive number of component level prototypes illustrating the need for students to be very effective at recognizing system interfaces, key functions of components, the ability to optimize at the

component level, and the knowledge to easily switch between component and system level thinking. All of the prototypes in this paper were built in-house likely due to the fact that these designs contain standard machining processes and the universities extensive prototyping resources were available. This often led to design ideas that could be more quickly evaluated. This may have also biased the team towards designs that could be quickly built in-house. However, one of the main goals of the design was to create a system that could be mass-manufactured using low-cost methods. These methods include process such as stamping and roll-forming which were replicable to a large degree due to the experienced fabricators available in-house to the design team. Therefore, these in-house designs are still viable representations of their mass-manufactured versions.

The data presented in this paper is one of three designs sought by the team. Interviews of with the designers for the other two prototypes are still in progress and will provide more details on the prototyping process for the team.

Effective prototyping skills and strategies are just one of the many tools engineers need to be highly effective engineers. More work needs to be done on developing prototyping strategies and best practices in utilizing prototypes in the design process.

ACKNOWLEDGMENT

This material is based upon work supported by the Department of Energy under Award Number DE-EE0005441.001. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the Department of Energy. The authors would also like to thank the design team working on the solar panel project at Georgia Tech Research Institute for their help during the data collection. Joseph Goodman receives research funding, he and Georgia Tech are entitled to sales royalty from Quest Renewables which is developing products related to the research described in this paper. In addition, Goodman serves as a Partner at Quest Renewables and he owns equity in the company. This study could affect his personal financial status. The terms of this arrangement have been reviewed and approved by Georgia Tech in accordance with its conflict of interest policies.

All data collection, and analysis was completed by Ethan Hilton and Julie Linsey.

STEM Literacy: Challenges implementing ‘E’ in Local Texas-STEM Academies

Michele C. Williams

Taking the LEAP Grant/Teacher Education
at University of Texas at El Paso
El Paso, Texas
mcwilliams2@utep.edu

Abstract— This paper focuses on the challenges apparent to implementing the engineering experience component within science, technology, engineering and mathematics (STEM) programs adopted at state designated academies in El Paso, Texas, based on a literature review, preliminary to potential research opportunities.

El Paso is ranked as one of the poorest metropolitan areas in the country, and improvements in growing STEM success can impact the region’s output of qualified professionals in those fields.

According to research studies, students enrolled in STEM schools significantly impact enrollment in college, through taking STEM subjects in high school and pursuing STEM careers through higher education. Eight local STEM academies have been established since 2006 and their educators and school leaders may need to revamp STEM efforts by addressing these engineering implementation challenges.

The literature reviewed includes national and state policies; local initiatives; integrated curriculum; national and state engineering standards; and school leadership. Some challenges schools face when pursuing STEM literacy are educator certification and training, state requirements, standardized testing, insufficient funding, engineering curriculum, among others. As a result of this literature review, future research opportunities are identified within STEM academies, which may guide education leaders towards best practices in engineering education and quality of STEM literacy.

Keywords—*T-STEM academy; engineering literacy K-12; STEM literacy, integrated STEM curriculum; STEM policies; HBS;*

I. INTRODUCTION

El Paso Texas, situated along the US-Mexican border, is ranked as one of the poorest metropolitan area in the United States. As a result, slightly less than 12% of the region’s inhabitants hold a college degree, according to the 2009 United States Bureau of Economic Analysis report on the region. The paucity of graduates is a concern for the region which is challenged by falling behind in the overall supply of qualified professionals. This literature review will include research-based claims that the more STEM-oriented metropolitan areas the better the performance in most economic indicators. Also, that more jobs in the U.S. require a strong background in STEM areas than the supply of STEM prepared individuals in our region.

Efforts for this paper were made possible by “Taking the LEAP Grant” awarded to The University of Texas at El Paso by the U.S. Department of Education’s Transition-to-Teaching Funds.

The creation of STEM schools during the last couple of decades resulted from public and private initiatives to improve and increase our student output with a STEM concentration. Students enrolled in STEM schools may have a significant effect on college enrollment, taking STEM subjects and/or following STEM careers. Only eight STEM academies at the secondary level have been established in El Paso since 2006.

As STEM literacy programs and designated schools continue to be promoted locally, there are concerns regarding the attributes and efficacy of a STEM-focused school. There are challenges to consider by school leaders. One key problem is that most teachers in these programs are trained in either science or mathematics and may not be trained in engineering or technology. Therefore, making it difficult to successfully integrate engineering in the curriculum.

II. SIGNIFICANCE OF STUDY

A. Integrating Engineering towards STEM Literacy

Overcoming the engineering implementation challenges is key to STEM literacy success for current and future schools with such programs. “Educators must confront and resolve a number of challenges if they are to advance STEM literacy” [1]. Roger Bybee explained it best: educators must stop using the term “STEM” without actively incorporating technology and engineering into their programs.

B. Local Economy Demands High Skilled Pipeline

According to Workforce Solutions, labor market data indicates the need for a high skilled talent pipeline in the community to meet the demand for the high skill high wage jobs. Local growth in economic development will face significant challenges if the required talent pipeline is not developed. El Paso area is a tri-state, bi-national area that requires a unique educational dynamic worthy of further understanding.

C. STEM Professionals: Supply & Demand Gap

The more STEM-oriented metropolitan areas the better their performance in most economic indicators [2]. About 20% of jobs in the U.S. require a strong background in STEM, and about half of those jobs may require at least a bachelor’s degree [2]. Currently, in the United States, only about 6% of all bachelor’s degrees are in science or engineering [3]. There is a gap between supply and demand of qualified individuals to fill STEM related jobs. Also, in the next decade, the

number of retiring engineers and scientists will increase without enough home-grown talent to replace them [4].

D. STEM Schools Increase STEM Focused Graduates

STEM schools may have a significant effect on students “enrolling in college, taking STEM subjects and/or follow STEM careers” [5]. Our local T-STEM designated schools must develop certain characteristics in order to develop and promote college participation in these fields.

E. Engineering Has Never Mattered More

“Engineering and engineers have never mattered more” [6]. These authors refer to the new developments in nanotechnology, biotechnology, material science, and photonics, as carrying potential for prolonging healthier lives and overall improving human living conditions.

F. Teacher Comfort & Efficacy Yield Student Success

Studies show that training teachers in an integrated STEM experience yields higher student achievement; improves teacher comfort and efficacy with these topics; and thus the attitudes and expectations of students towards STEM [7]. Increased insights and understanding of current program practices in local schools can provide us with the basis needed to support such engineering education programs.

III. STEM LITERACY POLICIES

A. National STEM Initiatives

President Obama, in his 2013 State of the Union address, signaled his strong support for STEM-focused schools as a way to motivate and prepare students to pursue STEM careers. The United States Congress has included this recommendation in approved legislation, the America COMPETES Act of 2007 [8] and re-authorization of same Act in 2010. President Obama confirmed the plan to create 1,000 new STEM focused schools by 2020 with at least 80% at the elementary and middle school levels. Furthermore, Obama authorized the recruitment and training of 100,000 high quality STEM teachers in 10 years based on recommendations from the President’s Council of Advisors on Science and Technology from 2010.

B. Texas STEM Initiatives

Texas has adopted the policy and created the Texas science, technology, engineering and mathematics (T-STEM) designation. Since 2006, about 91 schools in Texas have been designated T-STEM academies. As indicated in the Texas Education Agency’s website [9], the main purpose for these programs is to develop the capacity to design and/or replicate and sustain performance-driven school models, transform instructional practice to model real world contexts for learning to improve student achievement for all students, and to serve as demonstration sites to inform STEM teaching and learning statewide.

The literature reviewed about Texas initiatives revealed a tremendous support for the creation of these schools as well as the priority of STEM literacy. For example, “Educate Texas” has been nationally recognized for tapping into a bold and collaborative approach for creating transformational change for Texas students [10].

C. El Paso STEM Initiatives

The El Paso area has both private and public organizations supporting the prioritization of STEM literacy, such as the Workforce Solutions Upper Rio Grande, El Paso STEM Foundation, Community en Acción, and Workforce Solutions Borderplex, among others. To date, eight secondary schools within six different school districts in El Paso area prioritized a STEM program to some degree. According to Texas Education Agency, all T-STEM programs must be rigorous, STEM integrated curriculum utilizing the design process and high quality, contextually-based teaching and learning practice [9].

El Paso opened the first T-STEM academy in 2006, in Da-Vinci public charter school (6-12th) as stand-alone, the next T-STEM academy designations went to El Paso Harmony School of Science in 2008 as a stand-alone and the Transmountain Early College High School from El Paso Independent School District (ISD) as a combination. In 2009, Ysleta ISD opened a school-within-a-school T-STEM academy in Parkland High School (9th-12th). Irvin High School from El Paso ISD was granted the T-STEM designation in 2012 as a stand-alone T-STEM school for 9th and 10th. Harmony School of Science added a second stand-alone T-STEM 6th-12th in 2012. Two more academies were designated in 2014: Clint High School from Clint ISD and Montwood High School from Socorro ISD.

D. Engineering is Not Always Incorporated

STEM resides in multiple contexts today, such as educational, technological, economic, and political, according to Stephanie Marshall [11] as she provides rationale for re-designing these academies. She adds that, as educators adopt STEM policies, often times the implementation or interpretation of these initiatives does not include enhanced courses in engineering or technology, or some form of increased engineering and technology content in revised math and science courses. It is important for us to keep this in mind as we discuss STEM education advances in context.

IV. ENGINEERING IMPLEMENTATION: CHALLENGES & INSIGHTS

A. STEM Literacy Takes Time and Funding

It is suggested that STEM literacy could take about a decade to initiate, implement, sustain and evaluate as a national initiative [1]. As project administrators, we understand that time and funding are required to conduct the activities necessary to initiate, implement, evaluate, and sustain any kind of program in schools. The most important challenge facing STEM education, according to the findings from the National Survey on STEM Education [12] was inadequate and insufficient funding (64.2%). Moore & Smith

[13] also stress the importance of funding for not only professional learning experiences but also to back new research-based STEM integration innovations in K-12 curriculum. Often times, policies do not get to be fully implemented as intended due to lack of sufficient funding and time.

B. House Bill 5: Competing Endorsements?

Recently, the Texas Education Agency adopted House Bill 5 (HB5) requiring all high school students to select an 'endorsement' or subject cluster. Beginning 2014-15 high school students must complete 22 credits of 'foundation' courses and 4 credits in one of the endorsements [9]. The five endorsement areas are: Multidisciplinary Studies, Arts and Humanities, Business and Industry, Public Services, and STEM. Local high schools offer a STEM endorsement with five separate options: Computer Science/Technology Applications, Mathematics, Science, Combination, or Career and Technology education. It is within the Career and Technology or Combination options that engineering courses may appear.

Considering that high school students have five concentration areas to pick from, then another choice of five within the STEM area alone, it is unfortunately at a miniscule level that HB5 enforces the engineering literacy within the STEM tracks. However, these academies have the option of only offering the STEM endorsement to their students and none of the other clusters. The local T-STEM academies must decide if all of their students will have no choice but to complete the STEM endorsement, and if so, which one(s).

C. STEM Literacy: An Integrated Approach

STEM teaching should be a fully integrated approach. "STEM integration can provide students with one of the best opportunities to experience learning in real-world situations, rather than learning STEM subjects in silos." [14]. It is important to consider how the interconnections of STEM components work in order to integrate the disciplines meaningfully. This set of disciplines is very organically grouped: engineering requires the application of mathematics and science through the development of technologies. "In addition to a coherent and rigorous curriculum, successful STEM school initiatives design and implement integrated curriculum content." [15]. Repeatedly, within this literature review, research-based documents have strongly expressed the need and recommendation to integrate, and embed all subjects in order to build curriculum.

D. Explicitly Integrated & Explicitly Separated

As recommended by the members of the National Academies, "Integration should be made explicit" [16] when designing STEM initiatives. This recommendation calls for carefully thought out curriculum and corresponding assessments. Schools must adopt structural changes in order to allow learning each STEM discipline separately and interconnectedly as encountered in real-world situations [13]. "STEM education is an approach in which STEM subjects are integrated through an instructional method that uses design-

based, problem-solving, discovery, and exploratory learning strategies" [17].

E. Career & Technology Education as a Model

Career and Technology Education (CTE) programs provide excellent means to support an integrated STEM approach [4,18]. CTE offers hands-on experiences embedded in the curriculum. Additionally, instructors, as former practitioners, deliver curriculum thoughtfully and successfully to all types of learners, because content is directly related to real-world applications. CTE could be used as a model towards creating a successful integrated approach to STEM literacy. Academies may not have the support of a strong CTE program.

F. Engineering Teacher Certification: Not a Priority

The problem is that most STEM teachers are trained in either science or mathematics and may not be trained in engineering or technology [19]. Only the science and mathematics certifications are enforced as requirements to teach courses in any of the four fields. This can easily be justified by the sheer quantity of science and mathematics courses required and present in K-12 curriculum in comparison to the non-required engineering courses. When referring to local T-STEM academies, by definition of the designation intention, engineering should be placed in a higher priority, together with the science and mathematics.

G. State Tested Subjects Take Center Stage

In Texas, no engineering courses are tested. A few science and mathematics courses are tested as part of state accountability efforts. This priority may deter school officials from prioritizing engineering education.

H. Texas Lacks Embedded Engineering Standards

The National Research Council [20] was given the task to come up with the K-12 engineering education national standards. Instead, they advocated for embedding such standards in existing science and mathematics curriculum. After scholars from Purdue completed an engineering standards study, they concluded that there is a lack of engineering integration in STEM when they reported: "The fact that only 12 states integrate engineering into science curricula and only one into math points to a need for an emphasis on the academic nature of engineering" [21]. According to their findings, in Texas, the engineering content was explicitly found for high school career and vocational standards only [21]. In a standards-based education, the curriculum, teacher preparation, and assessments must align to those standards. Local T-STEM academies have to deliberately incorporate engineering content in their lessons and programs, even though they are missing in the mandated state standards.

I. Access to Engineering Curriculum

Schools may purchase ready-made engineering curriculum such as "Project Lead the Way" (PLTW), "Infinity Project", "Engineering is Elementary" (EiE), and "Engineer Your Life".

Local T-STEM academies may invest limited funds and adopt one of these programs, or may seek other alternatives. The Da Vinci School for Science and the Arts became the first El Paso T-STEM academy in 2006, and after reviewing options for engineering curriculum, school officials decided on customizing their own: "Curriculum for Engineering in High School" [22].

J. Educator expertise in engineering is uncommon

The National Academies listed Educator expertise as one of the implementation opportunities and challenges when integrating STEM in K-12 [16]. The second most important challenge facing STEM education, according to the findings from the National Survey on STEM Education [12] was insufficient professional development for STEM teachers (59.7%). At the University of Texas at El Paso (UTEP), has developed new courses and programs dedicated to better prepare educators teaching STEM areas, and in particular engineering. These new engineering teacher preparation pathways have been possible due to the joint collaboration of the College of Education and the College of Engineering, efforts partly funded by 'Taking the LEAP' grant from the Department of Education.

K. Innovative teaching strategies required

Engagement in project-based learning with an emphasis on design can be the key for successful engineering education programs today [6]. At the K-12 schools, teachers are very involved with the teaching and learning processes, so project-based learning should come more natural in implementation. Project-based learning promotes traits such as good communication, teamwork, and the lifelong learning needed when preparing engineers.

L. High Rate of LEP Students in El Paso Schools

Local demographics include Spanish speaking immigrants from south of the border, contributing to 79.2% of the Limited English Proficient (LEP) students [23]. Mein and Esquinca stress that our local LEP students face barriers when accessing content knowledge because of their language challenges [23]. Fortunately, UTEP offers teacher preparation programs specifically to address the challenges of dealing with LEP populations.

M. Leadership of Inclusion Towards STEM Literacy

Equal access to an exceptional STEM program must be a priority, and school leaders must encourage inclusion of underrepresented students. Leaders must foster a mentality of inclusion in which teachers can encourage girls' achievement and interest in math and science [24].

V. DISCUSSION: RESEARCH OPPORTUNITY

Although this literature review provided some answers pertaining to challenges mainly of an external nature, further research is required to investigate and report adequately on the functional workings of local academies. Only then can a complete overall picture of the challenges of engineering

implementation can be established. Such a study may provide insight and deeper understanding of how these designated schools impart engineering learning to students. This study could assist school leaders to understand STEM education and lead a culture of STEM literacy. This study may guide current and future local leaders the best practices of engineering literacy based on model school findings.

The issues surrounding the different academy configuration combinations within schools was not addressed in any of the literature, such as: combining early college high school with a STEM designation; or T-STEM with a charter school; or with other non-STEM endorsements.

Because half of the T-STEM academies in El Paso have been recently designated, there are just not enough studies published on their progress, challenges or successes. This is also true for policies at the district level regarding these academies and in particular for engineering implementation.

In an effort to emphasize engineering in STEM, inclusion of engineering in the K-12 curriculum has increased nationwide. Similarly, for the past 15 years, research on Engineering Education P-12 has increased tremendously [25]. Although at the local level, the number of T-STEM academies has increased, it is not clear how local engineering education has changed, due to lack of available literature at this time.

ACKNOWLEDGMENT

I want to acknowledge the encouragement & support from Peter Golding and David Carrejo.

Abstract— For all computer scientists the term ‘modeling’ is well known. It displays an often-used method, which is applied in each field of computer science to investigate, describe and plan problems or structures. With the help of models, large and complex structures are divided into smaller parts, which leads to a better understanding of the problem and often provides input for the solution. With the help of different types of models, different perspectives of one problem can be observed and discussed. These processes are not only part of computer science respectively computational thinking. Problem solving skills are needed in any domain and should be trained as well as possible in primary and secondary education. This could be supported by the computer science concept of modeling including processes like reduction, decomposition, abstraction, generalization etc. and appropriate techniques like UML Unified Modeling Language or the Entity-relationship model. We suppose that a consequent use of modeling beginning in different subjects during primary and secondary education can train and improve problem-solving skills. Before being able to verify this hypothesis, it is necessary to find a way to integrate modeling in schools despite of not being part of the curriculum. This is one aim of our project “Informatics – A Child’s Play”, which tries to implement different computer science concepts in different subjects of primary and secondary education. To reach this goal we firstly have to convince and train teachers. In this paper some topics of modeling are presented as they were adapted for workshops in primary and early secondary education considering the age and interests of the students as well as topics taken from their surroundings. Furthermore, we present first evaluation results concerning its acceptance and usefulness for teachers and students as well as their performance in understanding and applying modeling in different lessons.

Keywords—models, diagrams, general education, Entity-Relationship-model

I. INTRODUCTION

In today’s society, technology affects nearly everybody in different occupational fields and has therefore a deep impact in everyday life. It is obvious that more and more experts in technical areas are needed to develop, produce and service new artefacts. To reach children as early as possible the project ‘Informatics – A Child’s Play’ came to life. The main aims of it can be summarized as follows:

- Arousing interest in informatics¹, engineering and technology as early as possible.
- Improving and consolidating students’ and teachers’ knowledge about informatics (concepts, usage, career, etc.).
- Fostering general learning skills like text comprehension, problem solving, logical thinking or creativity.
- Developing and evaluating brain-friendly teaching material.
- Establishing computer science concepts in the long-term in primary education (a lot of them are already part of the Austrian curriculum for primary education, but are not recognized as such).

During the preparation phase of the project different existing workshops, which partly based on ‘Informatik erLeben’ (Experiencing Informatics) [1] or ‘Computer Science Unplugged’ [2], have been adapted or new ideas were elaborated. Additional new material had to be developed because of the idea to integrate computer science concepts in different subjects and sciences. One link to establish such a connection can be ‘computational thinking’. In [3] computational thinking is called “[...] a fundamental skill for everyone” and it is proposed to “[...] add computational thinking to every child’s analytical ability” [3]. Further [4] describes it as “[...] a problem-solving methodology that can interweave computer science with all disciplines” and points out that it focuses on “abstraction, automation and analysis” [4]. Especially abstraction and analysis of problems and their solutions can be related to different types of diagrams and models. In the following chapter modeling will be defined and a connection between modeling and general education will be shown. Chapter 3 will explain the study with the research questions, methods and some ample units. In chapter four some first results of the study will be presented.

II. MODELING IN GENERAL EDUCATION

A. What is modeling?

In computer science, models are a very important and common form of representation in different areas or levels of development, e.g. the description of processes or problems, a

¹ The terms informatics and computer science are used as synonyms in this paper.

program or an equation [5]. A model can be defined as “an abstract description of a real or planned system, including the essential attributes of this system needed for a certain objective. Modeling can be seen as the creation of such description.” [5, p. 4]. That means that the term ‘model’ refers to a simplified representation of the real world and builds the base for the present work.

The process of modeling includes different working steps and thinking processes like reduction, simplification, abstraction, generalization, hierarchization, or classification. They can be summarized in the following four steps:

- Defining the scope: in this step the borders should be found, which define the part of the system that should be described.
- Abstracting: During this step, unimportant details or special cases should be removed.
- Idealizing: the aim of this step is to ease the description by correcting non-ideal attributes.
- Describing: in this step the representation of the main attributes, like components, relations between components, interaction with surroundings, static structure or behavior of the system, are created with the help of modeling techniques [5].

The order of these steps can vary, depending on the modeling task.

B. Modeling in general education

Models are simplified representations of the real world. They can be represented in different ways (fig. 1): mental, physical or symbolic. Mental models – the first step in reducing the complex reality – describe the way people understand some domain of knowledge [6]. This happens in any domain and any subject in school. Hence, the concept of modeling is, in our opinion, definitely important for general education. The external representation of these mental models can be physical, like a scale model of a house, or symbolic in form of graphics, diagrams, or texts (verbal models).

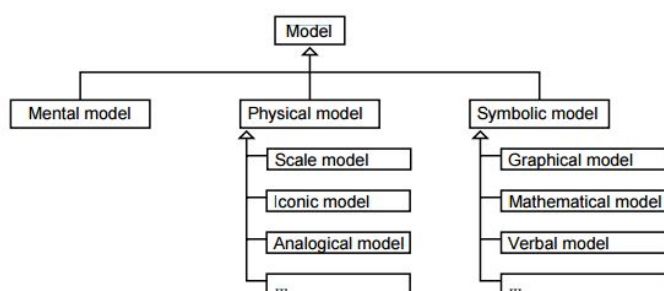

Fig. 1. Classification of models with respect to the representational form. [7]

Based on this classification, models and the process of modeling are part of any subject matter, in the curricula as well as in daily school life. Some subjects explicitly name the contents *models* or *working with models* in their curricula, e.g. mathematics, geometry, chemistry, geography or technical work. Other subjects use models or modeling without knowing

it consciously. Verbal models, that “describe a system by means of textual information” [6] are part of every subject e.g. in form of chapters in textbooks or summaries of texts in foreign languages etc.

Having a closer look to the process of modeling, its dimensions and the competencies needed like abstraction, reduction, simplification, classification, generalization etc. it becomes obvious that modeling is already an important, but mostly hidden part of general education. The primary school curriculum, for example, requires that

- teachers shall lead children to abstraction [8, p. 27]
- train the capacity of abstraction e.g. by using diagrams or symbols [8, p. 61],
- foster rational thinking processes by training basic cognitive processes like comparing, sorting, classification, abstraction, generalization etc. [8, p. 147].

C. Teaching Modeling: Techniques and Possibilities

For software development different models have to be used because each of them describes one aspect of the real system. To display the following aspects different modeling techniques can be used:

1. Structure: domain, entity-relationship, grammars
2. Attributes: domain, entity-relationship, logic
3. Relations: entity-relationship, logic
4. Behavior: finite automata, petri-nets, algebras, graphs [9]

As it can be seen the Entity-Relationship-model (ER-model) can be used to display three of these aspects. Therefore and because of its simplicity, this diagram type was perfect for our project.

This method of modeling was introduced by Peter Chen in 1976 [10] and is very useful to show objects with attributes and their relations to each other. Chen’s modified notation is easy to learn because its graphic notation includes only three basic shapes.

- An ‘entity’ is a collection of objects of the same type and is graphically displayed as a rectangle.
- A rhombus represents the ‘relation’ between entities.
- The ‘attributes’ of entities further describe these entities and are displayed as ellipses [9].
- Lines between the shapes show their connection to each other.

III. THE STUDY

A. Research Questions and Methods

The study on the use of modeling concepts and techniques in general education is part of the research project ‘Informatics – A Child’s Play?!’ that mainly aims at introducing informatics

concepts in different subjects of primary and lower secondary schools. Our main research questions concerning modeling are:

1. How and where can we introduce modeling in primary and lower secondary education?
2. Which modeling techniques are useful and practicable for teachers and students without informatics background?
3. Which dimensions of the modeling process are or shall be part of general education?
4. Is it possible to improve general learning competencies like abstraction, problem solving, text comprehension etc. by a frequent and varied use of modeling in primary and lower secondary education?

In order to answer these questions and to achieve a sustainable integration of the informatics topics, in this case “modeling”, different activities and research methods are necessary:

- *Development and implementation of teaching units and materials*
We developed new teaching units and materials based on existing curricula, topics, worksheets, activities etc. We gained data and ideas from content analyses of different curricula, interviews with teachers of different subjects as well as different worksheets and tasks that they provided us for the elaboration from the perspective of computer science. We offer different workshops for teachers and students in order to test and adapt the developed units and materials by considering findings of participatory observation, immediate feedback of the participants as well as interviews with teachers and students.
- *Usefulness and practicability of modeling techniques*
As the concept of modeling is not part of the curricula, we are firstly interested in the usefulness and practicability of modeling techniques for teachers and students without computer science background. To evaluate these aspects we use different methods, mainly immediate feedback, interviews with teachers and online-questionnaires.
- *Comprehension of modeling*
In order to assess the comprehension of modeling we analyze the answers of the participants to our questions during the workshops and we ask them to explain the concept of modeling to their colleagues. Furthermore, we evaluate their products – diagrams, posters and other materials. At the end of the school year, the students will also take a written test.
- *Assessment of general learning skills*
An eventual improvement of general learning skills like text comprehension or generalization will be evaluated by pre-post-tests. In part, we use standardized test, like some subtests of the HAWIK IV battery (matrices and finding generic terms) and the Salzburger Lese-Screening for the assessment of the reading comprehension.

B. Implementation of Modeling: Sample Units

We implemented the concept of modeling in two ways depending on the available time and/or the aim of the unit:

1. From a model to a text
2. From a text to a model

Both ways are useful and practicable (at least at a low level from the computer science perspective), but have different aims, advantages and disadvantages.

Starting from a model, e.g. the ER-diagram in figure 2 and 3, we can engage children to be creative. They can continue the diagram, tell or write a story, create similar diagrams for other topics of their choice etc. Furthermore, they can be used as example of how to represent subject specific knowledge in a structured way. In a first step, we introduce only the entities accompanied by the typical beginning of a fairy tale: “Once upon a time there was a knight and a princess. Suddenly a dragon appeared and ...”

Fig. 2. 1st part of ER-diagram: Knight – Princess – Dragon

Then we show the relations (verbs) between the entities (nouns) and invite the children to continue the story together: “... and threatened the princess. But, the knight could rescue the princess.”

Fig. 3. Extended ER-diagram: Knight – Princess – Dragon

In the last step, we introduce the attributes or characteristics of the different entities. Besides telling the story, we introduce also the basic use of the different shapes: rectangles for entities

(nouns like persons, animals etc.), rhombs for relations respectively verbs and ellipses for attributes (characteristics).

Depending on the available time, the children can now continue the fairy tale and/or extend the ER-diagram or even invent a new story. When the children continue the story, it is reasonable that the teacher should extend the diagram with appropriate shapes (on the blackboard or by means of cards) containing correct entities, relations and attributes.

The second way of introducing models is starting from a sample text on knights, princesses and dragons, containing already the correct shapes for entities, relations and attributes (fig. 4). This task may help to train reading competencies and to extract essential information. Furthermore, comparing it with the pictures, it can be used demonstrate the difference between concrete attributes like 'green' and generic terms, in this case 'color'.

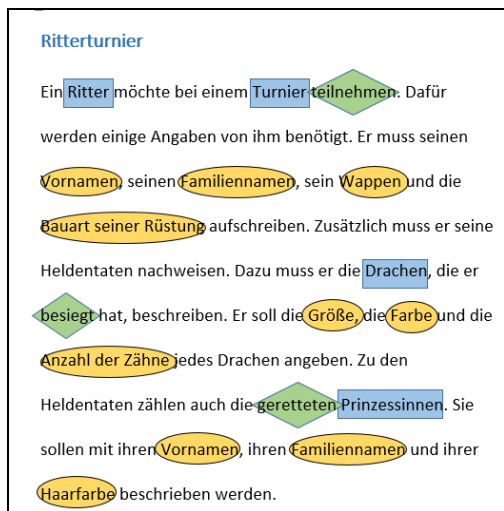

Fig. 4. Basic text for the ER-diagram 'Knight – Princess – Dragon'

IV. PRELIMINARY RESULTS

A. Practicability for teachers and students

Based on the interviews and discussions with 25 teachers in three workshops as well as the observation of students in primary and lower secondary schools we can definitely suggest modeling as a practical concept and tool for general education. All teachers said that entity-relationship diagrams are very useful for teaching and/or learning and that they would use them in one of their next lessons. However, as expected, most of them noted, that they would need more than one workshop before trying out the concepts on their own, because they were afraid of making errors. Only few teachers developed their own examples already after the first introduction into modeling, but rather as another form of mind map than as a correct diagram.

B. Comprehension of modeling

The answers and statements of the students during our workshops as well as the evaluation of their posters and diagrams showed that modeling seems easy to understand but sometimes difficult to apply. We evaluated the posters and

diagrams of students from two points of view: On the one hand, we checked the subject-specific or thematic knowledge (not informatics) as well as their capability to extract the essential information of given texts. On the other hand, we corrected the diagrams from the view of computer science in two steps. Firstly, we evaluated the correct use of the notation, i.e. the correct shapes for the different functions respectively word classes. In the second step, we focused on computer science and the correct concept of modeling including generalization. The division in two steps was necessary because of two reasons: On the one hand, when using e.g. ER-diagrams to visualize subject-specific knowledge or essential information of a text, it is often necessary to note some concrete attributes e.g. 'green' as color of the dragon in figure 3. However, using it in the ER-diagram it is not correct from the point of view of computer science, where models must contain generic terms, in the case above 'color' instead of 'green'. On the other hand, the process of generalization seems to be difficult for many participants. Hence, we decided to introduce generic terms only in a second step.

The first step was quite easy as mentioned by many participants. However, there are some striking aspects and errors from the view of computer science. Teachers and students tend to use ER-diagrams as another form of mind map. When designing an entity-relationship model most of the participants firstly concentrate only on entities (nouns) and relations (verbs), but seem to forget attributes. Furthermore, sometimes we found a verb and a noun together in one single shape, mainly when the noun is not the subject of a sentence as in the following example:

Fig. 5. Left: incorrect ER-diagram. Right: corrected ER-diagram

The second step respectively finding generic terms for the concrete names of adjectives of a text seems to be quite difficult for students as the immediate questions after the workshops, the observation of the students during the design of their own models as well as the assessment of the final posters showed.

V. CONCLUSION

Models are a basic concept for software developers and computer scientists. They are used to describe problems and can help to solve them. Competencies needed for the modeling process like abstraction, reduction, simplification, classification, generalization etc. shall be, in our opinion, part of general education. Some main aspects of modeling are even mentioned in different curricula of different subjects. Thus understanding these methods is useful for children of all ages. This paper should show different possibilities to integrate methods of modeling in primary and early secondary school. It focused on the entity-relationship-model and presented two ways to use this technique in a school unit. Following the opinions of participating teachers modeling methods are practical tools for teaching and learning. Students liked working with these concepts although they had some problems.

Abstract—DISSECT (DIScover SciEnce through Computational Thinking) is a project aimed at introducing students to computer science principles by establishing computational thinking (CT) as a problem-solving technique within middle school and high school Science, Technology, Engineering, and Mathematics (STEM) courses. While DISSECT has shown successful integration of CT into middle school and high school STEM curricula, illustrating the pervasive nature of CT, a question remained; “can CT also be infused into humanities courses (e.g., English, Art, History) in addition to scientific courses (e.g., Chemistry, Biology, Computer Science)?” The answer is positive. The objective of this paper is to present one approach to bridge the gap between CT and humanities through the curriculum of a 12th-grade English Literature course. The course blends CT practices with composition and literature to provide students with the ability to write critical and comparative analyses of selected literature. This paper will describe multiple modules that integrate computational thinking into the course, and discuss the results and assessment tools used to measure student competency in computational thinking.

Keywords—Computer science; Computer science education; Computational thinking; English literature; K-12

I. INTRODUCTION

Despite the ubiquity of electronic devices, the majority of the students who use them don’t understand the underlying technology (i.e., how the device actually works). This may be attributed to the lack of computer science (CS) courses in K-12 education; Code.org reports [1], “the majority of schools don’t even offer computer programming classes,” and only 25 states allow CS to count toward high school graduation math or science credits. Additionally, College Board presents data [2] that shows a low participation in the Advanced Placement (AP) CS Exam. Further, there aren’t enough qualified CS teachers because the CS teacher certification is “typified by confounding processes and illogical procedures” [3].

Because CS is deeply rooted in daily life, it is essential to provide all students and teachers with the knowledge needed to succeed in a computing world. The National Center for Women & Information Technology explains that present and future innovation require students to not only be computer-literate, but to possess the design, logical reasoning, and problem solving skills inherent to CS [4]. According to the Association

for Computing Machinery [5], there are several reasons to study CS including: CS is a pervasive science that provides necessary 21st century skills, enables people to solve complex problems, offers many types of lucrative careers, and offers opportunities for creativity and innovation.

DISSECT (DIScovering SciEnce through Computational Thinking) is a project aimed at introducing students to computational thinking (CT) as a problem-solving technique within middle school and high school Science, Technology, Engineering, and Mathematics (STEM) courses. Traditionally, the underlying concepts of CT including algorithmic design, reasoning with abstraction, and problem formulation and decomposition are taught within a CS course. DISSECT operates under the premise that these concepts are also fundamental in scientific disciplines, and hypothesizes that CT can also be discovered within non-scientific disciplines. DISSECT expects that by infusing and explicitly teaching CT within the context of non-computing disciplines, students benefit from pedagogy that enhances the learning and simultaneously provides a foundation for the principles and practices of CT. In the rest of this paper, we summarize DISSECT’s program design, describe modules that have integrated CT into a 12th grade Literature course, and present the assessment tools and results of the project.

II. PROGRAM DESIGN

A. Program Organization

The organization of DISSECT can be represented by a two-pronged approach. First, as indicated above, DISSECT builds upon the idea that CT is already embedded in the curricula of many disciplines, and can be made explicit; this enables a wider use of CT within curricula and enables students to understand CT. Second, DISSECT builds on a model that pairs graduate students (fellows) from computing-related disciplines with a middle school or high school teacher; each fellow-teacher team collaboratively conduct CT activities and the discovery of CT within the curricula. The ultimate benefit of this pairing model is the cross training that occurs between the teacher and fellow. While the fellow provides the CT expertise, the teacher offers effective K-12 pedagogies. This is key, because typically fellows do not have formal teaching experience and most teachers have not been trained in CT or

have not explicitly incorporated CT into their curricula. In particular, fellows will leave DISSECT with better communication skills, increased teaching abilities, and a deeper understanding of the relationship between the teacher's subject matter and CT. The teachers will acquire knowledge and practices of CT, and have access to CT modules that can be applied to their classrooms when fellows are no longer present.

DISSECT currently staffs one full-time coordinator; ten fellows from computing-related disciplines including CS, Electrical Engineering, Horticulture, and Agricultural Biology; and nine teachers from the Las Cruces Public Schools (LCPS) district in a wide range of classrooms including CS, Science, Zoology, Chemistry, Forensic Science, Biology, and English Literature.

B. Curriculum Design

CT is the "thought process involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" [6]. In 2006, Jeanette Wing argued [7] that CT is "a fundamental skill for everyone, not just computer scientists." This statement launched a debate among educators, researchers, and computer scientists about the instruction, application, and integration of CT into other disciplines. The curricula DISSECT develops and uses to introduce CT into K-12 classrooms is composed of a series of modules that aim to portray CT within the context of the course. Building upon the characterization of CT by the Computer Science Teachers Association [8] and College Board's AP Computer Science Principles [9], DISSECT builds on and integrates the following ten concepts into their modules. An *algorithm* is a process or sequence of steps to be followed to solve a problem. A *sequence of steps* is an ordered list of instructions. *Branching* involves a choice in an algorithm that leads to a different outcome depending on the choice. *Iteration* is the repetition of instructions. *Variables* are named pieces of data used by an algorithm that are subject to change. *Clarity* is an algorithm's quality of being certain or easy to understand. *Correctness* is the measure of reliability of the result of an algorithm or sequence of steps. The algorithm is correct if it produces the correct solution to the problem being solved. *Efficiency* is a measure of the performance of an algorithm. When compared to longer algorithms, shorter algorithms that produce the same solution are more efficient. *Abstraction* is the process of removing unnecessary information in order to keep the parts that are relevant to the problem. It is used to simplify the process of achieving a desired goal. Finally, *computational thinking* is a way of solving problems that involves reasoning with abstraction and thinking algorithmically.

In general, the fellow and teacher take one of two approaches to integrate CT into their course. The most common approach is to utilize existing course units and restructure the related activities to explicitly highlight CT concepts. As an alternate approach, the fellow-teacher team may choose a CT concept to highlight and then create a module that relates to both the course discipline and the CT concept.

III. IMPLEMENTATION: ENGLISH + CT

While DISSECT has shown successful integration of CT into middle school and high school STEM curricula [10], illustrating the pervasive nature of CT, DISSECT wanted to determine whether or not CT concepts (algorithms, sequence of steps, branching, iteration, variables, clarity, correctness, efficiency, and abstraction) could be integrated into a 12th grade English Literature course (ENG12). In particular, the choice of ENG12 was to reach students who did not have pre-conceived positive attitudes toward STEM or explicit experience with CT; generally, students are intimidated by math and science, thus CT may also induce a sense of fear. On the other hand, students tend to have a positive attitude toward arts and humanities (at the very least, they aren't scared of those subjects); this allowed DISSECT to explore and teach CT in a context that is less frightening and without preconceived notions.

The following sections describe the goals of ENG12 and modules that show the seamless integration of CT into the teaching of Literature.

A. English 12

The study has been conducted during the Spring 2014 (SP14), Fall 2014 (FA14), and Spring 2015 (SP15) semesters on three ENG 12 courses taught by Timothy Staley at Onate High School (OHS) in Las Cruces, New Mexico. Staley also taught two additional sections of ENG12 in Spring 2014 which will be referred to as "Control Class 1 (CC1)" and "Control Class 2 (CC2)" throughout this paper; neither control class was taught any modules that featured or explicitly introduced the DISSECT CT concepts. As a whole, the classes utilized the collaborative tools and services provided by Google's suite of Apps for Education [11].

The OHS Curriculum Guide [12] describes ENG12 as a course that "blends composition and literature into a cohesive whole as students write critical and comparative analyses of selected literature to... develop and improve critical thinking and analytical skills." Over the course of the class, students are introduced to, and tested on, the New Mexico Content Standards with Benchmarks and Performance Standards for English Language Arts [13]. Students enrolled in ENG12 are required to take the Literature End of Course Examination (EOCE) that tasks students to: 1) answer multiple-choice questions by thinking critically and 2) write an essay that demonstrates their ability to follow directions and their knowledge of the usage of literary elements in pieces of literature. The EOCE serves as a final exam for ENG12, and student scores are reported to Staley, OHS, and Las Cruces Public Schools district for various purposes [14] including "student grades, curriculum reviews, student graduation requirements, and for the Educator Effectiveness System."

In order to meet the course objectives and to prepare students for the EOCE, Staley's ENG12 courses were comprised of four units to enhance student analyses of four main pieces of literature: Lord of the Flies [15], song lyrics, Macbeth [16], and Siddhartha [17].

B. Unit Modules + CT

The existing ENG12 unit modules were enhanced to allow students to practice CT skills. Ensuring the content of the course remained consistent was an important design constraint during the integration of CT. A summary of each ENG12 unit module and its relation to CT is provided in the following sections.

Lord of the Flies: The Lord of the Flies (LOF) is a novel about a group of boys that are stranded on an island with no adult supervision. The major theme explored is the inevitability of chaos and loss of civilization when the boys are faced with the barbaric nature of the wilderness. This theme was mainly conveyed through the author's use of symbols. Symbols are objects, characters, and figures that are used to represent an abstract idea or concept. One of the goals of ENG12 is to teach students how to identify symbols and explain in a multi-paragraph essay how the symbols developed through the entire piece of literature.

CT was integrated into this unit through the LOF Symbol Development project by having students work collaboratively on a single Google Document to find every instance of eight symbols in the novel, and then forming groups to write a one-paragraph summary of the development of a symbol. In particular, this module was designed to provide students a collaborative avenue to learn and practice abstraction, a necessary skill for success on the writing portion of the EOCE.

For example, after a group of students identified the 125+ instances of "conch", a symbol representing societal order, they used abstraction to summarize the development of the conch:

"In the beginning of the novel, Piggy finds a conch near him and Ralph in the water. The conch starts off as a way to get everybody who is on the island together, and is used as a talking stick, whoever holds it has the right to speak uninterrupted. This started out well, because all of the children followed suit. That is until Piggy held the conch; he was the one person who they'd disregard and ignore while Ralph was the only one trying to enforce the rule. After some time, the children started to ignore the call to assemble when the conch was blown. This represented the beginning of the loss of order. By the end of the novel, total chaos ensues when Roger drops a large boulder on Piggy, killing him and smashing the conch into a million pieces. All order was lost and there was no going back to civilization."

Song Lyrics: By nature, song lyrics are full of poetic devices. This unit aimed to teach students how to identify elements of poetry (e.g., rhyme, repetition, etc.) in shorter pieces of literature (i.e., song lyrics).

The CT aspect of this unit centered on the Song Lyric Analysis Site. Students worked in pairs to complete the four components of the project: lyric analysis, poetry device data analysis, song critique, and website creation. A Google Document was used to annotate the song lyrics; a Google Spreadsheet was used to chart and analyze the amount of music and figurative language elements; Internet sources were used to garner peer-reviewed song reviews; and Google Sites was used to compile their analyses into a website.

Fig. 1. Macbeth ToonDoo Project: Example panel from planning to implementation

Macbeth: Macbeth was the focus of the third unit of ENG12. The play tells the story of Macbeth, a Scottish soldier that plunges into the depths of darkness to become king regardless of the consequences. The basic premise of Macbeth is that ruthless ambition leads to its own destruction.

To have the students practice their CT abilities, the unit project required the illustration of a scene of the play using ToonDoo [18], an online drag-and-drop comic-creation tool. Before implementation, students had to sketch out a storyboard to describe each of the eight panels of their chosen scene in detail. Figure 2 shows a student-created example of the planning and implementation of one panel in their scene. Although this activity did not provide a computing problem to solve or require students to write a computer program, the goal was for students to use their algorithmic thinking abilities to create a detailed step-by-step storyboard for their scene; this mimics the process of writing pseudocode before implementing it into a programming language. In addition to illustrating a scene, students had to comment on the significance of their scene to the play as a whole; students practiced abstraction by scanning their scene and analyzing the most important passages.

Siddhartha: Siddhartha follows the journey of self-discovery and enlightenment of a man in ancient India. This particular novel was introduced to the high school seniors to provoke deeper understanding about how enlightenment relates to knowledge, how knowledge relates to them and their goals, and how Eastern philosophy correlates to the Western World.

The Siddhartha unit project involved the creation of online blogs. Each student worked individually using Google Blogger as a creative outlet to reflect on ideas, plot structure, and Eastern philosophy within the novel. The targeted CT principle was algorithms through creativity; the goal was to end the semester with a project that the students could personalize and make their own, while practicing their writing skills and their ability to follow an algorithm (set of directions). Students were given documents with all of the necessary information to successfully complete the project and were graded on how well they followed directions. One of the blog topics dealt with the source material the author may have used when writing the novel. Students were given several ancient Buddhist and Hindi texts, and asked to use reasoning with abstraction to find the correlations between the texts and Siddhartha.

C. Additional CT Modules

In addition to increasing students' ability to analyze literature, Staley's course also aimed to help students acquire necessary college-ready skills. Each activity also highlighted CT concepts.

Introduction to Algorithms: The term "algorithm" is not part of the typical high school student's vocabulary. For that reason, it was necessary to introduce the concept through an engaging activity. This module was designed to teach students the definition and step-by-step nature of an algorithm, how algorithms are used in their every day life, and how to make an algorithm better. Real world examples of the algorithms students use in their lives included: brushing their teeth, writing an essay, finding a page in a novel, and other daily routines.

In order to show students that algorithms are better when the sequence of steps that are implemented are clear and easier to understand, they were given a sheet of paper and an algorithm to build a Mighty Mite [19] paper airplane. After 20 minutes of folding, no student successfully created a Mighty Mite because the instructions were intentionally ambiguous. After the frustration, the class completed the algorithm by discussing and rewriting any unclear instructions, allowing the class to successfully build their Mighty Mites.

Internet Source Reliability: It is imperative that graduating high school students understand how to find reliable evidence to support their claim when writing an essay. This module uses the CRAAP test [20] to give students an algorithm to determine whether the information given by a source on the Internet is reliable. The CRAAP test centers around five major criteria that help determine the reliability of an Internet source:

- 1) Currency: the timeliness of the information
- 2) Relevance: the importance of the information for your needs
- 3) Authority: the source or author of the information
- 4) Accuracy: the truthfulness and correctness of the content
- 5) Purpose: the reason that the information exists

This activity served two purposes: students learned how to apply an algorithm to evaluate Internet sources and gained a new, and appropriately skeptical, perspective about the information available on the Internet.

Prompt Analysis: Analyzing a prompt and providing a relevant response is a vital skill in college. Many times, essay prompts are very long and contain extraneous information which, if not read carefully, can lead to an unrelated essay response. Hence, the class was introduced to an algorithm to help them break down and better understand the instructions in an essay prompt, effectively abstracting only the necessary information:

- 1) Read the entire prompt.
- 2) Break apart the sentences.
- 3) Highlight all important words or phrases.
- 4) Replace one highlighted word or phrase with a synonym that makes sense to you.
- 5) Repeat step 4 until there are no more highlighted words or phrases.

This algorithm also served as a useful tool to be used on the EOCE that requires students to write an essay; the students practiced prompt analysis on the following sample prompt: "Write a multi-paragraph essay and support with evidence from literature you've read this school year. Identify a symbol and explain how that symbol was developed through the entire piece of literature." Together, the class used the algorithm and converted the prompt into a less intimidating prompt: "Write an essay with 3 – 4 paragraphs and support with quotes, examples, or scenarios from a poem, short story, novel, or song you've read this school year. Identify an object that has a deeper meaning and explain how that symbol was unfolded or expanded to become more important through the entire poem, short story, novel, or song."

Summarization: Another important skill that should be learned before college is the ability to summarize a long piece of literature. Students were provided a simple three-step algorithm to do so:

- 1) Selection: Highlight or write down important sentences
- 2) Rejection: Discard the sentences that are not crucial
- 3) Substitution: Convert the highlighted sentences into your own words without altering the main ideas or introducing your own opinions and biases

Along with the step-by-step process, the class discussed some key points to remember when tasked with summarizing any piece of literature. A summary should be objective, without criticizing the author or original source; contain short, simple and self-dependent sentences without redundant phrases or repetitions; and should not reproduce sentences from the original text.

IV. EVALUATION

To recap, this study has been conducted over the course of three semesters across three DISSECT classes (SP14, FA14, and SP15) and two control classes (CC1 and CC2). In total there were 108 students in Staley's ENG12 courses within the time frame of the experiment; Figure 2 shows the number of students in each section (28, 22, 16, 25, 17, students in the SP14, FA14, SP15, CC1, and CC2 classes, respectively). The ethnicity distribution of each class mimics the cultural diversity

of the school as a whole. Figure 3 presents OHS's student ethnicities and the ethnicity distribution of each section of ENG12. According to OHS [21], the student body is 73% Hispanic, 21% Caucasian, 3% African American, and < 1% Asian, Native American, Pacific Islander, and other. All ENG12 classes were composed of 73 - 85% Hispanic, 19 - 27% Caucasian, 0 - 13% African American, 0 - 7% Asian, and 0 - 5% Native American students.

In order to accurately assess student learning of CT, DISSECT utilized a variety of assessment tools and metrics. The following sections describe the assessment approach and results.

A. CT Assessment

Of course, many of the activities and course units were designed to indirectly teach students CT through modules that were relevant to the ENG12 course. At the end of the semester, a five-question test was distributed to the five sections of ENG12: SP14, FA14, SP15, CC1, CC2. The aim was to determine how effective the modules were at integrating CT into ENG12 by measuring the students' ability to apply CT. Below, we will describe the details of each question and then summarize student performance.

Algorithms through spatial reasoning: The first multiple-choice question was designed not only to test students' spatial reasoning abilities, but also to test whether or not the students could use algorithmic thinking in an abstract way. A 2-dimensional image of six different colored faces of a flattened cube and four 3-dimensional cubes (shown in Figure 4) were included with the question: "Using the image, you need to fold the flat cut out in your mind and choose the correct cube representation of the cut out." A successful algorithmic approach to solve the problem would be to mentally fold the flat cut out into a cube one face at a time. After every fold, the four choices should be analyzed to determine if any should be eliminated from the possible solution. After the step-by-step mental completion of the cube, the correct answer should be chosen.

Abstraction through data analysis: The concept of abstracting useful information from data was introduced in the Song Analysis unit of the course. The data question on the test asked students to analyze and determine the possible distribution of fruit from a pie chart, shown in Figure 5, which graphs fruit percentages. The multiple-choice question read:

Which of the following could be the possible distribution of fruit based on the graph?

- 1) 3 apples, 2 oranges, 5 bananas
- 2) 2 apples, 5 oranges, 3 bananas
- 3) 5 apples, 3 oranges, 2 bananas
- 4) 3 apples, 5 oranges, 2 bananas

Upon careful inspection of the legend, the solution is obvious. The red slice represents the 30% (3) apples, the blue slice represents 50% (5) oranges, and the orange slice represents 20% (2) bananas.

Fig. 2. ENG12 Student Distribution

Fig. 3. OHS Ethnicity Distribution

Fig. 4. CT Assessment Question: Algorithms through spatial reasoning

Fig. 5. CT Assessment Question: Abstraction through data analysis

Abstraction through analogy: The analogy question tested the students' ability to use their critical thinking skills to analyze the relationship between two objects. Analogies were not directly taught during the school year, so the question was relatively simple:

Milk is to cow as wool is to ____.

- 1) sweater
- 2) sheep
- 3) soft
- 4) farm

In order to solve this question correctly, abstraction should be used to determine the relationship between the two sets of terms: milk is to cow as wool is to sheep.

Abstraction through prompt summarization: Because prompt summarization was highlighted in the ENG12 curriculum, it was the focus of the fourth multiple-choice question. It instructed students to read a prompt and choose the option that best summarized the directions of the prompt.

Which sentence best summarizes the following prompt?

Works of literature often depict acts of betrayal. Friends and even family may betray their own values. Select a novel or play that includes such acts of betrayal. Then, in a well-written essay, analyze the nature of the betrayal and show how it contributes to the meaning of the work as a whole.

- 1) Write an essay that gives an example of a character in a book that may have committed an act of betrayal against a friend or family member.
- 2) Write an essay that explains how an act of betrayal was unfolded to become more important through a piece of literature.

The correct answer is 2; option 1 fails to require the analysis and development of the betrayal throughout the entire piece of literature.

Algorithms: Throughout the course, students were given many algorithms to accomplish English-related tasks (e.g., writing an essay, summarizing a prompt, analyzing Internet sources, etc.). This question was included to test their mastery at breaking down a problem into a sequence of steps. The question presented a picture of three blocks A, B, and C in an initial position (shown in Figure 6) and the goal was to move the blocks to achieve a specific position:

You have three blocks, A, B, and C that are initially in this position. Your goal is to move the blocks, one by one, in order to have A atop B and B atop C. What would be the correct sequence of steps to accomplish this?

- 1) B on C
- 2) C on B, A on C
- 3) C on floor, A on C, B on A
- 4) C on floor, B on A, C on B
- 5) C on floor, B on C, A on B
- 6) C on floor, A on B, C on A

This problem could be solved in different ways. A brute force trial of each multiple-choice answer will show that among the choices there is only one that will produce the goal position: 5. On the other hand, the problem could be solved logically by analyzing the goal position. It is known that in the end, block C should be on the floor, B on top of C, and A on top of B; these three facts lead directly to the correct solution.

Results: Overall, the students in the DISSECT classes performed better on the CT assessment than their peers in the control classes. Throughout the semester, the DISSECT-enhanced curriculum provided a heavy emphasis on

Fig. 6. CT Assessment Question: Algorithms

Fig. 7. CT Assessment Performance

algorithmic thinking and reasoning with abstraction. Figure 7 summarizes and compares the performance of each class on each question of the test. Below are the key results and short discussion.

All DISSECT classes, SP14, FA14, and SP15, outperformed both control classes in spatial reasoning, data analysis, analogy, and algorithms. The better performance in spatial reasoning and algorithms was expected because the Introduction to Algorithms activity had a spatial reasoning aspect to it (i.e., folding the paper airplanes) and, in general, many of the modules and activities highlighted or required algorithmic thinking. Furthermore, the Song Analysis project emphasized abstraction through data analysis, so SP14, FA14 and SP15 classes were prepared for this type of question. Regarding the analogy question, the two DISSECT courses did better, but not significantly. This could be attributed to the fact that the question may have been too simple, or that students were already familiar with these types of questions.

The results on the prompt summarization problem were not expected; considering performance, the SP14, FA14, and SP15 classes ranked second, third, and fourth, respectively. Specifically, this question featured an EOCE-like essay prompt. It is hypothesized that the DISSECT classes did not perform better than the control classes, because the control classes were also prepared for the essay-writing portion of the EOCE. Although, the fact that more than 64% of students in each DISSECT class answered the question correctly is a success.

B. EOCE Performance

LCPS requires every graduating senior to take the English Language Arts IV EOCE, which is composed of a reading and writing section. The maximum score for the reading and essay-writing portion of the EOCE is 24 and 20, respectively. Reading exams contain multiple-choice questions that utilize automated grading; the essay-writing portion is anonymously graded by English teachers. While Staley’s class aims to improve students’ critical reading skills, the CT modules

centered on augmenting students' analysis and writing abilities. Figure 8 shows the performance of the DISSECT and control classes on both sections of the EOCE, as well as the averages for both sets of courses. Regarding the reading section, the graph shows that all classes performed approximately the same on that portion of the exam; all classes received the same amount of critical reading instruction and practice. However, both DISSECT classes outperformed their peers in the control classes on the EOCE writing section; on average, the DISSECT classes scored three points, or 15%, higher than the control classes. EOCE performance data from SP15 was not available before submission.

C. CT Terms Assessment

In an effort to create a standardized form of assessment across all scientific and non-scientific DISSECT courses in the project, pre- and post-assessments are given to each student. The assessment centers around the CT terminology; students are provided with a list of concepts (CT, algorithms, sequence of steps, branching, iteration, variables, clarity, correctness, efficiency, and abstraction), and prompts them to circle, define, and give an example of each concept they are familiar with. By using this standardized document, DISSECT is able to determine how students' understanding of CT is changed throughout the school year across all classes and disciplines.

Each activity on the assessment was graded separately. The circling, or recognition, of terms was graded on a scale from 0 – 10, where each circled term was worth one point. Specifically, the document asked students to define and give an example of up to four terms, so the definition and usage categories were graded on a scale of 0 – 4, where each definition or usage was worth 0, 0.5, or 1 depending on the quality of the response. Figure 9 compares the pre- and post-performance of the ENG12 DISSECT classes on the CT terms assessment. As expected, the ENG12 classes improved in all three areas: recognition, definition, and usage of CT.

D. Post-ENG12 Feedback

A post-survey was also distributed to the ENG12 DISSECT classes to gather student feedback about the course and CT modules. One question asked students to disclose their attitudes about the class units. For each unit, they were asked whether they “hated”, “disliked”, “liked”, or “loved” the unit as a whole including the ENG12 content and related CT modules. Figure 10 charts the percentage of students who responded positively to the course units. In general, students enjoyed the Lord of the Flies, Macbeth, and song analysis units. In all classes, the Siddhartha unit was taught at the conclusion of the semester, and often felt rushed because 12th-graders are released seven school days before non-graduating students; at this point the graduating seniors showed a lower motivation for school and greater excitement for graduation and summer.

The class units, modules, activities, and access to course materials in the DISSECT courses required more technology than the standard English Literature class familiar to most high school seniors. Technologies used during the course included: the Google Drive suite (Documents, Spreadsheets, Presentations), Google Sites, Google Blogger, ToonDoo, and other online resources provided by the OHS Library. The post-survey included a question that asked students how much more

Fig. 8. EOCE Performance

Fig. 9. ENG12 CT Terms Pre- and Post-DISSECT Performance

Fig. 10. ENG12 Unit Feedback

Fig. 11. Comfort Level with Technology Post-DISSECT

comfortable they were with technology as a direct result of the class and the projects they completed. Figure 11 depicts the 60 responses of the DISSECT students. Overall, 52% of students felt they were “a lot more comfortable” or “more comfortable” with technology at the conclusion of the course.

Despite the positive results of the incorporation of CT into ENG12, the impact could have been greater if each student had been fully engaged. Students were asked to identify which factors negatively impacted their engagement with the ENG12 course and CT-related modules. We found that students were very willing to admit some of the factors that distracted them.

Fig. 12. Factors Impeding Full Participation in CT

Figure 12 shows the number of students across all DISSECT classes who selected a particular distraction. From the chart, it is clear that the factor that contributed to the highest level of disengagement was senioritis, an affliction of high school seniors characterized by a decline in motivation or performance. The next factors that had a significant effect on the DISSECT students were sleepiness, laziness, cell phones, and boredom. Smaller distractions included hunger and dehydration, personality clashes with the instructors, and the weather.

V. CONCLUSION AND FUTURE WORK

In this paper, we provided an overview of DISSECT, a project that aims to provide middle and high school students with essential CT skills. Adopting the perspective that CT is a tool that not only makes the learning of STEM classes more engaging, but also enhances the curricula of non-scientific courses (e.g., English) is unique to DISSECT. The modules presented show that CT can be seamlessly taught within the context of an English Literature course while remaining true to the course description, instruction requirements, and student performance expectations. On average, the students who were introduced to DISSECT modules that featured CT concepts performed 15% higher on the writing portion of the standardized EOCE. This suggests that CT should be explicitly taught as a problem-solving mechanism within the context of all courses, especially courses that are fundamental for success. For example, reading and writing are integral to learning, understanding, and communication in all disciplines, both scientific and non-scientific. Thus, if students can use CT to enhance their reading and writing abilities, they will be better equipped to pursue and succeed in the discipline of their choice.

Furthermore, assessment tools revealed that the integration of CT and English Literature was successful. The DISSECT classes demonstrated their abilities to use algorithms, algorithms through spatial reasoning and abstraction through data analysis; the classes also performed well, but not significantly better than the control classes, on abstraction through analogy and prompt summarization.

DISSECT has discovered an innate relationship between English Literature and CT. As DISSECT modules reach a level

of maturity within ENG12 and the student sample size grows, there will be room for further evaluation opportunities. If available, there could be interesting analysis of EOCE data comparing: DISSECT EOCE scores to control scores; DISSECT student performance to school-wide and district-wide performance; and student increase or decrease in performance from ENG11 to DISSECT ENG12.

ACKNOWLEDGMENT

The authors acknowledge the contributions provided by Criss Grubbs, Raena Cota, Dr. Sarah Hug, and all fellows. The data presented was collected under the approval of the NMSU IRB-11201, and supported by NSF grant DGE-0947465.

Using life course theory to frame women and girls' trajectories toward (or away) from computing

Pre high-school through college years

Abstract— In this study life course theory was used to synthesize research on women's underrepresentation in computing into 4 stages across their academic trajectory: pre high-school, high-school, college recruitment and college retention. The Association for Computing Machinery and IEEE Explore databases, as well as select journals that publish on women in computing, were searched for relevant work. The synthesis reveals issues of use and access at early ages, many knowledge or interests interventions at the pre high-school and high-school stage, the influence of stereotypical images of computing at the recruitment stage and exclusionary behavior and women's computing self efficacy as important issues at the retention stage. Next the paper discusses similarities and differences across the stages and lastly makes recommendations for future work based on the synthesis and life course framework.

Keywords—underrepresentation, women and girls in computing, computer education, life course theory

I. INTRODUCTION

Women are under-represented in most computing fields and their representation has decreased since 2003 [1]. Women's underrepresentation in computing has sparked research into many factors that may affect a student's trajectory toward or away from computing. These studies often examine distinct time periods on students educational trajectory, from pre high-school, high-school to college and beyond. However, to date few papers have attempted to integrate findings across studies as well as across time periods examined. The few reviews that do exist are either older [2]-[3] or limited in their coverage of students' academic trajectory[4]-[5]. In this paper we report on our ongoing work that attempts to address these limitations in women and girls' underrepresentation research in computing by reviewing and integrating the newest findings across several studies. In earlier work Xie and Shauman [6] advocated for a life course perspective for analyzing women's pathways through science fields. Later Castaño and Weber [7] extended the use of life course theory to computing fields in specific. Following these researchers [6]-[7] we draw on life course theory [8] to organize the results into four stages: pre high-school, high-school, college recruitment and college retention. While inferences cannot be drawn across these stages since most studies are not longitudinal, placing studies into stages and summarizing the findings within reveal some

plausible cross-stage factors that warrant further research. Finally some national data sources from the National Science Foundation and Computer Science Teacher Association are drawn on to supplement the literature review. By organizing the literature into distinct stages across the life course, connecting across those stages and comparing with national data, we aim to develop a more comprehensive understanding of women's underrepresentation in computing and identify new areas of research.

Creating a more comprehensive understanding is important because there are many environmental influences, agents and other factors that attract or repel girls and women from computing. Using life course theory we can integrate the findings into academic trajectory and find recurring themes across students' trajectories or critical junctures that may push or pull girls or women away from computing. Greater understanding of recurring themes or critical junctures can lead to more informed interventions, change and recruitment.

Lastly, following Frieze, Quesenberry, Kemp and Velaquez, Kvasny, Trauth and Morgan and others [9]-[14] we argue that research on women's underrepresentation in computing must take into account the cultural dimension of computing as a field, the cultural practices at particular institutions and the ways the those in the field conceive of gender as research concept.

II. THEORETICAL FRAMEWORK

Life course theory, often used in sociological research, frames the study of individuals or groups as (shared) pathways that are composed of series of roles people take on [8], [15]. These roles are situated within unique contexts and have different processes or conditions operating within each context. When applied to an educational setting, life course theory is often called educational trajectories or educational pathways for individuals or some larger aggregate of people, respectively [16]. Some researchers also call individual's trajectories life histories [17]. On either trajectories or pathways people start at one role within some context or contexts, such as a middle-school student in middle-school, and then transition into a new role within a new context, such as a high-school student in high-school. Castaño and Weber [7] proposed using life course theory explicitly for research on girls and women's

trajectories through computing fields. We build in this theoretical work by using life course theory to organize extant research on women and girls in computing. While few of the studies identified for this review conducted longitudinal research, this framework provides a means for organizing research at different stages of a students'

trajectory toward or away from computing. Direct connections between results at one stage and results at another stage cannot be made, due to different samples, timing, and design, organizing the studies by stages can help identify plausible connections that warrant further research.

In this review four stages toward or away from computing fields are examined: 1) pre high-school (preschool - middle school); 2) high-school; 3) college recruitment (undeclared majors and new college students who might enter computing fields of study); 4) college retention (students who have entered a computing field of study). Each stage is covered in sequential order from pre high-school to college retention. Table 1 summarizes research themes common to each stage, as well as papers that directly report on that theme. To conserve space only the first author of each paper is listed. These were identified through our synthesis of existing research. Note that other topics have been researched at each stage, but themes in table 1 have received more attention. The final column in table 1 indicates whether that theme primarily pushed girls/women away from computing, pulled girls/women toward computing or exhibited both a push and pull effect depending on some other condition (such as levels of self-efficacy).

III. METHODS

The Association for Computing Machinery (ACM) and IEEE Explore were used as the primary databases for identifying papers on women or girls in computing. Furthermore, a subset of the journals that have a record of publishing on women and girls in computing were also searched: The Journal of Women in Science and Engineering, Sex Roles and the International Journal of Gender Science and Technology. For the ACM and IEEE Explore databases the search terms "girls," "women," and "gender" were used since both databases focus on computing topics. For the additional journals, the same search terms and "computing" or "computer" were used.

To be included in the study, papers had to meet one of two criteria tracks. First, for empirical articles the study must: report on a computing topic, report results by gender, study a U.S. or Canadian sample and fit within the life stages studied for this review. It is important to note that, while studies related to any field of computing were included, there was a preponderance of studies examining computer science. Other computing fields that were covered include: computer engineering, information systems, computer-graphics, human-computer interaction and web development. Additionally, since this review targets recent work in computing, only papers published in 2000 or later were analyzed. The second track of studies, which were fewer in number, were theoretical or conceptual in nature. These were used to frame the empirical studies. To be included theoretical or conceptual studies must: be applicable to computing topics, study men/women or boys/girls and fit within the life stages studied in this review. If theoretical/conceptual studies reported any empirical results, they were only included if they studied U.S. or Canadian populations. To gain the fullest picture of research on women and girls as it relates to computing, we also examined the citations of included studies, if these citations met the criteria above.

Table 2 displays the number of review articles from each database, specific journal or citations. Note that table 2 contains all the papers in table 1 (those specifically tied to themes) and supporting papers we discuss in this review (that did not directly tie to the major themes).

An important point needs clarification before continuing. There is a vast amount of work studying women's underrepresentation at several stages of science, technology, engineering and math (STEM) academic study or careers. However, here we only reviewed research that investigated computing fields in specific. The major rationale behind this decision is that computing fields have displayed some stark differences from most other STEM fields in regards to women's representation. First, while the percent of women pursuing bachelors in most STEM fields have remained fairly constant or increased slightly over the past 20 years, the computer sciences have dropped from 28% in 2000 to 18% in 2012 as reported by the National Science Foundation [18], [19] (and displayed in Fig. 2 later in this article). Furthermore, in industrial settings women's representation in the computing workforce has also decreased dramatically, from 36% of the computing workforce in 1991 to 25% in 2009 [20]. These trends suggest there may be something unique happening within computing leading women to pursue fewer degrees and careers in computing. In light of this, and the lack of recent comprehensive reviews of computing research related to girls and women's underrepresentation across the stages of computing, we focus specifically on computing research to better understand the dynamics operating within this field.

Our review is ongoing and in future work we aim to incorporate computing graduate students and industry professionals' stages.

A. Stage 1 – Pre High-School

A process that starts early on and can influence the likelihood of young, pre-college children entering a computing field in is the somewhat nebulously named digital divide. In earlier work and public discussion the digital divide was often defined as those who did or did not have

Table 2

direct access to a computer [21]. As computers have become more prolific in schools, households, libraries and other venues, researchers have elaborated on other dimensions of the digital divide [22]-[25]. While direct access remains an issue, especially for minority groups (e.g. [26] reports that African American and Hispanic households have lower rates of computer ownership than White households) these other dimensions have increased in importance, particularly as preparation for pursuing computing degrees later in life. van Dijk [23] developed a four part scheme for the digital divide: physical access (direct access, same as past research); skills, which refers to differences in computing skills across groups; motivational, which refers to differences in desire/interest to use computers; and usage which refers to frequency of use in specific ways (e.g. basic vs. more complex uses). van Dijk [23] guides our review of pre high-school studies.

Identifying studies that examined pre high-school populations proved challenging. Meelissen [27], in a discussion of studies of computer competencies by gender, notes that many of these papers focus on collegiate populations. Nonetheless, we were able to identify a small set of studies that analyzed pre high-school students by gender in relation to different aspects of the digital divide outlined by van Dijk [23]. Willoughby et al's [28] work examined the teamwork dynamics of mixed gender teams for pre-schoolers and 5th/6th graders working on age-appropriate computing tasks. Somewhat surprisingly, they found in the mixed-gender preschool girls dominated computer use whereas for older children young boys dominated computer use. Ching, Kafai and Marshall [29] similarly found that until the researchers intervened (by having teams use fixed schedules for different tasks), 5th and 6th grade boys dominated more complex computer tasks (including programming) whereas girl team members were more frequently left recording team notes or conducting basic research. If one group dominates computer use this may lead to uneven development of computing ability, particularly higher order skills (e.g. programming).

Outside of the classroom Fields, Giang and Kafai [30] developed profiles for how middle school to high school aged boys and girls used Scratch, web platform for creating and sharing animations, games, simulations and interactive art. They report that girls were overrepresented in user profiles that used the platform the least and that boys were overrepresented in the profile of users that used the platform the most. In other words, boys used the platform and participated in the informal computing community to a greater degree than girls. Finally, Bain and Rice [31] found no differences in middle school boys and girls' attitudes, perceptions and general use of computers. It may be that young boys and girls have are not strongly distinguished by perceptions and attitudes toward computers at this age.

Another study by Cherney and London [32] on girls and boys between the ages of 5-13 found that boys played significantly more computer/video games (use) than girls. Bain and Rice [31] also found that boys used computers for games more than girls. Related research by Cotton, Shank and Anderson [33] found that middle-school boys had a

statistically higher percent of game system ownership (physical access), although both girls and boys reported high ownership (81 vs. 96). Playing video/computer games has been found to improve mental rotation abilities [34]-[35] which are relevant skills for computing fields like computer graphics and game development. More generally video games are seen as a common route into computing [36]-[37] However, the way in which games can serve as an entry for developing interest in computing remains a contested point in the literature [4],[38]-[40]. These different patterns in access, use and skill development may have an impact on high-school girls' involvement with computing as well.

Several papers also present interventions researchers undertook to increase young girls' interests or knowledge of computing [36], [41]-[44]. Most of these papers target middle school populations. These studies had students use tools such as the Alice programming software or Macromedia Flash to create interactive stories [41], games [42]-[43] or interfaces [44]. However, most of the studies we identified report mixed results [41], [43], [44] or report limited results [42].

B. Stage 2- High-School

At the high-school level many studies also focus on interventions to increase girls interest or knowledge of computing [45]-[52]. These studies vary in scope of the content they cover, the size and type of participants and the duration both of individual interventions and whether or not they were repeated. One of the most ambitious projects is called Georgia Computes! which ran for 6 years across the state of Georgia [47]. The project aimed to reach underrepresented populations in computing including young women/girls, African Americans and Hispanic students (grades 4th-12th) and also had professional development for secondary and postsecondary educators. Student interventions took the form of after school/weekend programs and summer camps. Georgia Computes! was one of the more extensive interventions we identified in this review.

Generally, many interventions reported positive post-intervention gains in young women's interest in or attitude toward computing [45], [47], [50]-[51] or computing classes [49], however some also reported mixed results [47],[51], null results [46] or loss of interest/attitude [52]. For example, in the Georgia Computes! students in their summer camps were significantly higher on post statements including whether they liked computing, were good at it, and were good at computing compared to their friends. Furthermore, comparing the 2006 and 2012 Georgia Computes! cohorts there was 237% increase in the number of young women taking the computer science advanced placement exam (CS AP). However, young women who took the CS AP exam continued to lag behind their male classmates on passing the exam, 37% to 54%, respectively. Dahlberg, Barnes, Buch and Rorrer [50] and Guzdial, Erickson, Mcklin and Engleman [47] study longer term impacts of their interventions (e.g. do students enter computing in college) which are important in light of challenges women face

pursuing computing degrees, as discussed in the following sections.

Some studies of high-school students also find they are largely unaware of what is covered in computing degrees in college [48], [53]. The Computer Science Teachers Associations (CSTA) published the results from a series of bi-annual national studies from 2005-2013 showing that less than 50% of the high-schools surveyed had CS AP classes [54]. In the same study CSTA also reported on the percent of young women in high school introductory Computer Science courses, visualized in fig. 1. Fig. 1 shows that over the past 6 years there has been a sharp increase in the number of introductory CS courses with 0-20% young women, suggesting fewer high-school aged young women are taking this course. This may also contribute to students' limited familiarity with computing degrees. A few qualitative studies of young women in high-school also indicate they are aware of difficulties women face pursuing computing degrees including intimidation and exclusion [48] or experience exclusion (e.g. having their work ridiculed based on gender) in high-school computing courses [55]. Exclusionary behaviors, often from male classmates, have been studied more frequently in college students and will be discussed in the college retention section. It is difficult to say how similar high-school and college behaviors are without more studies looking at computing classroom dynamics in high-school. Nevertheless, research finds that women enter college with less computing experience on average [5], [56]. It seems plausible the dimensions of the digital divide discussed earlier and limited advanced computer exposure in high-school contributes to this unfamiliarity. Young women's awareness of or experience with exclusionary behavior in computing classes or degrees may contribute to their low numbers in introductory CS courses, as displayed in fig. 1. Interventions are a promising start to addressing women's lower rates of computing enrollment. Additionally, studies that examined the trajectory of girls to young women in relation to computer experience, skills and interests would greatly benefit our understanding of women's underrepresentation and ability to create new interventions.

C. Stage 3- College Recruitment

At the earliest stage of students undergraduate work one researcher and her colleagues have conducted numerous experiments to identify potential deterrents to entering computer science. Cheryan and her colleagues [57]-[60] consistently find that women, but not men, express lower interest in pursuing a computer science degree after being exposed to a stereotypical presentation of a computer scientist. As Cheryan, Plaut, Handron and Hudson [61] explain this stereotype projects computer scientists as technology (and not person) oriented, singularly focused on computers (to the exclusion of other interests), lacking in interpersonal skills, highly intelligent, of a certain physical appearance (pale, thin), perhaps with glasses and male/masculine. While some of these attributes are positive (e.g. intelligent) others can be exclusionary. but if these images are projected by the field or other sources like media

Fig 1 - Percent of Classes with Different Ranks of Female Representation

people will act on the images they receive. As discussed in the college retention section, there is some evidence that these stereotypical attributes of computer science are present in the field as well.

An example of the experiments Cheryan and colleagues have run help demonstrate how stereotypical images of computer science affect women's interest. In Cheryan, Drury and Vishayapai [57] non-computer science students were assigned to 1 of 3 conditions: interaction with a computer science major who evoked stereotypical attributes, interacting with a computer science major who did not evoke stereotypical attributes or no interaction (baseline comparison). Interest in pursuing computer science was measured pre/post. Participants in the experiment were told the session was studying how people get to know others (i.e. they were not informed of the intent of the study until debriefing afterward). In the baseline group students were told that their partner did not show up and were "randomly" asked to evaluate their interest in a given field (all slips were computer science). Results showed that women expressed statistically lower interest in pursuing computer science when exposed to the stereotypical partner than the baseline or non-stereotypical condition. Men showed no difference across conditions. Cheryan and colleagues [57]-[60] have found similar effects on women's interest in computer science when exposed to other stereotypical imagery (e.g. a virtual classroom). In these studies Cheryan and colleagues also found that sense of belonging--whether a person felt they fit in with the field--mediated the relationship between exposure to the stereotypical condition and loss in interest. Thus it seems that these images negatively influence whether female students feel like they fit within the field. Issues of fit also arise while women pursue computing degrees.

D. Stage 4 – College Retention

For women who do enter computing fields, several qualitative studies have identified aspects of the academic culture similar to attributes of the stereotypical image (e.g. masculine/aggressive) of computing [56], [62]-[68]. For example, Garvin-Doxas and Barker [65]) conducted an ethnographic analysis for 2 years at a public research intensive university. One of their major findings was that male students engaged in "strutting" behavior, whereby they exaggerated their ability on a given topic/class and understated its difficulty. This behavior held for male students even when the student performed no different or worse than the average. This behavior inflated expectations for students and was often used to cast others as unable to succeed in computing. Across this study and others that identified strutting behavior in computing fields [56], [69] women were often targeted as academically unskilled, regardless of actual ability. More generally, other qualitative studies like Barker [62], who studied undergraduate research experiences in computer science, found that it was common for male students to understate female students' ability, regardless of their actual ability. Strutting, dismissive and exclusionary behavior complicate women's trajectory through computing and may plausibly be connected to some of the other research in this section including women's self-efficacy.

Self-efficacy is the belief in one's own ability to perform some task [70]. Several studies have found that females have lower self efficacy in computing [71]-[76]. Furthermore, some studies have shown that females in computer science have lower self-efficacy than males in computer science [74]-[76]. For example, Beyer and Haller [75] found that women in computer science had statistically lower self-efficacy in their ability to teach someone a computer software package; discuss the strengths and weaknesses of software packages; and write a complex program. Disturbingly, Beyer and Haller [75] and Beyer, Rynes, Perrault, Kay and Haller [76] has found that male non-computer science majors express greater overall self-efficacy than female computer science majors. Somewhat related, Lopez, Zhang and Lopez [77] found no difference between women non-majors and women in computer science self-efficacy. Furthermore, Redmond, Evans and Sahami [78] found that non-computing and computing major women had similar levels of math confidence, a construct similar to self-efficacy. It seems that that women's self-efficacy related to computers does not increase despite their progress in computing degrees. Indeed, studies of self-efficacy in other STEM fields often show women with lower or decreasing levels of self-efficacy as they advance in their degree (e.g. [79]). While the exclusive, dismissive behaviors of some male computing students are often studied separately from women's self-efficacy in computing, there is some overlap. For instance Lopez, Zhang and Lopez [77], who examined 359 women computing majors and 333 women non-computing majors, found that women computing majors reported statistically higher levels of gender stereotyping than non-majors. It seems plausible that the exclusionary behaviors may have impact on women's self-efficacy while pursuing computing

degrees, although this is something that needs to be researched further.

Looking at another aspect of the retention stage, Cohoon [80] examined men and women's attrition from computer science majors averaged over a 5 year period (1992-1997). While this data is older it is also one of the more comprehensive examinations of attrition by gender in computer science. Across 23 institutions in Virginia most (13) had slightly higher attrition rates for women, a few (5) had much larger attrition rates for women (over 15%). There were only 2 institutions with slightly higher rates of attrition for men (the rest were even). During this time, enrollment rates in Virginia were similar to national trends [80]. Margolis, Fisher and Miller [67] also found higher attrition rates for women in Carnegie Mellon's computer science department. Again, while it's not possible to directly connect this outcome to the exclusionary behavior women experience or lower self-efficacy women express, it seems plausible that both may have an impact on attrition rates.

Finally fig. 2 shows the graduation rates for men and women with bachelors in computing science from 1994-2012 (adapted from NSF Women, Minorities and People with Disabilities' Reports). Across the four stages we have reviewed research that suggests there gaps in use, access and computing skill between boys and girls in pre high-school years, interventions that have unclear long-term impacts and a general lack of awareness of computing fields in high-school, stereotypical images of computing that keep women from entering computer science and exclusionary practices, lower levels of self-efficacy and higher rates of attrition for women in computing. These studies were conducted in isolation and cannot be directly linked to each other; however it is plausible that at each stage of a women's trajectory toward or away from computing, these forces (likely along with others) resulted in the gender skewed distribution of bachelors graduates in figure 1. Longitudinal studies could shed light onto the complex trajectories that appear to lead more women away from computing at different stages.

IV. DISCUSSION

Surveying across the four stages reviewed, two composite (cross-stage) themes emerge: access to computing and orientation to computing. Across the stages, different individuals or conditions impede (or enhance) girls access to computing. This theme changes across stages; in pre high-school boys sometimes monopolize computer time, but in high-school and college classes, young women may be marginalized in computer classes. Outside of computing but in college stereotypical images may deter women as well. What access is being affected differs across stages as well, from computing time or classes to degrees and high-level computing skills. It appears that the severity of exclusionary behavior is most pronounced within computing degrees; however, this may be an artifact of limited research at the pre high-school and high-school stage and requires further study. The second composite theme focuses on the ways women or

Fig. 2 - Computer Sciences Bachelors Graduates by Gender

girls orient themselves toward computing. Coverage of this theme is different across stages; in pre high-school and high-school years the prevalence of interventions indicate low interest for women, but later in college studies find women express low sense of belonging or self-efficacy with computing. These orientations are of different kinds but they may overlap. Few studies seem to have examined these 3 factors interrelations (although some such as [75] captured interest and self-efficacy). All 3 factors are likely present across the stages, however not all have received equal attention at each stage.

These composite themes suggest some areas for further study. Issues of access deserve greater attention at the pre high-school and high-school level, as well as longitudinally or comparatively across these stages. Another avenue for further research is exploring the interrelations between self-efficacy, interest and sense of belonging in regards to computing as well as how these factors do or do not change over time. As suggested in the synthesis, there may also be a relationship between exclusionary behavior in computer science and women's self-efficacy and sense of belonging. Other longitudinal studies across subsets or longer portions of the stages identified here are also needed to better understand students' life course toward or away from computing including the long-term effects of interventions.

Finally, while pre high-school and high-school interventions were emphasized here, other interventions in college recruitment or college retention (e.g.[49]) may also help address the second composite theme. Furthermore, as we argued in the beginning of the paper, researchers examining women's underrepresentation in computing need to analyze the culture of computing professions, computing in the classroom and how gender is conceived in computing research. Some research addresses computing culture or

problematicizes how gender is conceived in computing research, such as those associated with the first composite theme. More critical research is needed if we aim to create a more open and equally rigorous computing field. The exclusionary behavior discussed earlier can affect male and female success and contributes little to computing excellence.

V. CONCLUSION

In this study we drew on life course theory to frame a review of research on women's underrepresentation in computing fields. Four stages were identified: pre high-school, high-school, college recruitment and college retention. Across the four stages we reviewed research that suggests there are gaps in use, access and computing skills between boys and girls in pre high-school years, interventions that have unclear long-term impacts and a general lack of awareness of computing fields in high-school, stereotypical images of computing that keep women from entering computer science and exclusionary practices, lower levels of self-efficacy and higher rates of attrition for women in computing. As this review develops we aim to incorporate later stages for women including graduate studies and to similarly review minorities in computing. For future work on women and girls in computing this review suggests the importance of taking a life course perspective and studying students' trajectories toward or away from computing. While academic career cohort studies may not be feasible in all cases, studies that look across two or more of the stages discussed here hold promise for better understanding the places of divergence and conditions or choices that affect whether women pursue computing.

Abstract— The objective of this research was to determine various motivational factors that influence high school students towards intended careers in engineering. This study utilized data from the High School Longitudinal Study of 2009, which surveyed over 24,000 students in 9th grade and again in 11th grade. We classified students into four categories of intentions: 1) *Not STEM Intending*, those who did not select a STEM occupation in either the 2009 or 2011 administrations; 2) *Leavers*, students who selected a STEM occupation in 2009 but not in 2011; 3) *Newcomers*, those who did not originally specify a STEM career in 2009, but who did in 2011; and 4) *Stayers*, those who chose STEM careers in both 2009 and 2011. Repeated measures analysis of variance modeled the extent to which the motivational variables, measured for both mathematics and science, were related to students' career intentions. Results show that occupational intentions change dramatically between 9th and 11th grades, and that the relationship between STEM intention and motivation is highly time-sensitive: Of the 6,788 STEM intending students in 2009 (29% of the total sample), only 3,560 remained STEM intending in 2011 (48% attrition).

Keywords—*motivation, careers; self-efficacy; persistence*

I. INTRODUCTION

For many years, the relationship between students' attitudes and their college and career intentions has been an important area of inquiry in STEM education. Betz & Hackett, for example, examined the impact that mathematics *self-efficacy* beliefs had on high schoolers' intention to select science majors in college. They surveyed upwards of 250 students and found that, not only are students' expectations for future success in mathematics significantly related to their choice of college major, but that young women and young men differed significantly in their mathematical self efficacy [1].

This seminal study is indicative of the general body of work in STEM intent and persistence. In general, research has found that students' beliefs about their abilities relative to mathematics and science subject matter help them form expectations of future success in that subject matter.

Moreover, inasmuch as students' perceive their earlier STEM experiences as indicative of future experiences in a potential occupational field, these perceptions also color their career intentions and occupational choices. Additionally, there has been reasonably consistent findings that these beliefs and perceptions differentially impact the intentions of women and under-represented populations for going into engineering and other STEM fields [2].

Sadler et al, in a huge study of US high schoolers found that males are about 3 times more likely to be interested in a STEM career than females [3]. Partial causative factors for this disparity include young women's beliefs in the *utility* of STEM for their future career goals, lack of role models, and young women having more developed communal goals, as opposed to individualistic goals, than young men [4] [5].

However, recent research indicates that change is in the works (see Marra et al.) [6]. While women represent far fewer professionals in the fields of science, technology, engineering, and mathematics both in the United States and abroad, the number of women in STEM fields is steadily increasing. Marra et al, suggest that recent reduction in gender differences can be partly attributed to more equitable preparation in mathematics and science. Ethnicity and socio-economic status are also known to influence intention for STEM careers, mediated by poorer academic success for under-represented groups [7].

One critique we can make of this body of research is that most of these studies draw upon samples of convenience, making estimation of effects difficult to project and disaggregate across pertinent subgroups. Additionally, the longitudinal nature of students' motivations and STEM intention is unclear. What happens that might influence a non-STEM intending student to choose to become an engineer? What experiences enable or constrain intentions to pursue technical and scientific occupations?

The objective of this research was to determine various motivational factors that influence high school students towards intended careers in engineering. Compared to other occupational fields, engineering-intending students compose a small minority, requiring relatively large samples to estimate population parameters. This study utilized data from the High School Longitudinal Study of 2009, a sample of 23,415 students, representative, nationally, of US 9th graders [8].

Clearly motivations and beliefs about the subject matter are influential factors. Cass et al report that interest, mathematics competence and performance, and mathematics recognition significantly predict choice of an engineering career, even after controlling for prior performance, and demographics. Thus, factors relating to *identity* within at least one domain (mathematics) are highly predictive of pursuit of STEM in general, and engineering in particular [4].

Identity is developed over time in a field, but there is evidence that consistency across the high school years is paramount for keeping students engineering intending. Adelman analyzed the transcripts of persons enrolled in the High School and Beyond longitudinal study (1982-1993) and their subsequent choices of major and occupation. He found that at age 28/29, the people who persisted in engineering displayed a consistent occupational goal, beginning in high school. Forty-one percent of engineers displayed a consistent goal through high school and through college, as compared to only 10% of engineers, who changed their career goals often [2]. Because many students move from discipline to discipline in college, the likelihood of a student with engineering intent going into university actually graduating with a degree in engineering is below 50%. This is especially true for women. Marra, et al studied nearly 200 undergraduate women to ascertain their efficacy-related beliefs and career intentions. They found that self-efficacy mediated students' career intentions, and that, at least for women, it should be a factor in deciding when to switch majors [6].

In a subsequent study, the authors found three factors impacting students intentions to leave engineering: 1) Poor teaching and Advising; 2) difficulty of the engineering curriculum; and 3) lack of belonging in engineering [7]. Likewise, Christensen et al report that the top three factors for predicting student interest in STEM were: 1) parental support; 2) a high quality/motivating teacher; and 3) self-motivation/feelings of efficacy [9]. We interpret these factors to indicate that students' STEM experiences, their self-efficacy and identity in STEM subject matter should be predictive of their intentions to stay or leave engineering or other STEM disciplines. What patterns exist across motivations and STEM intentions as students matriculate through high schools is the primary focus of the analysis reported here.

Seymour and Hewitt's seminal work supports these findings as students move on to the world of work. They identified two categories of students who leave

science/engineering programs: those who lose *interest* or become disappointed with the curriculum and those who feel they must leave because of a loss of academic self-efficacy in the competitive environment [10].

It has been shown that these motivational variables: Interest, Identity, Self-Efficacy, and Utility each impact the *effort* a student is willing to expend in academic subject matter, and that they interact to significantly predict academic performance in STEM subject matter [11]. In general, the model suggests that interest and perceived utility of the subject matter is a key driver of effort students are willing to expend, and that self efficacy and identity mediate students' goals for engaging and persisting in STEM. The purpose of the present study builds on this body of research to ascertain the *longitudinal* impact of these variables on the career intentions of high schoolers, with particular attention to engineering aspirations.

II. METHOD

A. HSLS: 09

The High School Longitudinal Study of 2009 (HSLS:09, NCES, 2011) is a long-term study of 21,000 9th graders in 944 schools administered by the National Center for Education Statistics (NCES, 2009). Data collected in the study focuses on students' decisions on what courses to take, what occupations to pursue, their aspirations for higher education and their reasons for engaging in these pursuits. STEM pursuits, in particular, including mathematics and science courses, majors and careers, are a special focus of the study.

The initial administration of the HSLS:09 began in Fall, 2009, surveying 9th graders on their past experiences in middle school, and on their current attitudes, motivation, and achievement. Students were surveyed again in the Fall of 2011, and a follow up survey was administered again in 2013 following graduation. Dropouts were also followed on this schedule. Future data collections are planned in 2016 and 2021 to learn about participants' life trajectories and markers of success. This study reports only on the first two administrations.

HSLS:09 generated a nationally representative sample of 944 high schools, including both public and private schools. This makes the data set representative of communities in the US. Following this initial sampling, approximately 25 ninth-graders were selected from each school. The resulting sample totals approximately 24,000 students, representative of all ethnic categories and socioeconomic strata. Students' parents, mathematics and science teachers, and other school personnel were then asked to complete surveys on their student's behaviors and experiences. We only analyze student data at the national level in this study.

B. Weighting

The HSLS:09 dataset provides several types of sampling weights to account for the complex survey design and produces estimates for the target population of choice. These weights

allow for multilevel analyses across a variety of factors (e.g., students within ethnicities, teachers within schools, etc.). For this study the two pertinent subpopulations described are Sex and Ethnicity. The appropriate variable weights provided by NCES were applied to provide accurate descriptive statistics for these factors. The survey items show minimal non-response bias. Some missing data, therefore, were imputed. For the present study, students' sex and ethnicity have some imputed scores.

C. Motivation Scales

Eighteen items from HSLs:09 were utilized in the construction of motivation and achievement indices in the present study. Table 1 provides a listing of items for each hypothesized scale. All items were rated on a 1-4 Likert scale ranging from 1 (Strongly Disagree) to 4 (Strongly Agree). Motivation for both mathematics and science were measured separately to account for differences in students' perceptions and experiences in the different subject matter.

D. STEM Intentions

STEM career intentions were measured using standard categories from the US Bureau of Labor Statistics: Computers/Mathematics, Architecture/Engineering, Life and Physical Sciences, and Healthcare Professionals. Any student who chose one of these four categories of occupations as "where they see themselves at age 30" was classified as STEM intending. With measures administered longitudinally at two points in time (2009 and 2011), we classified students into four categories of intentions: 1) Not STEM Intending, those who did not select a STEM occupation in either the 2009 or 2011 administrations; Leavers, students who selected a STEM occupation in 2009 but not in 2011; 3) Newcomers, those who did not originally specify a STEM career in 2009, but who did in 2011; and 4) Stayers, those who chose STEM careers in both 2009 and 2011.

III. RESULTS

A. Overall Results

Repeated measures analysis of variance modeled the extent to which each of the motivational variables was related to students' career intentions. Overall, males, students who identify more with math and science, students with parents who are engineers, Asian, Hispanic, and White students, and more affluent students have a higher probability of engineering intention in comparison to other students. However, STEM intentions changed dramatically between 9th and 11th grades. Of the nearly 6,800 STEM intending students in 2009 (29% of the total sample), only roughly 3,500 remained STEM intending in 2011. This is an overall attrition rate of 48% for the 2009 cohort.

The attrition away from STEM occupations is heavy across all occupational categories. Computer/Mathematics professions saw a drop from 350 original students to only 94 (a drop of 73%). Architecture/Engineering dropped from 1,035 to 363, an attrition of 65%. Physical and Biological Sciences saw the largest attrition, dropping from 1,055 to 208, an 80% rate. Health Professions, the category representing the

largest group of STEM intending students in 2009, dropped from 4,348 to 2,193 (50%).

But, there is hope! Students also select *into* Engineering and related fields. Computers/Mathematics jumped from 350 students in 2009 to 412 in 2011, Architecture/Engineering jumped from 1,035 to 1,169, while Health Professions jumped from 4,348 to 4,612. Only Biological and Physical Sciences showed a net drop in overall numbers of students who, as high

Total STEM Intending 2011							7,131

male, above the poverty line, expect to earn a bachelor's or master's degree, have parents who expect the student to go far in school, are engineers, or have an associate's degree or higher, or students who view math and/or science positively are more likely to be engineering-intending. Ethnically, Asians, Hispanics, and Whites seem to be more engineering inclined, although the trend did not seem as strong.

B. Leavers, Newcomers, Stayers

Table 2 provides a breakdown of students' career intentions for 2009 and 2011. Health professions represent the largest proportions of STEM intenders, closely followed by Architecture/Engineering and Physical and Biological Sciences. Computer Science and Mathematics bring up the rear with very low percentages of students intending to engage in these occupations.

We are most interested in any information we can find that might explain what the characteristics are of these three categories: Who stays in STEM, who switches out, and who switches in, and what characteristics and attitudes might influence these students' decisions. Table 3 provides a breakdown of Stayers, Leavers, Newcomers and Not-Interested students across the different STEM occupational categories surveyed. In terms of overall movement from one category to another, we see roughly equal proportions of students across all categories. 15.2 percent of students stayed STEM intending (Stayers), another 15.3 switched into STEM (Newcomers), while 13.8 elected some other STEM category as intended occupation, or could not choose. Table 3 shows

that Asians were more likely to stay or switch into STEM than other ethnic groups. While there is a slight tendency for underrepresented minorities to be not STEM intending, these differences are relatively small compared to Whites, with the exception of American Indian students.

Repeated measures ANOVA shows that, across all motivational variables, significant differences exist for Stayers, Newcomers, Leavers, and Not STEM Intending students. We see that those who switch into STEM experienced an increased identity, interest, self-efficacy, and feelings of utility for both mathematics and science, while those who switch out or remain not-interested in STEM careers showed reduced identity or no change in attitude. Those who stayed with STEM career intention maintained moderately high attitudes across these variables. Table 4 shows the magnitudes of these changes.

C. Sex differences

We found few differences overall when analyzing motivations by sex. Repeated measures ANOVA with sex as a fixed factor shows that males started out with higher motivation than females in 2009, but two years later, these differences became non-significant. It is important to note that, in accordance with the overall analyses above, *both* sexes tend to lose identity, feelings of utility, self-efficacy, and interest in both mathematics and science over time. However, for STEM intention, females are much more likely to have stayed with a vision of a STEM occupation at age 30 than males. Females, in fact, are almost twice as likely to remain STEM intending than males. They were also, however, marginally more likely to switch their intended occupation from STEM to some other occupation, or feel unable to make a choice. Table 5 shows the proportion of males versus females across categories of STEM intent. Females, typically were less likely to be uninterested in STEM careers than males, more likely to switch out of STEM, more likely to switch *into* STEM, and about twice as likely to remain STEM intending, than their male counterparts ($X^2_{(3 \text{ df})} = 846.13, p < .0001$).

D. Principle Components Analysis

To test the degree to which students' ratings of motivational variables in 2009 were associated with their ratings in 2011, we performed a Principle Components Analysis (PCA) on each of the mathematics and science-related scale scores for each respondent. PCA computes orthogonal eigenvectors (Principle Components) corresponding to the major and minor axes of a hyper-ellipse—the “cloud” of data plotted in n -dimensional space, n being the number of motivational variables in 2009 and 2011 collectively. We kept the administration years separate, because we are interested in detecting any changes in motivation associated with each year. The eigenvalues for each principle component represent the amount of residual variation accounted for by each successive axis in the solution. Figure 1 illustrates a scree test of the eigenvalues to distinguish “true” principle components—those that account for significant variation in the data—from “error” components—those that account for negligible variation. Two significant factors were extracted (see Table 7 for Principle Component scores for each dimension).

The first two dimensions account for close to 65% of the total variation in the data, while the remaining 20 components account for only 35% collectively. When the scale scores of all the motivational variables in the dataset are correlated with these two “true” principle components, we see that they fall out clearly by year. We can thus label these factors *2009 motivation* (Component 2) and *2011 motivation* (Component 1). Table 7 shows this pattern; students' motivations in 2009 are closely related to each other, but these 2009 motivations are only weakly associated with the same variables in 2011.

Figure 1. Scree Plot Showing Two Significant Principle Components for Motivation Variables Across 2009 and 2011

What does this mean? Essentially, it suggests that students' motivations are highly located in the moment. Their experiences in mathematics and sciences in one year may not be related strongly to their experiences in another year, and their motivations, being tied to the experiences at hand, seem to be highly unstable in the high school years..

Indeed, when Pearson correlations are computed for these variables across years, *none* of the 2009 scale scores correlates

strongly with *any* of the 2011 scores (no correlations showed a magnitude greater than ± 0.123).

IV. DISCUSSION

Results show clearly that US high schoolers typically change their career intentions between grade 9 and 11. This two-year period is one of high volatility, with people originally STEM intending no longer remaining interested, while others not originally STEM intending beginning to see STEM as a potential future pathway. Motivationally, the interest, identity, beliefs about utility and efficacy of these Leavers and Newcomers reflect their changing views towards mathematics and science subject matter. Leavers tended to grow more disillusioned with STEM, while Newcomers tended to grow more enamoured.

Table 7. Principle Component Scores for Two Extracted Dimensions.

Component		
Variable	1	2
2009		
Math Identity	.190	.753
Math Utility	.221	.809
Math Self-efficacy	.252	.806
Math Interest	.247	.794
Science Identity	.177	.752
Science Utility	.238	.798
Science Self-efficacy	.252	.795
Science Interest	.253	.787
2011		
Math Effort	.773	-.120
Science Effort	.739	-.080
Math Identity	.877	-.220
Math Utility	.856	-.230
Math Self-efficacy	.848	-.207
Math Interest	.776	-.118
Science Identity	.864	-.218
Science Utility	.852	-.249
Science Self-efficacy	.834	-.206
Science Interest	.743	-.084

Two critical findings are of note: First, overall STEM motivations in 2009 and 2011 are not closely related to each other. This is indicative of the volatility of students' future perspectives, and how they utilize proximal information to gauge their efficacy beliefs and project their future selves [12].

In practical terms, we speculate that students' experiences in mathematics and science coursework, coupled with parental support primarily, and extracurricular activities secondarily, greatly determine their motivations in the moment. It is likely that Leavers who had initially positive STEM experiences in the elementary and middle grades may have confronted difficulties in early high school that convinced them to be less enamoured with STEM and potential STEM-related careers. Likewise, Newcomers may have encountered excellent teachers, or mentors in extracurricular activities, and changed their beliefs for the better. The fact that Leavers, Newcomers, and Stayers made up equal proportions of students in the nationally representative sample means that there was only small increase in overall STEM intending numbers between 2009 and 2011. Given the importance of consistent STEM intent for predicting actual STEM occupations after college, it is highly likely that little net increase in the STEM workforce is upcoming in the near future in the US.

Second, our findings echo those of Marra et al, in that in the 11th grade, we find non-significant differences in the proportion of females and males who are STEM intending. Additionally we find little to no differences in STEM attitudes in 2011. Given that young females in the sample came into high school with generally lower attitudes and intent, there is a net positive in finding non-significant differences two years later. However, because both females and males tend to reduce in motivation towards STEM between their freshman and senior years, we still have an overall problem of attracting students to these critical fields [6] [7].

Abstract— In this paper we report our study on the problem of competency acquisition when students progress from one course to another and more generally, from one term to the next. We observed that some students moved on to a second programming course without acquiring some of the competencies in the first programming course. This leads to problem in the second course, especially when these competencies are pre-requisites for this course. We applied blended learning, which allows a student to learn at least in part through delivery of content and instruction via online media, to overcome this problem. Our approach is unique in the sense that we first assess student competencies and then develop targeted blended learning content to address competencies that have not been acquired in a pre-requisite course. We have applied the method to students doing the first year BSc Information Systems program.

Keywords—information systems, competency, blended learning, assessment, programming

I. INTRODUCTION

Online content for blended learning in engineering education helps supporting and stimulating student learning in different contexts: during class lessons, refresher courses and reinforcement, and sharing of content with subject matter experts from the industry. In this paper we report on a study undertaken to estimate the efficacy of targeted blended learning content using videos and practice tests as an instrument to support acquisition of programming competencies. Unlike other approaches, the uniqueness of our work is that we first assess student competencies and then develop targeted blended learning content to address competencies that have not been acquired.

Students doing the Information Systems Management Program are required to do the first programming course in Term 1 (August), titled Information Systems Software Foundation (ISSF). This course introduces students to building blocks of programming concepts such as object manipulation, repetition, decisions, etc. In the subsequent semester in Term 2 (January), students' progress to the next course, titled Object Oriented Application Development (OOAD). The course progression is designed such that some of the competencies acquired in the ISSF course are pre-requisites competencies for the OOAD course. These pre-requisite competencies are

assessed through the ISSF final exam and detailed analysis of students results show that some of these pre-requisite competencies may not have been acquired by students at the end of the ISSF course. Therefore it is possible for a student to get an overall pass mark in Term 1 for the ISSF course and then move on to the next course OOAD in Term 2, without having the necessary pre-requisite competencies for that course, which is a major issue. Therefore, in January 2013, we put in place an entry-test at the beginning of the OOAD course, based on the pre-requisite competencies that were failed in ISSF, and we informed the students about this test, one week in advance, for allowing proper revision. However, we observed that many students were still unable to demonstrate some of the pre-requisite competencies and failed the "entry test" of the OOAD course, or performed poorly compared to their final exam in ISSF. In order to overcome this problem, in December 2014, we introduced targeted blended learning by developing online videos along with practice tests to enable reinforcement, and students were required to view the videos and attempt the practice tests 2 to 3 weeks before the start of Term 2. A total of 203 students took part in the study. In January 2014 we observed a substantial improvement in the performance in the "entry test" compared to January 2013. We observed that, for similar tested competencies, 85% of the students performed better at the "entry test" of OOAD compared to the final exam of ISSF. A key takeaway from our innovative practice is that a competency driven, targeted blended learning using online videos together with associated practice exercises represents an important tool to refresh and reinforce previous learning in engineering education, and furthermore, to improve the student's progression across the curriculum by ensuring that pre-requisite competencies are acquired before moving on to the next course.

The paper is structured as follows: In Section II we review other related work in the areas of competency based learning and assessment and blended learning. In Section III we present some background information related to our work on the Learning Outcomes Framework (LOF) and the Course Life-Cycle Competency Framework (CLCC) that were developed at School of Information Systems. In Section IV we describe the initial approach adopted along with the results analysis showing the problems observed. Section V presents the

improved approach using targeted blended learning; we also give a detailed description of the process adopted in our study along with the results. Section VI presents a discussion on the usefulness of the presented approach and areas for future work. Section VII summarizes the conclusions from our work.

II. RELATED WORK

We review two areas of work that are related to the current research, namely competency based learning and assessment and blended learning.

A. Competency Based Learning and Assessment

Many higher education institutions have clearly defined learning outcomes for the program, and competencies for specific courses within the program [9], [14]. Some have also gone further and developed frameworks to successfully leverage the learning outcomes and competencies in a systematic way when designing, delivering or revising a course within the program [4], [5], [6], [17].

Assessment is a crucial component of learning. Hence having defined learning outcomes and competencies, the next step is to define assessments and then to map student performance in these assessments to competencies. For example, the Course Life-Cycle Competency (CLCC) framework developed at the School of Information Systems provides a systematic approach to assess competencies and then uses the results of this assessment to give valuable feedback to both students and instructors teaching the course [17]. Tovar and Soto provide a framework, where they assess basic competencies that high school students must have, before they can embark on a Computer Engineering program [4]. Here the emphasis is on identifying whether the students have the necessary pre-requisite competencies before starting the program. Bekki et al., propose a modified-mastery based learning approach that uses a finite cycle of formative assessments and feedback to demonstrate mastery of the competencies for the course [10]. This is achieved through use of three types of assignments; “evidence assignments”, which provide evidence of the students’ attempt to learn the topics; “competency assignments”, which assess the mastery of a competency; and “enrichment assignments”, which present challenges beyond what is covered in the course material and help extend students’ understanding of the related topics.

With more and more emphasis on online learning for higher education, e-assessment is also increasingly becoming important. Sitthisak et al., present a system for automatically generating questions from a competency framework, based on question templates, criteria for effective questions, and the instructional content and ability matrix [13]. Ilhai et al., show how a competency based assessment can be extended to online learning environments using assessment grid and feedback [12].

Competencies also provide a means for assessing student progression within the various topics in a course and across different courses in the curriculum [6]. Luca De Coi et al., present the concepts of “input competencies” and “output competencies” [8]. For a given course, the students apply their prior competency in the context of the given task or problem to

demonstrate the “output competency” for that course. Thus the “input competency” may also be defined as pre-requisite competency that the student must demonstrate before starting the course. This concept is very important when looking at competency progression from one course to another course in the curriculum.

B. Blended Learning

In blended learning online learning is systematically integrated with periodic face-to-face interaction with instructor [1]. There have been number of attempts in implementing blended learning in computer science and information systems programs [2]. However, there have been mixed result in terms of effectiveness, where some have reported positive learning impact and others see neutral or not much improvement in learning experience when compared to face-to-face learning.

Hadjerrouit applied blended learning for an introductory Java programming course and observed positive impact on students’ learning, which is attributed mainly to well organized and easy, any time access of the content [15]. Perez-Martin and Pascual-Nieta have successfully used blended learning in an operating systems course to encourage students to study after class. The results of this study revealed higher levels of engagement and higher frequency of study [3]. Reza experimented with using guided discovery and blended learning with learning management system in delivering a computer application course to business students with little or no IT background [11]. Analysis of student grades over a four year period strongly supported the blended learning approach. The study conducted in [16] investigated the effect of blended learning on novices’ understandings of introductory programming. The study revealed that blended and face-to-face methods had statistically similar effects on academic achievements in terms of the grades. However, face-to-face method was more effective on permanence in terms of retaining the knowledge over a longer period of time compared to the blended method. This highlights that though blended learning has benefits, there could be challenges when teaching certain topics that require deep cognitive processes and new approaches are needed to enhance permanence of learning.

In the subsequent sections, we report our proposed method to enhance blended learning effectiveness by targeting it to specific competencies that students failed to acquire.

III. BACKGROUND

A. Learning Outcomes Framework

Several frameworks have been proposed to incorporate learning outcomes and competencies into engineering education [9] [12]. In Figure 1, we show the key components of the Learning Outcomes Framework (LOF) implemented at the School of Information Systems, Singapore Management University [7].

The LOF consists of three major components: learning outcomes, competencies and assessments. While the learning outcomes have been established at the program level, competencies and assessments are defined at the individual course level.

For each 1st level learning outcome, several 2nd level learning outcomes have been defined (not shown in the figure), and each 2nd level learning outcome has several competencies attached to it. For a complete list, please refer to [5] and [7].

Fig. 1. Key Components of the Learning Outcomes Framework

The second important component of the LOF is competencies. Contrary to the learning outcomes which are defined at the program-level (and are, thus, common for all core as well as elective program courses), the competencies are defined at the individual course level. These competencies are defined by the teaching staff to describe “what the student is capable of doing” on completing the course. Core competencies refer to those competencies that all students are expected to acquire and demonstrate on completing the course.

For a specific course, in addition to the core competencies, two additional competencies can be defined namely, pre-requisite and advanced. Pre-requisite refers to the competencies that a student must acquire and demonstrate before starting a course; these are used as building blocks for the course in question. Advanced refers to those competencies that a subset of students doing the course may acquire and demonstrate on completing the course. Table 1 shows a sample set of core, pre-requisite and advanced competencies for the OOAD course.

When designing a curriculum it is best practice to have some higher level courses build on competencies acquired in the lower level courses. In the School of Information Systems Curriculum, course progression is designed such that the Object Oriented Applications Development (OOAD) course builds on the competencies gained in the previous course namely, Introduction to Software Foundations (ISSF). Therefore, a number of competencies in ISSF course form the pre-requisite for the OOAD course.

The third component of the LOF is assessments. The competencies are mapped to individual assessments in a course and the results of the assessments are analysed. This analysis provides insights into the extent to which the competencies have been acquired by the students. Several methods of assessments are used in the student evaluation process namely labs, quiz, project, exam, and case studies. For measuring the alignment within a course, in our framework, we use the course level competencies and assessments defined in the course.

TABLE I. SAMPLE SET OF COMPETENCIES FOR OOAD COURSE

Pre-requisite Competencies	<ul style="list-style-type: none"> • Explain the difference between classes and objects and know how to create an object using default or specific constructors. • Use effectively conditional constructs in Java to control the path of execution of statements. • Manipulate efficiently boolean, equality and relational operators used in conditional and repetition Java constructs. • Use and apply ArrayList structures for managing collections of similar classes of objects in Java • Know how to draw a memory state diagram to deduct an output trace. • ...
Core Competencies	<ul style="list-style-type: none"> • Understand and apply the basic principles of object orientation such as abstraction, encapsulation, modularity (object decomposition) and hierarchy. • Using the UML notation, create various design artifacts (such as use case model, domain model, sequence diagrams and class diagram) to fulfil a given set of functional requirements. • Read from a file and write to a file. • Know how to use and apply HashMaps structures versus ArrayLists structures in Java, for efficiently solving a problem. • ...
Advanced Competencies	<ul style="list-style-type: none"> • Understand and apply appropriately CSVReader and CSVWriter provided by the Java library. • ...

B. Course Life Cycle and Competency Framework

The Course Life Cycle and Competency framework, Figure 2, is adopted for delivering the introductory programming courses namely, ISSF and OOAD courses. In this approach, course competencies are leveraged during the five phases of a course, namely, content design, assessment design, content delivery and assessment, assessment feedback, and content review. In this paper we briefly describe the assessment feedback phase. The reader may refer to [17] for more details of this framework and the other phases.

Fig. 2. Course Life Cycle and Competency Framework (CLCC)

During assessment feedback, the instructor analyses the assessment scores and present feedback to the students. This is done immediately after the assessment is marked. The standard practice of presenting the scores, averages, etc., is adopted. In addition, and more importantly, a detailed walkthrough of the cohort competency acquisition map is conducted. The map contains the different competencies assessed in the particular assessment and for each competency, whether it was acquired or not acquired. The question thresholds set during the Assessment Design Phase are used to determine which competencies are acquired or not acquired.

For the questions, where the score is below the threshold, the related competencies for those questions are considered as not acquired. In this case, a detailed walkthrough of the common mistakes is conducted through a collaborative session with the student's participation.

Though the feedback is given at the cohort level, individual students will know their own mark for specific questions, and hence indirectly can identify the competencies they have fully acquired or not acquired.

In the next two sections, we describe the process and results analysis without and with targeted blended learning respectively. Both the approaches use the LOF and the CLCC framework across the various phases of the course life-cycle.

IV. PART 1: WITHOUT BLENDED LEARNING

A. Process

Figure 3 shows the process for progression from ISSF to OOAD course, during the academic year 2012-2013. The Course Life Cycle and Competency framework is adopted for delivering the ISSF course in Term 1.

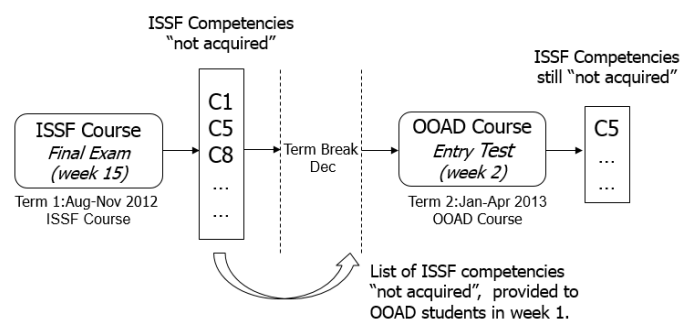

Fig. 3. Process without blended learning

At the end of each assessment, the students' results are analyzed and competencies not acquired by students are identified. Then using this result, an in-class walkthrough of common mistakes is conducted. This is done with active participation of the students, for example, by asking them to identify the mistakes done in the assessment. This approach provides an efficient way to "close the learning loop" by clarifying doubts and therefore reducing the understanding gap.

At the end of ISSF course the final exam tested the students on all the ISSF competencies (which are also pre-requisite competencies for the OOAD course). After the ISSF final exam

grading, a consolidated competency acquisition map was produced. This map revealed, for the entire cohort, those competencies that have been "acquired" and "not acquired". The focus was then shifted only to competencies that have not been acquired. However, even if some competencies are "not acquired", it is still possible for a student to get an overall pass mark in the ISSF course and then move on to do the next course namely, OOAD in Term 2. As discussed earlier, a set of the competencies in ISSF course form the pre-requisite competencies for the OOAD course. Therefore, this leads to a problem, where students do not have the necessary set of pre-requisite competencies before embarking on the OOAD course. To alleviate this problem, it was necessary to ensure that students revisit the content related to ISSF course and acquire the pre-requisite competencies required by the OOAD course. So, in the Week 2 of OOAD course, students were tested on some of the ISSF competencies, especially, those that have been deemed as "not acquired". Students were informed of the test in Week 1 of the OOAD course and given a week to prepare for the test. To help them revise, the list of the ISSF competencies "not acquired" was given to them.

B. Competency Acquisitions Results Analysis

Table II shows the results that compare the competency acquisition map across the "ISSF Final Exam" and "OOAD Entry test".

TABLE II. COMPARISON OF COMPETENCY ACQUISITION WITHOUT BLENDED LEARNING

Comp. Tested	In ISSF Final Exam Competency Acquisition (% of students)	In OOAD Entry Test Competency Acquisition (% of students)
C30 C37 C38	<p>51% "not acquired"</p>	<p>57% "not acquired"</p>
C25 C26 C9 C14	<p>26% "not acquired"</p>	<p>38% "not acquired"</p>
C13 C24 C26 C7	<p>14% "not acquired"</p>	<p>14% "not acquired"</p>

In Academic Year 2012-2013, there were 226 students who completed the ISSF course and progressed to the OOAD course. As seen from the results, there was no improvement in the competency acquisition. In fact, for the first two sets of competencies, there was a decrease of 6% and 12% respectively, and for the third set, no change. These results lead to the following conclusions:

- Neither the one week preparation time that was given to students nor did the list of competencies help them.
- Some students may have forgotten what they learnt in ISSF, due to the term break in between the ISSF and OOAD courses.
- Just by asking students to take a test to assess their competencies from the previous course does not help in improving the competency acquisition.

This led the teaching team to explore the option of targeted blended learning to help students acquire competencies that were not acquired in regular class sessions and also help retain the competencies that were acquired during regular class sessions and thus enhance the overall student performance and retention.

V. PART 2: WITH TARGETED BLENDED LEARNING

A. Process

Figure 4 shows the modified process with targeted blended learning for progression from ISSF to OOAD course, during the academic year 2013-2014. Most of the process is the same except for the introduction of the blended learning during the term break.

The teaching team prepared a set of nine videos that targeted the competencies that were deemed as “not acquired” by the student cohort after the ISSF final exam (see Table III).

TABLE III. VIDEOS FOR BLENDED LEARNING

Competencies Covered by the Videos, Exercises and Quiz	Tutorial Videos Prepared and posted on YouTube
C25 and C33	Topic 1: Meaning and various usage of the “null” Java Literal
C22	Topic 2: Constraints and implications of the “final” Java keyword
C8	Topic 3: Pre/post incrementation and decrementation
C8, C13, C16 and C17	Topic 4: Java operators, boolean expressions and loops
C13, C16 and C17	Topic 5: Looping until criteria is met, De Morgan’s Law
C27	Topic 6: Simple algorithms such as min, max, etc.
C33	Topic 7: Local and instance variables
C8	Topic 8: Java arithmetic operators
C9	Topic 9: Memory state diagram involving ArrayLists of objects.

Each video also has a set of self-work exercises which the students were expected to work on their own, immediately after

watching the video. Additionally, each video is accompanied by a self-quiz comprising of five to ten questions. Students are expected to complete this quiz, with unlimited number of trials without being penalized. Students are expected to view the videos, complete the exercises and quiz, two or three weeks before the semester starts.

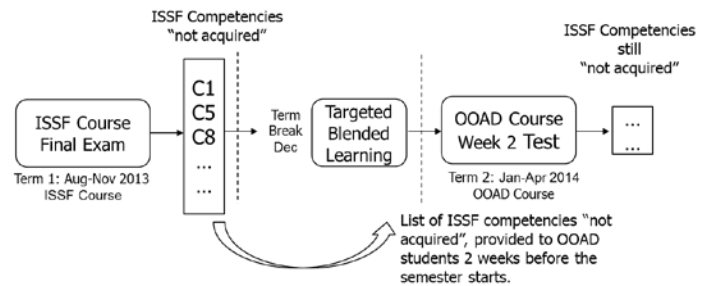

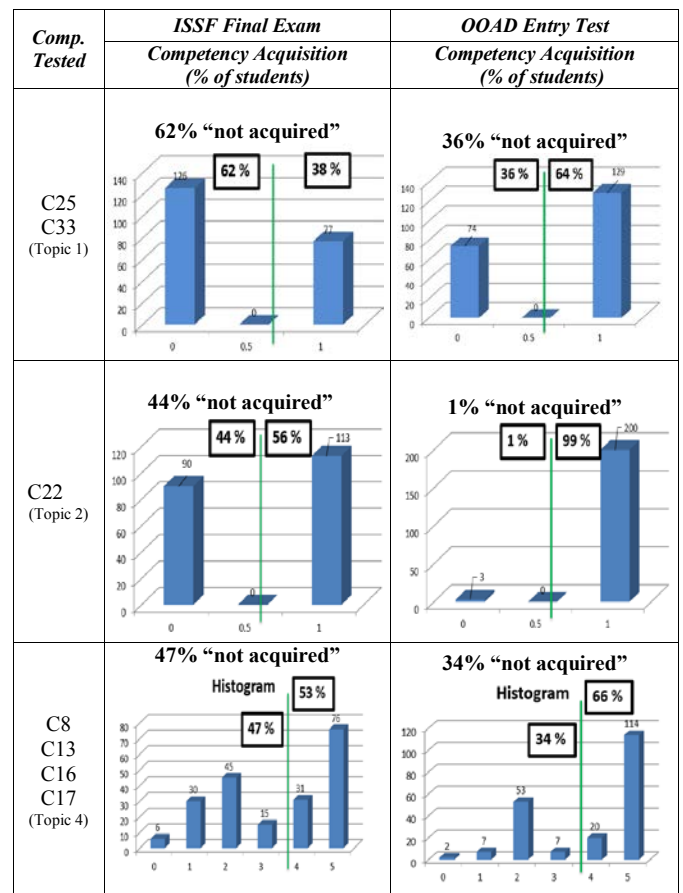

Fig. 4. Process with targeted blended learning

B. Competency Acquisitions Results Analysis

Table IV shows the results that compare the competency acquisition map across the “ISSF Final Exam” and “OOAD Entry Test” with targeted blended learning. In total in Academic Year 2013-2014, there were 203 students who completed the ISSF course and progressed to the OOAD course.

TABLE IV. COMPARISON OF COMPETENCY ACQUISITION WITHOUT BLENDED LEARNING

As seen from the results shown in Table IV, there has been a substantial improvement in the competency acquisition between the final exam in ISSF and the first test in the OOAD course. Table V shows the percentage improvement in competency acquisition between ISSF Final Exam and OOAD Entry Test for the different topics and the corresponding competencies. Across all competencies there has been an improvement in the percentage of students acquiring the competencies.

TABLE V. PERCENTAGE IMPROVMENT IN COMPETENCY ACQUISITION

Competencies Tested and Corresponding Blended Learning Modules	Increase in the number of students acquiring the competencies in OOAD entry test compared to ISSF final exam (% of students)
C25, C33 (Topic 1)	26%
C22 (Topic 2)	43%
C8, C13, C16, C17 (Topic 4)	13%
C13, C16, C17 (Topic 5)	5%
C9 (Topic 9)	33%

The results in Table V shows that the percentage of students who have acquired the competencies shown in the table is higher for OOAD entry test compared to those questions in the final exam of ISSF corresponding to the same set of competencies. This improvement was over a range from 5% higher to 43% higher.

Additionally, referring to Table III and IV, within the same cohort in academic year 2013-2014, we have seen a substantial improvement in competency acquisition.

This leads us to the conclusion that targeted blended learning help students to acquire competencies that were not acquired in regular class sessions and also help retain the competencies that were acquired during regular class sessions and thus enhance the overall student performance and retention. The experiment helps ensure that the students have then acquired the necessary pre-requisites competencies before embarking on OOAD, thus enhancing the overall student performance.

VI. DISCUSSION

The analysis of the results shows that the improvements in competency acquisition are not consistent across all the competencies. For example, referring to Table V, competencies C13, C16, C17, related to topic 5, have a moderate improvement of 5% whereas competency C22 related to topic 2 has a substantial improvement of 43%. We attribute this to the inherent difficulty of some topics and the associated competencies. With the cohort having a spread of very capable to weak students this is expected. This is in alignment with the grade distribution curve for the ISSF course.

One might argue that our results measure competency acquisition across two cohorts. We use cohort in academic year 2012-2013 for experiment without blended learning and academic year 2013-2014 for experiment with targeted blended learning. However, given the range of incoming student capability, the distribution of the capable and weak students' has remained more or less the same across these cohorts. Hence we can conclude that this does not adversely affect the results.

Informal chat with students has also revealed that using the blended learning content students were able to prepare at their own pace, time and place. The most important reason cited was that slow learners could watch the videos several times and practice the exercises multiple times. Additionally, the weaker students could also work at their own pace without the stress of having to complete the exercise within a given time limit. We also observed an improvement in the scores for individual students in these questions as shown in the results summarized in Table VI.

TABLE VI. IMPROVEMENT IN TERMS OF STUDENT NUMBERS

Number of students who performed better in OOAD entry test compared to ISSF final exam	173
Number of students who performed similarly in OOAD entry test compared to ISSF final exam	5
Number of students who did worse in OOAD entry test compared to ISSF final exam	25
Total Number of Students in the Cohort	203

Our approach of competency driven targeted blended learning has been applied for the transition from Year 1, ISSF to OOAD course. Since the results are very encouraging, future work will be aimed towards implementing and evaluating this approach to other academic years, for example, in Year 2, progressing from OOAD to Software Engineering course. Additionally, future work will also be aimed at developing a tool to alleviate the extra effort required in linking

competencies to assessment questions and in conducting a detailed analysis of students' results to derive the competency acquisition map. Currently, though the spread sheet approach works, the tool will facilitate the generalization of the process and help in its implementation across the different courses in the curriculum. This will result in an overall improvement of the teaching and learning in the undergraduate curriculum and therefore, enhance the competency level of the undergraduate students.

Another important challenge is how to motivate students to watch the blended learning videos, do the self-work exercises and self-quizzes especially 2 or 3 weeks before the semester's start. Our approach was to email the students the list of competencies that they need to master along with the URL to the video, lessons and self-work exercises and self-quizzes. Since the videos were uploaded to YouTube, we could not track if students actually viewed. However, we were able to track self-quizzes as they were posted on the School's Learning Management System. The LMS statistics showed that 90% of the students attempted self-quizzes. Hence there was not a major issue with students not doing the work at the end of the break period. Besides the email reminder, this conscientious behaviour could also be attributed to the Asian education culture.

VII. CONCLUSIONS

We studied the problem of competency acquisition when students progress from one course to another and more generally, from one term to next. We observed that some students moved on to a subsequent course (e.g. OOAD) without acquiring some of the competencies in the prior course (e.g. ISSF). This leads to problem in the subsequent course (e.g. OOAD), especially when these competencies are pre-requisites for this. We proposed a targeted blended learning approach to overcome this problem. The blended learning material comprises a set of videos along with hands-on exercises and quizzes, which address the specific set of competencies that were not acquired in the prior course (ISSF).

We evaluated our approach on the batch of students in the academic year 2013-2014 and observed that the targeted blended learning leads to substantial improvements in terms of the percentage of students whose scores went above the threshold which leads the corresponding competencies to be deemed as "mastered". We showed that these results were clearly better than those from the previous batch which did not have the targeted blended learning.

ACKNOWLEDGMENT

The authors would like to acknowledge the efforts of the teaching team involved in the design and delivery of the ISSF and OOAD courses.

Instructor and Graduate Teaching Assistant Development and Training for a Blended Linear Circuits and Electronics Course

Bonnie Ferri, Wendy Newstetter, David Majerich
School of ECE/College of Engineering/College of Computing
Georgia Institute of Technology
Atlanta, GA, USA
bonnie.ferri@ece.gatech.edu

Abstract—This paper discusses a training program that we are developing and are using for instructors who teach a circuits and electronics course in a blended format. The course has over 450 students enrolled in nine different sections each semester and has been taught in a blended format for six semesters. A key motivation for teaching the course in this format is to improve consistency across sections, which necessitates the need for training among the instructors on how to teach blended courses.

Keywords—*blended class, flipped class, development, training*

I. INTRODUCTION

The 2012 PCAST report titled *Engage to Excel; Producing One Million Additional College Graduates With Degrees In Science, Technology, Engineering, And Mathematics* [1] called on researchers and instructors alike to create learning environments that better engage and motivate students towards building a much needed STEM workforce. Achieving this vision in large enrollment introductory engineering courses is particularly challenging on several accounts. Such multi-section courses are taught by a collection of instructors with idiosyncratic teaching styles, differing personal interests in wanting or having to teach it, and differing personal priorities for what should be covered. Compounding these challenges is the unpredictable nature of who gets assigned to these courses. It could be a totally different group term to term, and in many cases, instructors could be graduate teaching assistant with limited or no teaching experience. In a study of 200 electrical and chemical engineering faculty in the USA and their use of research-based instructional practices (RBIS), while they were aware of such practices and 82.1% reported using some, the most common reason given for non-use was the fear that these strategies would take up too much class time [2]. This typical scenario works against achieving learning consistency across sections as well as wide-scale adoption of pedagogical innovation. Essentially, students can find themselves in a poorly designed and executed classroom, a moderately well-designed and executed one or a vibrant, highly interactive and motivating one. Since faculty members in many institutions are solely in

control of their classroom with little or no oversight, rectifying this situation can seem very difficult to achieve.

II. CIRCUITS AND ELECTRONICS COURSE

To address the problem of inconsistency in material coverage, varied use of research-based instructional practices and idiosyncratic teaching approaches, we implemented a blended format using MOOCs [3] in the Georgia Tech, large-enrollment, multi-section *ECE Circuits and Electronics* course. The online content of the course is provided by two MOOCs on the Coursera platform, *Linear Circuits* and *Introduction to Electronics*. Both MOOCs contain video lectures, videos of sample worked problems, automatically graded homework problems, and a discussion forum. The weekly schedule for all sections includes the online videos that are assigned and the homework that is due. There are two common tests and a common final, given outside of the normal class hours. The course also includes six in-class labs where students do experiments on their own myDAQ digital acquisition board [3]. The content of the course includes resistor network analysis methods, RC/RL/RLC first-order circuits and series second-order circuits, AC steady-state analysis, transfer functions and frequency response, AC power, basic op amp amplifier circuits, passive and op amp filters, and the introduction to diode and transistor circuits. The coverage is very broad but not as deep as that contained in circuits courses for ECE majors.

We have found that blending classes adds more flexibility of activities to a course than is present in a traditional lecture-style course. In-class activities can include mini-lectures covering more depth in a topic or presenting interesting applications, the instructor working extra sample problems, short quizzes, in-class labs, worksheets, and small-group discussions. The best mix of these activities can vary depending on the personality of the instructor, the prior experience of the students, and the topic being covered. A longitudinal study on the evolution of this particular course over a six-semester period demonstrates how a feedback mechanism can be used to adjust the mix of online and in-class activities to improve learning and reduce student workload [4]. That paper discusses the difficulties faced by a

person new to teaching a blended course. While this expanded variety of classroom activities and what Phillips refers to as transformed classroom “participant structures” [5] can be significant in changing the classroom climate and promoting greater engagement, for instructors well practiced in a lecture style class, transitions can be problematic.

The blended class model has received a great deal of attention over the last two years [3,6,7]. A new technology or methodology that experiences this level of attention often has exaggerated hype associated with it as illustrated in the Gartner Hype Cycle [8] shown in Figure 1. The initial successes by early adopters is often followed by a “trough of disillusionment” when the next wave of adopters do not reach the same successes. A number of problems encountered by faculty teaching blended classes are summarized in [9]. Since the technology or methodology is new, best practices are not yet established or widely known. As more people try the method and become proficient at it, then a level plateau is reached. We suggest that the particular hype cycle for the blended class model can be modified by proper instructor training on the method as shown by the added dashed line in Figure 1. An example of training materials for faculty is the online course for flipping classes [10].

Figure 1: Gartner Hype Cycle from [8] applied to blended learning with a modification showing the possible effect of instructor training.

We have built a model for instructor development that is apprentice-based, where a faculty member who is experienced in blending courses serves as a lead instructor of a course that has nine different sections that are all blended, ECE 3710. This model also serves other purposes: it ensures consistency in coverage among different sections of the same course, it provides the collaborative and exploratory benefits of a blended classroom, and it provides a structured mentorship program that gives teaching experience to graduate students who are interested in faculty positions. This course is a two-credit course, for non-majors, and is fifteen-weeks long and meets weekly for 110 minutes. Over 1100 students enroll in the course each year, primarily AE, ME, and MSE students for whom this is a required course as well as some biomedical and chemical engineering students who take it as an elective. During the fall and spring terms, 450 students each term are

distributed equally across nine sections of the course taught by one of eight or nine different instructors. The lead instructor is responsible for the online content of the course and coordination of the course activity among the sections. This lead instructor also acts as a mentor to the section instructors and provides training on teaching blended classes.

The current instructor development for *ECE 3710 Circuits and Electronics* includes 1) mentoring and modeling for how lessons should be taught using a blended approach; 2) creating and scoring in-class worksheets and quizzes; 3) creating and scoring examinations using a collaborative approach; and 4) small team (instructors of three) teaching of laboratory activities using a collaborative approach. Since moving to the flipped and blended format in Summer 2013, the section instructors have been either advanced PhD students who are hired as graduate teaching assistants for the course or one of two faculty members who have also served as the lead instructor for the entire course.

Instructors are given guidelines at the beginning of the term on how to conduct a class in the blended format. There are weekly group meetings with the lead instructor to discuss what needs to be covered. For any section with a new instructor for the course, the lead instructor does part of the first lecture in order to give the students in the class the motivation for why the course is being run that way and tips on how to take a course in that format, and to demonstrate to the instructors how to run the class. The lead instructor also goes into classes with new instructors two to three times during the semester to run an activity (to give the instructors a chance to observe). The lead instructor or an educational specialist observes all of the instructors during class two to three times per term and gives feedback. The lead instructor does one focus group in each section mid-term with feedback given to the section in order for them to make corrections. The lead instructor observes four out of nine lab sessions for each experiment and gives feedback to the three instructors in the class about how they interact with the students.

The need for instructor training is demonstrated in Table 1, which shows that several important metrics became worse in Fall 2014: the student workload went up, the average test score decreased, and the average homework grade decreased. Also, the DF rate went up (though the overall DFW rate decreased). These trends are correlated with the number of new instructors to the course that term, in fact, none of the five new instructors had ever taught any course in the past. (More detailed six-semester data summary is contained in [4].)

Another indication of the impact of the instructor is given in Figure 2, showing the results of student responses from a post survey in Fall 2014 across nine sections of the course. Students were asked to rate different instructional methods, shown in the table below the figure, on a scale of 1 to 4 where 1 = “little to no help”, 2 = “moderate help”, 3 = “significant help”, 4 = “one of the most helpful methods”. A total of 310 students completed the survey, and the results were averaged by section and each section average is plotted in the figure. A large spread among the averages for a given instructional method means that method is dependent on the instructor,

while tight bounds in the averages means that method is more independent of the section instructor.

The three topics that are most instructor-dependent showed the highest variation in responses: 1 Instructor lectures in class, 4 Recitation, and 6 Students working on problems during class.

TABLE I. COMPARISON OF METRICS FOR DIFFERENT SEMESTERS.

	Spring 2014	Summer 2014	Fall 2014
DFW Rate (DF/W rates)	19.7 (7.73/11.97)	19.97 (6.9/13.07)	16.82 (8.99/7.83)
Homework Ave	84.0	86.1	81.6
Exam ave	78.8	77.3	69.3
Student workload, ave. hours/week	7.06	6.64	7.37
Number of sections with new instructors course	1 of 9	0 of 3	5 of 9

Figure 2: Post-survey results of average ratings of the importance of 11 different instructional methods (see code in table) across nine sections of ECE3710, from 1 = “little to no help” to 4 = “one of the most helpful”

Code for Horizontal Axis:

- 1 Instructor lectures in class
- 2 Online videos of lectures
- 3 Online videos of sample worked problems
- 4 Recitation (in-class Q&A)
- 5 Instructor experimental demonstrations
- 6 Students work on problems in class
- 7 Simulations
- 8 Hands-on experiments
- 9 Homework
- 10 Using textbook
- 11 Tests and quizzes

III. FUTURE PLANS

To rectify instructor and instructional disparities in this blended environment, we plan to institute a more theory-driven approach to instructor training. Our new strategy is informed the Lave and Wenger’s (1991) notion of *communities of practice*, which brings to the fore important issues regarding membership, identity and social contexts that can promote or retard individual and unit changes [9]. Our goal is to build a community of reformed teaching instructors. We also subscribe to Roger’s (2003) theory of innovation diffusion which we feel is applicable at the individual, the unit and the institutional levels where the five stages of *awareness, interest, evaluation, trial and adoption* can and do play out [10]. Building from these theories we seek to develop a supportive educational innovation learning community.

Our new instructor learning experience will comprise four elements:

1. Development of a supportive community of practice for teaching transformation
2. Use of the Reformed Teaching Observational Protocol (RTOP) instrument for observation and training
3. Ambrose’s book *How Learning Works*
4. Videos of blended classrooms for analysis
5. Micro-teaching and evaluation sessions

We will commence with a 4-hour workshop where instructors new to the blended learning environment will engage in a number of activities that activate their prior understanding of effective and ineffective learning experiences. We will also introduce them to the RTOP instrument by watching and evaluating two physics classrooms on video. This activity will be the start of the developing an understanding of each classroom dimension measured in the RTOP instrument. In this workshop, instructors will also see videos of the blended *ECE 3710 Circuits and Electronics* classroom, to get a feel for the new role and its various dimensions that the instructor needs to played in this revised version of an engineering classroom. Finally, we will introduce them to the seven research-based principles that undergird robust learning.

Instructors will have the option of participating in a blended teaching practicum, a practicum that is based on a workshop series for ECE Teaching Fellows that we piloted in the Spring 2015. The practicum meetings will give instructors the chance to do microteaching, to get immediate feedback from their peers using elements from the RTOP as the basis for evaluation. We will also encourage member of this teaching cohort to observe each others’ blended classrooms for real-time evaluation and feedback.

A Feedback-Based Approach for Evolving a Blended Class Model for Large Enrollment, Multiple Section Circuits Courses

Bonnie Ferri, Joyelle Harris, Mary Ann Weitnauer, David Majerich
School of ECE/School of ECE/School of ECE/ College of Computing
Georgia Institute of Technology, Atlanta, GA USA

Abstract—The development of a feedback-based method for evolving the blended class format for large, multiple section courses is presented with the application to two circuits courses taught at Georgia Tech: ECE 2040 is a circuits course for ECE majors and ECE 3710 is a circuits and electronics course for non-majors. These are both multi-section, high-enrollment courses, with a combined enrollment of over 600 students per term. The courses utilize two MOOCs that provide all of the online content. ECE 3710 was first offered in a flipped mode in the Summer of 2013 and has evolved over five semesters based on feedback from the student surveys, focus groups, instructor feedback, discussion forum questions, and performance on tests. ECE2040 has been offered two semesters in the blended mode using a modified version of the blended model developed for ECE3710.

Keywords—blended class, flipped class, circuits, adaptation, feedback

I. INTRODUCTION

Broadly defined, blended learning is “the use of learning activities of differing kinds and venues to synergistically achieve overarching learning objectives” [1]. A narrower definition is “a hybrid classroom and on-line learning that includes some of the conveniences of on-line courses without the complete loss of face-to-face tact” [2]. Because of the advantages offered by blended courses, many educators are implementing them and exploring their benefits. Another expression, “flipped class”, is often used interchangeably with “blended class”. In both the flipped and blended courses, all students watch the same lectures online prior to class. The two modes are differentiated in this paper by how students spend class time. In the flipped mode course, in-class time is spent answering student questions about the online lectures and doing homework collaboratively in small groups with instructor help. The blended mode course has more variation in the activities done during class, including small group activities for discussion, quizzes, worksheets, projects, and hands-on experiments. Because there are so many components in the blended class model, both online and in class, the course format can be improved by evolving the mix of activities and resources over several semesters to improve student learning with a reasonable student workload spent on the course.

Several studies have compared learning outcomes, student success, and other figures of merit in blended versus traditional courses. Educators report that students preferred blended courses over traditional lectures [2]; grades were higher in blended classes [2-5]; and blended classes were better for measuring learning effectiveness and faculty

satisfaction [6]. Furthermore, positive results were reported for blended courses implemented in both two-year and four-year programs, in undergraduate and graduate programs, and in different subjects including accounting, math, management information systems, and health, among others [1-5].

Nevertheless, adopting and implementing a blended learning course can be challenging both for the teachers and the students. These challenges were summarized into eight different categories by Ocak [11]. Some instructors find it difficult to re-design a course while maintaining their current workload. Other educators struggle with the technical issues that accompany online course delivery. Students who are more familiar with traditional courses often resist the blended course format [9-10]. Also, learners have reported a lack of community and feelings of learning in isolation while taking blended classes [11].

The evolution of a blended course can alleviate many of the challenges faced by instructors and students, with each iteration seeking to learn from and improve upon the last. For instance, faculty at Pennsylvania State University reported how they changed a blended environmental engineering course from one semester to the next. During the first semester that the course was offered in a blended format, students were noticeably more involved in class, but they raised concerns about the amount of time they had to dedicate to the course. Hence, the instructor adjusted the course the next semester by reducing online lecture time (while covering the same material) and working more homework problems in class. This revision to the class eliminated student complaints about the time commitment and students became more engaged in solving problems during class [12].

While the aforementioned study reports insight gained during two semesters, this paper discusses a feedback-based methodology and resulting evolution of a course through six consecutive semesters. The method is applied to two large enrollment, multi-section circuits courses taught within the School of Electrical and Computer Engineering (ECE) at Georgia Tech. ECE 2040 Circuits is 3-credit hour lecture-based course given to ECE majors while ECE 3710 Circuits and Electronics is a 2-credit hour lecture-based course given to non ECE majors. There are 150-180 ECE students enrolled each term (fall and spring) in ECE 2040, which is divided into four sections taught by different faculty. There are 400-450 students enrolled in ECE3710, divided into nine sections taught by one lead instructor – a faculty member who manages the course – and individual instructors who are advanced PhD students. ECE 3710 covers topics in both circuits and electronics. The course for majors, ECE 2040, goes more deeply into each topic but excludes diodes and transistors from the ECE3710 Topics.

ECE 3710 was reformatted from a traditional lecture-based course in Summer 2013 to be offered in a flipped mode and then in a blended mode. The rationale for the change from the lecture style was to introduce hands-on experience into the classroom and to improve consistency across sections. We were able to add six in-class labs to the course because of the flexibility provided due to the flipped/blended format. Prior to the change in format, the inconsistency among multiple sections of ECE 3710 was examined through a survey of the instructors who taught the course. Because of the breadth, instructors experienced difficulty covering all the topics. The survey indicated that there was a mismatch in coverage of up to 25% from the syllabus and 50% among the sections. The standard range for the class average GPA was from 2.5 to 3.7 with large variations in how the grades were curved.

II. MODELS FOR LARGE ENROLLMENT COURSES

The circuits courses at Georgia Tech, like any large enrollment course, can be offered in different formats, such as multiple individual sections of medium size (40-50 students) that are independently taught or one large common lecture section (>150 students) with smaller recitation sections. Multiple individual sections have the advantage of providing potentially more personal in-class experience for the students and the disadvantage of inconsistency. Specifically, different instructors cover the material at different rates and in different depths. Also, the instructors may have different philosophies on summative assessment, including the relative weighting on homework, quizzes, tests, projects, and labs as well as how harshly the material is graded, leading to inconsistency in assessment and the final grades. The large lecture section model suffers from a climate during the lecture period that is not generally conducive to two-way student/instructor interaction, leading to a sub-optimal in-class social climate [13].

A third way to handle large enrollment courses is a blended model, where the course is offered in multiple sections but all students watch the same lectures online. Then the in-class time is spent in more interactive activities with collaborations between students and small-group interaction with the instructor. This is the model that was developed for ECE3710, with the first instance being taught in the summer of 2013. The online content in this course is delivered in two Massive Online Open Courses (MOOC), Linear Circuits and Introduction to Electronics on the Coursera platform (coursera.org) [14]. The specific format of ECE 3710 is that all nine sections use the same online lectures, and there were common homework and tests across the sections. This model seems similar to the large lecture model discussed above, giving the advantage of consistency in the lectures and assignments, except that the students are able to watch the lecture videos at their own pace and in their own time. These videos are broken into 10-12 minute lengths to accommodate the average attention span. Handouts of the video slides are provided to students. To facilitate active note taking and to keep students focused, only partial slides are provided. The videos show the instructors writing on the slides during the lecture. The movement of the pen or cursor helps to keep students focused and encourages students to take notes

actively. Every 4-5 minutes, the video is broken into a formative assessment quiz on a basic concept just covered. Students need to click on either the answer or the “skip” button to proceed. This gives them timely feedback on their understanding of the basic concepts [13].

Many of the features built into these online videos can be duplicated in a large lecture format: clicker questions can substitute for the in-video quizzes and the PowerPoint slides can be made more active by providing partial slides and having the instructor write on the slides during the lecture. A live lecture gives students the ability to stop the professor in real time to ask for clarification or more depth. However, very few students will stop the instructor with questions in a large lecture hall; hence, this benefit of a live lecture is not realized in actual situations. The features of online videos that cannot be duplicated in any live lecture are that the 10-12 minute length of the videos are appropriate for typical attention spans; the videos can be re-watched or paused and parts can be replayed; students have the flexibility to watch the videos anytime and anywhere; and students can choose the speed of play from 0.75x normal speed up to 2x normal speed.

III. OVERVIEW OF THE FEEDBACK PROCESS FOR BLENDING

The block diagrams in Figure 1 and 2 show the feedback mechanisms used in the evolution process for ECE3710. Each semester, we assessed ECE 3710 and used these assessments as measurements in a feedback loop to readjust the way that the class was taught the following semester. The student learning process in Figure 1 represents the system to be controlled. The MOOC analytics includes the data of when and how often students watch the videos and how many times they attempt the homework. Learning was assessed by examining the performance on particular topics on tests compared to the course outcomes. Low performance on an exam question was taken as an indication that the corresponding topic may be confusing. Common mistakes in the test responses were identified for intervention via course adjustments in future semesters. Another “measurement” for feedback was taken from the Piazza discussion forum [piazza.com], which was used for students to ask questions about the course. The most common questions on the forum asked for clarifications about the lectures and homework. The posted questions were used to gauge student understanding of the various topics. If there were a number of questions about a particular lecture or about a homework problem related to a particular lecture, the instructors collectively examined the source of the confusion. The adjustment was easy if the source of the confusion was ambiguous or poorly-worded problem statements, or an error in the video lecture.

Deeper levels of confusion that surfaced from either test problems or discussion forum questions needed to be addressed by a multi-pronged approach of adjustments. We added a number of videos of sample worked problems on these difficult concepts, targeted class worksheets, in-class mini-lectures that covered common mistakes in doing certain types of problems, and targeted in-video and in-class quizzes. The most sweeping change was in changing the ways that the material was presented in the lectures, either to add more details or to show different derivations and ways of examining

the concepts. While the discussion forum questions give indications of the sources of the confusion, the student answers and the follow-up discussions on the forums give ideas on better ways to present the material so that it would be understood by students more easily. Specifically, there are “super users” each time that the course is taught; these are students who give detailed, tutorial types of explanations. The follow-up responses show if other students understand the explanation.

One of the criticisms of blended classrooms is that students spend more time on task than in traditional lecture classes [11]. We are sensitive to weekly student workload and developed another feedback loop, shown in Figure 2, concerning student workload. According to [15], each credit hour should correspond to three hours of work per week. So a 2-credit hour class should represent an average workload of 6 hours per week. The end-of-term student surveys allowed us to track the self-reported average number of hours per week spent on the course. Other survey questions and student focus groups allowed us to identify specific components of the course that took an inordinate amount of time, essentially, a low ratio of value-added over time-spent. Observations taken during in-class labs along with instructor group discussions identified parts of the labs that needed to be stream-lined or eliminated. In addition to stream-lining labs, the number and type of homework problems, quizzes, and worksheets were adjusted. It should be noted that the feedback mechanisms in Figures 1 and 2 are coupled. If a concept is confusing, then it takes more time to learn. So, improving the quality of the learning process indirectly decreased the student workload.

Figure 1: Feedback mechanism for improving the student learning process.

Figure 2: Feedback mechanism for regulating student workload to the targeted value of R=6 for a two-credit hour class.

A. Iterative Improvement Process

ECE 3710 requires students to view 60-70 minute worth of online lectures per week and then come to class for 2 hours per week (2 credit hour class). The Linear Circuits MOOC was used for the first 60% of the course. The rest of the material was covered by in-class lectures for the first two offerings and online later by the Introduction To Electronics MOOC (used in Spring 2014, Summer 2014, and Fall 2014, Spring 2015).

Constants across all offerings of 3710:

- The learning management system used for all online materials was Coursera
- All homework is common across sections and is completed online and graded automatically
- Common tests across all sections (except Summer 2014)
- 2-minute graded quiz at the beginning of each class on assigned videos
- 6 in-class hands-on labs
- Extra credit was given for applications (either an analysis of a real system or building a real application)

Specific course adjustments that changed because of student performance or instructor or student feedback:

- Summative online quizzes were first mandatory, then made optional, and then eliminated completely
- Supplemental in-class lectures were added and then the length and type evolved over time
- Worksheets were introduced into the classroom
- Specific online lectures were revised and extra ones added
- Automated homework problems were broken into smaller parts
- Videos of extra sample worked problems were added
- Students were given explicit instructions on how to take a course like this.

Table I gives a summary of some of the trends over the 6-term period. An explanation of what was changed each semester and the feedback is given in the subsections below.

Table 1: Summary of course metrics

	Summer 2013	Fall 2013	Spring 2014	Summer 2014	Fall 2014	Spring 2015
Ave # tries per homework problem	2.56	1.90	1.88	1.97	1.93	1.89
DFW Rate (DF/W rates)	10.16 (3.9/6.3)	19.01 (9.4/9.6)	19.7 (7.7/12.0)	19.97 (6.9/13.1)	16.82 (9.0/7.8)	13.67 (5.3/8.4)
Homework Ave	80.2	83.0	84.0	86.1	81.6	86.0
Exam ave	71.5	69.8	78.8	77.3	69.3	75.1
Student workload, ave hrs/week	7.09	7.97	7.06	6.64	7.37	6.41
# students	128	405	401	131	434	417
# of sections with new instructors	1 of 3	2 of 9	2 of 9	0 of 3	5 of 9	2 of 9

Summer 2013: The pilot offering of the course was in Summer 2013 and included three sections of 45-50 students each taught by three different instructors using a completely flipped mode, where the in-class time was spent answering student questions about the online lectures and doing homework collaboratively in small groups with instructor help. The instructors stopped to give short lectures as needed for clarification on concepts. Adjustments were made for the next offering based on the following results from student surveys, observations, and Instructor and student direct feedback in focus groups.

Overall, the students were negative about the flipped-class model:

- in-class collaborative work was difficult because of the asynchronous nature of homework; ie, different students had reached different points in the assignment
- students preferred to have some in-class lecture time where they can ask questions as the material was being taught
- students had a very low tolerance level for technical difficulties with the platform especially with the automatically graded quizzes and homework

Fall 2013: Changes based on the summer pilot offering:

- Errors in the online resources were identified and corrected.
- Homework problems were broken into steps where students get credit for correct answers along the way to the final answer
- All instructors were told to give a brief 10-15 minute summary of the online lectures during class to give students some lecture time for asking questions.

The second offering of the course had nine sections of 40-50 students each (400 students total) taught by nine different instructors: one instructor who had taught the course in a flipped mode, five who had taught it in a traditional lecture mode, and three novice instructors. The change in the automatically graded homework problems resulted in a decrease in the number of average tries per homework and the average homework grade, as seen in Table I. Frustration on the homework went down due to the problems being broken into more steps. This gives feedback to students on a more fine grain level, and allowed them to gain confidence as they made correct decisions along the way to solving a bigger problem.

There was a lot of autonomy in the way that the instructors conducted the in-class sessions; this autonomy enabled us to see what did and did not work. However, some of the more experienced instructors who had taught the course in a traditional lecture style tended to lecture, stretching the “mini-lectures” into 30-40 minutes, resulting in a decrease in students viewing online lectures for those sections. At the other end of the spectrum, some of the novice instructors gave summaries of the online lectures that lacked insight or perspective, instead consisting primarily of a listing of what was covered. Students saw little value-added in those sections, so a significant number of students in three of the sections consistently left right after the in-class quiz at the beginning of class. The other sections had a much more engaged atmosphere, both between the instructor and students and among students. Those instructors were more flexible in how they conducted the class, adjusting activities during class based on student understanding.

A circuits concept inventory given at the beginning and at the end of the course highlighted some differences between sections. These results indicate that the pre to post gain was reasonably consistent across all sections, with the ones showing the largest percent gains belonging to the sections that had the most student engagement, based on an independent observer using an RTOP protocol [7]. We used

the mix of in-class activities in the most successful sections as a guide to new instructors for the following semester.

Overall student feedback to the Fall 2013 offering was still negative with the most vocal complaint being the total amount of time per week that the course required. Focus groups were done in each classroom, with almost 100% students in attendance and very active participation during the discussion. These focus groups identified three sources for high student workload:

- Need for more experience working problems
- Insufficient note-taking or lack of taking notes
- Automatically-graded homework had no partial credit

The first item related to students who wanted to be able to ask “why” questions while an instructor worked a problem a specific way, especially when there were different ways to work the problem. These students did not feel prepared to complete the homework and felt that it took more time than it should have had they had the chance to ask questions during an example or derivation in class. In all sections, there were opportunities for students to ask questions during class period, but the asynchronicity stymied all but the most organized students who had written down their questions while viewing the online lectures.

The second problem was much more multifaceted. To shorten note-taking time, we provided handouts of the slides for all of the lectures. However, the slide handouts, by design, partially complete in order to encourage active engagement with the videos. All of the figures, schematics, most of the text, and some of the equations were preprinted on the slides. On most slides, the instructors used a WACOM device to write on the slides, doing complete derivations, solving example problems, pointing out features of figures, etc. While some students actively took notes, a significant number (more than half, based on a show of hands in class) did not print the notes for note taking for various reasons. A surprisingly large number took no notes at all, thinking that they could just re-watch lectures as needed. Discussion with these students indicated that some watched the lectures 3-5 times each, spending much longer time per week than the instructors expected. Those that took notes in a separate notebook varied in their level of expertise and completeness, much like any other course.

As a result of the non-optimal note-taking strategies employed by students in the class, the total amount of time spent taking notes or extra time spent on homework due to insufficient note-taking was higher than the instructors had anticipated. Students who had insufficient or no notes also had difficulty studying for the exams.

The automatically graded online homework problems also increased student time on task, in both a constructive way and in a destructive way. From a destructive perspective, most students did the homework on scrap paper and entered their answer online. They then had no record of their work to help them study for tests, though solutions were given. The constructive way that homework benefited students was the immediate feedback and the chance to redo the problem to improve upon their performance. Most of the problems accepted numerical answers with the answer key accepting values within a set tolerance of the exact answer. No partial

credit was given, but students had five chances to solve each problem with the highest scores being the one that counted. In comparison, typical homework that is turned in weekly, graded mostly on effort, and returned 1-2 weeks later is neither timely nor directed. Students are on to the next topic before they realize that they did not understand the material. Students in ECE3710 work the homework problems approximately two times to achieve a grade of 80%-86%, see Table I.

In addition to the student surveys and focus groups giving feedback for course improvement, student performance on homework and on tests and the discussion forum topics and types of questions and comments were used to determine which online lectures needed revision. An example of a problem that was revealed in the discussion forums and on the tests related to the mechanics of node and mesh analysis. The original lecture included both topics together with a simple example for each. The revised lectures were split into different modules with more substantial examples.

Spring 2014: Based on feedback from Fall 2013, the following adjustments were made for Spring 2014:

- Students were given explicit instructions on how to succeed in a course taught in that format
- Students were allowed to use their notes to complete most of the in-class two-minute quizzes in order to encourage them to take notes and to come to class prepared
- Specific online lectures were revised and retaped based on students' level of confusion on those topics
- Some of the sections started giving worksheets in place of students doing homework in class

In addition, the second MOOC, Introduction to Electronics, was completed and replaced 40% of the course that had been taught with traditional lectures.

Nine sections of ECE3710 were offered in Spring 2014 with 401 students total: 7 of 9 instructors were returning from teaching the course in the blended mode in the fall, one new instructor had taught the course in the traditional method, and one new instructor had never taught a course previously. The explicit instructions to students included the following (along with an explanation of why this was important based on the prior semesters' findings, as explained above): print the slide handouts and take notes on them while viewing the lectures; do all homework in a notebook before going online to submit the answer; attend every class and stay to the end; etc.

Allowing students to use their notes during the in-class quizzes encouraged better note-taking and alleviated stress in class. Also, the types of quizzes were varied during the Spring term in one of the sections: most done individually, but more challenging ones were done in pairs. A few were inverse quizzes, where the students were asked to work in pairs to come up with two questions that the instructor might have asked. Those "quizzes" were graded on the appropriateness of the questions.

In order to give students more practice doing problems in a supportive environment, several of the sections in Spring 2014 gave worksheets (ungraded) during class for students to work on together. Just-in-time lecturing helped to alleviate misconceptions that came to light during these worksheets.

Feedback from the spring offering (surveys and focus groups) was no longer negative as we moved from a flipped model to a blended model. While many students still claimed not to like the "flipped classroom", overall performance in the course had improved to the point where the tests did not need to be curved (from an average of 7.7 points added per test in the fall to no points added in the spring. The discussions with the instructors indicated that the worksheets done in class were better than doing homework since students worked synchronously on them. Specifically, students came into class at different points in their completion of the homework while they all started at the same point on the worksheets, which facilitated collaboration.

During the spring term, we continued to monitor the student performance on specific topics in the course and on the corresponding discussion of those topics on the discussion forum. The revised video lectures on mesh/node/Thevenin alleviated the confusion seen in the previous term. Based on the discussion forum questions and comments for Spring 2014, we revised several lectures on the topics of sinusoids in circuits, complex numbers, and impedances for the next course offering.

Summer 2014: Three on-campus sections of ECE3710 were taught containing a total of 132 students. All of the instructors were returning as experienced in blending this course. In addition, a purely online section of 19 students was taught and three sections were taught in study-abroad programs. All of the off-campus sections used the online resources to varying extent, from complete reliance on them for the online section to supplemental for one of those sections. Those sections are not part of this study. During the summer term,

- The online quizzes were made optional in order to reduce the overall workload for the course
- Specific online lectures were revised and re-taped based on students' level of confusion on those topics
- Increased use of worksheets

Students preferred the immediate feedback obtained after in-class quizzes and the formative on-line (in-video) quizzes, but reported the online summative quizzes to be more time-consuming but less helpful. The in-class worksheets were viewed favorably by the students. The performance on the topics covered by the revised lectures improved on the tests and the number of discussion forum questions on those topics decreased. As seen in Table I, overall performance went up while student workload decreased. Student feedback from surveys and focus groups asked for more examples of worked problems.

Fall 2014: An increased demand in the course resulted in 8% higher enrollments from the previous academic year, and a large turn over in instructors caused transients in the course for Fall 2014. Changes made to the fall offering included

- Added 99 videos of an instructor working problems
- Revised some of the Intro. to Electronics video lectures
- Modified the purpose of the brief 10-15 minute lecture during class
- Required all instructors to use worksheets in place of homework during the in-class problem working sessions.

Early in the semester, based on student comments in focus groups, we modified the lectures to cover only new worked problems rather than an explicit summary of the online lectures. The instructors still emphasized the new concepts and methodologies as they worked the new problems, but this approach (rather than a summary) was acceptable to the diligent students who came to class prepared and did not want to waste time in explicit summaries. This approach also was acceptable to students who had not watched the lectures prior to class because they still saw the systematic problem solving methods. These students then went back to watch the online lectures later.

Spring 2015: The only negative feedback at the end of the fall term was that the labs were too long, so the adjustments made to the Spring 2015 offering of the course were to streamline the labs. We had students work the pre-labs collaboratively in-class in place of worksheets in a class period prior to the lab. In many cases, the pre-labs were the analysis of a problem followed by the actual lab where the students built the circuit to compare the theory to the experiment. So, the pre-labs were well-suited to be used as worksheets. Moreover, that extra class time on the labs (pre-labs, actually) allowed students to ask more questions on the concepts prior to the labs so that they were prepared better when they actually attempted the experiments.

The comparison of various metrics in Table 1 over the six-semester time period resulted from a combination of the adjustments made each term and the turn-over and training of new instructors. The exam average listed in the table included two exams and the final, without any exam curves being included in the table. In the actual grade weighting, curves were given on some of the exams as described below the table. Since the summer terms are shorter in length with more minutes per week, the summer workload numbers were adjusted to be consistent with the normal-length terms; that is, the reported average workload for summer was multiplied by 11/15 corresponding to 11 weeks for the summer versus 15 for the fall and spring terms. The first pilot offering in Summer 2013 had initial transients resulting in lower test scores, which were curved to obtain a DF rate that was lower than the subsequent terms. All of the terms used a straight scale for determining grades: 90-100 = A, 80-89 = B, 70-79 = C, 60-69 = D. The initial offering spent most of the in-class time allowing students to do homework, resulting in a lower weekly workload, though higher student complaints.

metrics: increase in homework and test average and a decrease in DFW and student workload. The exception was for Fall 2014. The anomalies in homework and test averages and the student workload would not seem to be linked directly to these adjustments made that term. The major factor in that term, however, was the general inexperience of the instructors where 5 of the 9 sections were taught by novice instructors who had never taught any course. In addition, several of the experienced instructors struggled with the best way of using worksheets in the class. With minor adjustments in Spring 2015, the metrics in Table 1 bounced back because the instructors had more experience. The experience of the lead instructor in training the new instructors in Fall 2014 highlighted the need for a more formal training process for instructors wanting to do flipped and blended classes. The details about the current instructor training and future plans are discussed in [15].

95% CI for the Mean

Component	Mean	95% CI Lower	95% CI Upper
Ohm's law	3.82	3.80	3.84

Individual standard deviations are used to calculate the intervals.

Figure 3 also demonstrates very small variance bounds on the self-perceived competence in the topics in the course. Students are asked to rate their level of understanding in a post-survey on the topics in the course, which are shown in chronological order of how they appear in the course, with Ohm's Law first and transistors last. Students are given the choice of 1 = "no understanding", 2 = "minimal understanding", 3 = "moderate understanding", and 4 = "solid understanding". The scale is magnified between 2.8 and 4 because the averages for all of the topics are very similar, so the magnification helps to see the very small variance levels. The plot includes N=310 students across all sections of ECE3710 in Fall 2014.

IV EXTENSION TO CIRCUITS COURSE FOR MAJORS

In Fall 2014, the lead instructor for ECE3710 also used the same materials to teach a section of ECE2040 Circuits, a 3 credit hour course for ECE majors in a blended format. Another instructor taught a second blended course section of ECE2040, each with section sizes of approximately 50 students. Two additional sections were taught using traditional-style lectures. The difference in the content of ECE2040 versus ECE3710 is that ECE 3710 covers all the topics in ECE 2040 plus add three weeks of basic electronics; however, the coverage is not as deep in ECE3710. A summary of the other differences in the course is listed in Table II. These differences are important because of the impact they have on the way that the course is blended.

TABLE II: COMPARISON OF GEORGIA TECH CIRCUITS COURSES

Fall 2014	ECE3710	ECE2040
Credit Hours	2	3
Student Workload	7.4 hours/week	8.8 hours/week
Required?	AE, ME, MSE	EE, CmpE
Enrollment	450 students per term	180 students per term
In-Class Labs	6	9 (blended sections) & 3-4 (traditional sections)
Online Lectures Assigned per Week	50-60 min	40-50 min
Online Homework	Yes, all	A mix of online homework and textbook homework
	Lead instructor coordinates sections, common homework and tests	Sections are run independently
Discussion Forum	Linear Circuits MOOC is synchronized with ECE3710, sharing the same homework and discussion forum	Discussion forum is limited to a single section

Another difference between the two courses is motivation, one is a required out-of-major course (3710) while the other (2040) is required of ECE majors. Thus the purpose and style of blending is different in 2040. In 3710, all of the topics are covered in the online lectures, while these same lectures constituted only about 2/3 of the lecture material for 2040, with the more complex material being done in class. The instructor who was experienced in blending ECE3710 made some adjustments in ECE2040 when compared to ECE3710:

- Mini-lectures were used to build depth on the online material both in theory and in working more difficult problems. Students were exposed to more real applications, demonstrations, and simulations.
- Since the course is taught to sophomores, emphasis was placed on developing an engineering way of approaching problems in terms of worksheets and in-class examples; homework problems that were done on paper and submitted (rather than graded online) and test problems were both graded heavily on their approach.
- Reduced the number of in-class worksheets from about 2 per week to about 1 per week. In all cases, scaffolding was completed by working one or more similar problems before the worksheets.
- Labs were done weekly, every Friday was a “bring your device day” (except for short weeks and weeks with tests)

- The students were given motivation repeatedly throughout the term on why we are blending the course and doing the labs. Understanding the value of the course approach helps to improve motivation.

Student self-perceived competence in the subject matter was examined through a post-survey. Figure 4 shows the average ratings for each topic for the one blended instructor (who had the most experience) and the average among two other sections that taught the class using a traditional lecture style.

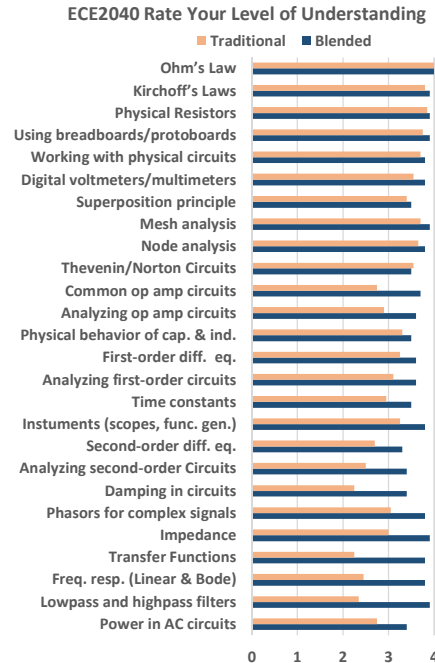

Figure 4: List of topics in order of appearance in the semester and the post-survey ratings (from 1= no understanding to 4=solid understanding) for a blended section (N=35) and two traditional lecture sections (N=30 combined).

The topics are listed in terms of their ordering in the course, starting from the beginning topics on the top to the end of the semester topics on the bottom. The dip in the traditional sections near the end of the term is reasonable in that the more complex material is often taught near the end of the term and students are usually more overwhelmed with all of their courses. The late term dip is not seen in the blended model. Students showed increased levels of confidence in the topic on phasors in all of the sections because that topic is covered in detail in another course, and that familiarity extends to the follow-on topic. Using the results in the figure, the next topics to be revised will be the second-order circuit responses, including the differential equation topics.

Figure 5 shows the post survey results from the blended version of ECE2040 where students were asked to rate the level of importance of the different instructional methods. The items marked with stars are methods that are more common to blended classes as opposed to traditional lecture-based courses. These topics all had very similar ratings from the students:

ECE2040: Importance of Instructional Methods in Helping to Learn the Material

Figure 5: Post survey of the instructional methods used in the blended class: 1 = little or no help; 2 = moderate help; 3 = significant help; 4 = one of the most helpful, N = 35.

The other ECE2040 instructor taught the course in the blended way for the first time in Fall 2014, and struggled with it, in spite of having taught the course in a traditional lecture style for many years, with high teaching evaluations. Student post-survey results for this section fell between the blended section and the two traditional sections shown in Figure 4 in each category.

This other ECE2040 instructor taught the course again the following semester (just ending at the time of this writing), again using the blended method, and made several modifications.

Instead of always giving prepared mini-lectures on material complementing the online lectures, the instructor put more emphasis on working examples interactively with the students. New material was introduced sometimes indirectly as part of the examples. The assigned homework document was displayed occasionally, to show which homework problem was related to the example just worked. An undergraduate who took the course from the same instructor the previous term and did well was hired as an additional teaching assistant. Both TAs were present and answered student questions during worksheet periods, thereby reducing the student waiting time for help.

Occasionally, when extra time was needed for live lecture on new material, there was neither a quiz nor a worksheet. The class schedule indicated when worksheets were “likely.” There were fewer problems per worksheet, and the worksheet problems closely resembled the examples just worked. The instructor would do parts of the worksheet problem at the board when she sensed that more than a couple of students were confused by the same thing. The worksheets were graded based only on effort and approach, and there was no penalty if the answer was not correct. The instructor decided it was OK that the quicker students would finish early and leave, so the slower students could have adequate time and attention from the staff. These changes created a more relaxed and positive atmosphere during class.

SUMMARY

This paper outlines a feedback approach to evolving a multi-section, large enrollment course over the period of five semesters. Two circuits courses were evaluated in this study, ECE 3710 and ECE2040. ECE3710, the course for non-majors, was offered in the blended format in order to improve

consistency among 9 sections of a course and to introduce the hands-on experiences. Consequently, almost no new material was introduced during class time in ECE3710 and more reliance was placed on the online videos. Also, ECE3710 covers more topics, though in less depth than ECE2040, making ECE3710 have a faster pace. The reason for blending ECE2040 was more pedagogical in nature, again to add the hands-on activities but also to improve learning. The combination of having more motivated students in 2040 (ECE majors versus non-majors), a slower pace of new topics, the mix of covering the lower-level material online and higher-level and more depth covered in class, made the blending experience more rewarding for the ECE2040 students.

Abstract—Haptic devices are electro-mechanical tools controlled by computers that allow to recreate the sense of touch. They enhance the sense of interaction with virtual objects from purely visual to haptic and visual. One of its application areas is in training environments, where the users can interact with virtual objects to learn procedures or tasks. In this paper we describe the use of haptic devices to improve the learning process of basic physics concepts from electromagnetism and the haptic tools via simulation of magnetic forces in 3D. We have created three scenarios with different distribution of charges: point charge, line charge, and plane charge. Each scenario was properly calibrated and has different force feedback (quadratic, linear, and constant) depending on the scenario. We wanted to investigate how forces are perceived by students. A user study was carried out to assess students' perception and knowledge acquired when they were working with the system. Results suggest that students from the treatment group achieved better understanding than those from the control group. Results also indicate that 95% of the students considered that the use of haptic devices combined with appropriate virtual environments facilitated them to understand the nature and origin of electrical forces.

Keywords—Virtual Environments, Physics Simulations, Electromagnetic Forces, 3D Computer Graphics, Haptic Devices

I. INTRODUCTION AND PREVIOUS WORK

Throughout history, teachers and their use of lectures have become the most effective way to acquire new knowledge [1]. Nevertheless, as a result of the constant progress in science and technology, new alternative solutions in the area of learner-centered approaches have been developed. One of them are different types of simulations, control systems, and learning environments, some of them used via the internet, establishing the area of Technology Enhanced Learning (TEL). The new options allow students to enhance their learning by allowing them to acquire knowledge and skills via virtual environments [2].

One of the novel areas uses haptic devices that reproduce

the sense of touch for users interacting with a virtual environment. Advances in the field of electromechanical and computer technology have enabled the development and creation of various types of applications with haptic devices such as the Novint Falcon[®] or SensAble Phantom Omni[®] in Figure 1.

Fig. 1. a) Falcon Novint[®] and b) SensAble Phantom Omni[®] are USB-connected computer controlled haptic devices that were used in our experiments.

Haptic devices have been used in many fields such as navigation, education, e-commerce, medicine, gaming, and arts [3]. One of the most important areas where haptics have been implemented for teaching is in medicine. For example surgical operations, such as stitching and minimally invasive surgeries, have been used to train doctors [4], [5], [6]. Although haptic devices can be used in many different fields, it usually does not make a big sense to create virtual simulations of structures that can be physically fabricated in real world, such as mass-spring systems. Haptics can be effectively applied in areas where the actual force is either out-of-scale ranging from nano structures [7], [8], molecules [9] to astronomical scales [10], or for complex structures such as granular materials [11].

In traditional physics courses, students often have difficulties visualizing and perceiving basic concepts of physical phenomena. This problem worsens when abstract and non-tangible concepts are involved, i.e., electromagnetic interactions between charges [12], [13]. On one hand, real laboratories and

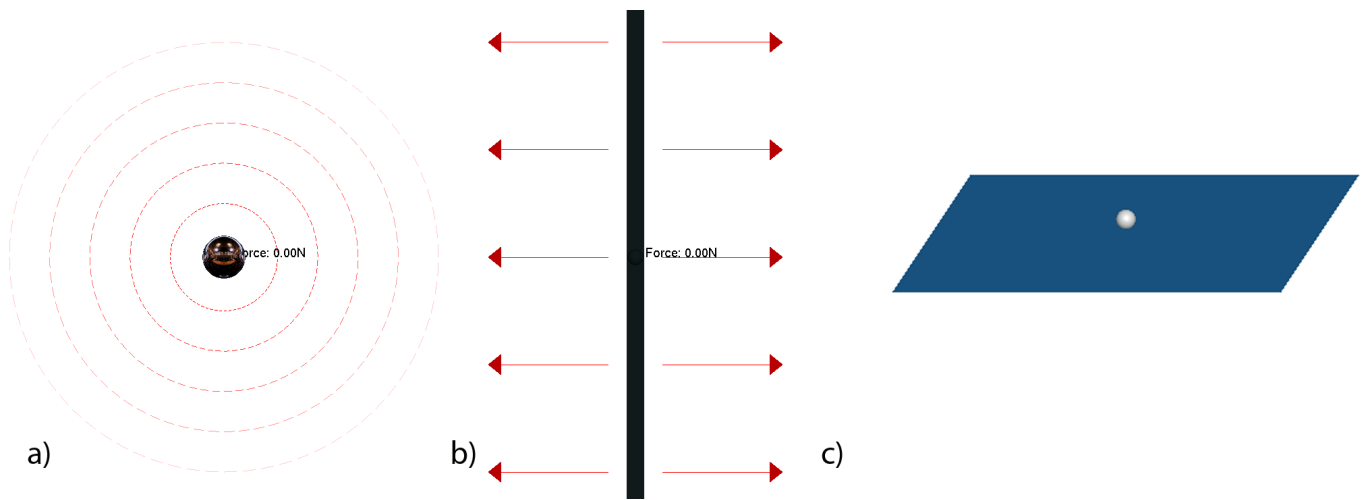

Fig. 2. Three experimental setting used in our testing point charge (a), infinite line charge (b) and infinite plane (c).

online simulators have traditionally been used to help students recreate appropriate physical scenarios [14]. Nevertheless, real laboratories are not always available in educational institutions, or they do not have all the necessary equipment to carry out suitable experiments. On the other hand, although online simulators constitute an alternative to real laboratories, most of them only address the sense of sight and in some cases the sense of hearing [15].

Electricity and magnetism concepts symbolize the basis of many current and novel technologies; however, undergraduate students often find the concepts difficult and confusing [16]. Some of the major deficiencies relate to a qualitative misunderstanding of the Maxwell's equations (expressed qualitatively); misunderstandings about the relationship between the electric fields and its sources, and the application of these concepts in problem solving [17]. Specifically, students have difficulties with electromagnetic induction and electric potential and electric energy [18].

In order to offer students a deeper perception of physical phenomena in virtual simulators, some authors have used haptic devices in online experiments. These studies had been carried in different settings, ranging from elementary school to graduate students, and they covered different physics areas, such as mechanics [19], [20], electricity and magnetism [21], [22], or heat and temperature [23]. However, although these researches helped students to better understand the nature of some physics phenomena, they are not usually applied to the field of electricity and magnetism that serve as the basis for different disciplines.

Physics educational researchers have identified the value of simulations in providing visualization of the different abstractions and complexities found in electromagnetism concepts [18]. We argue that through the implementation haptic technologies, in addition to computer simulations, can enable virtual hands-on laboratories that simulate real life scenarios or even physical abstractions. On the other hand, electromagnetism-related concepts, such as electric fields and distributed charges, are topics that have received little attention in regards to the implementation of haptic technologies. Sanchez et al. [22] investigated the efficacy of using visual

only and visuohaptic simulations for improving the learners' understanding of electromagnetic concepts. The findings of this research indicate no significant difference in the two treatment groups. Authors hypothesized that one potential reason for not identifying significant differences was attributed to students' inability to interpret touch in the context of the visualization. In order to test this hypothesis qualitative studies are needed to describe how students conceptually interpret the sense of touch. Host et al., conducted a qualitative study where they explored two different modes of using the haptic simulation in [24]. One was referred to as the force mode and the other one as force-and follow mode. The first mode allowed the learner to experience the force of the electric field and the latter one allowed the probe to be moved along the shape of the electric field. In this study authors found that before students interacted with the visuohaptics model they displayed struggles to distinguish between the concept of polarity and electric field. Host et al., hypothesized that this misunderstanding may be the source of unscientific views that all non-polar molecules are void of an electric field [24]. Authors also proposed that to remedy this problem scenario would be to directly engage electric field concepts into teaching polarity and intermolecular interactions [22]. They concluded that an integration of tactile interaction may induce an active integration of electric field knowledge with molecular charge distribution.

In this paper we explore how haptic devices can be used to effectively aid learning experience in traditionally difficult concepts from physics, namely in electromagnetism. We have developed an interactive simulator that uses three scenarios with different distribution of charges: a) point charge, b) infinite straight line of charge (hereafter, "line charge"), and c) infinite plane of charge (hereafter, "plane charge"). These scenarios can be seen in figure 2. The dependencies of the electric field strength on distance R from these charge distributions are $1/R^2$ (point charge), $1/R$ (line charge), and independent on distance (plane charge) [25]. We used haptic simulation to verify if the students are able to distinguish among the different scenarios and if they can interpret the forces correctly. The experiments were designed in 3D, and they were coupled with haptic devices.

A user study was carried to assess students' perception and knowledge acquired when they were working with the system. They were tested by engineering undergraduate students at Tecnológico de Monterrey in Mexico City and our results suggest that the use of haptic devices combined with appropriate virtual environments facilitate students to understand the nature and origin of electrical forces. Our results show that the use of haptic devices helped students to better understand electrical forces (95%), and 95% of the students stated that they would like to have haptic simulators to visualize other physics scenarios.

II. EXPERIMENT DESIGN

Electricity and magnetism provide the basis of many current and novel technologies and although undergraduate students are exposed to these concepts early in their studies they still find the topic difficult to understand. There are several reasons for this problem, among them is the complexity of mathematical concepts, and the difficulty to visualize the actual interaction of charges in the 3D space. Because of this, we have designed three experiments that provide the basic interactions, yet expose the essence of the actual interaction. The three settings were point charge, line charge, and plane charge. Each charge provides different force feedback applied to a point charge in the 3D space. The point charge experiment has quadratic attenuation with the distance. Infinite line experiment (line charge) provides linear attenuation, and an infinite plane experiment (plane charge) applies constant force independently of the location of the point charge.

A. Theoretical Framework

Embodied cognition was the theoretical framework that guided this investigation. Embodied cognition posits that bodily experiences are a key component of cognition [26]. Here, human construction of knowledge is considered closely linked to sensorimotor interactions in the world [27]. Traditional work in the cognitive sciences has primarily focused on the mind as an abstract information processor. These same views have argued that connections to the outside world (via perceptual and motor systems), were not considered relevant to understanding cognitive processes [27]. On the other hand, Artificial Intelligence has been re-thinking the nature of cognition focusing on the fact that thinking and understanding occurs in complex environments and by manipulating external props [28].

Some of the assumptions or views of embodied cognition are that it is situated, is time-pressured, is for action and body based [27]. It is also assumed that embodied cognition is used to offload cognitive work onto the environment and that the environment is part of the cognitive system [27]. In this regard, tactile sensations could stimulate learners to access and integrate embodied knowledge into their cognitive processing of abstract scientific concepts. Therefore, experiencing a coordinated visual and tactile representation of electric field concepts could have a potentially deep-seated influence on students' construction of knowledge concerning invisible and macroscopic phenomena.

B. Point charge

This experiment enables the learner to feel the electric force between two point charges that has quadratic attenuation as the

function of the distance of the charges. Charge Q_1 is fixed at the origin of the coordinate system at location $[0, 0, 0]$, and charge Q_2 is controlled by the user. It is connected to the haptic cursor, and it can be freely moved at different distances from Q_1 in the 3D environment (Figure 2 a).

The values of both charges can be chosen in the interval of $-20\mu C$ to $+20\mu C$. If learner chooses values that have different signs ($Q_1^+ Q_2^-$ or $Q_1^- Q_2^+$), he will feel the attraction force generated. On the other hand, if the learner chooses values that have equal signs ($Q_1^+ Q_2^+$ or $Q_1^- Q_2^-$), he will feel the repulsive force generated. The actual force is described by the Coulomb's law

$$\vec{F} = k_e \frac{Q_1 Q_2}{R_{QQ}^2} \hat{r}, \quad (1)$$

where $k_e = 8.987 \times 10^9 Nm^2/C^2$ is the Coulomb's constant, \hat{r} is the radial unit vector, and

$$R_{QQ} = \text{dist}[Q_1, Q_2]$$

is the Euclidean distance between the locations of charges Q_1 and Q_2 .

The purpose of this experiment is for students to realize that the force between point charges is proportional to the product of the charges magnitude and inversely proportional to the square of the distance between the charges.

C. Line charge

In the second experiment, shown in figure 2 b), the system displays a long straight-line charge fixed along the y -axis and a user-controlled mobile test point charge Q_2 .

The values for the linear charge density, λ , of the line charge can be set between the interval of $-20\mu C/m$ to $+20\mu C/m$, and the point charge can be chosen in the interval of $-20\mu C$ to $+20\mu C$. As in previous experiment in Section II-B, the x , y , and z -axes are shown and the forces that the user feels are calculated according to the sign of the values selected for the point charge and the straight-line charge. The equation for the force applied to a charge within the influence of the infinite charged line is calculated according to

$$\vec{F} = k_e \frac{2\lambda Q_2}{R_{Q\lambda}} \hat{r} \quad (2)$$

and

$$R_{Q\lambda} = \text{dist}[Q_2, \lambda]$$

is the distance between the point charge and the infinite line. Note that the attenuation is linear as the function of the distance of the charge from the line.

In this experiment the students are expected to understand that the force between a long charge line and a point charge is proportional to the product of the charges magnitude and inversely proportional to the line charge-point charge distance.

D. Plane charge

In the last experiment shown in figure 2 c), the learner senses the force generated by the interaction of a large plane of charge fixed at the yz plane and a user-controlled mobile

Fig. 3. Guiding lines connected to the coordinate frame were used to better orient the user in the 3D environment in point a) line b) and plane c) configurations.

test point charge Q_2 . The exerted force does not depend on the distance and is constant, because the plane is infinite.

The value for the surface charge density σ , of the plane charge can be chosen by the learner between the values of $-20\mu C/m^2$ and $+20\mu C/m^2$. The point charge value can be set between the interval of $-20\mu C$ to $+20\mu C$. As in the previous simulators, the forces that the user perceives are calculated according to the sign of the values selected for the point charge and plane charge

$$\vec{F} = 2\pi k_e \sigma Q_2 \hat{r}. \quad (3)$$

As can be seen, the actual force \vec{F} does *not* depend on the distance from the plane.

The goal of this experiment is to let students realize that the force between a large plane of charge and a point charge is proportional to the product of the charges' magnitude, and it is independent from the distance between them.

III. VIRTUAL SIMULATOR

We have developed comprehensive learning simulation systems that use haptic devices. The system was developed in C++ and uses OpenGL and GLSL for visualization. We used GLM for math processing and Chai3D [29] for haptics rendering.

Our implementation allows to use a SensAble Phantom Omni[®] or Novint Falcon[®]. All simulations were executed on a DELL T7500 Workstation equipped with Intel XEON E5620[®] processor clocked at 2.4 GHz, with 12 GB RAM, and NVIDIA GeForce 9800 GX2[®] video card, Windows 7 64 bits operating system, and on an ASUS G750JX-MBS1-H laptop, with Intel Processor i7-4700HQ[®] clocked at 2.39 GHz, with 8 GB RAM, and NVIDIA GeForce 770m[®] video Card. The user testing were performed by using the laptop and by using the Falcon Novint[®] haptic device shown in Figure 1 a).

The Point Charge and the Line Charge simulations were developed as 3D environments due to the nature of their interaction forces, as can be seen in figures 3-a and 3-b. The Point Charge, the charge Q_1 was displayed as a small sphere and its interaction forces were calculated to avoid Q_2 penetration. A line was created for the Line Charge to trace a long box. This line was placed on the y -axis and collision detection was enabled to show that Q_2 cannot enter the line. It is important to note that in both simulators the size of the moving object representing the charge Q_2 changes according to its location relative to the user because of the perspective projection to provide a better depth perception. Additionally, guiding lines connecting the haptic cursor with the projection to the axis of the Euclidean coordinate system were used to provide guidance (Figure 3).

The Plane Charge simulator is symmetrical in 3D and was developed as 2D representation showing the x and y -axes, as can be seen in figure 3-c. However, the user could navigate the scenario using the all three axis. The plane was created as a mesh to enable the simulation provide collision detection in the plane. Finally, as in the previous simulators, guidance lines were implemented to locate the user in the space.

Figure 4 shows a student interacting with the haptic device during an experimental session.

Fig. 4. A student interacting with the Plane Charge simulator. Students can freely explore the virtual scenario by using a haptic device. Depending on the position of the haptic interaction point, students can feel the interaction force in that position.

IV. EVALUATION PROCESS

During the January - May 2015 term, a focus group of 20 freshmen students of a undergraduate Electricity and Magnetism course at Tecnológico de Monterrey (Mexico City) were invited to test the three developed experiments. The testing sessions were one week long and the students were able to use the simulators coupled with haptic devices.

Each session consisted of a brief introduction and demonstration of how the system works followed by exercises for each simulator. They were asked to explore the system and solve some exercises using the haptic device in order to sense the interaction forces between the different charge distributions, as can be seen in figure 5. Each student explored the system for approximately 30 minutes. At the end of each session, students were asked to provide general comments

Fig. 5. Students solving exercises using the Point Charge simulator. Students followed instructions for each simulator where they can apply the knowledge they learnt in the classroom to check if the values were correct.

about the virtual systems. After that the students were also asked to answer two short multiple-choice questionnaires:

- i) A post-test, which aimed to seek whether they were able to identify the direction of the force and its dependence to the distance between the test point charge and the different charge distributions (Table I).
- ii) A perception questionnaire, which was created to assess students' overall opinion to the simulators (Table II). Likert scale was used, in this questionnaire using the values: Total Agreement (TA), Agreement (A), Indifferent (I), Disagreement (D), and Total Disagreement (TD).

By applying both questionnaires, we could measure if the student felt that this system could help them to better understand the nature and behavior of electrical forces. The post-test was also applied to 20 freshmen students of a different Electricity and Magnetism course, a control group, in order to compare the results between both groups. Even though the treatment and control groups had different professors, both groups covered the same syllabus, provided similar exercises, same lectures, and same learning resources about the concepts developed in the simulators. Therefore, students had same academic backgrounds and characteristics.

TABLE I. POST-TEST QUESTIONNAIRE APPLIED TO TREATMENT AND CONTROL GROUP.

Post-test questionnaire				
1) What kind of force is felt between charges of the same sign?				
a) Attractive	b) Repulsive	c) Depends on the magnitude of charges values		
2) What kind of force is felt between charges of opposite sign?				
a) Attractive	b) Repulsive	c) Depends on the magnitude of charges values		
3) The value of the electric force between point charges located at distance R is proportional to:				
a) R^2	b) R	c) Does not depends on R	d) $1/R$	e) $1/R^2$
4) The value of the electric force between a line charge and a point charge located at distance R is proportional to:				
a) R^2	b) R	c) Does not depends on R	d) $1/R$	e) $1/R^2$
5) The value of the electric force between a plane charge and a point charge located at distance R is proportional to:				
a) R^2	B) R	c) Does not depends on R	d) $1/R$	e) $1/R^2$

V. RESULTS AND DISCUSSION

The results of the post-test applied to the treatment and the control group are shown in figures 6 and 7. Results from the perception questionnaire (applied only to the treatment group), can be seen in figure 8.

As can be seen in figures 6 and 7, most students in both groups answered correctly the first two questions which were focused on their understanding of how the interaction force behaves (attraction or repulsive force). Nevertheless, in questions three to five, related to the dependence of the electric force to the distance between the different charge distributions, interesting differences appeared when the treatment and the control group were compared. In question number three, where the right answer is the option "e" - $(1/R^2)$, the results for this question are very similar for both groups (treatment: 60%, control: 55%). On the other hand for question four (electric force between point charge and line charge), the right answer percentage (option "d" - $1/R$), although both percentages are low, was higher in the treatment group (25%) than the one obtained in the control group (only 5%). Finally, in question five, the electric force between a point charge and a plane of charge, 75% of the members of the treatment group answered it correctly (option "c" - Does not depend). This value is higher compared to the one obtained in the control group (only a 50%). In summary, students from the treatment group achieved better results than those from the control group. This result suggest that the use of virtual learning environments coupled with haptic devices can help learners to better recognize and understand the strength of the electric forces.

TABLE II. PERCEPTION QUESTIONNAIRE APPLIED TO THE TREATMENT GROUP.

Perception Questionnaire
1) Point Charge experiment helped me to better understand the behavior of the interaction force between point charges.
2) Line Charge experiment helped me to better understand the behavior of the interaction force between a line charge and a point charge
3) Plane Charge experiment helped me to better understand the behavior of the interaction force between a plane charge and a point charge
4) Manipulating Point Charge experiment was easy and intuitive
5) Manipulating Line Charge experiment was easy and intuitive
6) Manipulating Plane Charge experiment was easy and intuitive
7) Point Charge experiments graphics are appropriate and attractive
8) Line Charge experiments graphics are appropriate and attractive
9) Plane Charge experiments graphics are appropriate and attractive
10) The three experiments, as a whole, helped me to acquire better perception of the interactions forces between the different charged distributions
11) I would recommend simulations with haptic devices to learn other concepts of Electricity and Magnetism
12) I would recommend simulations with haptic devices to learn other concepts of Physics

Results of the perception questionnaire suggest, as can be seen in figure 8, that the students of the treatment group totally agree or agree on the fact that the virtual simulator helped them to better understand the behavior of electrical forces. Moreover, they specified that the manipulation and visualization of the system was in general appropriate, and they would recommend simulations that use haptic devices to learn other concepts of the Electricity and Magnetism course, as well as for other physics topics. The average results were calculated using Total Agreement and Agreement. The highest average obtained in the questionnaire was the acceptance that simulators helped them to better understand electrical forces (92% for questions 1 - 3). There is also a high average of 87% stating that the system manipulation was easy and intuitive (questions 4 - 6). On the other hand, the lowest average of acceptance was obtained in the questions related to the visualization of the system (72% for questions 7 - 9). This can be interpreted as the need for the graphics of the simulators to be improved, in particular, in the perception of depth.

The general acceptance percentage was also rather high; 95% in question 10 suggests that students considered that the three experiments helped them to acquire and to better understand the perception of the interactions between different charge distributions. Finally, similar to the previous question, the average result for questions 11 and 12, 95% suggests that haptic simulators are recommended to visualize other physics scenarios. Results from the last part of the questionnaire (questions 10 to 12) can be further supported by the general comments that the students from the treatment group also provided.

Fig. 6. Treatment group results obtained in the post-test.

Most of these comments were positive and motivating. Typical ones were: "I liked the (haptic) simulator because it shows more realistic scenarios than those seen in class", "they (haptic simulators) helped me to better understand the behavior of electric forces", "the simulations (using haptics devices) are interactive and didactic". Furthermore, there were other comments that invited the authors to improve the visualization of the experiments, the 3D perspective, and other students even encouraged the authors to create new simulators.

We believe that the high failure percentages for the treatment and control groups obtained in the question related to the line charge experiment (question four) is due to the fact that students do not recognize that the force strength increases for shorter distances, but they have troubles in disclosing between the linear and quadratic attenuation.

VI. CONCLUSIONS AND FUTURE WORK

We have shown our implementation of a 3D haptic simulations and how it was used to assess learning experienced

Fig. 7. Control group results obtained in the post-test.

in traditionally difficult concepts from physics - electromagnetism. Our interactive simulator uses three scenarios: point charge, line charge, and plane charge, where each scenario provides different force feedback: quadratic, linear, and constant, respectively. The third dimension was added to enrich the visualization and our system includes a three-dimensional coordinate system that shows the projections of the haptic cursor on the coordinate planes.

A user study was carried out to assess students' perception and knowledge acquired when they were working with the system. They were tested by engineering undergraduate students at Tecnológico de Monterrey in Mexico City and our results suggest that the use of haptic devices combined with appropriate virtual environments may facilitate conceptual understanding of the nature and origin of electrical forces. Results of the post-test for the three experiments were better in the treatment group than in the control group. The best result was obtained when students used the Plane Charge simulation, but positive acceptance was obtained for the Point Charge. The poorest results were found in the Line Charge simulation.

Students' perception of the virtual environments was overall positive. They stated that the experiments helped them to better understand the behavior of electric forces, the manipulation of the experiments was easy and intuitive, and that the visualization was appropriate and attractive, although it still could be improved to provide better perception of the depth. They also manifested that the three experiments helped them to acquire a better perception of the interactions forces between different charge distributions, and they would recommend the

Fig. 8. Perception questionnaire results. This graph shows the acceptance and usefulness of the simulators according to the results obtained in the perception questionnaire.

use of virtual simulators coupled with haptic devices to learn other concepts of electricity and magnetism and other abstract Physics topics.

There are several possible avenues for future work. A more comprehensive study with more participants could be performed. It would be interesting to experiment with other concepts from magnetism, applying forces over wires of arbitrary shapes, among others. Several participants had difficulties in disclosing the force strength dependence on distance (linear vs. quadratic attenuation). It would be beneficial to conduct a novel study that would quantify and describe what were the reasons for these issues.

ACKNOWLEDGMENTS

This project was supported by the *Fondo Novus 2014* grant. The authors would like to thank Rosa María García-Castelán for her participation and support during the testing process, and we sincerely thank the reviewers for their insightful feedback.

Expression Tasks for Novice Programmers

Turning the Attention to Objectivity, Reliability and Validity

Abstract—The understanding and transfer of mathematical expressions in a programming language is essential for studying engineering. Our experience of recent years shows that students increasingly struggle in reading, understanding and eventually transferring mathematical expressions to a programming expression so we need to provide many relevant tasks to help students overcoming this challenge. From educational psychology as well as our application-oriented research we know that the success of learning can be operationalized with objective, reliable and valid tasks only. Thus, we perceive tasks not only to be a training but also to be an empirical measuring instrument. However, tasks that are not theory driven are likely to be not suitable to measure the learning outcomes of students in an objective, reliable and valid manner. We'll present two different successful approaches that were developed individually at two different locations. Both propose a formal task description as well as a process model for task development that will facilitate the transfer of mathematical expressions to programming expressions. The tasks generated are valid and allow objective and reliable measurements of the students' learning outcomes. Our proposed tasks can also be used to iteratively improve and individualize introductory programming courses.

Keywords—Engineering Education, Computer Aided Instruction

I. INTRODUCTION – ENGINEERS NEED TO HANDLE EXPRESSIONS WELL

Mathematical expressions play an important role in engineering education. In the curriculum, understanding them is a prerequisite for subjects like statics, physics, measurement, mechanical or electrical engineering and thermodynamics. With the increased use of computers, students must become competent in translating a mathematical expression into a programming language expression (e.g. C#, FORTRAN or spreadsheets).

Unfortunately, students struggle to read, understand and eventually transfer mathematical expressions to programming expressions, and this has been worsening in recent years [1]. Students seem to no longer develop a deep mental model of expression evaluation, since the graphing calculators and computer programs they typically use give them the final result of any expression without explaining the intermediate steps. Such a mental model essentially involves understanding the tree structure of mathematical expressions. In order to set a sustainable foundation for further studies (in this course as well as in the curriculum), we must help our students develop such a

deep mental model. In this paper, we propose a set of tasks to help students learn mathematical expressions, and illustrate them with sample implementations.

II. OUTPUT ORIENTATION – TASKS AS SEEN FROM AN EMPIRICAL PERSPECTIVE

A skill or competence is a latent property that can only be operationalized (observed and measured) by a corresponding performance [2,3]. Tasks can be used to operationalize skills [3], but only if they are objective, reliable and valid [4]. This is due to the fact that tasks conform to empirical measurement, thus, requiring empirical standards. We define tasks that allow an objective, reliable and valid observation and measurement as competence-oriented tasks.

Objectivity and reliability are problematic when the task and / or the solution representation are ambiguous (i.e. not objectively assessed and therefore not reliable). Recent task reviews for novice programmers have shown that this is indeed a problem (see [4,5]). We address this problem by applying a formal task description (see [6]). The validity of a certain task in relation to a specific competence is ensured by developing a systematic procedure to create a possible (valid) task from a given competence (see [4]). In this paper, we propose to use a systematic procedure for the task of evaluating and writing expressions.

According to [4] the top down-process of creating tasks begins with the identification of a manageable number¹ of operationalizable target skills, either following a) an expert analysis, b) a curricular guideline such as [7] or c) local curricular requirements. Since not all skills needed can be operationalized in the same easy way [8] we focus on cognitive skills only. Non-cognitive skills (such as motivation) still remain important, but are out of the scope of our current work.

¹ We recommend choosing at most 3-5 top level skills because more will likely become impossible to handle during the short period of the course.

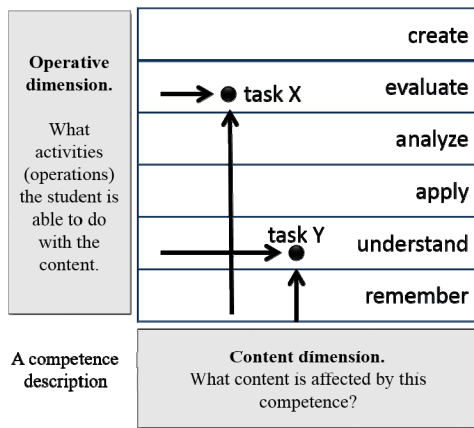

Figure 1 - Visual representation of a competence description [8].

The procedure we will follow is as follows: 1) We select a small number of necessary cognitive skills; 2) We identify the relevant learning objectives for which we have to consider the students' prior knowledge; 3) We enlist the actions (operations) we'd like the students to be able to do with the learning objectives. Those operations provide us with so called task types (4), meaning that every task type describes an individual superset of tasks with identical properties². If needed the identified task types can be ordered using an appropriate taxonomy, e.g. [9] or [10]. 5) Finally, we create atomic tasks³ following the requirements of the task type (see [4,8] for a detailed discussion of this procedure).

Figure 2 - Top down process of creating valid tasks [8].

The procedure above provides a number of empirically valid task. To ensure their objectivity and reliability a formal task description has to be used to avoid any kind of ambiguity⁴. The formal and procedural approach to develop tasks makes them more than just a practicing tool. They can now be used to empirically study the success of a certain didactic teaching approach. Furthermore, the existence and degree of desired expression skills can be observed and measured empirically.

² Similar to a superclass.

³ [3,11] recommend aligning the tasks (constructive alignment) to meet both the students (exam) as well as the lecturers (skill acquisition) requirements. This can be easily achieved by using the same collection of tasks for lectures, practicing sessions as well as the final exam.

⁴ For a discussion of how to describe tasks formally see [4,6].

III. COMPETENCE ANALYSIS – FROM SKILLS TO VALID TASK TYPES

The process of identifying appropriate cognitive skills⁵ is influenced by external guidelines (ACM/IEEE) and local curricular requirements. However, as experts we also have the option to identify needed skills ourselves. Since the overall goal is to teach the fundamentals of programming, understanding and transferring mathematical expressions to programming expressions can be seen as one of the top level competencies.

But what content is relevant concerning the transfer of mathematical expressions? We identify the following tasks for expressions: 1) remember expression syntax elements⁶, 2) understand an expression's semantics, 3) apply the transfer of a mathematical expression to a programming expression with a given how-to-proceed algorithm, 4) correct and 5) optimize a given expression. This provides us with 5 task levels⁷ and at least one task type per level.

TABLE I. ANDERSON'S TAXONOMY APPLIED TO OUR DOMAIN⁸ INCLUDING TASK TYPES.

Level	Anderson	Explanation
6	create	Yet undefined.
5	evaluate	Optimize expression: OPEXpr – Optimize expression with parenthesis
4	analyze	Correct expression with errors: CIMEXpr – Correct implementations of mathematical expression with errors CEXpr – Correct expression with errors
3	apply	Implement mathematical expression with given algorithms: IMEXpr – Implementation of mathematical expression RIMEXpr – Reverse implementation of mathematical expression, e.g. form mathematical expression from implementation
2	understand	Evaluate expression with given Input: EMEXpr – Evaluate mathematical expression EEXpr – Evaluate expression CEEXpr – Complete evaluate expression Problems
1	remember	Identify syntax elements (non terminals): EXprTree – Expression tree

IV. TASK ANALYSIS – FROM TASK TYPES TO VALID TASKS

In order to learn to evaluate mathematical expressions, students must understand the concepts of 1) operators and operands; 2) precedence of operators; 3) associativity of operators; 4) arity of operators; 5) that an expression is evaluated one operator at a time by the computer; and 6) the semantics of individual operators in an expression. These can be succinctly summarized by the evaluation tree of the expression. We will now develop valid tasks for the given task types and describe them formally using a unique table-based

⁵ As we'd like to discuss identified task types in detail we'll keep the explanation of this step as short as possible. For an extensive discussion see [4].

⁶ Such as literals, operators, braces etc.

⁷ Currently no task type for level 6 (create) has been developed.

⁸ Taken from [4], modified.

template. Also, we want these tasks to be usable in a computer-based learning environment, so that we can generate exercises efficiently (see [12,13]).

A. Level 1: Remember Expression Syntax Elements

1) Expression Tree (ExprTree)⁹

TABLE II. DESCRIPTION OF THE EXPRESSION TREE TASK TYPE.

Property	Details
Competency ^a	Remember (recall) syntax and semantics of expressions, statements, constructors, fields, properties, methods and operators.
Level	1 (remember)
Given ^b	Expressions ^c .
Main operator ^d	Construct the expression tree of the expressions.
Solution representation ^e	Tree
Assurance ^f	The expressions don't change the value of variables, so they do not contain ++, --, assignment, complex assignment like +=, return-method-invocation with parameter modifiers (ref or out), object creation or array creation. Variable references and literals do not lock up in the expressions in parenthesis, e.g. (5) or (a) is not allowed. LINQ-expressions or similar expressions with methods of the class Array or List are not allowed.
Assessment ^g	Subtractive ^h .
Notes ⁱ	The following types of subexpressions exists: the variable-reference, the literal, the return-method-invocation, the cast-expression, the unary-expression, the binary-expression, the tertiary-expression (?-operator)
Hint ⁱ	For this operator an algorithm exists.

^a. Target competence this task belongs to.

^b. All given information provided to the student (initial state).

^c. The number of expressions to work with, provided as a table.

^d. Main action (operation) the student has to do.

^e. Formal description of how to represent the worked out solution.

^f. Bordering the solution space by excluding unwanted scenarios.

^g. Clarifying the way of how this task is being assessed.

^h. Starting with all points. Every mistake one (or more) points less. This way of assessment has been described in [4].

ⁱ. Additional notes or hints to provide some extra information.

a) Detailed Algorithm¹⁰:

The problem-solving algorithm, which is provided to the students as well, demonstrates that we want the students to evaluate the given expression the same way a parser does. This helps them understand that not (only) algebraic but digital rules apply when evaluating expressions.

1. Identify operands: variable-references and literals.

2. Identify sub-expressions recursively. The sub-expressions are: member-access, array- and indexer-access, return-method-invocation, unary-expression (operators +, -, !, ~), cast-expression, binary-expression (operators *, /, %, +, -, <<, >>, <, >, <=, >=, is, as, ==, !=, &, ^, |, &&, ||, ??), and tertiary-expression (operator ?)

⁹ We adhere to terms of the C # programming language.

¹⁰ To solve this task students need to follow a given algorithm, which enlists every step.

Parenthesized-expressions are treated as extension of the sub expression.

Expressions (as well as sub-expressions) can be marked as fully evaluated only if there's no operator at the right hand side, which is of a higher order and which has not been evaluated yet. Because parenthesis and the "," in the argument-list are not treated as operators the search for operators of a higher priority is interrupted.

b) Remarks:

In the case of C# we can construct a lambda-expression from such an expression, if we don't have a constant expression. Constant expressions are evaluated by the compiler.

c) Example: ExprTree: Expressions 01

Nr	Expression
1	9 % 6 - 6 % 9
2	2 * y / (x + 1)
3	2 * (y / (x + 1))

Solution ▶

Nr	Expression
1	
2	
3	

B. Level 2: Understand an Expression's Semantics

1) Completely Evaluate Expression (CEExpr)¹¹

TABLE III. DESCRIPTION OF THE COMPLETELY EVALUATE EXPRESSION TASK TYPE.

Property	Details
Competency	Understanding of evaluation of expressions and return-methods.
Level	2 (understand)
Given	Variable ranges, expressions, input.
Main operator	Notice the complete evaluation of the expressions with the inputs.

¹¹ There is also a simplification of this task type, in which students need to specify only the final result without labeling the intermediate results (EExpr: Evaluate Expression), which we do not describe here.

Property	Details
Sub operators	Expression tree List of all operators for the basic-values-types, e.g. bool, int, char, double and string and the semantic of the operators
Solution representation	Tree
Assurance	See expression tree task type. The input is inside valid variable ranges.
Assessment	Subtractive.
Hint	For this operator an algorithm exists.

a) Detailed Algorithm:

Repeatedly calculate the values of sub-expressions and write down their values.

If the sub expression is a variable-name, we write down the value of the variable. If the sub expression is neither a literal nor a variable-name and doesn't contain the operators '&&', || or '?', we evaluate the value of the sub expression.

If the sub expression contains one of the operators '&&' or ||, then the value is determined as follows: If the result of the evaluation of the left operand is true for || or false for &&, we write down the value of the left sub expression and skip evaluating the right sub expression. Otherwise, we also evaluate the right sub expression, followed by the overall expression.

If the sub expression contains the operator '?', then the value is then determined as follows. If the value of the first sub expression is true, the second sub expression is evaluated and its result is returned. If the value of the first sub expression is false, the third sub expression is evaluated and its value is returned.

b) Remarks:

Mathematical Set	Corresponding Type in C# Remarks
Boolean set	bool Associative and distributive
Set of integer numbers	int only a subset of the set of integer numbers Associative and distributive in the case of unchecked Not associative and distributive in the case of checked
Set of real numbers	double Not associative and distributive

If we use return-method-invocations in the expression with possible exceptions, then the operators will no longer be commutative.

c) Example: CEEExpr: Expressions 01

Variable ranges

In: double x, y;

Out: basic-value-type

Nr	Expression
1	3 + 4 * 5
2	2 * y / (x + 1)
3	2 * (y / (x + 1))

Input

x = 2; y = 3;

Solution ►

Nr	Expression
1	
2	
3	

2) Problets

TABLE IV. DESCRIPTION OF PROBLT TASK TYPE.

Property	Details
Competency	Understanding of evaluation of expressions.
Level	2 (understand)
Given	Expressions (without variables).
Main operator	Write down the complete evaluation of the expression.
Sub operators	Expression tree Complete evaluate expressions List of all operators for the basic-values-types, e.g. bool, int, char, double and string and the semantic of the operators
Solution representation	Tree
Assurance	See expression tree task type.
Assessment	Subtractive.
Hint	For this operator an algorithm exists. The algorithms is a combination of the algorithms for expression tree and complete evaluation expressions. In the case of operators && and may be that the expression tree is not complete. In the case of the operator ? the expression tree is always not complete. Because we use literals it isn't necessary to mark the literals.

a) Remarks:

Evaluation task can be illustrated with an example from problets (problets.org), which are problem-solving software tutors designed to help students learn programming concepts by solving problems. The problets on expression evaluation (arithmetic, relational, logical, assignment and bitwise) reify the evaluation of a problem by requiring the student to identify the evaluation tree, one operator at a time, as shown in Figure 1. When using a problets on expression evaluation, students are required to use the procedure described above to evaluate the expression, again, as shown in Figure 1.

The advantages of requiring students to identify the evaluation tree en-route to evaluating the expression are: 1) the

evaluation process is emphasized just as much as the final product, i.e., the final answer; 2) in order to qualify for full credit, students must develop the correct mental model of expression evaluation and cannot simply guess the final

answer. In other words, students must use an objective, valid and reliable process to evaluate expressions.

b) Example:

Arithmetic - Practice

Edit View Options Format Help

Evaluate the following expression step by step.
Click and drag the mouse to indicate each step.
Enter intermediate result when prompted.
If you need help entering your answer, click on [Show Explanation] in the right hand panel.

9 % 6 - 6 % 9

3 ✓

6 ✓

-3 ✓

You correctly identified all 3 steps in the solution.
You correctly calculated all 3 intermediate results in the solution.
The operators in the expression are: % - %
They are evaluated in the following order, based on their precedence:
% % Highest Precedence (Evaluated Left to Right)
- Lowest Precedence

9 % 6 returns 3, the remainder when 9 is divided by 6 using ordinary division
6 % 9 returns 6, the remainder when 6 is divided by 9 using ordinary division
3 - 6 returns -3

Next Problem

Figure 1: Evaluation of an arithmetic expression with 3 operators: student answer in the left panel; correct answer in the right panel, along with explanation

Logical - Practice

Edit View Options Format Help

Evaluate the following expression step by step.
Click and drag the mouse to indicate each step.
Enter intermediate result when prompted.
If you need help entering your answer, click on [Show Explanation] in the right hand panel.

true || false && true

false ✗

✗

Short Circuit ✓

true ✓

The left-hand-side of && operator is always evaluated before its right-hand-side.
Since the left side evaluates to true, the right side of || is short circuited.
false && true is short circuited
true || false && true returns true

Next Problem

Figure 2: Evaluation of a logical expression: incorrect solution entered by the student in the left panel; correct answer and feedback shown in the right panel

3) Operator Task

In addition to learning the evaluation tree, students must also learn the semantics of individual operators, e.g., in Figure 1, they must understand that % operator returns the remainder of dividing one integer by another. The semantics of operators are reflected in the intermediate results students are expected to enter after each step of evaluation. Note that problems grade both the evaluation tree and the intermediate results entered by the student. Sometimes, intermediate results can alter the evaluation tree, as shown in Figure 2, where the right operand of a logical operator has been *short-circuited*. Both the figures 1 and 2 illustrate cases where evaluation of a programming expression differs from the evaluation of mathematical expression (% operator and short-circuit evaluation).

Controlled evaluations have shown that using problems helps students learn expressions [14]. Students have been using problems to learn expressions in C++, Java and C# since fall 2004.

C. Level 3: Applying the Transfer

1) Implementation of Mathematical Expression (IMExpr)¹²

TABLE V. DESCRIPTION OF THE IMPLEMENTATION OF MATHEMATICAL EXPRESSION TASK TYPE.

Property	Details
Competency	Implementation of mathematical expression.
Level	3 (apply)
Given	Variable ranges, mathematical expressions
Main operator	Notice the expressions
Sub operator	For every sub expression of a mathematical expression exists one sub operator.
Solution representation	Table with columns "Nr" (number of the expression), "expression"
Assessment	Subtractive for every expression.
Assurance	The mathematical expression can notice with help of the class Math and the operators. The mathematical expression does not contain symbols like sum, product, minimum, maximum, exist or for all. The variable-names have only one letter.

TABLE VI. SUB OPERATORS

Math. Expression Example	C# Expression	Contraction
Comment		
(...)	(...)	Parenth
Parenthesis are taken from the mathematical expression		
Parenthesis are every times use as pair.		ParenthPair
Parenthesis are every time round parenthesis because we do not use array-element-access		Parenth-Round
xy	x * y	ProdExpr
The multiply sign must be used at a product.		
$\frac{x+1}{x+2}$	((x + 1) / (x + 2))	QuotExpr

¹² In case the solution is exchanged with the given information a reverse task type can be described where the students need to identify a mathematical expression from a given programming expression. We call this task type RIMExpr: Reverse Implementation of Mathematical Expression.

Math. Expression Example	C# Expression	Contraction
Comment		
The nominator and the denominator of a quotient must be put into parenthesis. The quotient must be put into parenthesis if an operator of same or higher priority stands besides the quotient on the left or right.		
$1.2 \cdot 10^{23}$	1.2E23	ScientificLit
$\frac{1}{n}$	1.0 / (double)n	QuotIntExpr
If we have a quotient of int-expressions then we have to use the conversion into double-expressions. This is dangerous because we know that it isn't necessary in this strict form. The quotient must be put into parenthesis if an operator of same or higher priority stands besides the quotient on the left.		
$\ln x$	Math.Log(x)	Func
At a mathematical function the argument must be put into parenthesis.		
$ x $	Math.Abs(x)	FuncAbs
\sqrt{x}	Math.Sqrt(x)	FuncRoot
e^x	Math.Exp(x)	FuncExp
x^y	Math.Pow(x, y)	FuncPow
$-x^y$	-Math.Pow(x, y)	FuncNegPow
The negation of power is done after calculation of power.		
x^{y^z}	Math.Pow(x, Math.Pow(y, z))	FuncPowPow
The power of power is calculate by calculation of the inner power first.		
$\ln^2 x$	Math.Pow(Math.Log(x), 2)	PowFunc
The power of a mathematical function in a mathematical expression we find after the name of the function and we have to use it after the result of the function.		
$\sin xy$	Math.Sin(x * y)	FuncProd
The product with a variable or literal "extends" the use of the mathematical function.		
$\sin x \sin y$	Math.Sin(x) * Math.Sin(y)	ProdFunc
The product with a mathematical function doesn't extend the use of the mathematical function.		
$\sin x + y$	Math.Sin(x) + y	FuncSum
The sum doesn't extend the use of the mathematical function.		
$x = y$	x == y	EqualExpr
$x \neq y$	x != y	
$x \leq y$	x <= y	RelatExpr-Simple
$1 \leq y \leq 4$	1 <= y & y <= 4	RelatExpr-Complex
The behind each other execution of relational expressions of double expressions are divide into two part which are connected with the operator &. The complex relational expression must be put into parenthesis if an operator of same or higher priority stands besides the expression on the left.		
$\neg p$!p	LogNot
$p \wedge q$	p & q	LogAnd
$p \vee q$	p q	LogOr
$p \vee r = q \wedge r$	(p r) == (q & r)	LogVgl
For an equality expression of bool-expression we have to use for the left and the right side parenthesis.		
$\begin{cases} -x, x < -1 \\ x, \text{sonst}; d.h. x \geq -1 \end{cases}$		CondExpr
$x < -1? -x: x$		

Math. Expression Example	C# Expression	Contraction
Comment		
The conditional expression with the operator ? has exactly three operands, the operand 0 before ?, the operand 1 after ? and the operand 2 after.. The condition after otherwise we do not realize.		

a) Remarks:

The rules for solving this problem algorithmically were identified with the help of the software program Scientific Workplace. Unfortunately, we can't afford using this software for our classes.

The rules of evaluation are very strict and inspired from the fact that a mathematical expression is a tree. To avoid ambiguous trees we prohibit commutativity, associativity as well as distributivity because they all lead to equivalent expressions but completely different trees. This, again, demonstrates a difference between mathematics and programming where rules for term transformation doesn't apply.

b) Example: IMExpr: Expressions 00

Variable ranges

In: bool p; bool q; double x; double y;
Out: basic-value-type

Nr	Mathematical expression
1	$\frac{2y}{x+1}$
2	$2 \frac{y}{x+1}$
3	$\sin^2 x^6 y + 1$
4	$\neg p \wedge \neg y \leq x + 1 \leq 3 + y$

Solution ►

Nr	Expression
1	<code>2 * y / (x + 1)</code>
2	<code>2 * (y / (x + 1))</code>
3	<code>Math.Pow(Math.Sin(Math.Pow(x, 6) * y), 2) + 1</code>
4	<code>!p & (-y <= x + 1 & x + 1 <= 3 + y)</code>

◀

D. Level 4: Analyze the Correctness of an Implementation

1) Correction of the Implemetation of a Mathematical Expression with Errors (CIMExpr)

TABLE VII. DESCRIPTION OF THE CORRECT IMPLEMENTATIONS OF MATHEMATICAL EXPRESSIONS WITH ERRORS TASK TYPE.

Property	Details
Competency	Correction of implementations of mathematical expressions with errors ^a .
Level	4 (analyze)
Given	Variable ranges, mathematical expressions, expressions
Main operator	If in the implementation of a mathematical expression you find an error then correct the error and give the name of the sub operator which isn't correct used. If in the implementation of a mathematical expression you could not find an error then write down the expression again.
Sub operator	see IMExpr
Solution representation	Table with columns "Nr" (number of the expression), "expression" (expression without error) und "sub operator"

Property	Details
Assesment	Subtractive for every expression.
Assurance	see IMExpr The expressions only contain maximum one error

^a. Syntax- or semantic errors may occur.

a) Example: CIMExpr: Expressions 01

Variable ranges

In: bool p; bool q; double x; double y;
Out: basic-value-type

Nr	Mathematical Expression
1	$\frac{2y}{x+1}$
2	$2 \frac{y}{x+1}$
3	$\sin^2 x^6 y + 1$
4	$\neg p \wedge \neg y \leq x + 1 \leq 3 + y$

EXPRESSIONS WITH MAXIMUM ONE ERROR

Nr	Expression
1	<code>2 * y / (x + 1)</code>
2	<code>2 * y / (x + 1)</code>
3	<code>Math.Pow(Math.Sin(Math.Pow(x, 6) * y + 1), 2)</code>
4	<code>!p & (-y <= x + 1 <= 3 + y)</code>

Solution ►

Nr	Expression	Sub Operator
1	<code>2 * y / (x + 1)</code>	
2	<code>2 * (y / (x + 1))</code>	QuotExpr
3	<code>Math.Pow(Math.Sin(Math.Pow(x, 6) * y), 2) + 1</code>	FuncSum
4	<code>!p & (-y <= x + 1 & x + 1 <= 3 + y)</code>	RelatExpr-Complex

◀

E. Level 5: Evaluate (optimize) a Given Expression

1) Optimize Expressions with Parenthesis (OPEXpr)

TABLE VIII. DESCRIPTION OF THE OPTIMIZE EXPRESSIONS WITH PARENTHESIS TASK TYPE.

Property	Details
Competency	Optimize the number of parenthesis
Level	5 (evaluate)
Given	expressions
Main operator	Find an expression with a minimal number of parenthesis which has the same expression tree as the given expression.
Sub operator	ExprTree
Solution representation	Table with columns "Nr" (Number of the expression), "Expression" (Expression with the same expression tree)
Assesment	Subtractive for every expression.
Assurance	The Expressions are correct.
Notes	There are expressions, where it is impossible to delete parentheses.

a) Example: OExpr: Expressions 02

Nr	Expression
1	<code>((2 * y) / (x + 1))</code>
2	<code>(2 * (y / (x + 1)))</code>

Solution ►

EXPRESSIONS WITH NUMBERED PARENTHESIS

Nr	Expression
1	12 2 3 31 ((2 * y) / (x + 1))
2	1 2 3 321 (2 * (y / (x + 1)))

SOLUTION

Nr	Expression
1	2 * y / (x + 1)
2	2 * (y / (x + 1))

◀

V. SUMMURY AND FUTURE WORK

Mastering expressions in such a way that they can be transferred from their mathematical representation to a programming representation is an important prerequisite engineers need when learning programming. Firstly, we showed that a competence can only be operationalized (observed and measured) with the use of competence-oriented tasks (objective and reliable understood and assessed, valid concerning their corresponding competence). In terms of expressions the procedure of creating such tasks has been demonstrated focusing on the explanation of the resulting task types, which include at least on example. It has been found that problets are an excellent tool to address at least two competence levels. However, the amount of research in the field of operationalizing programming skills deeply is still too limited.

ACKNOWLEDGEMENTS

We'd like to thank Prof. Dr. Azizi Ghanbari (University of Greifswald, Germany) and Prof. (em.) Dr. Schott (TU Dresden, Germany) for numerous discussions about output-oriented education. A special gratitude goes to Prof. Dr. Urban (University of Applied Sciences Zittau / Goerlitz, Germany) for many years of valuable contributions to the presented task types. We'd also like to thank numerous students of mechanical engineering and other courses of the University of Applied Sciences Zittau / Goerlitz, Germany for their helpful feedback. Partial support for this work was provided by the National Science Foundation under grant DUE-1432190. We'd

also like to thank the anonymous reviewers of this article for their helpful suggestions and comments.

Abstract – Previous researches have pointed out that simulation games can be an effective tool for enhancing the students' motivation to learn and understand complex subjects. Although the decision to use a simulation game is made mainly by the instructor, the students' perceptions are also important in order to support its usage. The increasing interest in educational simulation games motivates us to investigate relevant factors that influence the adoption of simulation games in Software Engineering courses. Based on a theoretical adoption model and on the evaluation of a specific simulation game, we identified crucial aspects beyond the ones usually considered, such as incorporating more industrial settings phenomena and pedagogical elements. These aspects are not always considered in Software Engineering simulation games, as we identified after an evaluation. Therefore, we concluded that this class of simulation games does not address suitably the adoption attributes that we found relevant.

Keywords—simulation games; software engineering; adoption

I. INTRODUCTION

When we analyze the Software Engineering educational field, nearly every approach to teaching this subject is based on lectures and work group projects. However, judging from the dissatisfaction of industrial organizations [1], [2], it seems that these approaches are not sufficient for preparing future software engineers. In this field, simulation games represent an opportunity to present relevant concepts to the students.

Interest in using simulation games for educational purposes has steadily increased in the past years [3]. Researchers have pointed out that attracting and sustaining students' engagement and improving pedagogical outcomes are key rationale for using these games [4], [5]. The benefits of using a simulation game approach to education include, among others, practicing skills, improving critical thinking, and developing social abilities [6], [7], [8].

In the Software Engineering field, simulation games are commonly used for enhancing and reinforcing the learning and understanding of complex themes such as software processes [9], [10]. This complexity is represented by intrinsic software development characteristics such as

multiple feedback loops and the cause-effect delays [11], [12].

Simulation games in a Software Engineering curriculum suitably fits as a complementary component to lectures, projects, and readings [6], [13]. Our previous experience has demonstrated that it is important to use simulation games complementary to other educational techniques, which should be accompanied by an adequate amount of direction and guidance given to the student [7], [13].

Despite the learning potential of simulation games and the increasing interest on them, their adoption in a formal educational context remains limited [14]. This study investigates the potential factors that influence on the simulation games adoption in the academic environment.

Using a theoretical adoption model, we identified the determinants for the game adoption considering different perspectives. In order to verify the model applicability, we analyzed a specific simulation game, SPIAL [15], collecting information related to each adoption attribute and comparing them with findings in other simulation games. SPIAL is a graphical and interactive simulation game that we developed with the aim to improve Software Engineering education in dealing with the complexity of what happens in a software development organization. We evaluated SPIAL using three methodologies supported by a specific framework [13]: (1) Semiotic Inspection Method; (2) Experiment; and (3) User Test. The results have shown that crucial aspects were missing in the games' design, such as incorporating more industrial settings phenomena and pedagogical elements. This point was in agreement with a previous experiment involving students' answers and empirical observation [15]. This confirms the need to address more suitably the adoption attributes in the development of games.

The remainder of this paper is structured as follows. Section 2 outlines a discussion about the main aspects presented in this article. Section 3 describes the methodology used to evaluate the simulation games. Section 4 presents the results and Section 5 presents a discussion of them. Section 6 concludes the paper with the final considerations and future work.

II. BACKGROUND

In this section we present: (A) a discussion of adoption models from Information Technology domain and from the simulation games domain; (B) some results related to a literature review of Software Engineering simulation games; (C) the simulation game, SPIAL, used to collect detailed evidence of the discussed adoption model; and (D) a specific evaluation method used with SPIAL.

A. Technology Adoption in the Classroom

According to De Grove and others [14], the adoption of simulation games can be suitably framed in the broader context of Information Technology adoption. In this context, the studies of Venkatesh and others [16] and Sabherwal and others [17] have examined the individual's adoption and continuance usage intentions. According to them, there is a consensus that adoption is impacted by the attributes of innovation, the individual characteristics, and other contextual factors.

When considering the range of adoption studies, it is clear that a multitude of determinants has been proposed to explain the user adoption behavior [14]. Integrating all these determinants in one model would be problematic since they address too broad requirements. However, considering the crucial role of different stakeholders in deciding to adopt a new technology, different perspectives should be taken into account, such as instructors and the school context [18].

In this work we employed three attributes [19] during our evaluations: *perceived usefulness*, *perceived ease of use* and *work compatibility*. *Perceived usefulness* refers to the perceived benefits of technology adoption. *Perceived ease of use* refers to how easily a technology is adopted. *Work compatibility* describes the fit between the technology adoption and the work environment. The first two attributes came from the most basic Technology Acceptance Model (TAM) [20]. This model has been widely employed in the field of technology and education [21]. It is a robust model that can be extended with additional factors. Since we are also interested in evaluating the academic context where the game will be incorporated, we also included the *work compatibility* attribute. According to Sun and Jeyaraj [19], *work compatibility* is a critical innovation attribute and contributes significantly to the intention to adopt.

B. Simulation Games Review

Through a Systematic Literature Review, we surveyed computer-based simulation games used for teaching Software Engineering subjects [13], [22]. The selected Software Engineering simulation games are depicted in Table I, with a description of methodologies used in their evaluations.

Table I shows that basically, we can divide the simulation games in two groups: those whose final goal is to develop a software project within a certain set of constraints, and their rules are based on the Software Engineering lessons, such as SESAM, SimSE, SimJavaSP, MO-SEProcess; and those whose final goal and rules are specific to each simulation game context (e.g. to manage a

project), such as, The Incredible Manager, SimVBSE, qGame and TREG. In most of the games, the evaluations have been preliminary and informal in nature. Exceptions include SimSE, SESAM and RCAG. These evaluations results helped us to collect evidence from the adoption attributes.

TABLE I. COMPUTER-BASED SIMULATION GAMES [13].

Game	Area/Role	Evaluation
SimSE [6]	Software Engineering concepts / Project Manager	In-class use / experiment with post-questionnaire / pre-post test experiment/ observational study
SESAM [23]	Software Engineering concepts / Project Manager	In-class use / pre-post test experiment and controlled experiment
The Incredible Manager [24]	Project Management / Project Manager	Experiment with post-questionnaire
SimJavaSP [25]	Software Engineering concepts / Project Manager	Experiment with post-questionnaire
MO-SEProcess [26]	Software Engineering concepts / Team member	In-class use
SimVBSE [27]	Value-Based Software Engineering / Project Manager	Not described ⁽¹⁾
qGame [28]	Requirements Engineering / Project Manager	Not described ⁽¹⁾
TREG [29]	Requirements Engineering / Workshop facilitator	Not described ⁽¹⁾
iThink [30]	Requirement elicitation / Requirement Engineer	In-class use
SimSys [31]	Software Engineering concepts / Software Engineering Student	Not described ⁽¹⁾
SDM [32]	Software Engineering concepts / People and Project Manager	Experiment with post-questionnaire
Ameise [33]	Software Project Management / Project Manager	In-class use
Venture [34]	Social factors, cultural and linguistic differences in GSD / Software Engineer	Interview with users
eRiskGame [35]	Risk Management / Project Manager	Not described ⁽¹⁾
RCAG [36]	Requirements Collection and Analysis / Several roles	Pre-post test controlled experiment

(1) The evaluation was not described in the research paper.

C. SPI Simulation Game

SPIAL [15] (*Software Process Improvement Animated Learning Environment*) is a graphical, interactive, and adaptable simulation game (Figure 1). The game goal is to improve the Software Engineering learning, using simulation. Several Software Engineering topics are explored within the context of a Software Process Improvement project. These aspects were based on CMMI-DEV version 1.3 [37]. CMMI was chosen because it is the most widely known SPI reference model. CMMI defines 22 process areas. Each process area consists of a set of goals and these must be implemented by a set of related practices in order to satisfy the process area. Levels in CMMI describe an evolutionary path recommended for an organization to improve the processes it uses. CMMI supports two paths (or defines two forms of representation) using levels. One path, Continuous, enables a selection of process areas customized to the organization goals. The other path, Staged, enables the improvement of a set of related processes by incrementally addressing successive sets of process areas [37]. Continuous representation is defined using capability levels while Staged representation

is defined using maturity levels. In SPIAL, the simulation model can be tailored to simulate continuous or staged improvements.

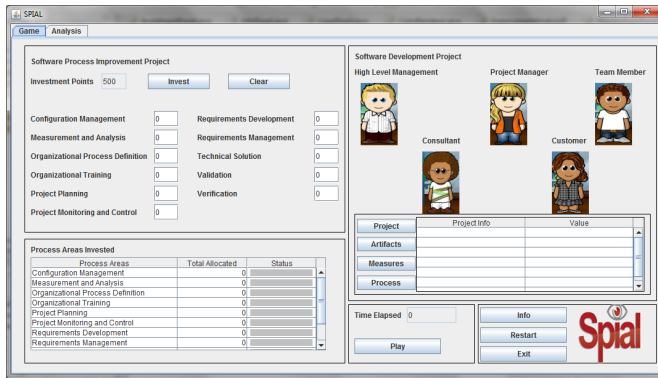

Fig. 1. SPIAL Graphical User Interface.

SPIAL was developed with the goal to provide students with a more realistic experience in software development processes within the academic environment. SPIAL allows students to practice SPI techniques and the best practices of Software Engineering. SPIAL is a single-player game in which the player takes on the role of a manager of an SPI group in a software development organization. SPIAL's scope covers both a development project and an improvement project. The player is given a process improvement task and he or she can interact with other stakeholders (high level management, project manager, team member, consultant, or customer) represented as non-player characters, i.e. a character controlled by the computer (see Figure 1). The type of improvement that is required is stated at the beginning of the game and it can include, for example, cost and defect reduction and productivity improvement. In order to complete the task, the player can make investments for improving specific process areas of a software development project. A good investment strategy will result in improvement of process areas and a bigger budget for further investments. The player can visualize project estimations, indications of process areas capability level and decide in which process areas to invest. During the development project, the player can visualize the effects of his/her selections on the outcomes (productivity, defect, cost, and time-to-market measures) and, if needed, change his/her investments. The final outcome is a score that represents how close the results are to the initial proposed target. During the game, the non-player characters communicate the effects of the player's actions through bubbles over their heads.

D. Semiotic Inspection Method

The Semiotic Inspection Method [38], [39] has been proposed within the Semiotic Engineering theoretical framework. Semiotic Engineering perceives HCI (*Human-Computer Interaction*) as a designer to user metacommunication. That is, a twofold communicative process, because the designer to user communication is achieved through user-system communication.

The system's interface is a complete and complex message sent from designers to users. This message is formed by signs. According to Peirce [40], signs are anything that stand for something (else) in someone's perspective. The message conveys to users the designers' understanding of whom the users are, what problems they want or need to solve and how to interact with the system in order to achieve their goals. This designer-to-user communication is indirect, since users understand the intended message as they interact with the interface. When users do not understand aspects of this message, a communication breakdown takes place [38].

Semiotic Engineering theory classifies the signs in an interactive system into three classes of signs: metalinguistic, static and dynamic [39]. Metalinguistic signs are signs that refer to other interface signs. They are instructions, tips, online help, error and informative messages, warnings and system documentation. Static signs express and mean the system's state; they are motionless and persistent when no interaction is taking place. Dynamic signs express and mean the system behavior. Their representations unfold and transform themselves in response to an interactive turn.

The Semiotic Inspection Method (SIM) [39] examines the designer's metacommunication that users are exposed to as they interact. The goal is to identify communication breakdowns that may take place during the user-system interaction and to reconstruct the designers' metamessage being conveyed by the system. To do so, the evaluator analyzes the message being transmitted by signs at each level.

This method is carried out in five distinct steps [39]: (1) an inspection of metalinguistic signs; (2) an inspection of static interface signs; (3) an inspection of dynamic interaction signs; (4) a contrastive comparison of designer-to-user metacommunications identified in steps (1), (2), (3); and finally (5) a conclusive appreciation of the quality of the overall designer-to-user metacommunication. At the end of steps (1), (2) and (3), the evaluator reconstructs the metamessage being conveyed by signs at that level, filling out the template of the designer to user communication. The evaluator also identifies potential communicability problems that may take place at that level. In step (4) the evaluator contrasts the metamessage generated in the previous steps and checks for inconsistencies or ambiguities among them. It is not expected that the messages generated by each sign level to be identical, but they should be consistent. Finally, in step (5), the inspector reconstructs a unified metacommunication message, judging the costs and benefits of communicative strategies identified in previous steps, and generates the evaluation report.

III. METHODOLOGY

For our work, we contrasted and compared the development and application of SPIAL with evidence collected from other simulation games. Our aim is to identify aspects that influence on the game adoption in a Software Engineering course.

Drawing an analogy with the software development processes, the game development can be structured in the following stages: problem conception, development and validation. We collected data related to these three stages in order to achieve our aim.

1) **Problem conception:** We collected additional information concerning concepts related to industrial practices and pedagogical elements [8] (discovery, practice, competition, critical thinking, goal formation and completion) employed in the game definition. These factors represent aspects that instructors may use during their lectures. In addition, we searched for information that would identify who participated in the game conceptual definition. The innovation aspects were also considered as they are important for the verification of the work compatibility attribute.

2) **Development:** Since our goal is to evaluate factors that ease the simulation game adoption, we focused more on interaction aspects than on implementation issues. In this stage, we collected information regarding the graphical user interface, focusing on elements that motivate and promote students' engagement and learning. In addition, we identified the proposed integration possibilities of the simulation game with the lectures, for instance, whether it is given an introductory explanation about the game, or whether there is an analysis of the achieved results together with the students. They are important for the verification of the work compatibility and perceived ease of use attributes.

3) **Validation:** Specific validation techniques, such as experiments are valuable tools for all practitioners who are involved in evaluating and choosing between different methods, techniques, languages and tools [41]. We identified which stakeholders were involved in the validation step, the methodologies used to validate, and whether the expected results were achieved. This information is important to define the work compatibility and perceived usefulness. Table II lists the mapping between the information collected and the innovation attributes.

For our data analysis, we extracted text containing information, presented in Table II, from SPIAL and other simulation games studies. The evidence developed in this research rests mainly on the identification and analysis of this information. Reliability and validity are dependent on the careful analysis of the research papers.

TABLE II. MAPPING ATTRIBUTES.

Innovation attribute	Information collected
Work compatibility	Concepts, pedagogical element, integration with the class, stakeholders involved in the problem definition and in validation.
Perceived usefulness	Benefits and stakeholders involved in validation.
Perceived ease of use	Integration with the class, and graphical user interface.

IV. RESULTS

In this section we describe our empirical findings. We detailed in each section the findings related to SPIAL comparing with findings related to other simulation games, which were presented in Table I.

A. Problem conception

During SPIAL development we were concerned about representing situations close to the reality of the industrial environment. Therefore, we investigate the domain of our simulation game. Through a literature review, we gained an up-to-date view of the SPI area, allowing us to identify and characterize the actual results of SPI initiatives. In addition, we collected 57 Software Engineering rules from textbooks and other Software Engineering simulation games. Both rules and industrial practices were used to represent the game behavior, to teach the best practices and to calibrate the simulation model.

Comparing SPIAL with other games, we observed that in some of them, such as SESAM, SimSE and MOSEProcess, the rules are also based on Software Engineering lessons. However, we did not find a detailed investigation about the industrial practices as in SPIAL. Other observation is that the game designers, in most cases, were involved with the Software Engineering course, such as in Deliver!, SimSE, and SESAM and there were no deep investigation whether the game meets the needs of other educational environments. The designers locally tried to propose a solution to their lectures, which were mainly based on their feelings and experience.

Analyzing the pedagogical elements we observed that these games have a considerable number of common aspects. The designers supposed users using a "trial and error" strategy, since the signs presented at the interface are limited in their message communication. The players discover the knowledge as they play the game, critically thinking about their decisions. In addition the goal is clearly stated at the game beginning. The competition is not well explored; one counter-example is qGame that presents a ranking of the best players. Only few games, such as The Incredible Manager and SimVBSE, do not use score as an evaluation tool.

B. Development

The games' interfaces were, in general, quite simple, employing basically static elements, such as in SPIAL. Exceptions include the Second Life games, such as MOSE-Process and TREG. In the set of the analyzed games, we found essential features that enhance motivation and, in consequence, the effectiveness of learning which are: not too easy nor too difficult life-like challenges (e.g. constraints on budget, defects, and time); interaction; a mechanism that provides feedback from the other team members (e.g. dialogues); graphical representation; and some indication of performance (e.g. score). Not all games presented random events, but this is also an important feature to enhance challenge and in consequence motivation. Few games provide some adaptation features

(e.g. SimSE, SPIAL, and The Incredible Manager), this is due to the complexity of design and interaction of the learning environment. qGame is an example of game which allows different levels of difficulty.

When considering the initial training, SimSE differs from other simulation games. SimSE designers provided supporting materials, including video tutorials and manuals to different stakeholders. Unfortunately, none of the assessed simulation games provided any guidance for carrying out the revisiting session which is generally referred to as debriefing sessions [42]. When executing a debriefing session, it is possible to evaluate how close the players' performance is to the target and what is needed to bridge this gap.

C. Evaluation

As presented in Table I, the evaluations mostly have been preliminary and informal in nature – SimSE, SESAM and RCAG are exceptions. However, even with these informal evaluations, there is some indication of their learning effectiveness. In SPIAL, we used the student appraisal, like in the other games, but we also brought other evaluation techniques. Part of our approach was inspired by SimSE, since it is an example of simulation game that more extensively evaluated the learning process it promotes.

We evaluated SPIAL using three methodologies supported by a specific framework [13]: (1) Semiotic Inspection Method; (2) Experiment; and (3) User Test.

C.1 Semiotic Inspection Method

An inspector conducted the first evaluation of SPIAL, carrying out the technical application of SIM. In this case, the inspector scenario is a student playing SPIAL.

After conducting all SIM steps, a unified analysis was produced, highlighting the main communication breakdowns. The analysis of SPIAL showed that getting the whole message is the result of "trial and error" interaction. A number of feedback information was presented during the whole game, such as measurement charts and improvement analyses. However, important aspects to understand the core behavior were missing, such as the reason why sometimes investments do not produce any improvement. In addition, some interface improvements should be done to allow a better interaction, moving elements from the analysis tab to the main tab. We produced a new game version, with some modifications, in order to provide more guidance to players. A more elaborated interface design was left as a future work; we only made changes related to feedback with the aim to release, as soon as possible, a new game version for the experimental activities.

C.2 Experiment

We carried out two experiments with undergraduate students of a Software Engineering course. The Software Engineering course at the Department of Computer Science at Federal University of Minas Gerais, Brazil, is taught in one semester (60 hour class).

In the first experiment our aim was to gain a better understanding of SPIAL effectiveness as an educational tool. We also determined the strengths and weaknesses of SPIAL through the feedback of the students who played it. We recruited 12 undergraduate Computer Science students to participate in this pilot experiment (one student gave up, leaving us with 11 students). In both experiments, students had a previous training about CMMI and basic Software Engineering concepts in the undergraduate course. Since this experiment was conducted during the beginning of the semester, we decided to give a brief training session in order to reinforce these concepts. This training session took 30 minutes. Then each student answered a background and a pre-test questionnaire, before playing SPIAL, and a post-test, after playing it.

On average, students found the game quite enjoyable and they had fun during the game play. They also felt that the game duration is appropriate and it is relatively easy to play. They agreed about adopting this game in a Software Engineering course as a complementary approach. They moderately learned new concepts; however, they felt this game is more successful in reinforcing concepts taught in Software Engineering course than teaching new concepts.

This pilot experiment showed that SPIAL does indeed seem to have potential to be a useful tool in teaching Software Engineering. The students' opinion gave us a valuable guidance about the ways that SPIAL needed to be enhanced.

In the second experiment, we applied UGALCO framework [13] in order to evaluate the game experience, adaptivity, learning experience and usability dimensions. We structured the experiment in the same way as the first one. In total, 16 students participated in this experiment and 15 completed. The students' answers were mapped to a value range $R = [0,1]$, where a "strong negative" is encoded as "0", a "weak negative" as "0.25", undecided as "0.5", "positive" as "0.75", and a "strong positive" as "1". The Communicability was evaluated through the SIM application. The learning experience was also evaluated through specific questions about SPI knowledge. These questions were organized according to the Bloom's Taxonomy [43]. This set of questions was presented to the students in a pre and post test format. One example of SPI question presented in both tests is: *List three metrics that can be used to monitor a Software Process Improvement initiative (Bloom's category: Knowledge on the remembering level)*. Table IV presents the average results.

The highest scored attribute was the learnability, i. e. the students understood how the game play works. The least scored was the learning goals, in which students were able to reinforce concepts presented in the lectures. Thus, they felt that they did not gain a great amount of new knowledge.

When we evaluated the number of correct SPI answers in the pre and post test, there is no statistical difference, i. e. we were not able to track the real learning effect considering this kind of evaluation.

TABLE IV. AVERAGE RESULTS FOR UGALCO'S ATTRIBUTES [13].

Dimension	Attribute	Avg.
Game Experience	Challenge	0,5
	Competence	0,7
	Immersion	0,7
	Positive affect	0,7
Adaptivity	Cognitive and motivational aspects	0,6
Learning Experience	Learning goals	0,5
	Content appropriateness	0,6
Usability	Operability	0,5
	Understandability	0,6
	Learnability	0,8
	Attractiveness	0,5
	Satisfaction	0,6

A. User Test

Although the first two evaluations provided us important data, the insight gained into an individual student's play process was limited to questionnaires. Therefore, we conducted a simple user test, where two students were observed and then interviewed about their experience.

The user test occurred in a one-to-one setting – one subject and one evaluator. As corroborating with the previous experiments, both students reported that they reinforced SPI concepts playing SPIAL, but they were not sure about what new concepts were presented to them. They failed in achieving the game goals in their first attempt. After the completion of one failed game, they hurriedly and eagerly started a new one with the aim to succeed. At the end, we observed that they came with similar new knowledge about the game strategy.

One student reported that he was not anymore challenged and interested in playing the game after discovering its fixed rules and behavior. Both students indicated that some functionalities, providing quite important feedback, were not easy to find, and they suggested interface redesign. They agreed that they learned using the strategy of “trial and error”. They were engaged when playing SPIAL. This was evident in their body language and their comments during the game play. Both students agreed about adopting SPIAL in a Software Engineering course as a complementary approach.

V. DISCUSSION

We had collected some indications that can help verifying the issues of adopting the Software Engineering simulation games. This analysis is based on the results presented in the previous sections and it is focused on the adoption issues. We structure our results in the findings described below: (F1) restricted number of represented industrial settings phenomena; (F2) lack of academic context analysis; (F3) insufficient evaluation; (F4) restricted interface elements; (F5) insufficient representation of pedagogical elements; and (F6) lack of supporting material.

F1: The main goal of simulation games is to bring to the classroom the use of highly-realistic simulators to illustrate to students, using real world data, the phenomena of Software Engineering working practices. As we pointed out, there was no comprehensive investigation of industrial phenomena with the aim to incorporate the latter in these

games. In SPIAL, we identified the core virtual world processes from the analysis of SPI initiatives reported by organizations in research papers. In most of the research studies, it was not defined the improvement context. This brought some difficulties during the reuse of information and restricted the number of phenomena represented into the simulation game. We observed this problem when we conducted the validations. Students were undecided regarding some aspects of SPI initiatives presented in SPIAL, in some cases they felt that they learned only basic new concepts (i.e. not advanced concepts) of SPI, and some students reported that they only learned the basics about the industrial settings of SPI initiatives. When analyzing the causes of this limitation, we were hindered by the difficulty to find Software Engineering data in the literature or with appropriate quality level. Even when available, industrial data are often noisy.

F2: Prior to any simulation game development it would be interesting to analyze the academic context where they would be incorporated. This includes the analysis of the instructors', universities' and students' needs. As we observed, this analysis was quite superficial or non-existent in the Software Engineering simulation games. In SPIAL development, for example, we have studied the common mistakes of students in the team-based projects and the instructor impressions of the students' main difficulties. In general, more investments are needed in order to define the game context, which facilitates the analysis of the game play benefits.

F3: There are different perspectives involved in the game design and development that should be suitably addressed during the evaluation. In our previous discussion, we identified: (i) different stakeholders (instructors, designers and students) needs and expectations; (ii) generalization of the game usage, i.e. evaluation in other contexts (e.g., universities, classes); (iii) improvement of the game evaluation *per se*, e.g. carrying out formal experiments; and (iv) performing the evaluation after the game play, using, for instance, the debriefing sessions. These additional experiments and evaluations are important to verify the potential of the simulation games as educational tools.

F4: It is common for the simulation games to have graphical user interfaces in which the simulated physical surroundings are displayed, creating a fun, game-like atmosphere. Most of the games employed static and simple elements in their design. In SPIAL's evaluations, a better interface design was pointed out as an improvement opportunity. Additional enjoyment, motivation and engagement can be achieved using more sophisticated game features and dynamics. This will ease the learning about a particular Software Engineering process, making it more memorable, and hence, more effective.

F5: An analysis of the pedagogical elements should be considered an important step during the game development. In SPIAL, we did not address this task in a suitable way, reflecting in some negative feedback during the experiments. This is also true for the other simulation games. Valuable areas of research include the improvement

of the learning evaluation mechanisms, and evaluation of the effects of competition and communication among players.

F6: Developing a new simulation game involves not only the creation of the software but also development of supporting material. As we discussed above, it is not usual among the analyzed Software Engineering simulation games to have this type of documents, including tutorials, manuals, and supporting web pages. This impacts directly on the adoption of the game in wider and diverse contexts.

In general, these games did not address suitably the adoption attributes that we found relevant, highlighting that there are still important aspects to be researched and enhanced in the field of Software Engineering education and simulation game development.

VI. CONCLUSION

This work presented a study of the challenges and opportunities for adopting simulation games in Software Engineering classes. We analyzed a specific simulation game, SPIAL, collecting information related to adoption attributes in different development stages. The adoption model covers three attributes: perceived usefulness, perceived ease of use, and work compatibility. Finally, we compared the findings with evidence collected from other Software Engineering simulation games.

Our experience with this study has highlighted some important aspects that can be used to enhance the field of Software Engineering education and simulation game development. The most concrete result is the set of issues that emerged during our analysis. These issues can guide new developers and instructors in the design and selection of educational simulation games. It was identified: (i) the restricted number of represented industrial settings phenomena; (ii) the lack of academic context analysis involving instructors', universities' and students' needs; (iii) insufficient evaluations of (iii.1) different stakeholders perspectives, (iii.2) of the game itself and (iii.3) after the game play; (iv) restricted elements used in the interface design; (v) insufficient representation of pedagogical elements; and (vi) lack of supporting material.

As a future work, we plan to address some of these issues in the SPIAL environment, mainly incorporating other phenomena that happen in the industry and improving the supporting material and interface design. We will also propose a game development process that will incorporate the issues that we found relevant.

Digital Lockdown: A 3D Adventure Game for Engineering Education

Rasha Morsi, Shawn Mull

Engineering Department

Norfolk State University

Norfolk, Virginia, USA

rmorsi@nsu.edu, s.j.mull@spartans.nsu.edu

Abstract— Gaming in education has gained a great deal of interest for its potential positive impact on student learning. Video games can be a powerful learning tool, with the potential of reaching a wide range of people with diverse learning styles. Students in today's college classroom are known as 'digital natives'; those who grew up with technology all around them (cell phones, laptops, and tablets). These students often know more about technology than their parents and teachers. Games have a positive impact on how young people learn complex things. Content, skills, creativeness, and system thinking are just a few things that can be learned from games. This paper focuses on the design and implementation of a 3D educational game for deployment on the PC and Mac. Currently, no truly 3D games are available that focus on teaching core concepts in Digital Logic Design or Electrical and Computer Engineering concepts in general. This work presents an overall design and implementation of an educational 3D adventure game to address Number Systems, Boolean algebra, and Combinational and Logic Design in the scope of the Electrical and Computer Engineering curricula. Digital Lockdown is a game, developed in Unity 3D, that takes place in an outer space engineering research facility. The research facility has been placed on digital lockdown due to an experiment gone wrong and the player must use his/her knowledge of digital logic to override the lockdown protocols. The player is faced with tasks that help assess basic knowledge of digital logic. The game also contains learning zones where the player can go in order to learn the information needed to complete the tasks.

Keywords—*Engineering education; serious games; digital design; games in education*

I. INTRODUCTION

In the education arena, 'gaming in education' has gained a great deal of interest for its promising positive impact that it can have on students. The natural behavior of the way students learn has changed with the rapid advancement of new technologies over the last few years. In most cases, if not all, students learn the best when they are motivated and have an interest in the subject matter. It is rare that a student will like every subject that s/he is taught, however, by introducing the subject matter in the form of a game, a motivation to learn can be created.

The teaching methods often used in the higher education system include lectures and lab classes. The method that is used most often is lectures [2]. Jeremy Schneider, author of the book "Chalkboard: What's Wrong with School and how to Fix It", stated that it is "now possible to teach students effectively and respectfully. Advances in technology allow for personalized instruction, fascinating content, direct immersion in learning, immediate feedback, and the opportunity for mastery. Yet modern education ignores this potential, leaving classrooms essentially unchanged for more than a century." [1]

In a typical lecture, a teacher will stand in front of the class teaching while the students sit and take notes. One problem with this method is one teacher cannot meet the needs of all students for various reasons beyond the teacher's control. Students in the same class may not have the same learning style as others. This can cause some students to learn at a slower pace while others to learn at a faster one. To compensate for this, instructors sometimes try teaching at a medium pace. However, when this is done the students who learn at a slower pace start to fall behind and the students who learn faster become bored and lose focus [1]. This makes it hard for "lectures to meet the optimal learning pace of all students because one teacher cannot deliver dozens of customized lessons simultaneously [1]."

Bill Gates, the chairman of Microsoft, made an interesting statement at the 2005 National Education Summit address on high schools. He stated [3], "Training the workforce of tomorrow with the high schools of today is like trying to teach kids about today's computers on a 50-year-old mainframe. It's the wrong tool for the time." The way students learn has evolved to a point where traditional teaching methods of sitting in a lecture room for hours at a time listening to a professor talk and taking down notes are no longer ideal. Students are failing to retain the information presented to them in the classroom and sometimes divert their attention to more entertaining things such as their mobile devices.

During a summit on Educational Games, held by the Federation of American Scientists, the Entertainment Software Association, and the National Science Foundation, approximately 100 experts were called to discuss games in education [4]. It was proposed that "people acquire new knowledge and complex skills from game play [4]." These

discussions among others have presented a need for the development of games for education. These games need to be both educational and entertaining at the same time. Edutainment is a term that has been coined to describe content that is designed to educate and entertain at the same time. Digital Lockdown is a game designed to be just that, an edutainment experience for engineering students.

II. BACKGROUND

Many different types of games exist, however, they all fall into two main categories, 'Games' and 'Serious Games'. A game can be defined as "A system in which players engage in an artificial conflict, defined by rules that result in a quantifiable outcome [5]." Some characteristics that make up a game are achievable goals and rewards.

In digital games, which is the focus of this work, there are goals that the player or players are trying to reach. "The act of achieving goals is rewarding and reinforces actions that allow individuals to continue completing goals [6]." Achieving goals can be anything such as completing a game or unlocking new content in a game. This cycle of completing goals and being rewarded can keep a player engaged for hours on end [6].

According to Digital Marketing Ramblings [7], each month, approximately 263 million people play Angry Birds. This is just one of many games played daily worldwide. Games can be fun, engaging and sometimes addictive and have the ability to reach a lot of people. Some research has been conducted to assess the use of games in education. More needs to be done. Presented below are data and sample research findings that help present the case for the need for games in higher education, especially in engineering education.

A. The Status of Games in Education

In 2014, the Entertainment Software Association (ESA) conducted an industry survey where 59% of Americans were found to regularly play video games, 32% of which are between ages 18 and 35 [8]. Another significant statistic is that 53% of Americans who own a device to play games on, do so using a smartphone, and 41% play games using a wireless device [8]. Game sales have also been on the rise. In 2013, consumers spent more than \$20 billion on digital games. This number is expected to grow even more in the upcoming years [9].

Using games in education has been traditionally employed in the K-12 arena [10], [11], [12]. Higher education has been lagging behind despite the fact that digital natives have been in college classrooms for years. A Study by the National Association of Advisors for Computers in Education (NAACE) was conducted involving 800 students at Long Field Academy to see the effect of mobile devices used in education. Apps from the Apple App Store that pertained to the subject matter of a class were used on the iPad by students as an aid to help understand basic concepts of the subject matter. These apps included graphing apps for math, GarageBand for music, Brushes finger painting app for art, and many more. Students were able to communicate directly with the teacher from the iPad through email [13]. The results showed that 69% of the

students felt more motivated to learn and the average grade for students had improved.

Some work has been conducted in the higher education area [15] [16] where professors have seen the positive effect video games can have on education. In a report from McGraw-Hill Education, "Gaming has been one of the most popular trends in education in recent years. While all students have their own unique and preferred style, learning by actively engaging with a subject is a learning method shown to appeal to a large number of today's students [16]." McGraw education released a game called "Government in Action". This game has proven very useful in the classroom and is gradually being accepted by students with more than 750,000 students playing each year. One professor, Jason Seitz, who uses the game in his classroom, says "Government in Action helps my students tie all of the concepts in my course together to develop a deeper understanding and knowledge of the subject [16]."

III. METHODOLOGY

Digital Lockdown is currently developed for the PC with implementation for mobile devices under development.

A. Game Design

Digital Lockdown is a 3D educational adventure game that takes place in an outer space engineering research facility. The research facility has been placed on digital lock down due an AI drone project gone wrong and the AI drones have taken over the space station. To make matters worse, the research facility is going to self-destruct and now the player must use his/her knowledge of digital logic to override the lock down protocols and escape. The game is designed to allow the player to practice solving problems dealing with number systems, Boolean algebra, and combinational logic design. There are learning areas throughout the game that the player will go to in order to learn the information needed to complete each task.

B. Game Characters

Digital Lockdown has various characters that the player will come across throughout the game. Some of the characters will be friendly and help guide the player along the journey. The characters involved in this game are as follows:

- Player (main) – the player is an Electronics Engineer conducting research at the Creative Gaming and Simulation (CGS) space station. The player is controlled by the user throughout the length of the game.
- CGS Drone, Patrol Bot, and Mine Bot (foe) – are artificial intelligence (AI) enemies that are trying to take over the space station.
- Commander Simmons (friend) – the commander of the CGS space station. His role in the game is to guide the player to the shuttle hangar.

C. Level Design

In Digital Lockdown the player goes through 2 levels: Level 1 "The Escape" and Level 2 "The Hangar." Throughout

level 1, there are a combination of experiences including learning, assessment, and gameplay that correspond to the overall story of the game.

Fig. 1 Digital lockdown level design

Level 1	Level 2
<ul style="list-style-type: none"> Number Systems Boolean Algebra Combinational Logic Circuit Design 	<ul style="list-style-type: none"> K-Map minimization Combinational Logic Circuit Design

Level 1 starts with the player in the living quarters of the Creative Gaming and Simulation space station. When the level starts, a prompt appears giving the player background information about what is going on and what s/he needs to do. Once the player enters a name and selects ‘start’, the level will begin.

The first object the player can interact with in the game is the learning table for number systems (Figure 2). At this table the player can learn/refresh basic knowledge of digital logic concepts. Each table that the player interacts with informs him/her about a different concept pertaining to digital logic. Topics covered are: Number Systems, Boolean algebra, KMap minimization, and Combinational Logic Circuit Design. When the player feels comfortable enough with number systems, for example, s/he can attempt to complete the various tasks throughout the game to escape from the space station. Once the player has completed all the tasks in level one and reaches the elevator to go to the hanger, level 1 will end and the player will be brought to a summary screen which provides gameplay feedback (Figure 2). After reviewing the summary, the player will be taken to level 2 (“The Hanger”) after selecting the “Next Mission” button.

The hanger level (Figure 3) is the last level in the game in which the player must complete the damaged circuit in the hanger control room in order to disable the self-destruct protocol within 10 minutes. To do this, the player must minimize the given Boolean expression using KMaps. After completing the assessment, the player will then have to fight his/her way to the hanger bay entrance to escape off the space station.

Fig. 2 Digital lockdown level design

Fig. 3 Level 2: The hanger (showing enemies)

IV. GAME PLAY

A. Assessments

Digital Lockdown is developed to include assessments as well as fun gameplay. While the player is going through the game and achieving goals/completing tasks, s/he has to fight back against the CGS enemies. These enemies (Figure 4) attack randomly which affects the player’s health score (Figure 5).

Fig. 4 CGS enemies

Fig. 5 Game screen showing score, menu, and messages

Figure 6 shows one of the assessments in the game – Binary Conversions. Every door the player has to go through includes this assessment. If the player does not provide the correct conversion, the door will not open and the player can try again. Conversion is entered by clicking the red and green lights above the door to create the binary combination in question.

Fig. 6 Binary conversion assessment

The binary conversion assessment is randomly generated however the truth tables and Boolean expressions used are randomly selected from a predefined list of questions.

B. 3D Content Interaction

The game provides a combination of 2D and 3D interaction in order to enter the responses to the digital design problems. Figure 6 shows the 3D interaction of clicking on the lights to enter a binary combination. Figure 7 shows the 3D KMap problem the player has to solve in order to escape off the ship. In order to enter a value in a cell, the player clicks on the cell and it rotates between blank, 0, and 1 values. The player then groups the cells (shown in Figure 7 by cell text turning green) and enters the minimized expression. Once the minimized expression is generated, the player can then build the circuit (Figure 8)

Fig. 7 Truth table information HUD for KMap problem

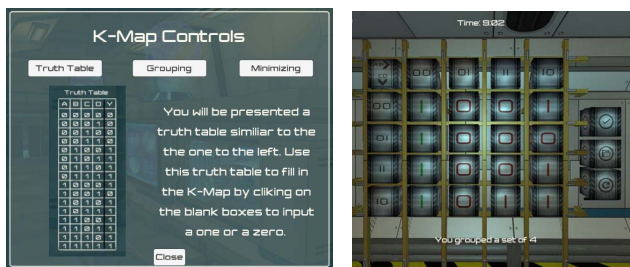

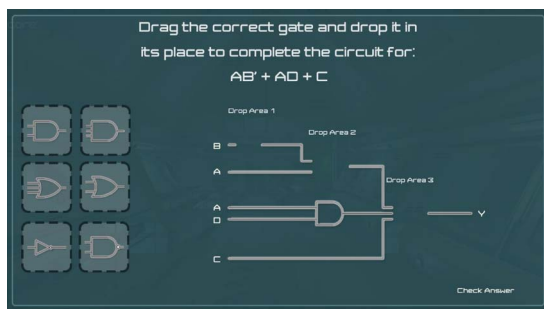

Fig. 8 Circuit design

V. CONCLUSION

A 3D adventure game comprised of two levels was developed using Unity 3D for use as a resource for Digital Logic Design. The game contains learning content, adventure gameplay, and assessment of learned content. Content and assessments are designed in both 2D and 3D interfaces. The game is designed to be fun while still incorporating education. Content includes decimal to binary conversions, Boolean minimization, KMap minimization, and combinational circuit design. Future work includes creation of gameplay using sequential logic and evaluating the game using the developed evaluation process. The game is expected to be formally evaluated in fall 2015 and spring 2016. Future work also includes converting the question generation for the remainder of the assessment to random generation of problems. This will involve a change in the script-based assessment to allow just-in-time assessment of textual input from the player's response.

Email: armando.toda@gmail.com

Abstract—Gamification has achieved many positive outcomes in many fields, ranging from economics to education. This method consists in applying game concepts, mechanics and aesthetics in non-gaming applications, aiming to improve a person or group's engagement and commitment to perform a task. These concepts can range from extrinsic motivators as points, levels, leaderboards and achievements, to intrinsic ones as competition, cooperation, sense of achievement and decision making. It also have been proved that these concepts also aids in the construction and improvement of cognitive, social and emotional behaviour of a person or group. Based on the previous work of developing an online learning environment to aid in Math Lessons on basic education, this paper presents the evaluation of a Gamified Online System (SiGMa) focused on Math problems solving. The application contains a module that randomizes the values of the users' selected problems, which are divided in three areas (Arithmetic, Combinatorics and Geometry) in order to make them memorize the logic rather than answers when solving Math based questions. The system was also implemented with Gamification concepts to improve the engagement of students. The tests were applied with a group of 30 Math teachers that were exposed to the system for 3 consecutive months. Those professionals evaluated the usability and pedagogical properties of the Gamification concepts implemented within the application as: problem solving, correct classification, difficulty, context, engagement, reflection, support, interaction, visual interface, information, error recovery, message exchange. The tests also evaluated the relevance of each one of the implemented gamification concepts as: goals, rewards, points, levels, progress, time pressure, achievements, leaderboards, chances, renewal and relevant statistical information. The tests achieved positive results, above the average stipulated by the authors in the evaluation. The paper also present the preliminary tests that were made with a group of selected students, in order to test the systems' efficiency.

I. INTRODUCTION

The advent in IT area allowed the emergence of technologies to aid in the learning process. This emergence can be represented in the form of new Learning Objects [1] as Virtual Learning Environments and Game based learning methods [2].

The second one can be described as the use of digital games and its core concepts to aid in the learning process. Those concepts can be divided in groups, depending on the author, to describe the Ludification of Culture as stated by [3]: Use of games, game elements and playful interactions.

Among the Use of Games concepts is inserted the Gam-

ification concept. This consists in using gaming elements in non-game contexts [4]. This process is often used when the application, or method, focus at training or conducting an specific user behavior [5].

This concept is also useful when implemented within application since it provides statistical data [6]. This data can be used to enhance the gamification process, consequently improving the learning process. Even though, there is not a formalization of evaluation process in order to measure its efficiency [7].

Based on the above, this work aims to present the short term evaluation of the Gamified Math System, of [8], after a 3 months of use. This evaluation focus at verify the pedagogical properties of the system in order to prepare it to use within a classroom.

This work is divided as follows: Section II aims to explain some concepts related to game-based learning and games in education. Section III presents the gamification concepts. Section IV presents the implemented system and the method of evaluation of the study while section V presents the outcomes. Finally, section VI presents a brief discussion followed by the conclusions and future works.

II. GAME-BASED LEARNING

The influence of computers in education can be seen on the emergence of new Learning Objects (LO), which can be defined as an entity focused on knowledge construction [1].

According to [9], the young generation is more immerse within the new technological advances, acquiring its knowledge through the interaction within it. According to [10], one of the modalities that are gaining adepts are digital games and simulations.

The author [10] also defends that those environments can be explored through a constructivist thinking, since these are focused on problem solution. Therefore classifying it as Interactive Learning Environments. This occurs, according to [2] because the player is in a constant learning process within the game, due the continuous feedback given by the system to evaluate the players actions.

Thus, studies about the integration between digital games and education have emerged in the last decade. These studies

aims to identify the properties and characteristics within these systems and how it influences the educational process of students and teachers, positively [11] [12].

Those aided in the emergence of what some researchers call Game based learning, which according to [4] can be divided in 3 main groups: Serious Games, Gamification and Gameful Design. Those concepts derives from digital games.

According to [13], Gameful Design is the game logic applied to the user experience. It manifests through the aesthetic elements and the usability of the system, rather the game elements itself. As for Serious games, this concept can be defined as the game itself aimed to train a group or individual [14]. The main differences can be seen on Table I:

TABLE I. GROUPS DIVISION ACCORDING TO [4]

	Game logic	Game elements	Game	Fun
Gameful Design	X			
Gamification	X	X		
Serious Games	X	X	X	
Digital Game	X	X	X	X

Table I demonstrates the groups division, where each one have its own properties in a way these properties does not interfere with another one. Figure 1 demonstrates a graph with a summary of the primary objectives of each group.

Fig. 1. Summary of primary objectives according to Deterding [15]

As can be seen on Figure 1 depending of the direction, the concepts has more of each one of the attributes. It also demonstrates the summary of the concepts, gamification focusing on game elements with a purpose not involving gameplay. Gamification, for instance, involves the use of game logic and elements (Table I) with an intent (Figure 1).

This purpose can mean the improving of a person, or group, engagement and motivation, training, or behavioural adaptance. This however, does not involve a directly gameplay as a serious game or digital game, meaning that the users' interaction are limited to the extense of the gamified application or method.

III. GAMIFICATION

Gamification can be defined as the use of game mechanics, concepts and aesthetics outside its main scope, aiming to motivate, engage, training, education or modify a behavior through intrinsic and extrinsic motivators [16], [6], [5], [4].

This occurs due the game's property to maintain the player engaged for a long time period. This property was the motivation of studies that focus on understanding te engagement effect [17]. It works on through the extraction of the game elements. However, firstly it is necessary to understand some digital game concepts.

A. Concepts and Mechanics

Reseachers in the past few years tried to conceptualize digital game concepts in order study and identify its properties. The author [18] proposed a framework (Game frame) to use game concepts within ludic application, extracting 19 game concepts that can be observed on Table II.

TABLE II. GAMIFICATION CONCEPTS EXTRACTED BY DIGNAN [18]

Objectives	Competition	Opportunities	Time pressure
Scarcity	Puzzles	Novelty	Levels
Social pressure	Cooperation	Currency	Renovation
Decision	Information	Progress	Points
Sensation	Rewards	Classification	

Table II presents the concepts extracted by [18]. He explains that each one has its own advantages and disadvantages. However it is not necessary the use of every concept in an application in order to achieve the desired outcome.

This concept is also explored by [6]. The authors discuss the implementation of gamification, where they explain that is needed a study about what is intended to gamify. This occurs due many thoughts that gamification is an universal panacea [6] however to achieve the desirable results, a deep research on the field is needed.

IV. SiGMA

A. System and Method description

The Gamified Math System (SiGMA) is an application aiming at student's training of math concept. It is implemented with gamification concepts to engage and motivate the students in problem solving activities. This work aims to continue the work made by [8] by focusing on the evaluation of the system.

The system is composed in 2 main modules: User (students) and Administrator. The User module contains the problem solving functionality, where the user is able to select a Theme, followed by a subtheme and its level. The theme and levels representation are based on the ones defined by the committee of Brazilian Math Olympics of Public Schools (OBMEP): Arithmetics, Combinatorics and Geometry, levels 1 to 3.

The subthemes were divided by a process, created by the authors, to insert the questions. This process assured that each question would have its variables values randomized, in order that the user is able to solve the same question many times without memorizing the answer but rather the logic. The

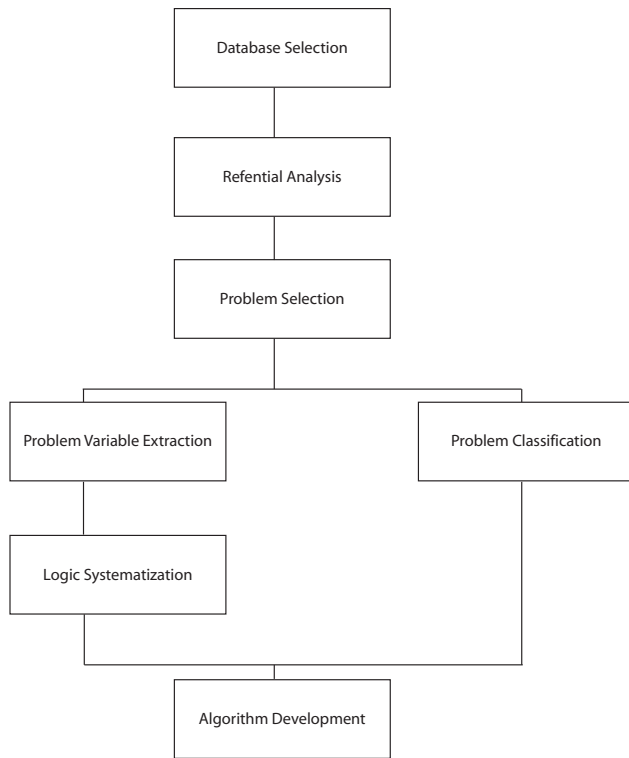

Fig. 2. Process flux

process began by selecting the databases, as can be seen on Figure 2.

As can be seen on Figure 2 Followed by the Database selection, we choose which questions are going to be codified, in order to do so we divide the Selection Phase in two fluxs, one to identify its subtheme and the other to identify the logic of the answer. By identifying those two properties, but mainly the problem logic, we can turn the question in an algorithm that will be codified to be inserted within the system.

The subthemes were based on the National Math Curriculum, and extracted with the aid of Math teachers. Initially, as the system focused on Arithmetics theme, we were able to identify 10 subthemes in 93 questions that were analysed by the process. Each question is able to belong to one or more groups. This division can be seen as:

- Basic Operations
- Logical Problems
- Greatest Common Divisor
- Least Common Multiple
- Fractions
- Factorization
- Euclidean Division
- Divisibility Criteria
- Periodic Phenomena
- Multiple and Dividers

To exemplify this method, we selected the following question from OBMEP 2010 database: Question 8 - Maria's Car. This questions was inserted in the Basic Operations subgroup and its variables are bolded within the text.

8. Maria's Car - The **alcohol liter costs \$0.75**. Maria's car is able to **travel 25km with 3 liters of alcohol**. How many dollars Maria will spend to **travel 600km**?

This problem contains the following variables: liter cost (0.75), liter consumed (3), mileage distance (25), and travelled distance (600). To solve this problem it is firstly necessary to find the mileage per liter (seen on Equation 1) to find the answer seen on Equation 2.

$$mileageperliter = \frac{mileagedistance}{literconsumed} \quad (1)$$

$$answer = \frac{travelleddistance \times litercost}{mileageperliter} \quad (2)$$

By analysing the equations generated to solve the problem, it is possible to create the algorithm to generate the random values of each variable. Through this process, we generate the algorithm 1 that describes the logic of the problem.

Algorithm 1 Maria's Car

```

liter cost ← random(0,10..3,00)
mileage distance ← random(20..50)
travelled distance ← random(100..1000)
liter consumed ← random(2..5)
mileage per liter ← mileage distance / liter consumed
answer←(travelled distance×liter cost)/mileage per liter

```

Algorithm 1 follows the same logic used to solve the questions. The values can be randomly generated which makes the system more dynamic and force the students to think about the logic rather the answer of each question. This algorithm is converted to a PHP code that will be inserted within the system.

B. System Gamification

In order to implement the gamification of the system, the authors selected the game concepts based on the division made by Dignan [18]: Points, levels, progress, classification, rewards, time pressure, opportunities, renovation, novelty, information and objective.

Points are given to the users when those scores a question. By accumulating those points, the user is able to achieve a new level which can also represent the progress within the system. The classification can be observed in the division of two main modules (User and Administrator), as for the Rewards are represented by the achievements implemented within the system.

Those achievements are directly influenced by the user points, levels and time pressure (represented in the system through a counter). The opportunities can be seen through the access to each question, equal to all users. Renovation

and novelty can be represented through the insertion of new questions and the logic of the system, that generates new values to the same question.

The data is represented in the form of statistics that can be seen on the player profile. Finally, the system objective is focusing at training the students in math concepts and problem solving.

C. The study

To evaluate the system, the authors initially began by evaluating the functionalities and pedagogical properties of the system through a questionnaire, based on Whitton's research [19]. The authors created this method to evaluate and validate educational and training applications with game-based learning concepts.

This evaluation consists in verifying two criteria: Development and Interface. The first one aims to analyse the functionalities of the system, and some pedagogical properties. The second focus on the visual features within the application (Table III).

TABLE III. CRITERIA ESTABLISHED BY WHITTON [19]

Development	Interface
Active learning	Flexible interaction
Engagement	Social Support
Adequation	Easy navigation
Reflection	User control
Equal opportunities	Error recovery
Continuous support	Visual interface

Table III demonstrates the criteria and its attributes to be evaluated. The evaluation of the system began with a group of math teachers that lasted 3 months. The interviewed group of math teachers, evaluated those properties in order for the authors prepare the system to be applied with students.

This second evaluation also aims to evaluate each one of the gamification concepts implemented within the system, in order to analyse its effectiveness and acceptability by the math teachers.

V. RESULTS

The evaluation initially began with a group of 30 math teachers that would be interacting with the system for 3 months [8]. This initial evaluation did not analysed or questioned the teachers about the acceptance of each of the game elements, since not all of them were implemented. However, this questionnaire intended to evaluate the current state of the gamification concepts that were inserted.

During the evaluation period, the extrinsic concepts were inserted in the system to be measured. These can be represented through Points, Levels, Achievements, Progress, Leaderboards, User History and Profile, which contains the user statistics.

The evaluation was performed through a questionnaire using a Lickert scale, from 1 to 5, where 1 is defined as [Strongly disagree] and 5 as [Strongly agree]. The first evaluation achieved positive results in many topics, even though all of the topics did not accomplished an average score (Table IV).

TABLE IV. RESULTS FROM THE FIRST QUESTIONNAIRE

Implementation	Average
Active learning	3.9
Engagement	3.7
Adequation	3.4
Reflection	3.8
Equal opportunities	2.9
Continuous support	2.1
Gamification proposal	4.2
Interface	Average
Flexible interaction	3.2
Social support	2.4
Easy navigation	3.5
User control	4.2
Error recovery	2.6
Visual interface	3.7
Gamification concepts	4.1

Table IV demonstrates the results of the first evaluation, without all of the gamification concepts. Most of the results were above the average, however two of them scored below the average: Continuous and Social support.

Those two attributes are represented in the system as the feedback and the interactions with other users. In the initial phase, the system did not have a properly feedback page for this functionality, which made the user return to the initial page in order to solve new problems. As for the interactions, the system had no explicit feature that could represent this concept in the beginning of the tests.

After the initial feedback from the math teachers, some improvements were made in the system in order to attend the feedback given by the interviewed group. After 3 months passed, and improvements were made, the same group would evaluate the system through a questionnaire using the same Lickert scale and evaluating the same concepts, however in this phase, they also evaluated each one of the gamification concepts that were implemented. The results can be seen on Table V.

TABLE V. RESULTS FROM THE FIRST QUESTIONNAIRE

Implementation	Average
Active learning	4.2
Engagement	4.0
Adequation	4.2
Reflection	4.0
Equal opportunities	4.1
Continuous support	3.8
Interface	Average
Flexible interaction	4.6
Social support	3.9
Easy navigation	4.5
User control	4.1
Error recovery	3.9
Visual interface	4.6

Table V refers to the outcomes in the final evaluation after 3 months using the system. All of the topics achieved more than 50% of acceptability. By comparing those two evaluations it is possible to observe that the system achieved a positive state to be used with the students (Table VI).

As can be seen on Table VI, the topics had an overall increasing. This occurs due the implementations and continuous feedback that were given by the math teachers, as they used the system for the first time. The evaluation of the gamification concepts was also positive, which means above the average in the scale, as we can see on Table VII.

TABLE VI. COMPARISON BETWEEN BOTH RESULTS

Implementation	1st Q.	2nd Q.
Active Learning	3,9	4,2
Adequation	3,4	4,2
Engagement	3,7	4,0
Reflection	3,8	4,0
Equal opportunities	2,9	4,1
Continuous support	2,1	3,8
Interface		
Easy Navigation	3,5	4,5
Visual Interface	3,7	4,6
User Control	4,2	4,5
Flexible Interaction	3,2	4,6
Error recovery	2,6	3,9
Social Support	2,4	3,9

TABLE VII. EVALUATION OF THE GAMIFICATION CONCEPTS

Gamification concepts	Average
Objective	4.3
Points	4.3
Level and Progress	4.3
Time pressure	4.2
Achievements	4.2
Leaderboards	4.4
Opportunities	4.5
Renovation	4.1
Data	4.5

Table VII demonstrates the evaluation of the gamification concepts by the math teachers. These concepts were based on the ones extracted by [18] and achieved a positive score above the average.

VI. DISCUSSION, CONCLUSIONS AND FUTURE WORK

The results of this work demonstrated that the system is ready to be applied within a classroom, being used by the students to train math concepts. The feedback given by the math teachers were very important in order to complete it. They also said that the system will be very useful to be applied within their learning methods and exercises.

Teachers also commended the gamification concepts, claiming that those concepts would be the best thing to caught their students attention, since this kind of process is a part of their routine. They also praised the achievements, which made some references to pop culture icons that are also a part of their students routine.

Even though, the work still has some limitations as: (i) study with a group of students (ii) measuring the OBMEP efficiency of the students within the group (iii) a module to provide administrator functions to the teachers (iv) expansion to the other areas covered by OBMEP.

Based on the comments and feedback given by this group, this work achieved the objectives it had proposed and the system is ready to be applied with a group of students that will evaluate their overall performance in classroom and math competitions.

Based on the same feedback, some future works include the creation of a Teacher's module, where they will be able to create, maintain or manage a classroom outside their classroom. Another future improvement consists in improving the Gamification process within the system, by modifying some concepts and insert new ones, as a collaborative problem solving.

VII. ACKNOWLEDGEMENT

This work has received funding from the CNPq project number 487430/2013-1. Armando Maciel Toda is supported by CNPq grant, process number 380996/2015-4.

Abstract — In the last decades, education has been supported by technology in order to reach more people and produce significant benefits to teaching and learning. Part of the success of technology and education is due to the capacity technology can adapt teaching and learning to different contexts. More recently, we noticed an increase in the use of game elements (gamification) in educational environments, which intends to promote students' engagement and, consequently, improve their learning experience. However, we do not know if the use of these elements brings the promised results. In this paper, we conducted an observational analysis focusing in XP (experience points) and Badges, checking their correlation with the students learning, in order to investigate the influence of these gamification elements.

Keywords— *game elements; gamification; environment learning.*

I. INTRODUCTION

It is known that learning is a determining factor for the autonomy of any individual and to the development of the society. According to [1] learning is a product of interaction. Depending on the chosen learning design, students can interact with instructors and tutors, with content and / or others [2]. However the type of interaction and the environment in which this mediation occurs can be impaired by personal or interaction factors. Based on that, there is an excessive concern with the learning process. To improve individual learning, some researches take into account the effects of technology applied on learning.

Technology is a great tool to support the current demand for knowledge, which is evidenced by the increasing amount of online courses [3]. This new educational paradigm intends to provide education to anybody, from anywhere and at anytime [4]. Among the existing technological approaches to education, Intelligent Tutoring Systems (ITS's) are gaining more prominence in the educational setting.

In [5] Intelligent tutoring systems (ITSs) are defined as computer-assisted learning environments, which are highly adaptive, interactive and based on computational models developed according theories from the learning sciences, cognitive sciences, mathematics, computational linguistics, artificial intelligence, and other relevant fields [6] [7]. According to [8], these systems are based on cognitive learning theory, which is interested in how the information is organized in human memory.

There are ITSs for algebra, basic mathematics, statistics, assessment and learning in knowledge spaces, physics and computer science [5]. Basically, there are four elements inherent to ITSs [9]: (1) the “knowledge domain”, which includes the knowledge that teachers want students to learn. (2) The “teacher module”, which is responsible for selecting and presenting instructions and teaching styles, as well as learning scenarios. (3) The “student module”, which represents student's personal data, their predicted capability for a particular course and her/his current state in specific knowledge domains. (4) The “user interface module”, which is used to facilitate the interactions of both teachers and students with the system.

The four modules are present in all ITSs' architecture, but some of these systems use other techniques in order to increase commitment, motivation and the students' focus on particular tasks. Gamification is a technique for these needs. It consists in the application of game mechanics in environments that are not normally game environments [10]. There are some ways to classify the elements that compose a game or a gamified activity. One of these classifications can be found in [11], which categorizes them in: mechanic elements, story elements, aesthetics elements, and technological elements.

Literature shows some examples of gamification use in ITSs, for example: Ribbon Hero 2 is an Office add-on that allows users to learn and train some skills. Another example, Khan Academy introduced badges and points through individual tutoring for students [12]. Other studies like [13]

present a game-based tutoring environment that teaches mathematical concepts such as Cartesian coordinates, symmetry and iteration to middle school and high school students. In this study, authors found that the integration of game elements fostered higher engagement in learning, and facilitated students' use of the system beyond class time.

In [14], a common way to bring game elements to an ITS is by adding badges (or trophies) and XP (experience points). In Duolingo platform, for example, XP are used to track users' progress in learning a language. In Khan Academy, badges are awarded to users who complete certain (series of) activities/tasks. Gamification use in education motivates different point of views. On one hand, some researchers state, "The current hype of gamification will unavoidably discourages the most creative elite user" [16]. On the other hand, some studies present studies positive impacts of gamification on the educational context [17]. According to [18], the same pedagogical results were obtained using a learning outcomes between a narrative-centered game-based ITS and a non-game tutor.

In this study, we did an observational analysis on the use of gamification elements in an Intelligent Tutoring System. The main objective was to evaluate whether, or not, gamification, improves student's learning. This analysis intends to investigate the correlation between gamification elements and learning in an online learning environment called MeuTutor®. We will check if badges, XP and BKT indices have any degree of correlation. For that purpose, we used the Pearson Correlation Coefficient, to measure the degree of correlation and its linear correlation signal between the variables [23]. Moreover, we used the R¹ statistical language to conduct the analysis.

This paper is structured as follows: Section II presents the some background knowledge used in this study. Section III presents the methodology used. Section IV presents the observational study, including its business and technical problems. Section V presents the statistical analysis applied on MeuTutor's data. Section VI presents and discusses the results. Section VII presents our conclusions and future works. Finally, Section VIII presents the acknowledgements.

II. BACKGROUND

According to [17], gamification uses game elements like point, badges, leader boards, stories and other elements, to enhance skills and engagement, maximize learning, promote behavior changes and socialization. Some of these elements are partially dependent [19], for example challenges, achievement and badges are related within the gamification process: challenges may, or may not be offered; once offered these can be performed by users; when completed the users receive the gains (achievements), that may be represented by a badge.

There are various elements also associated with the gamification process, including badges and XP as mentioned before. Badges are awarded to users when they perform defined (series of) tasks or activities. Experience points (XP) are the most common pointing system in gamified environments. They serve the purpose of watching, ranking and guiding the user, and also indicates how engaged a user is [19]. In MeuTutor, badges are awarded if the students successfully complete some complex activities a certain number of times (make 10 new friends, evaluate 5 videos of a specific domain, complete a part of the cognitive path, etc.). XP are awarded when students do some simple tasks, which makes them progress (level up) in the environment (correctly solve problems, evaluate a video, answer a quiz, etc.) [20].

MeuTutor is an intelligent online learning environment [20], which monitors students' learning in a personalized way, focusing on the quality of teaching and students' performance. Its objective is to prepare students for the ENEM² ("Exame Nacional do Ensino Médio"). It offers school subjects such as: Mathematics, Portuguese, Physics, Portuguese Literature, Chemistry, Biology, Geography, History, Spanish and English. However, only Mathematics is available for free. The other subjects are unlocked in the paid version.

The learning environment provides a huge variability of questions for students to test and practice what they have learned. In addition, the environment provides some gamification elements, including 28 badges distributed in 4 categories: social, collaborative, gamification and knowledge (Figure 1 and Table I).

Figure 1 - Trophies, Level and XP elements

There are 2 badges in the social category, which intends to stimulate interactions among users in the learning environment. There are 2 badges in the collaborative category, and these badges are provided to students, to stimulate cooperation in the learning environment. There are 3 badges in the gamification category, to stimulate engagement between the users and the learning environment.

A total of 21 badges compose the knowledge category, which are related to knowledge acquisition in the school subjects available, such as: correctly solve a problem, answer tests, watch videos, etc. Each discipline has at least one badge

¹ R is a fully integrated suite of routines for manipulating data, calculation and graphics [24].

² A Brazilian exam that grants students access to some public universities

related to it. In this study, we considered only badges related to the mathematics (free) domain, 12 badges (1 exclusively associated to mathematics domain, and 11 general-purpose badges). A detailed description about these purposes is described in Table I.

TABLE I.

Badge's Classification				
<i>Id</i>	<i>Trophy name</i>	<i>Condition</i>	<i>Category</i>	<i>Purpose</i>
1	Darting	Complete 50% of the topics offered by the environment.	Knowledge	General
2	Evolving	Advance one level	Knowledge	General
3	Testing the knowledge	Make the first mock test	Knowledge	General
4	Always learning	Complete the first subject	Knowledge	General
5	Gauss	Reach level 11 in math	Knowledge	General
6	Skull	Correctly answer 10 problems in a row	Knowledge	General
7	Teacher	Complete 100% of the topics offered by the environment.	Knowledge	General
8	Tireless	Learn a subject without stopping in the middle	Knowledge	General
9	Scholar	Complete 3 subjects in the same week	Knowledge	General
10	Perspicacious student	Correctly answer 5 problems in a row	Knowledge	General
11	Improving the knowledge	Complete 5 subjects	Knowledge	General
12	Simulation Perfect	Correctly answer a mock test	Knowledge	General

Source: created by authors.

In the learning point of view, MeuTutor® calculates the student's performance and gathers information related to each curriculum (topics) the students interacted with. Currently, they evaluate these interactions, at curriculum level, using a technique called BKT (Bayesian Knowledge Tracing), an efficient model to evaluate the learning process.

The BKT is a common way to determine students' knowledge in adaptive skills, in educational systems and cognitive tutors. The BKT, in essence, is supported by the Hidden Markov Model (HMM) for modeling the student's knowledge based on five parameters: (1) the probability that the student has any initial knowledge on a particular topic (curriculum); (2) the successful acquisition of new knowledge

by the student; (3) forgetfulness; (4) guessing; (5) and making a slip [22]. It tracks and monitors changes in the state of the student's knowledge during practice [22]. For each student's response to a question, the model adjusts its prediction whether the student knows the ability, or not. Within MeuTutor® the estimated rate for measuring learning is 95%, i.e., if a student achieves this percentage in the activities associated with a particular curriculum, the system considers that he/she learned that content. Based on that, it is worth consider that BKT was only used to define which curriculum would be included in the analysis.

III. METHODOLOGY

In this section, we describe the planning and execution of the proposed analysis.

Our first step was to schedule some brainstorming sessions with MeuTutor® team. We used these sessions to better understand the learning environment and the way the game elements were applied. We presented our intentions and objectives, and discussed with the development team, which data should we analyze in order to reach what we proposed.

After that, we spent some time accessing and exploring the environment. During this step, we detected the need to categorize the badges available, once they had different purposes. We later checked with MeuTutor® team if the categories were aligned with their original ideas about the badges. We also collected information about the experience points (XP) and the learning index (BKT).

Our next step was to search books and articles containing studies about the process of learning with and without the aid of technology, more specifically the use of gamification.

After understanding the aspects of the interaction between the learning environment and the user, we requested the necessary data for the analysis. We required data on the users' interactions with the game elements, and data on their learning experience (performance and knowledge state). We received the data into two XLS files. One containing the registries of 4000 students retrieved according to their number of accesses, the other registries of 100 students retrieved according to their gamification level in the environment. Given our purpose, we chose the second file.

Examining the file, we noticed the necessity to treat and enrich the data. Initially, we filtered the data available in order to keep only those pieces that were relevant to our analysis. This way, we removed everything but data about the users' achievement (XP and badges, only) and data on the students' performance (number of problems solved, and number of problems solved correctly) and their learning experience (curriculum they learned). We also removed data on the badges that were not related to the Mathematics domain.

In order to measure learning, we calculated a coefficient we named Knowledge Coefficient, which was created using the data on the students' performance and learning experience. It is composed of the number of problems solved correctly, divided

by the total number of problems solved, multiplied by the sum of the curriculum the students' learned (BKT score $\geq 95\%$), as show in Figure 4.

However, different curriculum have different demands and difficulty. In order to deal with this issue, we divided the MeuTutor® cognitive tree (curricular structure for a certain domain, in this case Mathematics) into eight large blocks (Figure 2) according to their distribution.

Assuming that the 21 curriculum available represent 100% of the knowledge students need to acquire in order to “master” the Mathematics domain, each of the eight large blocks in the proposed division, contributes with 12.5% of this amount of knowledge. If a certain block has more than one curriculum associated with it, the total value for the block (12.5%) will be divided by the amount of curriculum associated. Knowing that the content offered by MeuTutor® was created to be similar to that taught in schools (Brazilian), we can see that the knowledge acquired by the students is the sum of each curriculum in this established hierarchical sequence.

Matemática Básica		12.5%
Razões e Proporções	1.5625%	Conjuntos e Funções
	0.78125%	Sequências
	0.78125%	Matrizes, Determinantes e Sistemas
	0.78125%	Polinômios e Equações Algébricas
BLOQUEADO		1.5625%
Estatística e Probabilidade		1.5625%
Lógica		12.5%
BLOQUEADO		12.5%

Sólidos geométricos	1.38%	Circunferência
	1.38%	Triângulos
Áreas	2.08%	Trigonometria
Medidas em sólidos geométricos		12.5%
Troncos e semelhança de sólidos	6.25%	Geometria analítica
Números complexos		12.5%

Figure 2. Curriculum's Weight.

Finally, we did a correlation analysis using this data we pre-processed (filtered and enriched). For this parte, we used R to analyze the correlation between the gamification elements, Badges and XP, and students' learning in an online learning environment.

IV. OBSERVATIONAL STUDY

In this section, we present our problem (business and technical), our research questions, goals and metrics.

We needed to define the variables, the situation and the context to be analyzed. In the same way, we defined what problem would be “attacked” and what hypotheses would be examined, considering the scope of study. In Figure 3, we illustrate our GQM.

A. Business Problems

1. **Problem:** Do the games elements Badges and XP influence in students' learning in the MeuTutor® environment?
2. **Research questions:**
 - a. Is there a correlation between the amount of badges students have and their learning?
 - b. Is there a correlation between the amount of XP students have and their learning?

Metrics for validation:

- a. The number of badges and XP per student.
- b. The number of problems solved.
- c. The number of problems solved correctly.
- d. The number of curriculum effectively learned (BKT $\geq 95\%$).

B. Technical Problems

1. **Problem:** Does the achievement of games elements, Badge and XP, positively influence or negatively in the learning process in MeuTutor® environment?
2. **Research questions:**
 - a. Do badges influence learning?
 - b. Do XP influence learning?

C. Goals, Question and Metrics

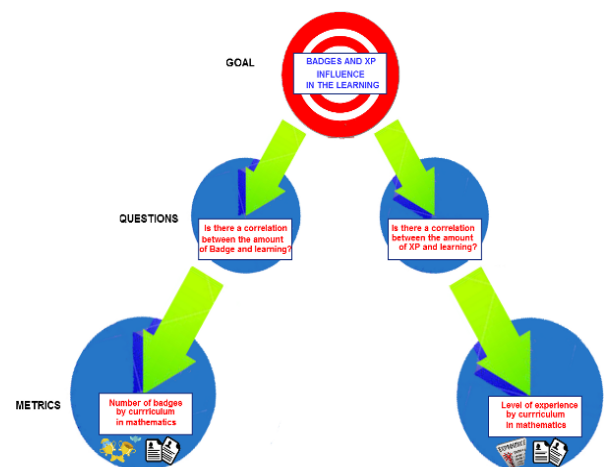

Figure 3. Illustration of GQM process.

TABLE II.

V. ANALYSIS

The analysis process described in this chapter is composed of five steps, as follows: data retrieval, data treatment, correlation analysis, results and discussion.

A. Data Retrieval

Analysis have one or more data sources, in this study, data came from a gamified online learning environment called MeuTutor®, as described in section III, after the decisions made in some brainstorming sessions, and actual use of the environment. We were able to better understand environment's dynamics and mechanics, which was vital to guide requirements for data to be used in the analysis. As mentioned, we requested data about the students' interactions and learning experience in general.

B. Data Treatment

However it was necessary to treat and enrich the dataset, in order to keep only those data related to badges, XP, BKT score (for the curriculum in the Mathematics domain), as well as data on problems solved (the total amount of problems solves and the amount of problems solved correctly) A dataset was After receiving data, it is noticed which some data founded in the dataset is not relevant for the analysis, thereby, was necessary a treatment of data. This treatment consists of choose a dataset to analysis, filter the features, definition of weights and creation of table for analysis.

a. Choosing a Dataset

We received 2 datasets. The first, consisted of 4000 students selected by their number of accesses. The second, consisted of 100 students selected due to their level in the environment. Both datasets contained the same set of features.

We opted for the second dataset, where students were selected by their levels. In it we found 100 students distributed among levels 1 to 6.

b. Filtering Features

Based on variability of the received data in the dataset, it was necessary to filter the features to be used in the analysis, keeping the features: XP, Badges, BKT score for the Curriculum, number of problems solved and number of problems solved correctly. Other features were not considered in this analysis.

The curriculum which has less than 95% of BKT score were not considered in the analysis, once according to the BKT, these curricula were not learned.

c. Weights' Definition

In order to define the level of learning of a student, this analysis considered the learned curriculum only. We also applied weights to each curriculum (Table III), according their interdependence and the importance of each curriculum to complete the cognitive tree.

d. Knowledge Coefficient

We used the information gathered of created above in order to generate an equation to measure the students' knowledge coefficient. It uses the number of problems solved correctly, divided by the total number of problems solved, multiplied by the sum of weights of the learned curriculum (Figure 4).

$$\text{Knowledge Coefficient} = \frac{\text{Number Questions Answered Correctly}}{\text{Number Questions Answered}} * \sum_{i=1}^n \text{Weight}_i$$

Figure 4. Knowledge coefficient equation

C. Correlation Analysis

For the analysis we considered students in levels 1 to 4. Each group contained 14 students randomly chosen. Levels 5 and 6 were not considered, because there were not enough students with these levels (less than 14 students).

The correlation among Badges, XP and the knowledge coefficient (KC) is described in the tables IV, V, VI and VII, for students in levels 1 to 4, respectively.

TABLE IV

VI. RESULTS AND DISCUSSION

The results show a weak correlation between XP and learning for students in level 1, but a higher correlation between badges and learning.

For level 2, the analysis shows no correlation between XP and learning, and a lower correlation between badges and learning, compared to level 1.

For level 3, the analysis shows no correlation between XP and learning, and an increase in the correlation between badges and learning, compared to level 2, however still lower than level 1.

For level 4, the analysis, once again, shows no correlation between XP and learning, and a negative correlation between badges and learning.

These results (summarized in Figure 5) may indicate that the gamification elements studied, are gradually losing their relevance to the learning process, in MeuTutor®, which can indicate a problem in the design of these elements (their purpose). According to the pedagogical and development teams at MeuTutor®, the effort to achieve a badge increases, as a geometric progression, throughout the levels. In others words, is more difficult to earn badges as the student level up.

However, this behavior is not characterized in tables IV to VII, despite the decrease in the correlation (tables IV and V), the correlation in level 3 is practically the same of level 1. However, in level 4 the correlation has a negative value, which may indicate that the effort to achieve a badge from level 4, may be deviating students from learning.

Figure 5. Correlations through the levels

The analysis revealed a low to insignificant correlation between XP and learning. Indicating low or no influence among the variables analyzed. That is, the users experience points are not crucial to effective learning, at least for levels 2, 3 and 4.

The results presented in the analysis, also suggest that there is a gap in the transition from level 1 to level 2 that can be corrected if the parameters to award each badge is changed.

We believe that the most advanced students behave differently, once they are familiar with the dynamics of achievements, not being too much influenced by achieving badges and XP. Nevertheless, we have evidences of the influence of badges in the students' learning process, while XP has almost no influence in this process.

Based on the badge correlation behavior, two hypotheses arise: (1) the badges were not well distributed or designed along the levels; (2) the badges are important/interesting, only, in the beginning of the course.

Our suggestion is the redistribution of the effort to achieve the badges, which may provide more significant results. In level 4, we saw a negative correlation (-0.2669913) indicating that a change is also needed in the distribution of the badges for the considered levels.

VII. CONCLUSION AND FUTURE WORKS

In this study we intended to analyze if there is any kind of correlation between some gamification elements and students performance. More specifically, we wanted to detect the influence of Experience Points and Badges on the students learning. Our target environment, is a gamified online learning environment called MeuTutor®.

We gathered data from the interactions of 100 students, and filtered them in order to keep only data related to their achievement of the game elements of interest (Experience Points and Badges) and data related to their learning experience (curriculum they learned, the amount of problems solved and the amount of problems solved correctly). The sample size and the data quality was appropriate for the correlation analysis.

The results showed that there is correlation between the variables investigated and learning. Badges were considerably correlated to learning, while Experience Points were just lightly correlated.

We concluded that, in order to keep XP and Badges significant to learning, it is necessary to correctly design them considering the demands and differences of the different levels (of a gamified environment), carefully plan and distribute the effort to achieve them, and make them meaningful.

As future work we intend to further investigate other methods and scenarios to verify the correlation between gamification elements and learning. We also intend to perform new analyzes for different game elements and check other types of influences (for example, do the interactions change in periods close to important tests and evaluations.

VIII. ACKNOWLEDGEMENTS

We would like to thank MeuTutor® team for providing us access to the necessary data to plan and implement our analysis. We would also like to acknowledge the financial support provided by CAPES/CNPQ.

Santo André, SP, Brazil
{keiko.nishida, juliana.braga}@ufabc.edu.br

Abstract— This paper presents the process and the result of a systematic literature review about educational games in which the main theme is electricity consumption, executed from January to March 2014. The systematic review is characterized by the use of a method that aims to answer the questions of the researcher with rigor in the search, making trends and biases of the researcher interfere as little as possible on the results. The research questions raised were: 1) Are there educational games about electric power consumption? 2) How were these games used? The theme choice was made as a result of the environmental issues assigned to it and the consequences that consumption can generate. The result of the work, obtained from a survey in the ACM Digital Library, Elsevier (Science Direct) and Springer scientific research bases, revealed the existence of seven papers, which responded the questions made. The results indicate a lack of papers in which use approaches of the games are reported - highlighting the need for further investigation and share. It is believed that this work contributes to the academic community by presenting a list of games and their uses, and the knowledge from this type of research serves as an incentive for new games and different approaches to be designed and created.

Keywords—systematic review; educational games; energy consumption; energy education; use of educational games.

I. INTRODUCTION

Energy is part of practically all society's sectors and it is used in many everyday activities, being responsible to ensure welfare and services to humanity [1].

Throughout history energy consumption has increased dramatically and according to estimates it will continue to increase in the next years, if consumers present the current consumption rates [2], [3].

Increase in energy consumption means not only increasing the provision of good services which enables well-being, but can also mean an increase in social and environmental problems, such as increased greenhouse effect, soil, air and water contamination.

Based on these issues, it is important to think in ways to facilitate the discussion and study about energy issues. In this paper, the use of educational games is suggested, as they have the potential to stimulate learning, critical thinking and creativity [4].

The game within the educational practice, however, requires care from its users, because its misuse can not help to

promote learning by not contributing to the teacher's objectives. Therefore, the knowledge of games and their use approaches can be considered important because from this perspective they are a source of examples for those who want to use this type of material. In order to investigate if there were academic papers about energy issues and their use approaches, we tried to make use of a method known as systematic review of the literature, as it seeks to be rigorous and eliminate, as much as possible, partiality in the search of papers.

II. ELETRIC ENERGY CONSUMPTION

Energy is one of the most important elements of modern society. It is present in our everyday lives as power, health, leisure and in all of our routine activities as well as in practically all sectors of society, such as the environment, the economy, politics, and others. It is responsible for the creation of riches based on natural resources and the consequent provision of services, from which humanity has been benefited throughout history [1].

Since the Primitive Man to the Technological Man, energy consumption has grown considerably. This grow was possible due to, above all, the scientific discoveries made over time. Examples are the use of coal as a source of heat and the extraction of mechanical energy from winds and waterfalls. Later, the Industrial Revolution and the invention of steam engines, internal combustion engines and the electricity, as well as the use of nuclear energy also favored the availability and stimulated the need for energy [2].

About electricity, specifically, there are estimates that if the global consumption do not decrease, the world will need around 2.400 GW in 2030 to satisfy different kinds of needs and in order to do so, it will be necessary to construct new sources of energy power [3], [5].

The sources of energy generation are classified, in simplified form, in renewable and non-renewable. The renewable source is the one that is returned to the natural conditions in a short period of time, as example of this type we have wind and hydropower potential. On the other hand, the non-renewable source is the one that is not replaced quickly by nature, such as oil and coal [2].

Although these sources guarantee much of what is currently being enjoyed, allowing a better quality of life for the population, it is necessary to think that the implementation and

the use of these sources affect directly the health of the planet and consequently the welfare of all living beings [1].

These different sources of energy, whether renewable or not, affect the planet in some way. The effects of these sources on the planet can be classified in three categories - local, regional and global impacts and dimensions [2]:

Local impacts and dimensions: in this category it is included air, superficial water bodies and soil pollution. The air is contaminated mainly by the burning of fossil fuels and solid waste, evaporation and volatilization of solvents and fuels, and emissions from industrial processes that emit toxic and carcinogenic substances, as well as particulate matter and gases such as nitrogen oxides (NO_x), sulfur dioxide (SO_2) and carbon monoxide (CO). Water and soil, on the other hand, can be contaminated by the use of pesticides and fertilizers, oil and fuel leaks and leachate from landfills.

Regional impacts and dimensions: acid rain and sea pollution. The reaction of NO_2 and SO_2 with water results in formation of nitric acid (HNO_3) and sulfuric acid (H_2SO_4), creating acid rain, that affects all types of ecosystems. Sea pollution happens, in general, by the leakage in international or interstate waters or, groundwater contamination by the infiltration of toxic substances.

Global impacts and dimensions: The increase of the greenhouse effect, bio-cumulative pollutants, radioactive waste, biodiversity loss and desertification of the oceans. The greenhouse effect is intensified by the emission of gases such as carbon dioxide (CO_2) and methane (CH_4) which are released mainly from deforestation and fossil fuel burning. The bio-cumulative pollutants are represented mainly by heavy metals and radioactive materials, originating mainly from emissions of coal power plants, leakages and nuclear tests.

Due to all these impacts which have social consequences, such as diseases that can be acquired through consumption of contaminated water, and polluted air inhalation, among others, it is important to think about efforts to save energy. Energy saving is usually focused on two aspects: technical, related to the efficiency of technologies for greater use of energy; and changes in lifestyle, which is related to the way in which energy is used [1].

About energy saving, some authors [6] say that the choice of energy sources, as well as their use, are not and should not only be determined by politicians and professionals with expertise in this area, but by everyone who is perceived as agent of these changes. Among the characteristics that these agents must have, the authors say that in addition to the scientific knowledge of energy, it is important that these people are aware of the impacts and consequences of its energy generation, as well as knowledge of the consequences that individual consumption has on the global community.

Preparing people with knowledge, values and self-consciousness is not an easy task. For this reason, efforts and investment programs in different levels, resources and people who can help to accomplish it are important.

One way to facilitate this kind of formation is using educational practices. This paper suggests the ones which use games.

III. EDUCATIONAL GAMES

Educational games allow to create scenarios in which it is possible to reproduce in a simplified and didactic way environmental problems, which are considered complex and enable ecological, social, financial and technical issues and solutions to these issues from a perspective that goes beyond the disciplinary vision [7].

According to [8], records of the use of games in educational activities have already been found since antiquity. Aristotle, for example, encouraged its use as a contribution to prepare children for adult life. Later, with the rise of Christianity, games had no place in the educational context because they were considered a form of crime, remaining "forgotten" until the Renaissance.

It was exactly during the Renaissance period that the games regained their significance in education, being multiplied and applied in various areas of knowledge, such as geography, mathematics and philosophy.

In the eighteenth century, with the emergence of the encyclopedia, games became popular, favoring the exchange of ideas and therefore the creation of new types. The nineteenth century, in turn, presented the expansion of historical games, running even as a political marketing, and the growth of games was used to stimulate science and mechanical content. This situation lasted until the World War I when the military games began to gain prominence.

With the end of the war, the sports games became more valued and in the 1960s, they began to reoccupy a role in educational processes and have since fluctuated considerably.

Although games have made important contributions to the educational field for a long time, as noted, it is important to acknowledge that the use of this type of material requires care, from both parts, from those who develop and from those who apply them.

Regarding the use of games as elements of educational practice, [4] the advantages and disadvantages of this type of material can be listed as follows:

1) *Advantages*

- Fixing concepts already learned in a motivating way to the learner;
- Introduction and development of difficult concepts to improve understanding;
- Learning to make decisions and evaluate them;
- Significance of apparently incomprehensible concepts;
- Provision of the relation between different disciplines (interdisciplinary);
- The game requires active participation of the learner in the construction of his own knowledge;
- The game promotes socialization and the awareness of teamwork;

- The use of games is a motivating factor for who is learning;
- Among other things, the game favors the development of creativity, critical sense, "health" competition, the various forms of the use of language and pleasure in learning redemption;
- Activities with games can be used to enhance or restore skills that the students need;
- Activities with games allow teachers to identify, diagnose some learning errors, attitudes and difficulties of learners.

2) Disadvantages

- When the games are misused, there is the danger of giving the game a purely random character, becoming an "appendix" in the proposed activity. Learners play and feel motivated only by the game, without knowing why they are playing;
- The time spent on gambling activities is larger and if the mediator is not prepared, there may be a sacrifice of other content for time;
- The misconceptions that all concepts should be taught through games. So, classes generally turn into real casinos, without any sense to the student;
- The loss of "playfulness" of the game by the constant interference of the mediator, destroying the essence of the game;
- Coercion from the mediator, requiring the learner to play, even if he does not want to, destroying the willingness that is inherent to the game;
- The difficulty of access and availability of materials and resources about the use of games in education that can support the work of those who apply games.

Despite the advantages of using games, it is important that the teacher is perceived as an intermediary and moderator of this tool, and is responsible for searching and selecting the games, as much as the methodologies to be used, aiming at facilitating the learning objectives [9].

Based on the advantages as well the disadvantages, it is important to know the games and use approaches. This study made use of a systematic review in order to distinguish whether there was work on games that dealt with energy consumption issues and also the reports of its use approaches.

IV. SYSTEMATIC REVIEW

The review of literature is commonly one of the initial steps of a survey for allowing the researcher to understand and analyze materials that present findings, techniques, operating modes and relevant information about their questions. In addition, it contributes to the minimization of errors and avoids unnecessary work, such as duplication, for example [10].

The studies that contribute to the literature review are called primary studies. They are the "regular" studies, which were made from test to check hypothesis, so the review is considered a secondary study, it depends on the primary studies, constituting an attempt to build knowledge from papers and articles already performed [11].

One way to execute a review of literature and therefore get primary education is through systematic review, also known as synthesis of systematic research, integrated search review and integrative review [10].

The systematic review is characterized by the use of a method that aims to answer the investigator's questions with rigorous search, making the researcher's trends and biases interfere as little as possible on the results. Trends and biases can be understood, for example, as the tendency to employ certain terms used in the search without taking into account other possibilities. This type of review can be performed by using a process consisting of three phases, namely: planning, conduct and review report, which will be explained based on the work of [12].

A) Planning of the Review

The planning is based on the protocol elaboration, which specifies the methods to be used to do the review, such as: the questions to be solved, the sources for the search, inclusion and exclusion criteria of the papers found. It is recommended to review the protocol in pairs of people.

B) Conduct

In this step, the database to be used is defined. The selections of studies and evaluations based on inclusion and exclusion criteria, defined in the revision protocol, are done. After the assessments, data are extracted, recorded and submitted. The presentation can be in tables and/or in graphs.

C) Review Report

The review report concerning the publication of data, can be done in technical reports, sections or chapters of academic papers, such as dissertations, theses and articles on events and publications.

Although the different steps have been sequentially presented, it is important to know that they can occur in an iterative way, allowing each step to be improved throughout the process [10].

From the analysis of the descriptions of the steps suggested by [12] one can notice that to perform a systematic review does not mean only to review from a protocol, but, to conduct a literature review, in which collected data will be analyzed to meet certain objectives. The literature review in this process can be seen as a means and not as an end.

The systematic review performed in this paper was done in January 2014, in order to verify the existence of studies about the use of games that dealt with electricity consumption.

The systematic review followed the steps suggested by [13]: planning, conduct and report (Figure 1)

Fig.1.Steps of the systematic review in this paper.

V. SYSTEMATIC REVIEW ABOUT ELETRIC ENERGY COMSUPTION

As previously mentioned, the systematic review aims to answer the questions of the researcher, in this sense, the questions to be answered by this review were:

Q1. Are there educational games about energy consumption?

Q2. How were these games used?

The reason for asking the first question (Q1) was to identify the existence of games that only dealt with the electricity consumption theme (excluding therefore those games that have the consumption of electricity as one of its many themes or sub-themes). The second question (Q2) intended to provide subsidies to recognize and analyze later pedagogical approaches in which these games were used in teaching, serving as referral sources for teachers, who wish to plan their activities with the use of games.

1) Sources, research selection criteria and construction of search strings

To perform the systematic review the bases which the search should be performed was defined. The bases of these studies were selected by their popularity, ACM Digital Library, Elsevier (Science Direct) and Springer. It was also decided that as the papers were being read and they referred to other games, Google Scholar would be used in an attempt to find papers about them. For this investigation the authors have chosen to do the research on academic bases because they wanted to know how the theme “electric energy consumption” had been explored in the academic area.

The search for papers was done by selecting key terms (called search strings), which aimed to answer the questions of the systematic review (Q1 and Q2) and the combination of these terms with logical operators (also known as Boolean operators) which purpose was to indicate to the search engine how the combinations of strings must be done – for this work the logical operators AND and OR were used [14], [15].

The strings have passed through tests. They were built in the English language and were adapted according to each base specificity.

Tests and adaptations were done with the strings. The tests involved different combinations of strings in different bases and all of them were randomly chosen publications, returned by the search engine. In the publications, the presence of terms used in the strings were manually verified in order to be validated.

Tests were also done with the terms relating to the title, abstract and text, as predecessors of the strings. It was done because the use of different predecessors can return different results.

Additionally, tests were conducted to understand the operation of each research base: how the words had to be inserted, how the terms of title and abstracts had to be considered, how to use special characters, like spaces and symbols.

Searches were conducted at the beginning of January 2014, as described below:

A) ACM Digital Library

By limiting the search engine, it was observed, at this stage, the restriction of searches was done by paper abstracts. For this reason, the term Title came prior to the first string.

The following strings were inserted into the search field at the bottom of the page. The quotation marks indicate that both terms contained in them should be searched and parentheses, on the other hand, were used to indicate which set of operations should be performed first.

Title
(Game OR play OR advergence OR serious gaming)
AND
(Education OR training OR breeding OR accomplishment OR teach OR learn OR instruction OR guideline OR pedagogical)
AND
("Save Energy" OR "consumption energy" OR "energy engagement" OR "domestic energy" OR "power energy" OR "energy efficiency" OR "save electricity" OR "electricity environment" OR "electricity savings" OR "household energy" OR "energy reduction" OR "energy conservation" OR "energy awareness")

These strings returned 75 papers.

B) Elsevier (Science Direct)

The same strings used in the previous bases were applied to the Elsevier (Science Direct) base, which were inserted in the search field, observing a title of work search in the first string. 52 papers were returned on this base.

C) Springer

During the tests, it was noted that this base had a different search engine when compared with others. It was necessary to insert one string after another. In total 138 papers were found.

D) Google Scholar

Google Scholar was used after the analysis of the publications found by search strings in order to locate specific studies, which were mentioned throughout the text. Searches consisted in the use of games names that were mentioned in the publications located by search strings. Although possible, the strings were not used in this search system, since it combines the results of different studies bases.

2) Selection Criteria: inclusion and exclusion

After the papers survey was done through the systematic review, with a total of 265 papers, the selection of studies that answered the research questions started (Q1. Are there

educational games about power consumption? And Q2. How were these games used?).

The selection was done based on inclusion and exclusion criteria:

A) Inclusion criteria

- If different studies discuss the same game, both should be analyzed
- If the papers that were found were about pilot studies or preliminary tests on the games use, they should be analyzed;
- If during the search at Google Scholar, papers about games that were not found before, were found by the search strings, they should be considered for analysis;
- Studies with any publication date;
- Studies about any kind of games: electronic, board games, etc.;
- Studies about games declared as educational;
- Studies about games for any level of education;
- Studies about games for players of all ages.

B) Exclusion criteria

- Duplicated studies;
- Studies that are not written in English¹
- Studies that do not deal specifically with games about electricity consumption;
- Studies that did not report the experience on games usage;
- Studies about games that were not declared as educational;
- Studies about gamification.

3) Data Extraction

After the papers selection process based on the exclusion and inclusion criteria, the abstract, introduction and conclusion were read and, when needed, other parts of the studies were read.

VI. RESULTS

Among the papers that were found by the systematic review, the preliminary results showed 59 papers that could answer the research questions. However, after the analysis based on the inclusion and exclusion criteria, the number of studies dropped to 7.

The number of papers found on the databases that answered the research questions Q1 and Q2 is shown in the graph 1.

Graph 1: Selected papers by database that answered Q1 and Q2.

The complete list of the papers with titles, publication year and database where they were found can be seen in the following chart:

TABLE1. PAPER TITLE, YEAR, GAME AND BASE

Paper Title	Year	Game	Base
A digital game-based learning system for energy education: an energy conservation pet	2012	Ecopet	Google
EnerCities, a Serious Game to Stimulate Sustainability and Energy Conservation: Preliminary Results	2011	EnerCities	Google
Enercities: educational game about energy	2010	EnerCities	Google
Exploring the use of a game to stimulate energy saving in households	2012	Energy battle	Google
Makahiki: an open source game engine for energy education and conservation	2012	Makahiki	Google
Serious gaming change adolescent's attitudes towards saving energy; preliminary results from the Enercities case	2011	Enercities	Google
The contract: an educational computer game analyzing and optimizing renewable efficiency in schools	2009	Contract	Springer

The presence of these publications can answer the first question of this systematic review, about the existence of educational games related to energy consumption.

Games usage

The second research question, as presented previously, was about the games usage: *How were these games used?*

Before introducing the uses, however, it is important to know that the uses were extracted from the interpretative reading of the works found by the systematic review and that the authors of this article did not have any kind of contact with the paper's authors and or people who have used these games.

¹The English language was selected because it is the most used language in academic papers.

A) Contract (Kontrakten) [17]

That is a computer simulation of a school and its energy consumption and heating, in which students were divided into groups that represented fictional companies, that would compete with each other to get a contract to implement energy saving systems to be used in the school.

In the simulation, the groups used to have a fixed amount of money, that should be managed taking in consideration the improvements desired, which would add points to the group. The group with the highest score would be considered the champion.

The game was applied in three schools in Denmark, with students from the 7th to 10th grades and ages between 12 and 16. To have access to the game, the teachers should download it from the internet, as well as the instruction manuals, introductory presentation, a brochure and a poster of the game.

The points, which the groups were competing for, were divided into the following categories: green points (related to environmental aspects), points related to energy saving and points for heating saving. In order to receive these points, firstly, the groups would be familiarized with and explore data from their school related to energy consumption and the construction of a fictional building. The data about energy consumption were added by the teachers, based on real data from the school. This was used to make the students think in improvements that could be made in their own schools, taking into consideration the costs of applying it. After that, the group could choose one of the topics listed below to be specialized in:

- Lighting/ equipment;
- Heating insulation;
- Heating sources;
- Venting;
- Interior design / Planning;
- Solar energy
- Wind energy;
- Human factor.

After that, the groups received texts related to the chosen themes and solved small problems that were presented, including the creation of devices that could improve the energy efficiency of the school. The solutions were then analyzed by the teachers and they directed the students to the next phase, where they could obtain the points. It is important to acknowledge that all the groups could analyze what was being done by the others, and then in turn they would learn with their classmates. This also improved their competitive spirit.

B) Ecopet [18]

The system simulated and monitored the environmental variables of the places where a virtual animal lived (avatar). The target of the game was to ensure that the avatar, specifically a dog, could live comfortably, but saving energy. So, the gamer would control the electronic devices of the place

and try to achieve the highest energy saving possible, while keeping the animal comfortable.

The choice of the animal theme was made taking into consideration the positive effects of the human-animal interaction.

The game was built so the players could use strategies to promote self consciousness about energy savings, allowing them to feel motivated and so the learning could happen.

23 volunteers were then selected; they were postgraduate students aged 23 to 31 years old from a university in Taiwan. They had to answer to questionnaires before and after the game, their interactions and reactions were also filmed and analyzed. The questionnaire referred to their day-to-day energy consumption habits and also their knowledge and motivation for saving energy .

C) Enercities

In this game, the player had to balance people (social approach), planet (environmental approach) and profit (economic approach) taking into consideration the demand in energy of a city. The player had to implement power saving measures, aiming to lower the CO₂ emissions and also the fossil fuels usage in electricity generation for the city. The decisions influenced the players score on people, planet and profit categories. When good actions were taken, the player received more space to expand his city and to use extra bonus for the game. Furthermore, the gamers could post their scores on the social network [19].

The game was played by high school students in five European countries, monitored by their teachers. In the first moment, quantitative tests were done, where 800 students answered online questionnaires about the game. After that, a qualitative study was done only with 76 students from different schools. Questionnaires were answered by the students after playing the game. There was also a control group that did not play the game. The aim of these questionnaires was to evaluate if there was learning due to the use of the game [20].

The game was used in regular classes or in projects that specifically dealt with the energy theme [20].

D) Energy Battle [21]

This game was performed in three phases. The first one was two weeks before the beginning of the completion. In this phase meters were installed in the players' houses, so some measurements could be made. At this point, the players did not have access to their consumption information. In the second phase, the gamers received instructions about how to use the meters and how to register on a website to receive information and tips about energy savings. On this website they could also receive feedback about their energy consumption and the classification of all the teams. The third phase was the moment where the energy measurements were taken after the end of the game, which lasted 8 months in some houses.

Some questionnaires were answered and interviews were made with some people, one month and eight months after the end of the competition. The main target was to evaluate if the habits executed during the game were incorporated to the people routine.

According to the interviews, extreme habits, which were those where people lost their comfort inside their houses, were abandoned once it stopped being an strategy to win the game. One example was to share only one computer. Despite this, people said that the new habits were incorporated to their daily routine (changing the lighting, and adding less water to the boiler).

E) Makahiki [22]

This game was part of a competition called Kukui Cup, where students from the Hawaii University formed groups, determined by the floor where their dormitories were located. From that, the players had access to tasks that should be performed through one digital screen, called Smart Grid. Such tasks were divided into activities, appointments, events and tours. The player received points for each task completed; these points could come from individual or collective tasks.

The main component of this game was the Smart Grid, where the players should check which tasks they should fulfill. To receive the points related to their activities, the players should send the answers to the administrators through the system. The answers could be texts or illustrations. The administrators should approve or reject the student activities. If accepted, the player would receive the points. If rejected, he received a feedback explaining the reasons for the rejection. After the feedback, the student could fix his activity and send it again.

The appointments were actions considered sustainable that the players should fulfill or make for a five days period. Example: reduce time during the shower, shut down the lights when leaving a room. The events and tours were related to activities done inside and outside the campus (the reading of the article did not give more details about the tasks).

The students had daily targets for energy savings and could access the webpage of the system where the information about consumption was available. The points were converted into tickets which the players could bet in a raffle for any prize they would be interested in. In an effort to get more participants, the game considered two types of bonus: social and references. In the first type, the player received a point if he could fulfill a task with another person (watch an event, for example). In the second, the player should indicate a new participant. Once this new person accepted, both were rewarded with points.

The best players -those who had more points - had access to a change of game design, which is called the visual canopy, where there was a forest background with trees, shrubs and grasses. The canopy members had a set view from the canopy (treetop) and could communicate with each other and with management, receiving special missions that were not in the smart grid. They also had access to advanced energy consumption views of other players.

After the use of the game, some evaluation in the form of questionnaires and interviews were made to know if the students felt motivated and also their impression on the game.

VII. DISCUSSION AND CONCLUSION

The results presented by the systematic review indicate a lack of publications where the use approaches of games on electricity consumption are reported - highlighting the need for further investigation and sharing. It is also important to note that information about what happened in the players' real life after playing the game was not detailed and it could be a very interesting contribution of these studies.

The results also showed that different kinds of games like electronics, competitive, in group or for one player, for any age have the potential to make people think about energy consumption. It can be done in a variety of scenarios such as, in the construction of a city, in the management of it, to help a virtual animal survive or in a competition in real life. However, if we think that energy problem is complex and draw together different areas such as technology, social and environment, it is interesting that the games try to explore all of them or if they do not do it, at least, they let the student know that maybe it is important for him to try to discover more about it by himself.

The existence of the papers that relate and share the experience of using games that are pertinent to this theme can be considered a tool to help planning activities that include the use of games.

Publications related to these issues are important because the electricity consumption issues related to property is used in various sectors of society, and its growing consumption has generated a number of impacts in different orders, namely, social and environmental impacts. This subject, which can be addressed with the use of games requires care, because although it has lots of potential for use in educational activities, it requires thought and planning. An additional study about this planning, the possible effects of the teacher being present or not and the reflections of the students is a recommendation of this paper.

It is believed that this paper contributes to the academic community by presenting a list of games and their uses. The awareness of this type of research can serve as an incentive for new games and different approaches can be designed and created.

Engaging Students inside the Classroom to Increase Learning

Kristi J. Shryock

Department of Aerospace Engineering
Texas A&M University
College Station, TX
kshryock@tamu.edu

Abstract—From overhead transparencies to interactive documents, teaching and learning engineering has changed dramatically over the years. A flipped or hybrid course is a pedagogical model that reverses typical lecture and homework elements of a course. Class time is used for discussions and group activities with lecture materials being introduced in an on-line format. As research has shown, this model allows students to typically demonstrate higher levels of learning.

This paper will detail the associated learning by students through the author's transition from a typical lecture-based sophomore-level engineering class to a hybrid model. The author will address how learning can be increased through the use of active engagement tools, such as iClickers.

To address this question and gauge the overall impact on student learning, a post-course survey was used to measure the perceived value for students. In addition, evidence for improved student engagement was gathered qualitatively to compare with previous experiences. Results show that active engagement tools helped students become active learners, increased interaction with peers and instructor, and helped them evaluate whether material was understood to motivate further learning. Moreover, students benefitted from the instructor being able to pinpoint misconceptions earlier due to instant feedback from students in the class.

Keywords—iClickers, clickers, active learning, classroom engagement tool, audience response system, flipped, hybrid, inverted

I. INTRODUCTION

New technologies have rapidly changed the scene of the typical classroom. From overhead transparencies and chalk to interactive documents and on-line applications, teaching and learning engineering have evolved from the classroom elements of even ten years ago. In a traditional classroom, faculty formally introduce material in lecture, and students learn the material through reading the textbook and completing homework and demonstrate attainment of knowledge through work on exams. While the opportunity is there for students to obtain feedback through class questions and office hours for the faculty, few students take advantage of this resource [1]-[2]. In addition, faculty members typically deliver information in a one-way format, which leaves little room for student engagement and critical thinking. This type

of setting is contrasted with the inclusion of online or secondary instruction beyond the main classroom setting, which prepares the student to enter the classroom with exposure to the material and an understanding based on these resources. The additional instruction offers methods of presenting lecture or additional course material outside of the classroom, which in turn enables the professor to utilize a portion of class time for working examples and holding higher-level discussions on the material. Common monikers for this type of classroom structure include hybrid, flipped, or even inverted classes [3]. While the literature distinguishes between the three types, the terms are used interchangeably in this work to describe students constructing an understanding individually prior to entering the classroom through the use of pre-readings and videos with the instructor then facilitating a higher-level discussion to encourage engagement and critical thinking skills.

The use of audience response systems, such as iClickers, allows students to respond to polling questions during the classroom setting. Students have a physical remote that is linked in the class to record responses. While there are a variety of tools that can be used with smart devices, the use of an iClicker remote ensured access to the polling system since having a smart device was not a requirement. Tools, such as iClickers, in the classroom allows an instructor to quickly and effectively gauge the understanding of students in class and a student to anonymously determine understanding of a concept relative to others in the class. Multiple studies have found that student use of iClickers has shown to be effective in the achievement of concept retention [4]-[7].

Therefore, this study addresses how learning can be impacted and student interactions increased through the use of active engagement tools, in this case an iClicker. Examples are provided, and results obtained included. In addition, the introduction of class preparation materials is also evaluated.

II. BACKGROUND

Learning theorists conclude human learning takes place in two phases: transmission and assimilation [8]-[12]. Learners in the transmission phase acquire information in their conscious minds. Examples of learning by transmission include listening to lectures and reading a course textbook. Assimilation, on the other hand, describes learners taking information acquired during transmission and utilizing the information beyond simple recall. It involves learning by more hands-on endeavors, typically completed by homework,

lab work, and cooperative learning activities. Figure 1 illustrates the relation of these two types of learning phases to Bloom's Taxonomy [13].

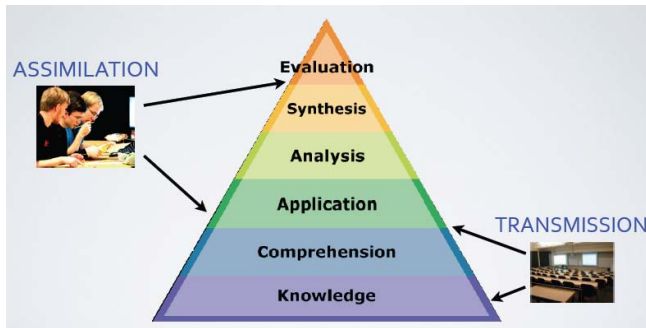

Figure 1. Relation of assimilation and transmission to Bloom's Taxonomy [8].

The traditional model of teaching devotes class time to the transmission phase of learning and leaves the higher order complex task of assimilation for students to complete outside of the classroom [12]. In Bloom's Taxonomy, the cognitive load increases as a student progresses higher up the pyramid from bottom to top. The traditional class provides the greatest accessibility of assistance at the bottom of the Taxonomy. Anderson and Krathwohl revised Bloom's Taxonomy into two dimensions developing a continuum between knowledge domain and cognitive domain [14]-[15]. This theoretical framework also shows the cognitive load increasing as a student moves from a lower form of cognition, such as remembering, to a higher level with creating. A difference in this framework, however, is the second dimension along a knowledge continuum. As shown in Figure 2, the traditional class provides assistance to students in the top left area of the taxonomy table through learning in the transmission phase while outside activities cover the other portions. A flipped or inverted classroom allows for transmission to occur outside of class while assimilation transpires in class. This format allows students to benefit from hands-on instruction from the professor during the higher order tasks and leaves the less complex tasks for students to handle individually prior to arriving in class.

Knowledge Dimension	Cognitive Process Dimension									
	Remember	Understand	Apply	Analyze	Evaluate	Create				
Factual	Transmission		Assimilation							
Conceptual										
Procedural										
Metacognitive										

Figure 2. Relation of assimilation and transmission to Anderson and Krathwohl's Taxonomy Table [14].

Some faculty may have concerns about incorporating this type of format in the class. For example, questions may arise on what to use the classroom time for in this type of setting and how to engage students in the face-to-face portion. As discussed by Dr. Talbert in his presentation on flipped

classrooms [8], he addresses these areas in the perceived challenges of flipping a course.

"Students will not come to class, how to create engaging in-class activities, students will not read, students will become overwhelmed, how to produce quality videos and make them interactive, updating materials, time necessary to create, edit and revise material, technology will not work, student buy-in, available resources, accountability, and value added."

He also discusses how benefits provided in this type of format quickly outweigh the challenges presented.

"Students will retain more, students can develop questions, modeling, lectures available for review, access true mastery, accountability, individual learning, instructor growth, class time is more productive, and reusable learning objectives."

A flipped or inverted class allows a student to actively inquire about lecture content, test skills in applying the knowledge, and obtain peer instruction during discussions on the material [16]. During the class time, professors serve as advisors and facilitators to allow the opportunity for students to delve deeper into the subject matter. This provides a stark contrast to a traditional lecture where students many times do not have time to reflect upon the material as it is being taught. By having resources available outside of the classroom, students may utilize the resources, such as readings, videos, and learning activities as many times as needed. The use of active engagement tools inside the classroom enhances the process of changing the typical lecture style format. While developing or assimilating these resources can be time consuming at the beginning, the benefits of engaging students both inside and outside the classroom are shown to outweigh the time involved.

While the notion of an audience response system, such as an iClicker, has been prevalent in some form of approach since the early 1960s, technology enhancements over the years have definitely increased their usability in the classroom, especially incorporating active learning methods. Instructors are able to pose questions through prepared slides or impulsively during class discussions. The iClicker allows students to enter answers presented in a multiple-choice or numeric input format. Numerous studies have used iClickers in classes, but many narrowly assess their impact. Czekanski and Roux [4] focused on how short-term concept retention was affected due to the anonymity provided by the devices. Their study showed such tools were valuable in aiding short term concept evaluation. In the work by Mayer et al, [5] the main prediction was that using clickers would lead to a greater student-teacher interaction. The belief was greater interaction would lead to deeper cognitive processing and increased learning. Evaluating exam scores did show a small, but significant, grade improvement for the section incorporating clickers. Research by Schmidt, Garcia, and Webber [6], specifically used clickers to evaluate the level of information

gained by means of a self-directed education using development of a podcast. Clickers were used to provide information related to material learned by the students. The researchers assessed comfort and participation using the tool. They found students were content using the clickers, but the tool did not affect their participation level in the course. A study by Head [7] addressed the classroom experience and real-time assessment using clickers. The author found the tool helped explanations by teachers through the real-time feedback from student responses. Hogan and Cernusca [17] focused on the perception by millennials on the enjoyment and engagement in the classroom environment. In the longitudinal study, the researchers evaluated perception by incorporating the tool not only at the course level but also at the university level. They found students on average required two semesters to significantly shift their perception and view clickers as supporting class activities. Not addressed in the previous works are how the tool can be used in an inverted class and how expanding feedback related to enjoyment and engagement areas allows for the potential of significant changes to be observed after one semester. In addition, specific methods for faculty to incorporate the tool in an active learning environment beyond simply asking questions anonymously were not fully described.

III. METHODS

To implement the active learning tools, the author identified a core, required, first semester sophomore-level engineering statics course taught during the Fall 2012 semester in the Aerospace Engineering Department at Texas A&M University (TAMU). The course consisted of two credit hours and was a common course type to many engineering majors at TAMU. Only one section of the course was taught in the department each semester, and the author had taught this course each semester for the last three semesters.

During the semester, students were assigned pre-work for class, which included textbook readings, on-line resources, videos, etc. This provided a context for students coming prepared for a dynamic classroom experience full of discussion, team work, and problem-solving. During the class, an active engagement tool, iClicker, was used to poll the audience on multiple-choice and numeric questions and facilitated working with peers. In addition, relevant instruction was provided by the faculty in areas where lack of knowledge could easily be identified.

The techniques utilized to analyze the implementation of active engagement tool in the course were qualitative. An on-line end of course survey with specific questions related to the use of active engagement tools was administered and provided qualitative results. Students anonymously completed the survey outside of class. A confirmation page showing completion of the survey was submitted as part of a final homework assignment by the students. There was 97% participation in the final survey with 73 students completing the survey. In addition, twenty percent of the students were randomly selected to orally discuss their final exam to detail

where they made mistakes and their thought process in achieving the results obtained. The researcher also compared the final exam scores from the section that used the tools with two previous semesters of the course offering by the same instructor where the active engagement tools had not been used.

A. Survey Instrument

The post-course survey contained a total of 64 questions inquiring about general course details, such as preparation for the course and future plans with 29 of the questions specifically covering the active engagement tool utilized in the course, which was iClicker. Factor Analysis was employed to identify the number of factors that explain most of the variance observed within a larger set of variables. The questions related to the tools evaluated through this work related to three factors, which were identified as: a) enjoyment of using clickers in the course, b) engagement of students in the classroom, and c) engagement of students outside of the classroom. The three factors and several of the questions were similar to those posed by Hogan and Cernusca [17] in related work. This survey instrument differed, however, from the previous work by expanding each of these areas and including questions on resources for the inverted class. Students evaluated each question in the survey using a five-point Likert Scale with 5-Strongly Agree, 4-Agree, 3-Neutral, 2-Disagree, and 1-Strongly Disagree. The researcher used a one-sample t-test on each of the questions to determine if the mean of the sample was greater than the comparison value of three, which would indicate the students being neutral on that particular question.

B. Final Exam

Each semester, the instructor typically keeps the questions on the final exam relatively similar with minor modifications/clarifications. This allowed an end of semester comparison between the group utilizing the active engagement tools and two prior semesters where no such tools were employed. The researcher used an ANOVA test to see if the means of the final exam scores from separate semesters were different from each other. In addition, students were randomly selected to meet with the instructor and detail their thought process on the final exam to assess their learning. Although not directly compared, the students in the three semesters were similar in nature.

IV. RESULTS

Administering the post-course on-line survey provided results in three areas previously discussed including enjoyment, engagement inside the classroom, and engagement outside of the classroom. The instructor used iClickers in the class, so a large number of questions asked in the survey related to this tool. In addition, final exam scores allowed a direct comparison of scores received by students who had used the active engagement tools versus two semesters where no such tools were employed. An alpha level of .05 was used for all statistical tests.

A. Survey – Enjoyment of Using iClickers in the Course

Results related to enjoyment of using iClickers in the course are reported in Table 1. Eight questions were asked in this category related to the iClicker in the areas of: ease of use, enjoyment, satisfaction, and recommendation in other courses.

All eight questions related to enjoyment of using iClickers showed there was a statistically significant mean difference, at the .05 level, in response rates. The highest values for mean related to ease of use, satisfaction, and helpfulness of instant feedback with the tool. Overall, using iClickers in the course provided enjoyment for students.

Table 1
Enjoyment of Using iClickers in the Course (N = 73)

Question	<i>M</i>	<i>SD</i>	95% CI for Mean Difference	<i>p</i>
Q5: I found iClickers easy to use.	4.73	0.45	1.62, 1.83	0.000*
Q6: I enjoyed using iClickers in class.	4.26	0.80	1.07, 1.45	0.000*
Q20: I am satisfied with the use of iClickers in this class.	4.30	0.70	1.14, 1.46	0.000*
Q26: I found discussion associated with iClicker questions made the course more enjoyable overall.	4.12	0.73	0.95, 1.29	0.000*
Q29: I would recommend using iClickers in other courses.	3.96	0.84	0.76, 1.16	0.000*
Q19: I felt more engaged in class material because iClickers were used.	4.22	0.73	1.05, 1.39	0.000*
Q23: I found it helpful to get instant feedback of my learning through the use of iClickers.	4.30	0.64	1.15, 1.45	0.000*
Q24: I found it helpful to have my answers to iClicker questions displayed anonymously during discussions.	4.29	0.68	1.13, 1.45	0.000*

Note: The comparison value for each of the questions was three. * $p < .05$

B. Survey – Engagement of Students in the Classroom

Results related to engagement of the student in the classroom are reported in Table 2. Eight questions were asked in this category related to the iClicker in the areas of: become a more active learner during lecture, increase interaction with peers, increase student to teacher interactions, affect attention displayed during class, understand course materials, affect class discussion, make material more interesting, engage in class material; use feedback, enhance learning, and prefer classroom delivery of material.

All eight questions related to engagement of the students in the classroom showed there was a statistically significant mean difference, at the .05 level, in response rates. The highest values for mean related to the tool helping the students become a more active learner during the class and helping gauge their knowledge level of the material being taught.

Overall, students felt the active learning tools provided engagement in the classroom.

Table 2
Engagement of Students in the Classroom (N = 73)

Question	<i>M</i>	<i>SD</i>	95% CI for Mean Difference	<i>p</i>
Q8: The iClicker questions helped me become a more active learner during lecture.	4.33	0.67	1.17, 1.48	0.000*
Q9: I found iClicker questions useful in increasing my interaction with other students.	4.22	0.65	1.07, 1.37	0.000*
Q10: I found iClicker questions useful in increasing my interaction with the professor.	4.12	0.76	0.95, 1.30	0.000*
Q11: Using iClickers helped me pay attention during class.	4.29	0.74	1.12, 1.46	0.000*
Q12: Using iClickers helped me gauge whether I am following the course materials during class.	4.32	0.67	1.16, 1.48	0.000*
Q13: Using iClickers helped me to assess if I understood material being covered.	4.24	0.74	1.06, 1.41	0.000*
Q14: Using iClickers helped me to remember the material covered in lecture.	3.94	0.79	0.76, 1.13	0.000*
Q25: I found discussion associated with iClicker questions enhanced my learning in the course.	4.14	0.61	1.00, 1.28	0.000*

Note: The comparison value for each of the questions was three. * $p < .05$

C. Survey – Engagement of Students outside the Classroom

Results related to engagement of the students outside of the classroom are reported in Table 3. Ten questions were asked in this category related to the iClicker or class set-up in general in the areas of: completion of pre-work, assessment of understanding of material, remembering of material being taught, motivation for class preparation, modification of learning, mental effort in the course, and preparation for exams.

Nine of the ten questions related to engagement of the student outside classroom showed there was a statistically significant mean difference, at the .05 level, in response rates. As a whole, this group of questions received lower scores for the values of mean than the other two previous sets. The highest values for mean related to the use of using pre-readings to prepare for class and their effect on preparing for class and using the iClicker tool to grasp material covered in class. Overall, students felt the active learning tools provided engagement outside of the classroom.

Table 3

Engagement of Students outside the Classroom (N = 73)

Question	M	SD	95% CI for Mean Difference	p
Q2: I completed the pre-readings (book material or additional reference material) for the course.	4.03	0.69	0.87, 1.19	0.000*
Q3: I felt the pre-readings helped me be prepared when I came to class.	4.06	0.57	0.92, 1.20	0.000*
Q15: Using iClickers in the class motivated me to come to class prepared.	3.84	0.88	0.63, 1.04	0.000*
Q16: I modified my learning of material after class based on results from iClicker questions.	3.27	0.92	0.06, 0.49	0.013
Q17: Having discussion in class increased my interest in class material.	3.89	0.78	0.71, 1.07	0.000*
Q18: Using iClickers made material we covered in class more interesting.	3.82	1.00	0.59, 1.06	0.000*
Q21: The iClickers caused me to put a lot of mental effort into class.	3.48	0.90	0.27, 0.69	0.000*
Q22: iClickers assisted my ability to grasp the material covered in class.	4.03	0.65	0.88, 1.18	0.000*
Q27: The iClicker questions helped me prepare for exams.	3.63	0.97	0.40, 0.85	0.000*
Q28: I would prefer to have a straight lecture provided each day in class instead of discussions.	1.97	0.90	-1.24, -0.82	0.000*

Note: The comparison value for each of the questions was three. *p < .05

D. Final Exam

The final exam scores for three different semesters were compared using an ANOVA test. All three semesters had similar final exam questions, and the same instructor taught the course each of the three semesters. There was not a significant difference in the final exam scores received between the semesters using different instruction tools.

The researcher also interviewed students about their work on the final exam to determine the level that students could describe their mistakes. The instructor has conducted similar sessions with students in previous semesters and has not seen the level of understanding received after using the active engagement tools. Students who had incorporated the active engagement tools could more readily discuss their mistakes and see how the work they had completed was flawed. The researcher found that the process of learning is not necessarily noted on the number of correct answers the participants received. Rather the learning came when the participants were asked to note what they did wrong and if they were able to fix their error.

E. Instructor Feedback

The instructor found feedback received from using iClickers was exceptional. The iClickers provided a quick snapshot of the understanding by the students on a particular topic. Responses received helped guide the discussion. With the results anonymously displayed on the screen, students felt comfortable in sharing an answer using iClickers while they might have held back if oral answers were shared that identified who provided the answer. In addition, the instructor found instant feedback on the level of understanding by the students very beneficial. Multiple choice questions typically started the class discussion. The following figures showcase two prevalent scenarios witnessed by the instructor in using iClickers in the classroom. As shown in Figure 3, the bar chart on the left represents the range of answers received after a multiple choice question was posed for the students to answer individually. The instructor also projected this image of the results received for the entire class to see. Without focusing on specific values for each of the answers of A-E, it was clear students had a wide range of understanding regarding the question posed. The instructor then asked the same question again but allowed student peer interaction discussion to occur before the answer was provided a second time. Basically, students were encouraged to discuss the question with students seated close by. As shown from the bar chart on the right hand side, students overwhelmingly answered the question correctly with only a few students selecting an incorrect answer. The instructor then discussed the incorrect solutions and corresponding reason for being incorrect. Of course if the bar chart on the right in Figure 3 was received at the initial probing, the instructor discussed the inaccuracies of the incorrect answers briefly and did not utilize peer interaction.

Figure 3. Visual display of multiple choice answers received from students using iClickers with initial answers displayed on the left and results after peer interaction enabled on the right.

The bar charts in Figure 4 display a similar scenario as in Figure 3. In this interaction, however, students were almost evenly split between two possible answer selections after peer interaction occurred. Therefore, the instructor provided additional instruction on the topic, discussed possible misconceptions, and allowed a second peer interaction discussion to occur, which allowed students to work through an understanding of the problem posed. Results would then normally be similar to those received on the right side in Figure 3. Otherwise, further class discussion followed.

Figure 4. Visual display of multiple choice answers received from students using iClickers with initial answers displayed on the left and results after peer interaction enabled on the right.

Input answers using iClickers are not limited to multiple choice questions. Frequently the instructor would ask more in-depth calculation-based questions after initial discussions using multiple choice questions had occurred. Using iClickers to input numerical answers allowed the instructor to spontaneously gauge the understanding of students as work progressed on a problem without having to have previous multiple choice questions generated. If a wide variety of answers ensued, more discussion and teaching would occur. In addition, problems could be completed in between class meetings, and the class period could commence with students providing numerical responses to problems completed for the class.

Common questions and concerns from students related to grades received for work through iClickers. Upfront, the instructor discussed grading policies related to iClickers. Most feedback students provided was handled as a participation grade. However, the instructor did note some questions related to expected learning. These were denoted prior to querying and were graded accordingly.

Students generally provided complimentary feedback related to the use of active engagement tools. Two free-response questions on the post-course survey related to iClickers and the course in general provided insightful comments. A few examples are provided.

"[iClickers] were very enjoyable to use and kept me focused. Overall, it was a much more pleasant experience than just sitting in class and listening to an hour-long monologue."

"I enjoyed the iClicker questions sometimes. It was also very hard to prepare for lectures at times. If I ever failed to prepare for lecture then my learning ability for that class was hindered."

"Even though I hate having to take iClicker quizzes, they are very helpful and would definitely like to see more use of them in the AERO courses."

"Honestly, the iClicker discussions were probably more helpful than anything."

"The iClickers were actually exceptionally helpful. (I say actually after having an unpleasant experience with iClickers in CHEM 107.) They helped gauge my performance in AERO 209 and helped me stay on top of the material."

A couple of comments from students provided suggestions for using the tool in the classroom. For example, the following comment shows the importance of the discussion that follows the introduction of the iClicker question and not simply the use of the tool itself.

"Sometimes the questions go by really fast; not enough time to think about it, versus on paper where a person can see every problem."

The vast majority of the questions on the survey asked for input on the active engagement tool. As a whole the comments were overwhelming positive related to the three areas of enjoyment, engagement inside the classroom, and engagement outside the classroom. Only a few of the questions addressed details on the materials used in the inverted class format. However, these materials contributed to further discussions in the classroom setting where the active engagement tool was utilized.

V. CONCLUSIONS

The main focus of this work was on using an active engagement tool, iClicker, in the classroom. As part of the study, however, the author also inverted the classroom experience whereby students entered the classroom prepared for a more in-depth learning experience. The tool alone did not provide the engaging experience, however. For example, some faculty have used the polling tool simply as a means to check attendance. It was through the use of peer interactions and classroom discussions that the tool positively affected the learning experience for students in the class as shown by the feedback of students.

The instructor also determined that to be successful with an inverted course, high quality resources and a structure for utilizing the resources were vital for students outside of class. Tools utilized outside the classroom, such as pre-learning videos and document resources, were available to students through an on-line course management system. In addition, having interesting and challenging problems for students inside of class was also vital to keep students engaged. In the in-class discussions and problem solving sessions, iClickers provided individual accountability, instant feedback, and documented grading.

Overall, the experience provided a beneficial experience for the instructor and students. While results showed encouragement for refining the use of active engagement tools in subsequent semesters, the results on examinations of students will need further review. The tools provided students a variety of ways to learn the material. The researcher found learning came when the participants were asked to note what they did wrong and if they were able to fix it rather than what might have been attributed to a numerical grade in the course. Additional evaluation and fine-tuning will need to occur. The study provided evidence of learning being impacted and student interactions increased through the use of active engagement tools.

Can Student Engagement be Measured?

and, if so, Does it Matter?

Abstract— Students in an introductory science course offered both face-to-face and on-line at the University of Michigan used a web application that allowed them to respond to questions, pose questions and take notes. The data from their participation were recorded, quantified and compared with their resulting grades on exams to ascertain to what degree measures of student participation were related to student learning. These measures of student participation were augmented by data from the university's student information system, which provided background information. Data was also collected from a number of surveys administered over the semester. Analyses of the data revealed some strong relationships between grades and the degree and quality of student participation. Moreover the behavior of students varied significantly when stratified by their incoming GPA. The empirical relationships reported here provide evidence-based affirmation that student participation is related to learning and suggests that the strength of GPA as a predictor of grades may be due more to a lack the study skills and/or motivation rather than cognitive ability.

Keywords—student engagement, learning analytics, student outcomes, LectureTools

I. INTRODUCTION

Student engagement is widely thought to be a key predictor of student achievement. We all have a sense of what an engaged student looks like [1-3]: they participate by asking questions, challenging assertions and completing assignments. As we are able to digitally measure more and more of how a student participates, to what degree will it be possible to identify a suite of measures that can quantify engagement so we can identify underperforming students earlier in the semester?

Active participation is known to improve learning [4, 5] but typically instructors dominate the class with presentation [6, 7] and offer few opportunities for students to actively participate. Verbal questions from students tend to be limited to a small percent of class participants [8] in these environments. While it is widely accepted that the ideal learning situation tends toward lower student to instructor ratios the economics of post-secondary education are such that it is unlikely that large introductory courses are going to go away in at least the near future. So how can we use learning analytics to improve the pedagogical value of the large lecture hall?

Here we consider a broader suite of measures than previously available for a large introductory science course. The course, Extreme Weather, was offered at the University of Michigan in the winter 2014 semester with 168 students. Data collected in this class was divided between those extrinsic and those intrinsic to the course:

- Extrinsic Measures
 - Incoming Grade Point Average
 - Interest in course content
- Intrinsic Measures
 - Attendance in class
 - Participation in class activities
 - Correctness in class activities
 - Taking notes
 - Posting questions
 - Indicating confusion

Each of these intrinsic measures of participation requires the student to engage with the material being presented during class. While there are many other ways for students to engage with the class content these methods are often the most common.

The intrinsic measures are made possible through use of LectureTools, which allows students to respond to a wide range of questions as a web-based replacement for clickers, view the instructor's slides, take notes synchronized with the

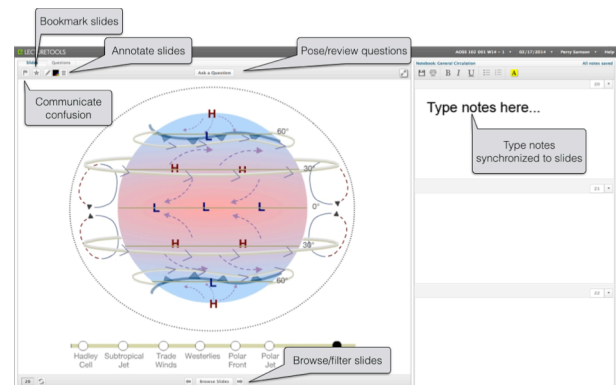

Fig. 1. Student view of LectureTools identifying their ability to take notes, annotate slides, bookmark slides, note confusion, answer questions from the instructor and pose questions to the instructor.

slides and pose questions to the instructor. While use of the tool was not mandatory more than 90% of the students voluntarily elected to use LectureTools. All the student actions are recorded to a database and made available to the instructor.

The data collected by LectureTools allows not only an examination of how student participation is related to outcome but by combining these data with data from the university's student information system (SIS) it is possible to also identify how students with differing incoming Grade Point Average (GPA) behave differently in class. Others have illustrated that student outcomes can often be predicted using current GPA's of students [9]. But for instructors this understanding is less valuable than what can be done in their own class to promote student success. In other words can we identify what it is that successful students do in class that is different from less successful students?

II. METHODS

A. Course Structure

The course studied, *AOSS 102, Extreme Weather*, is offered every semester at the University of Michigan and is offered for students as one of many "science distribution" courses to fulfill a science requirement. In the winter semester, 2014, the course was offered as a hybrid course streamed in real time with the option that students could participate in person or remotely. Students used LectureTools, which allows students to participate synchronously from wherever they are to answer questions, pose questions, annotate slides, take notes and indicate confusion.

B. Data Collection

1) Collecting Intrinsic Data

The course was both streamed live and recorded every class day using Echo360 (<http://echo360.com/capture-options>) so students could have the choice of physically coming to class or

viewing lecture remotely and synchronously. In either situation students could use LectureTools (see Figure 1), which allowed the students to:

- Type notes synchronized with the lecture slides
- Answer questions posed by the instructor
- Indicate confusion
- Pose questions to the instructor and view responses
- Print lecture slides and notes for off-line review.
